Introduction & Objectives

• **General guideline** : European Water Framework Directive (2000) → Reduce pollutant in water. In France : ECOPHYTO (2008-2018) → reduce amount of pesticide used by 50 %.

• **One dimensional models** : widely use in regulation procedure for pesticides leaching in U.E : MACRO, PEARL, PRZM (*FOCUS 2001*).

• **Context** : in tile drained soils, the drained water dynamic affects transport of water and solute in soils. Preferential flow is also recognized as a key process for pesticide exportations in structured soils (e.g, Jarvis, 2007).

• **Our objectives** :

- Estimate the role of the drained water table and preferential flow in pesticide fate.
- Evaluate advantages, disadvantages and efficiency of MACRO and HYDRUS-2D using a long term validation period.

2- Models description & Methodology

MACRO 5.2 (Larsbo & Jarvis, 2003)

HYDRUS-2D (Simunek & al, 2012)

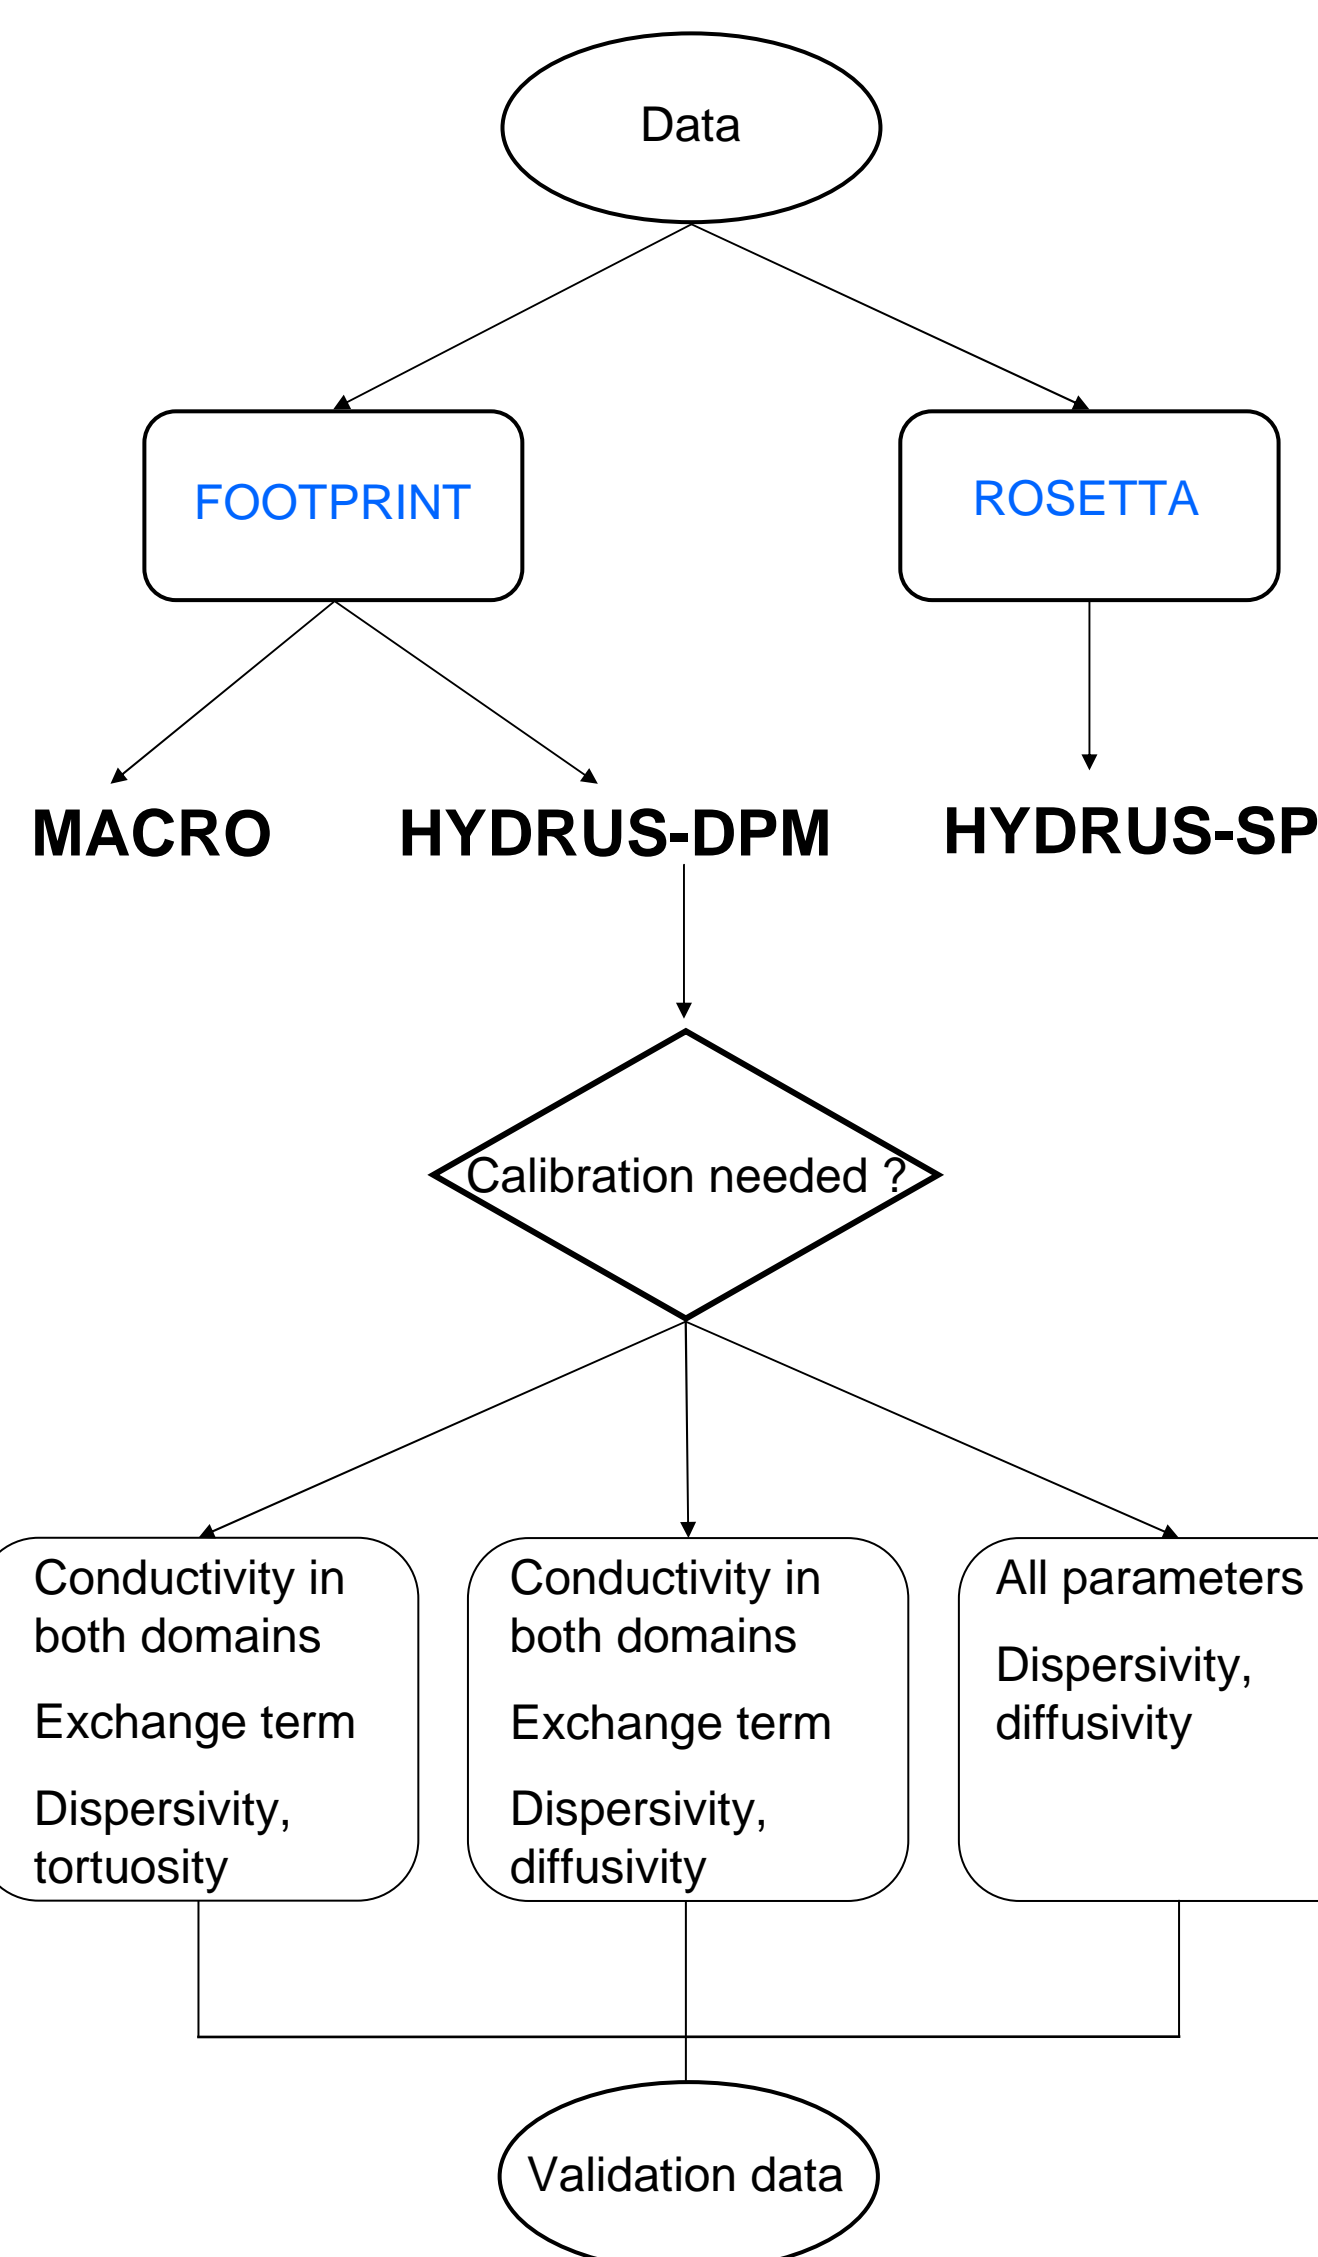

Initial condition : 6 months « blanks » simulation for 2005-2006. For the validation step, continuity was assumed between years (water and solutes).

Upper boundary : Hourly rainfall. Evaporation and transpiration rate calculated by MACRO and also used by HYDRUS. Water and solute enter into matrix domains.

Parameterization

Hydrodynamics parameters estimate by **pedotransfer function**. We used FOOTPRINT pedotransfer function for both dual permeability models as HYDRUS-2D do not provide such data.

Calibration

Inverse solution was used for the **simple porosity** model. For dual permeability models, we decided to calibrate only few parameters based on sensibility analysis.

Validation was performed on a **10 years period** for **water, isoproturon** (IPU) and **diflufenican** (DFF).

Conclusion & perspectives

Solute transport : it's seems that pesticides are mainly transport by macroporosity in our soils. HYDRUS-DPM results will certainly give some additional proofs.

• **MACRO** : give acceptable results for water, and once calibrated for Isoproturon. Problem to correctly simulate pestistant and strongly sorbed component → A need for some chemical processes representation. Some code problems in this version (tillage, kinetic sorption).

• **HYDRUS-2D** : can be used to represent complex problems → Yet **convergence problems** is time consuming (no bug report). Dual-permeability need 17 parameters (for water) which can lead to some convergence and equifinality problems. No roots and crop evolution in time → problematic for validation procedure. However HYDRUS can certainly provide significant **informations on water and solutes processes**.

• **Next steps** :

- Compare initial and calibrated results with simulations using field and laboratory data : Conductivity and retention curves, physico-chemicals key parameters in each layer.
- Use both physical and **chemical non-equilibrium** to account for formation of bound residues in soils and sorption kinetics.

Pesticide Behavior in Soils, Water and air. 2-4 september 2013, York University (UK)

1-Field description

• The site of la Jailliére is an European reference for drained soils (Fig.1), and used for homologation.

• Located in North West of France. The climate is temperate oceanic with 705 and 724 mm of precipitation and potential evapotranspiration, respectively.

• Long term monitoring for water (1987-2013), Nitrate (1988-2013) and pesticides (1994-2013).

• Short step data for bromide and two pesticides :
-Diflufenican (DT50 = > 140 d, Koc = 2000 L.Kg⁻¹)
-Isoproturon (DT50 = 15 d, Koc = 124 L.Kg⁻¹)

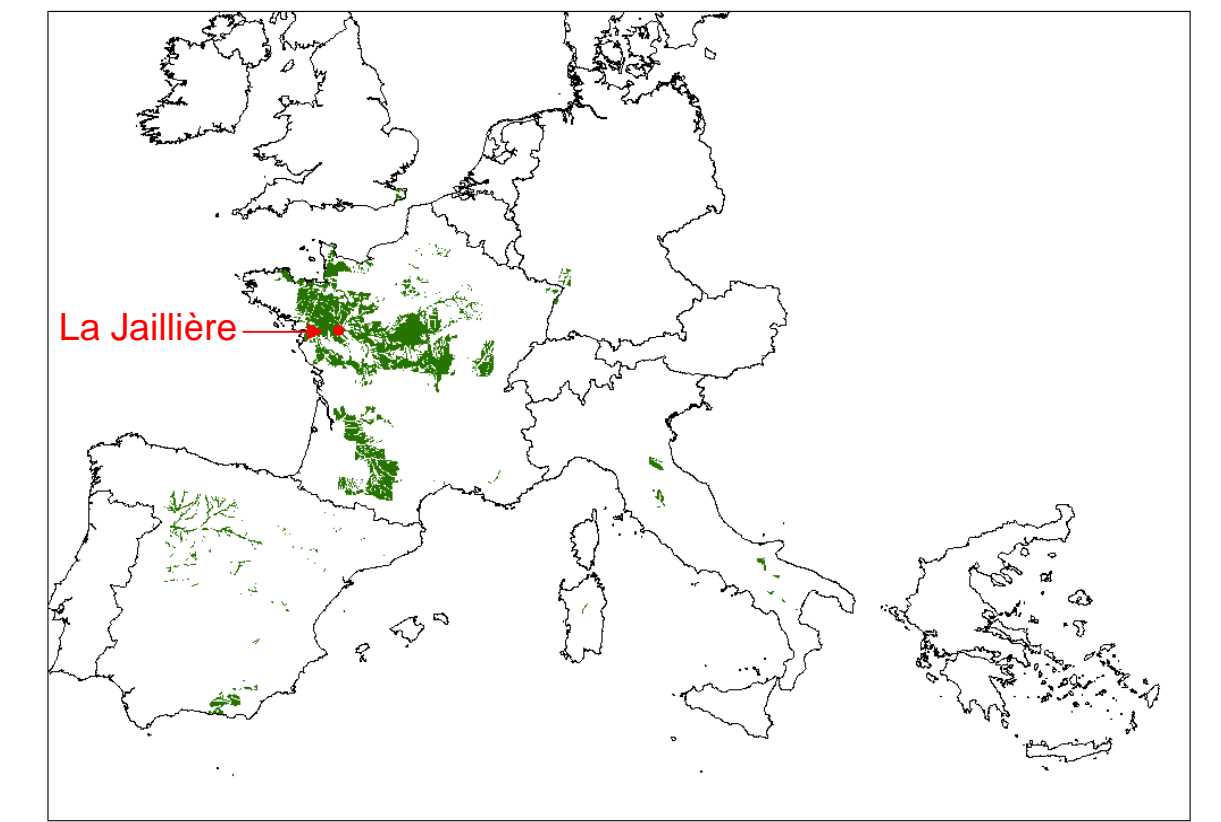

Fig. 1 : Location of the site of la Jailliére and distribution of this drainage scenario (D5) in Europe (FOCUS, 2001).

Tab. 1 : Main soil characteristics of the plot T4.

Horizon	Thickness	Clay (%)	Silt (%)	Sand (%)	O.M (%) ^a	Bulk density (g.cm ³)	pH (water)	Structure

3- Results & discussion

DATA

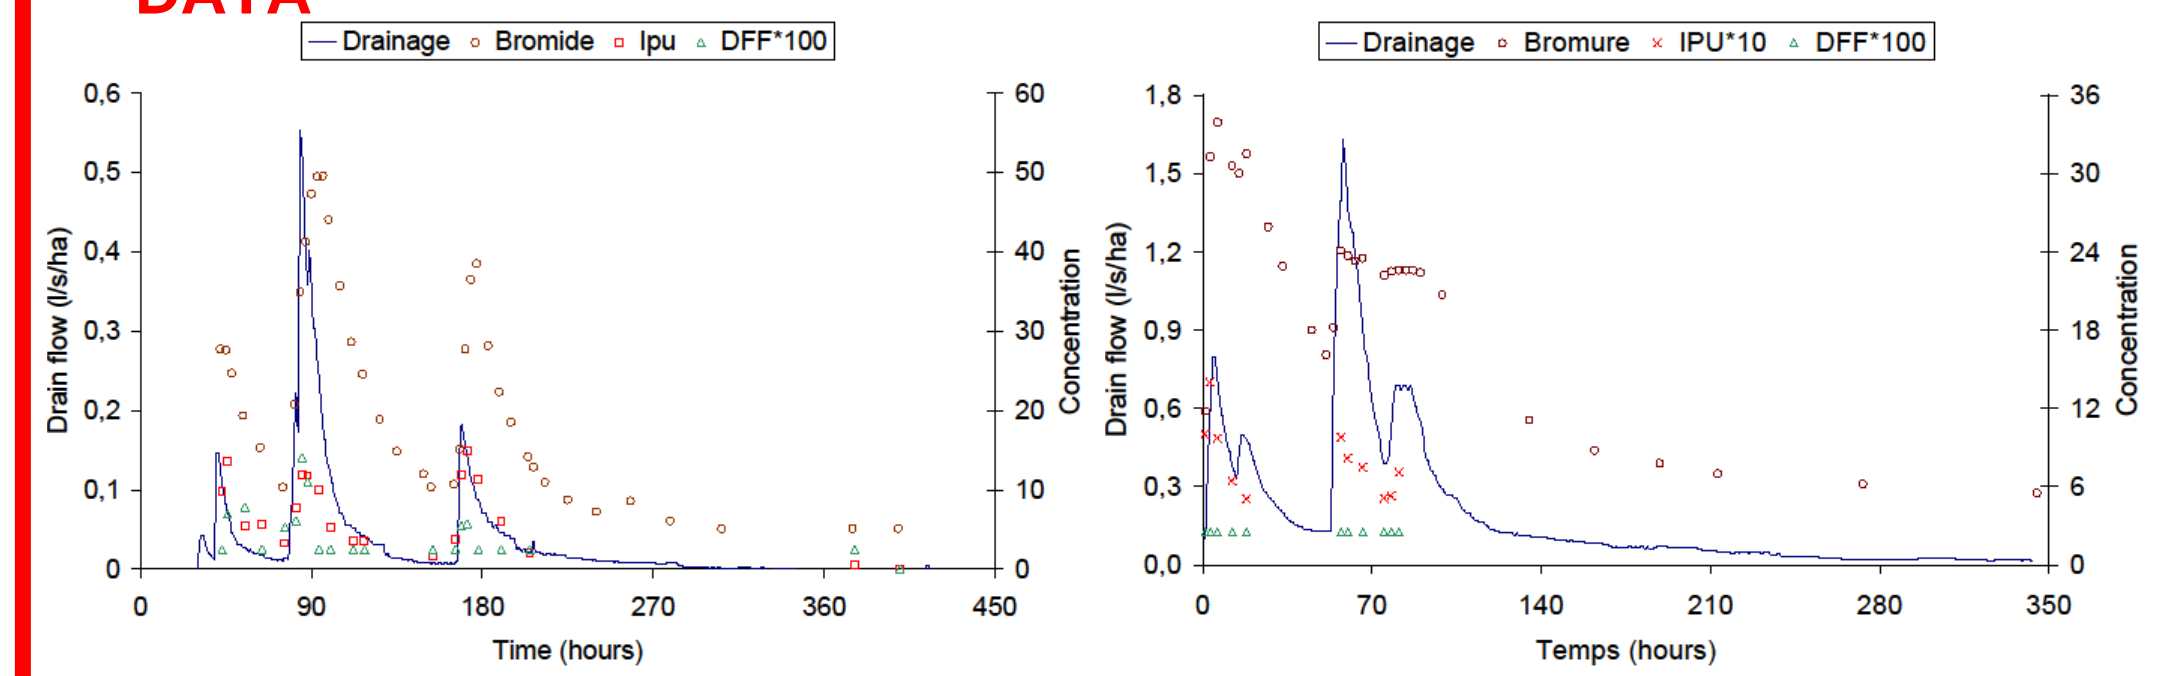

Fig. 2 : Measured drained flow and bromide, isoproturon, diflufenican concentrations during two periods : (left) Following application (december) and (right) During the intensive drainage season (february). Concentrations are expressed in mg.L⁻¹ for bromide and µg.L⁻¹ for pesticides.

Bromide lag behind peak of drainage following application and is simultaneous with drainage during the intensive drainage season (IDS).

Pesticides peaks are ahead drainage and bromide peaks in both season.

→ Does the drain water table dynamic influence pesticides exportations ?

Simulation

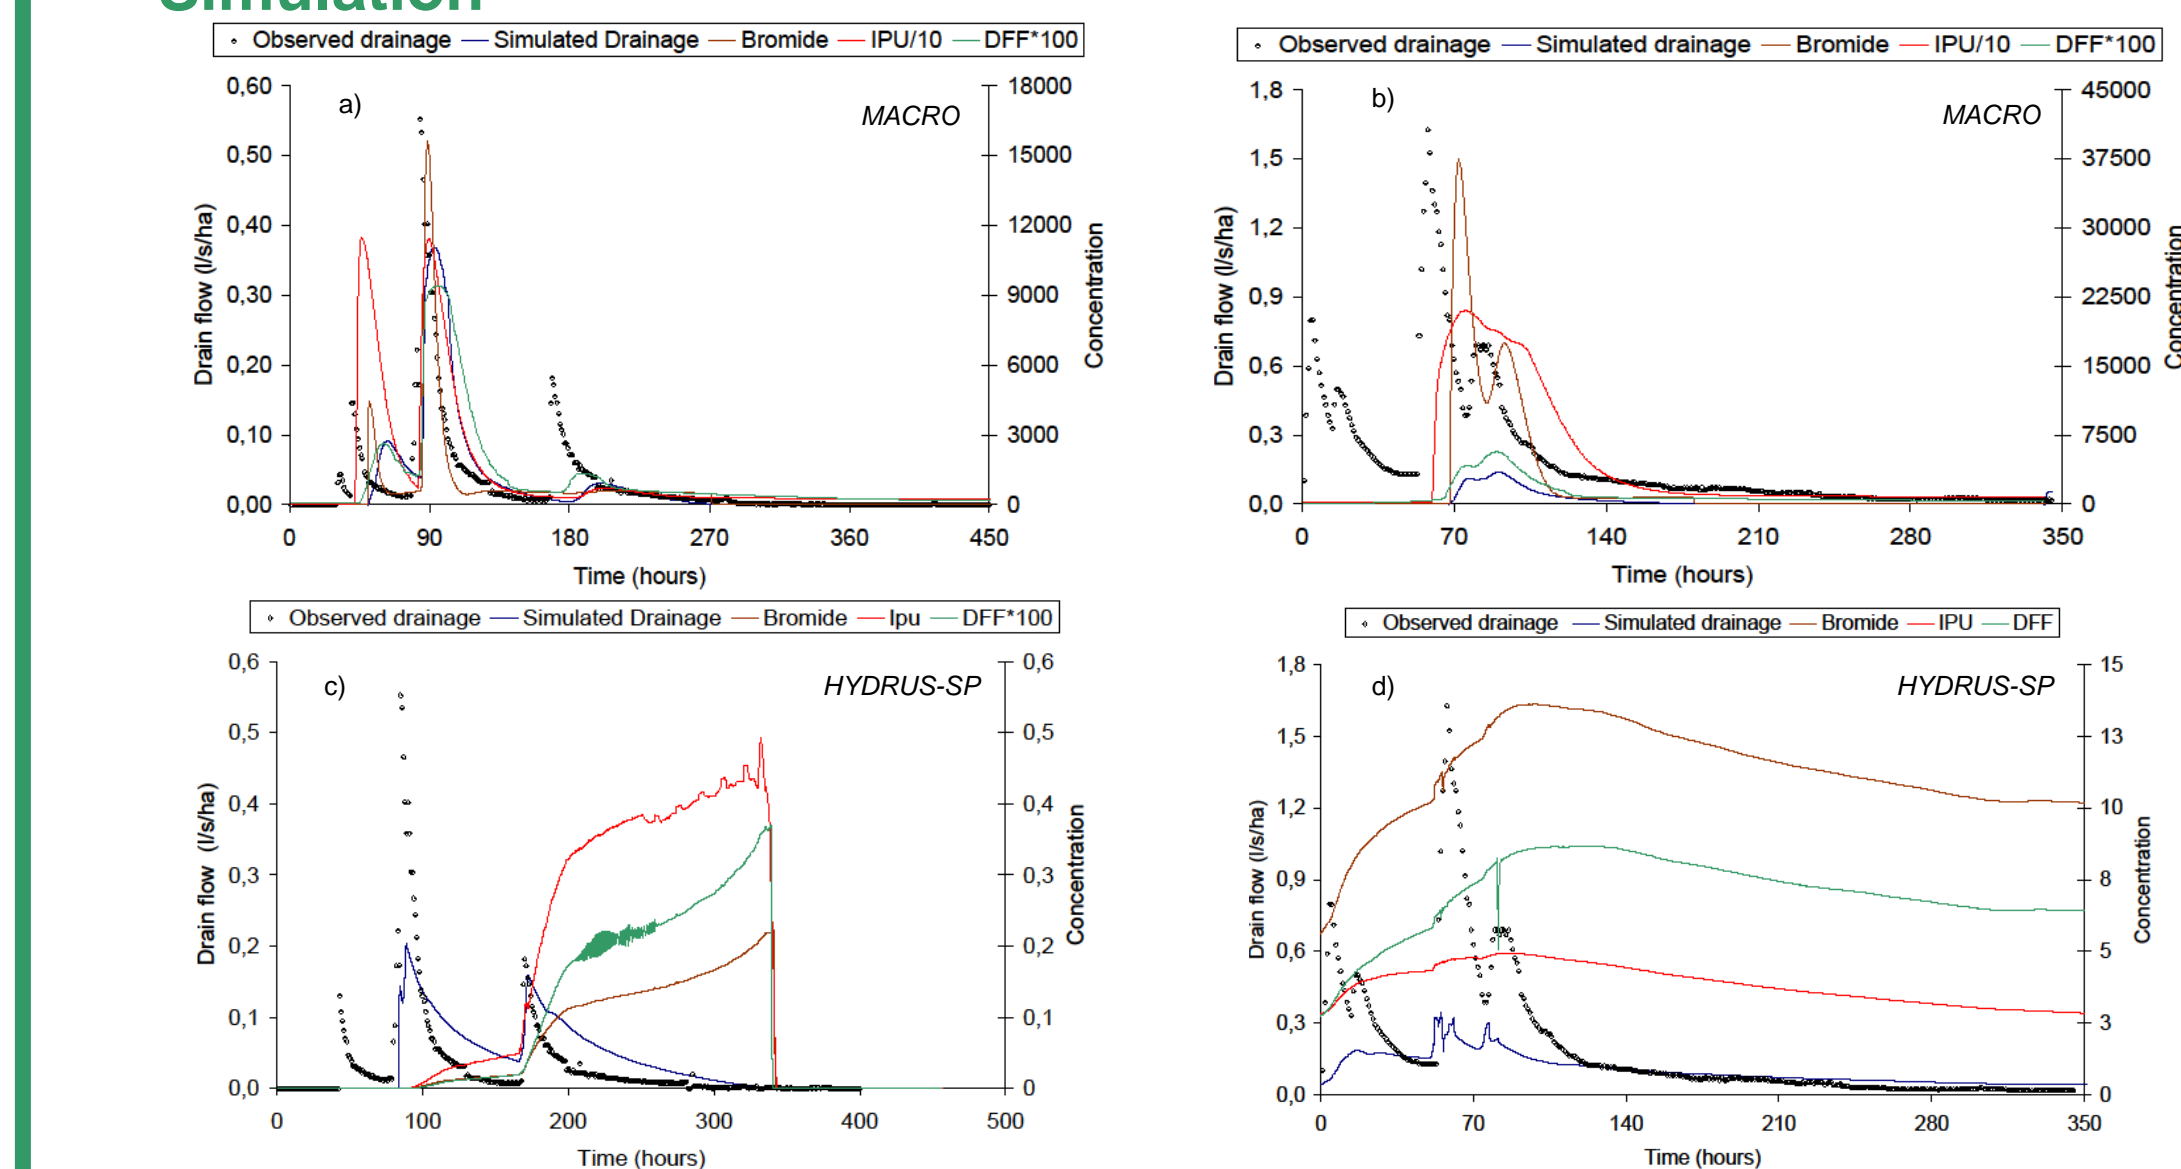

Fig. 3 : Simulated drainage and bromide, IPU, DFF concentrations following application (a) and during the IDS (b) for MACRO (c) and HYDRUS-SP (d). Concentration are expressed in mg.L⁻¹ for bromide and µg.L⁻¹ for pesticides.

• Both models underestimate drainage during the beginning of the season and during the IDS, with initial parameters.

• **MACRO** overestimates concentration of all solutes following application and during IDS.

• Inverse problem is observed for **HYDRUS-SP**. Concentrations increase with time until the beginning of the IDS (fig. 3d).

CALIBRATION

Fig. 4 : Bromide dynamics and concentrations for different values of a) the mass transfer coefficient in MACRO, b) dispersivity in HYDRUS-SP with the associated bromide distribution and c) bromide dynamic and concentration simulated with HYDRUS-SP during IDS with the associated bromide distribution.

Both models correctly simulate drain flow (Fig. 4a,b,c).

MACRO can't describe bromide dynamic following application (Fig. 4a). However, once calibrated, concentrations are in the range of data for bromide and IPU for the two periods of monitoring, yet underestimate for DFF.

HYDRUS-SP partly represents bromide dynamic (Fig. 4b, 4c) but concentrations are still increasing following application. Predicted pesticide concentrations are low.

VALIDATION

Tab. 2 Drainage (Dc), isoproturon and diflufenican cumulated flux simulate by MACRO and HYDRUS-SP compared to the 10 years data. Data in **bold** represent acceptable results. Simulated data in **blue** and **orange** fail to predict water and solute, respectively.

Year	Data			MACRO			HYDRUS-SP		
	D _c (mm)	IPU _c (mg/ha)	DFF _c (mg/ha)	D _c (mm)	IPU _c (mg/ha)	DFF _c (mg/ha)	D _c (mm)	IPU _c (mg/ha)	DFF _c (mg/ha)
1995	500	-	-	403	0	0	434	0	0

2003	329	0	0	185	0	11	205	0	15
2004	236	2131 ^a	228 ^a	231	23510	5	248	2247	25
2005	10	0	0	75	0	12	82	0	3
2006	121	1016 ^a	8.5 ^a	122	127500	28	125	210	20

Drain flow : Cumulated drainage is reasonably well predicted by **MACRO** with or without calibration. However, Nash-Sutcliffe coefficient (between 0.2 and 0.7) and analysis of hourly data (not shown here) shows underestimation of simulated drain flow during IDS for all campaigns. **HYDRUS-SP** underestimate cumulated drainage due to overestimation of transpiration and runoff.

Solute : **MACRO** and **HYDRUS-SP** do not match Isoproturon exportations and fail to predict DFF exportations during the campaign following application without calibration. Once calibrated **MACRO** matches well IPU losses and overestimates long term exportation of DFF; **HYDRUS** does but this is due to a really slow migration. For the same reason HYDRUS simulate low IPU exportation due to higher degradation rate.

HYDRUS-DPM

Some problems occurred in the last week concerning upper boundary conditions. We realized that the parameter governing repartition of water and solute between matrix and fractures was stuck. Thus, all solute and water got in macroporosity and change flow and flux dynamics. We solve the problem (thanks to J.Simunek) but others problems have happened since.
