**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

HAL Authorization

## 1. Context and objectives of the study

- Anthropogenic activities: fine-grained sediment fluxes modified significantly → environmental and societal issue [1]
- One of the issues: fine sediment infiltration (or clogging) → detrimental for bed structure and permeability  
→ How to restore rivers ? How efficient are flushing operations ?
- Hydraulic conditions for erosion and deposition of fine and coarse mixtures poorly known:  
→ difficulties for optimizing restorations
- Experiments in controlled environment with several strategies at constant cost (same volume of water input) to flush fine sediments in a clogged bed

Fine sediment deposits on a gravel bar in the Arc River (France) after a dam flushing event

## 2. HHLab tilting flume (Irstea)

## 5. Four flows tested

Same volume  
Different shapes

Characterization of the bed before and after the hydrograph

## 3. Bed material characteristics

## 6. Bed surface characterization

Average form ( $k_{sf}$ ) and grain geometrical roughness ( $k_{sg}$ ) of the bed before and after each flushing experiment and average erosion ( $E$ ) all along the flume

	$k_{sf}$ (mm)		$k_{sg}$ (mm)		$E$ (mm)
	initial	final	initial	final	
Exp 1	3.3	1.1	0.7	0.5	4.7
Exp 2	1.8	1.0	0.6	0.6	9.0
Exp 3	2.2	2.4	0.6	1.3	9.7
Exp 4	2.2	1.5	0.9	0.8	8.6

For a flat gravel bed: grain roughness  $k_{ss} = 3.2$  mm form roughness  $k_{sf} = k_{sg}$

Top view final beds

## 4. Initial conditions

Initial bed = result of infiltration experiment with specific vertical structure [4]

**Infiltration experiment:** Fine sediment laden-flow (with constant fine sediment concentration) recirculates over a clean gravel bed for hours, without mobilisation of gravels until the vertical structure of fine sediment deposits is stabilized.

bridge of sand  
deposit of beads

Sand dunes with deposits of beads on top.

## 7. What is the best strategy ?

- With a given amount of water, best strategy to wash fine sediment from the surface with a limited mobilisation of the coarse matrix is a rising hydrograph (increase of  $k_{sg}$  to a value close to the one of the gravel bed).
- Gravel bed free of fines over a larger depth than one gravel grain was never obtained (even with higher discharges in a supplementary experiment).
- Increase of discharge between Exp 1 and 2 was inefficient and leads to more erosion (Shields number 0.037 to 0.055 for gravels).
- If the bed needs to be entirely preserved, lower discharges can partially clean the surface.
