9 Short title: Muscle properties, pig breed and rearing system

10

11 **Abstract**

12 Conventional pork production, based on highly selected breeds for growth efficiency  
13 and carcass leanness, is generally considered to decrease pork quality. In contrast,  
14 non-selected breeds produced in extensive systems are associated with high pork  
15 quality, which is generally attributed to higher intramuscular fat (IMF) content and  
16 less glycolytic muscle metabolism. The present study aimed to determine  
17 biochemical, histological and quality traits of loin and ham muscles of pigs from  
18 selected Large White (LW) and local French, non-selected Basque (B) breeds. Pigs  
19 were reared in a conventional indoor (C, slatted floor), alternative (A, indoor bedding  
20 and outdoor area) or extensive system (E, free range, B pigs only). A total of 100  
21 castrated males were produced in two replicates, each containing 5 groups of 10 pigs  
22 based on breed and system: LWC, LWA, BC, BA, and BE. The glycolytic longissimus  
23 (LM) and semimembranosus (SM) muscles, and the deep red (RSTM) and superficial  
24 white (WSTM) portions of semitendinosus muscle (STM), were studied at 145 kg  
25 body weight. Overall, breed induced stronger effects on muscle traits than the rearing

26 system, among which the E system induced greater changes. The lower muscle  
27 growth of B pigs was associated with fewer muscle fibers and a smaller cross-  
28 sectional area (CSA) of glycolytic fibers ( $P < 0.01$ ). The SM was less glycolytic and  
29 more oxidative in B than in LW pigs ( $P < 0.001$ ). The WSTM followed a similar trend,  
30 with a larger relative area of type I fibers in B pigs. In contrast, the LM and RSTM  
31 were more oxidative in LW pigs. B pigs had higher IMF content and ultimate pH in all  
32 muscles, along with lower glycolytic potential, less light and redder meat in the LM  
33 and SM ( $P < 0.001$ ). Compared to the C system, the A system induced only a shift  
34 towards a more oxidative metabolism in the LM and a smaller fiber CSA in the RSTM  
35 of LW pigs ( $P < 0.05$ ), without influencing pork quality traits. Compared to BC pigs,  
36 BE pigs had a more oxidative and less glycolytic muscle metabolism, along with  
37 higher ultimate pH, lower lightness and redder meat ( $P < 0.01$ ), but similar IMF  
38 content. Overall, results indicate that influences of breed and rearing system on  
39 muscle properties depend on muscle type, and that IMF content and fiber type  
40 composition are unrelated traits that can be modified independently by genetic or  
41 rearing factors.

42  
43 **Keywords:** muscle fiber type, muscle energy metabolism, intramuscular fat, pork  
44 quality, breed

#### 45 46 **Implications**

47 Compared to conventional production of high-performing pig breeds, non-selected  
48 local breeds, often produced in outdoor or extensive systems, generally have better  
49 pork quality. Muscle biology (fiber type composition, metabolism and lipid content)  
50 and pork quality traits differed greatly between selected Large White and local

51 Basque pig breeds. Moreover, compared to conventional systems, the extensive  
52 system further improved Basque pork quality, while the alternative system (bedding  
53 and outdoor area) had less influence on muscle and pork properties. Independence  
54 between fiber type composition and lipid content allows each to be controlled by  
55 genetics or pig breeding to optimize pork quality.

56

## 57 **Introduction**

58 In the context of consumers' increasing expectations for improved sustainability of  
59 production systems, animal welfare and eating quality of meat products (Font-i-  
60 Furnols and Guerro, 2014), pork products from local pig breeds reared in extensive  
61 systems have an excellent image among consumers (Bonneau and Leuret, 2010).  
62 Several local pig breeds have been maintained as a genetic-diversity reservoir; they  
63 generally have a lower growth rate and lean meat content, as well as higher fatness  
64 and eating quality, than selected breeds (Pugliese and Sirtori, 2012). Moreover, their  
65 phenotypic traits resulting from their genetic potential can be modulated by rearing  
66 factors such as final slaughter weight and age, feeding, climatic conditions, space  
67 allowance and physical exercise (Rosenvold and Andersen, 2003; Leuret, 2008).  
68 The local Basque breed reared in extensive conditions and slaughtered at ca. 145 kg  
69 body weight (BW) in southwestern France is an example of a diversified pork chain  
70 that results in high-quality and typical products recognized by the Protected  
71 Designation of Origin label (Mercat *et al.*, 2019). Among muscle biological  
72 characteristics that confer high quality, intramuscular fat (IMF) content is an important  
73 trait that should reach 2-3% of fresh muscle to achieve satisfactory pork tenderness  
74 and juiciness and acceptable visual perception by consumers (review by Listrat *et al.*,  
75 2016). However, the association between IMF content and pork quality is not always

76 reported due to the influence of many other factors, such as the post-mortem  
77 decrease in pH, aging conditions and cooking methods. Muscle fiber type  
78 composition also influences pork quality through its effects on pH, water holding  
79 capacity, color and muscle microstructure (review by Lefaucheur, 2010). Increasing  
80 the percentage of fast-twitch glycolytic fibers in pig longissimus muscle (LM)  
81 increases the rate and extent of the pH decrease and meat lightness, and decreases  
82 protein solubility and water holding capacity. In contrast, a higher percentage of slow-  
83 twitch oxidative fibers increases pork flavor, tenderness and redness (Kang *et al.*,  
84 2011). In addition, increasing the cross-sectional area (CSA) of muscle fiber is widely  
85 reported to decrease water holding capacity and pork tenderness (Lefaucheur,  
86 2010). Fiber-type composition and IMF content differ greatly among muscles and are  
87 influenced by genetic, animal (e.g. age) and environmental factors, but relationships  
88 between the two traits remain controversial (Lefaucheur, 2010). It is commonly stated  
89 that oxidative muscles contain more IMF than glycolytic muscles (Bereta *et al.*, 2014;  
90 Jeong *et al.*, 2017); however, other studies do not support this assessment (Kang *et*  
91 *al.*, 2011).

92 Lebret *et al.* (2015) observed that pigs of the local, non-selected Basque (B) breed  
93 had higher quality pork than pigs of the conventional Large White (LW) breed. The  
94 objective of the present study was to determine the biological properties of muscle  
95 that explained this difference. We hypothesized that B pigs have higher muscle  
96 oxidative metabolism and IMF content and lower fiber CSA than LW pigs. Since  
97 outdoor or free-range rearing of pigs can increase muscles' oxidative metabolism and  
98 influence their energy stores (i.e. IMF content and glycolytic potential (GP), which  
99 can influence pork quality (Bee *et al.*, 2004; Gentry *et al.*, 2004)), we also  
100 hypothesized that biological properties of B and LW pig muscles would differ

101 depending on their rearing conditions. Therefore, we aimed to determine the  
102 biochemical, metabolic and histological traits of loin and ham muscles that influence  
103 the pork quality of B and LW pigs reared in a conventional indoor, alternative (indoor  
104 bedding and outdoor area) or extensive free-range system (B pigs only), with the  
105 ultimate aim to identify breeding and rearing practices that improve pork quality.

106

## 107 **Materials and methods**

108

### 109 *Animals and experimental design*

110 Lebret *et al.* (2014, 2015) described the experimental design in detail. Briefly, 100  
111 castrated male pigs from the pure local B (n = 60) or LW breed (n = 40) were used.  
112 The B pigs came from two breeding farms of the Basque pork chain (Mercat *et al.*,  
113 2019), while the LW pigs came from the INRA experimental herd. All animals were  
114 free of the RYR1 and PRKAG3 mutated alleles. Pigs were produced in two  
115 experimental replicates (R1 and R2), each including 30 B and 20 LW pigs. In each  
116 replicate, at a mean BW of 35 kg, 20 B littermates (from 10 B litters each in R1 and  
117 R2) and 20 LW littermates (from 10 and 7 LW litters in R1 and R2, respectively) were  
118 placed in a conventional (C, one pen per breed, indoor slatted floor, 1.0 m<sup>2</sup>/pig) or  
119 alternative housing system (A, one pen per breed, indoor bedding and free access to  
120 an outdoor area, 2.4 m<sup>2</sup>/pig), until slaughter at ca. 145 kg BW. LWC, LWA, BC and  
121 BA pigs (n = 10 (one pen) per treatment and replicate) were fed the same standard  
122 growing (2.29 Mcal/kg net energy, 18.0% CP, 3.40% crude fat, 0.83% digestible  
123 lysine; from 35 up to 75 kg BW) and finishing (2.14 Mcal/kg net energy, 14.7% CP,  
124 1.60% crude fat, 0.75% digestible lysine ; from 75 kg BW to slaughter) diets. Pigs  
125 were fed *ad libitum* until the average feed intake of 2.5 kg/d and per pig was reached,

126 corresponding approximately to 75 kg BW in each treatment. Then, the daily feed  
127 allowance was progressively increased up to 3.0 kg/d and per pig up to 110 kg BW  
128 and maintained at 3.0 kg/d and per pig until 145 kg BW. Pigs were weighed at the  
129 start, during and at the end of the experiment, and average daily gain (ADG) was  
130 calculated individually. Feed consumption per pen was recorded weekly, and  
131 average daily feed intake (ADFI) and feed efficiency were calculated per pen for each  
132 treatment and replicate. LWC, LWA, BC and BA pigs were slaughtered at the INRA  
133 slaughterhouse in four sessions, each including pigs from the four treatments.  
134 In addition, in each replicate, 10 B pigs, half-littermates of BC and BA pigs, were  
135 placed at 35 kg BW in an extensive production system (E, outdoor free-range  
136 system, 2.5 ha/pig) on a Basque chain farm, until slaughter at ca. 145 kg BW. BE  
137 pigs had free access to natural food resources (acorns and chestnuts) and were fed  
138 a standard supplementary growing-finishing diet (2.15 Mcal/kg net energy, 15.5%  
139 CP, 1.95% crude fat, 0.70% digestible lysine) according to local farming practices  
140 (allowance of 1.4 kg/d up to 2.2 kg/d and per pig from 35 kg up to 75 kg BW; 2.2 kg/d  
141 up to 2.6 kg/d and per pig from 75 kg up to 110 kg BW; 2.6 kg/d to 2.3 kg/d and per  
142 pig from 110 kg up to 130 kg BW; and 2.0 kg/d and per pig from 130 kg until  
143 slaughter at around 145 kg BW; Lebret *et al.*, 2014; Mercat *et al.*, 2019). BE pigs  
144 were weighed individually to calculate ADG. The ADFI and feed efficiency of BE pigs  
145 could not be calculated because their feed consumption, including both the  
146 supplementary diet and the natural food resources, could not be determined. BE pigs  
147 were included in the experiment 5 months, and BC and BA pigs 3 months, before  
148 LWC and LWA pigs in order to slaughter all pigs at 145 kg BW during winter in  
149 January (R1) or February (R2). BE pigs were slaughtered in a commercial

150 slaughterhouse (Saint-Jean-Pied-de-Port, France). Slaughtering conditions of the two  
151 slaughterhouses used in the experiment were standardized as much as possible.

152

### 153 *Carcass and pork quality traits*

154 According to the handling practices of the Basque pork chain, all pigs were  
155 slaughtered after 36 h of fasting by exsanguination after electrical stunning (350 V, 4  
156 A), in compliance with national regulations for slaughterhouses. Weights of the hot  
157 carcass and cold half-side carcass, as well as the loin and back fat primal cuts, were  
158 recorded. Pork quality traits were measured for all animals in the loin (LM, first  
159 lumbar vertebra level), as presented by Lebret *et al.* (2015), and in the ham  
160 semimembranosus muscle (SM). Measurements included IMF content, GP, ultimate  
161 pH (pHu, 24 h post mortem), lightness and hue angle. The semitendinosus muscle  
162 (STM) was completely excised from the LWC, LWA, BC and BA pigs of R1 (n = 40)  
163 and weighed. Since the STM is heterogeneous, with a deep red (RSTM) and a  
164 superficial white (WSTM) portion (Figure 1; Listrat *et al.*, 2016), the IMF content and  
165 pHu of both portions were measured. See Supplementary Material S1 for details of  
166 the methods.

167

### 168 *Metabolic enzyme activities*

169 Enzyme activities were measured in the LM and SM of all R1 and R2 pigs, and in the  
170 RSTM and WSTM of LWC, LWA, BC and BA pigs of R1. Within 40 min post mortem,  
171 muscle samples were taken from the LM (last rib level), SM (external part, 2 cm  
172 deep) and central portions of the RSTM and WSTM; cut into small pieces; promptly  
173 frozen in liquid nitrogen and stored at -80°C. Activities of lactate dehydrogenase  
174 (LDH), citrate synthase (CS) and  $\beta$ -hydroxy-acyl-CoA dehydrogenase (HAD) were

175 determined as markers of glycolytic metabolism, oxidative capacity (tricarboxylic acid  
176 cycle) and lipid  $\beta$ -oxidation potential, respectively, as described by Lebret *et al.*  
177 (2002) and detailed in Supplementary Material S1.

178

### 179 *Histological analyses*

180 Muscle fibers were typed in the LM of all R1 and R2 pigs and in the RSTM and  
181 WSTM of LWC, LWA, BC and BA pigs of R1. From the samples taken to measure  
182 enzyme activities, sub-samples parallel to the muscle fiber axis were promptly frozen  
183 in isopentane cooled by liquid nitrogen and stored at  $-80^{\circ}\text{C}$  until analysis, performed  
184 as described by Larzul *et al.* (1997) and detailed in Supplementary Material S1.  
185 Briefly, 10  $\mu\text{m}$  thick transverse serial sections were cut in a cryostat ( $-20^{\circ}\text{C}$ ), mounted  
186 on glass slides and stained for acto-myosin ATPase after preincubation at pH 4.35 to  
187 distinguish contractile types I, IIA and IIB, or stained for succino-dehydrogenase to  
188 identify metabolic red oxidative (R) and white glycolytic (W) fibers. Combining both  
189 stains, fibers were classified as type I (slow-twitch oxidative), IIA (fast-twitch oxido-  
190 glycolytic), IIBR (fast-twitch oxido-glycolytic) or IIBW (fast-twitch glycolytic). From  
191 each sample, four fields containing ca. 250 fibers each were randomly chosen to  
192 determine the percentage, CSA and relative area of each fiber type using digital  
193 image analysis. The total number of fibers (TNF) in the RSTM and WSTM was  
194 determined by multiplying the mean number of fibers per unit area (calculated from  
195 three fields per sample using a projection microscope) by the transverse area of each  
196 portion (determined as described in Supplementary material S1).

197

### 198 *Statistical analyses*

199 Statistical Analysis System (SAS) software (version 9.4, 2013, SAS Institute, Cary,  
200 NC, USA) was used to analyze the data (details in Supplementary Material S1). Data  
201 for the ADFI and feed efficiency of LWA, LWC, BA and BC pigs, for which the pen  
202 was considered the statistical unit, were analyzed using ANOVA (GLM procedure),  
203 considering the treatment (4 levels) and replicate (2 levels) as fixed effects. Contrasts  
204 between breeds and between the A and C systems for a given breed were  
205 determined (Lebret *et al.*, 2014). For all other traits, the animal was considered the  
206 statistical unit. First, data were analyzed using ANOVA (GLM procedure), considering  
207 the treatment (LWC, LWA, BC, BA and BE) and replicate (R1 and R2) as fixed  
208 effects to calculate residues. The normality of residues was checked (Shapiro-Wilk  
209 test,  $P \geq 0.05$ ). When necessary, data were log- or square-root transformed to obtain  
210 a normal distribution of residues, which were checked using the same test.  
211 Subsequently, contrasts between breeds were determined from the ANOVA using  
212 only the LWC, LWA, BC and BA pigs, to balance the production systems between  
213 breeds. Within each breed, contrasts between rearing systems were determined to  
214 evaluate effects of the A vs. C system for the LW breed, and the A vs. C and E vs. C  
215 systems for the B breed. Means were calculated by treatment. When residues could  
216 not be normalized, a non-parametric method (NPAR1WAY procedure, Kruskal-Wallis  
217 test) was used to determine effects of the breed and of the rearing system within a  
218 given breed; their medians were calculated by treatment.

219

## 220 **Results**

221

222 *Growth performance and carcass traits*

223 As previously reported in more detail (Lebret *et al.*, 2014), B pigs had lower ADG  
224 than LW pigs (Table 1). ADG did not differ between LWC and LWA pigs, but was  
225 higher for BA pigs and lower for BE pigs than for BC pigs. Consequently, B pigs,  
226 especially BE, were older than LW pigs at slaughter. LW pigs had higher ADFI and  
227 feed efficiency than B pigs. LWA pigs had similar ADFI as, but lower feed efficiency  
228 than, LWC pigs, while BA pigs had higher ADFI than, but similar feed efficiency as,  
229 BC pigs. B pigs had fatter carcasses, with higher back fat and lower loin proportions,  
230 than LW pigs. Compared to the C system, the A system increased the loin proportion  
231 in LW pigs, but did not influence proportions of carcass cuts of B pigs. In contrast, the  
232 E system decreased the carcass fatness of B pigs.

233

#### 234 *Biochemical and quality traits of longissimus and semimembranosus muscles*

235 B pigs had higher IMF content in both the LM and SM than LW pigs (Table 2). No  
236 significant differences in IMF content between A and C systems were observed  
237 within each breed, or between E and C systems within the B breed. B pigs had  
238 higher pHu and lower GP, lightness and hue angle (indicating redder meat) in both  
239 muscles than LW pigs. Within each breed, the A vs. C system did not influence pHu,  
240 GP, lightness or hue angle. In contrast, BE pigs had higher pHu and lower lightness  
241 in both muscles than BC pigs. BE pigs had lower GP in the SM than BC pigs, but  
242 they did not differ in the LM.

243 Breed effects on metabolic enzyme activities differed between muscles (Table 3). B  
244 pigs had lower CS and HAD activities in the LM than LW pigs, while the opposite was  
245 observed in the SM. LDH activity in the LM did not differ between breeds but was  
246 lower in the SM of B than LW pigs. Within each breed, compared to the C system,  
247 the A system increased CS activity in both muscles and HAD activity in the SM of LW

248 pigs, but did not influence LDH activity in either muscle. BE pigs had higher CS and  
249 HAD activities than, but similar LDH activity as, BC pigs in the LM. In contrast, BE  
250 pigs had lower LDH activity than, but similar CS and HAD activities as, BC pigs in the  
251 SM.

252

### 253 *Histological properties of the longissimus muscle*

254 B pigs had a lower percentage of IIA fibers and a higher percentage of IIBW fibers in  
255 the LM than LW pigs, but they did not differ in the percentages of I and IIBR fibers  
256 (Table 4). B pigs had lower mean fiber CSA than LW pigs, but differences varied  
257 among fiber types. B pigs had smaller IIBW fibers and larger I fibers than, and similar  
258 CSA of IIA and IIBR fibers as, LW pigs. Only the relative area of I fibers was higher in  
259 B pigs than in LW pigs. The influence of the A vs. C system on fiber types varied by  
260 breed. LWA pigs had higher IIBR and lower IIBW percentages than LWC pigs, while  
261 BA pigs had a higher IIA percentage than BC pigs. The A vs. C system did not  
262 influence fiber CSA in either breed, but resulted in a lower relative area of IIBW fibers  
263 in LW pigs and a higher relative area of IIA fibers in B pigs. Compared to BC pigs, BE  
264 pigs had a larger CSA of I fibers and a higher percentage and larger relative area of  
265 IIA fibers at the expense of IIBW fibers.

266

### 267 *Biochemical, quality traits and histological characteristics of the semitendinosus* 268 *muscle*

269 B pigs had a lower proportion of STM in the half-carcass than LW pigs, but the  
270 proportion of STM did not differ between A and C systems within each breed (Table  
271 5). B pigs had higher IMF content (Table 5) and visual marbling (Figure 1) in both the  
272 RSTM and WSTM than LW pigs, especially in the WSTM. B pigs had higher pHu in

273 both STM portions than LW pigs, with generally higher pHu in the RSTM than in the  
274 WSTM. Breed did not influence CS or HAD activities in the RSTM or WSTM, but B  
275 pigs had higher LDH activity in the RSTM than LW pigs. Regardless of the breed, the  
276 A and C systems did not differ in enzyme activities, IMF content or pHu in the RSTM  
277 or WSTM.

278

### 279 *Fiber type composition of the semitendinosus muscle*

280 B pigs had 16% smaller TNF in the STM than LW pigs, exclusively due to a smaller  
281 TNF in the WSTM (Table 6). TNF did not differ between the A and C systems in  
282 either breed. Breed differences in fiber types varied by STM portion. B pigs had a  
283 lower percentage of I fibers in the RSTM than LW pigs but higher percentages of  
284 IIBR and IIBW fibers. In contrast, B pigs had a higher percentage of I fibers in the  
285 WSTM than LW pigs but similar percentages of IIA, IIBR and IIBW fibers. B pigs had  
286 smaller mean fiber CSA in the RSTM and WSTM than LW pigs, due to a smaller CSA  
287 of all fiber types in the RSTM, but only of IIB fibers in the WSTM. Compared to LW  
288 pigs, B pigs had a larger relative area of IIBR at the expense of IIA fibers in the  
289 RSTM, and of I fibers at the expense of IIB fibers in the WSTM. No effect of the A vs.  
290 C system was observed on fiber type percentages in either the STM portion or breed.  
291 The A system resulted in smaller CSA of all fiber types in the RSTM of LW pigs, with  
292 no effect in B pigs. Fiber CSA in the WSTM did not differ between A and C systems  
293 regardless of fiber type or breed. Overall, relative areas of fiber types did not differ  
294 between A and C systems in the RSTM or WSTM.

295

## 296 **Discussion**

297 Unlike the local B breed, which has not experienced genetic selection, the LW breed  
298 has been selected for a high growth rate, feed efficiency and carcass leanness,  
299 which likely indirectly resulted in selecting animals with a larger adult body size.  
300 Consequently, at a given BW, B pigs are older and fatter (Lebret *et al.*, 2014), and  
301 closer to their adult size, meaning that they are physiologically more mature than LW  
302 pigs. Muscle mass depends on the TNF, CSA and length of fibers. Since the TNF in  
303 pigs is established by the end of the fetal period (review by Lefaucheur, 2010), post-  
304 natal muscles grow exclusively by increasing both the CSA and length of fibers. In  
305 our study, the lower muscle mass of B pigs than of LW pigs was associated with both  
306 smaller TNF and mean fiber CSA, indicating that the smaller TNF in B pigs was not  
307 compensated by larger fiber CSA at the same slaughter weight. Similarly, smaller  
308 TNF and fiber CSA were reported in Meishan, a Chinese breed with low muscle  
309 growth potential, than in the LW breed (Lefaucheur *et al.*, 2004). Gil *et al.* (2008)  
310 made the same observation when comparing other local pig breeds to selected pig  
311 breeds. Smaller CSA of IIB fibers and larger relative area of I fibers have been  
312 associated with higher pork quality, especially water holding capacity and tenderness  
313 (Lefaucheur, 2010). These histological properties observed in the LM of B pigs but  
314 not LW pigs may contribute to the higher eating quality of B pork (Lebret *et al.*, 2015).  
315 Within each breed, the lack of difference in the mean fiber CSA in the LM and WSTM  
316 between the A and C systems agrees with the systems' relatively weak effects on  
317 body composition. Similarly, the mean CSA in the LM and loin proportion in B pigs  
318 did not differ between the E and C systems. However, the smaller CSA of all fiber  
319 types in the RSTM of LWA pigs than of LWC pigs was not expected and requires  
320 further study. Unfortunately, the STM characteristics of BE pigs could not be  
321 assessed in the present study.

322 Pork quality traits are influenced by genetic factors, environmental factors and  
323 slaughter conditions (Rosenvold and Andersen, 2003), and higher quality is generally  
324 reported in local rather than “conventional” selected pig breeds (review by Bonneau  
325 and Lebret, 2010). The LM and SM of B pigs had lower GP, higher pHu and IMF  
326 content, lower lightness and a redder color than those of LW pigs, which explains  
327 their higher eating and technological quality (Lebret *et al.*, 2015). Based on  
328 descriptions of differences in muscle metabolism between wild or non-selected pigs  
329 and selected pigs (Wimmers *et al.*, 2008; Lefaucheur, 2010), B pigs were expected to  
330 have lower glycolytic and/or higher oxidative metabolism than LW pigs. These  
331 differences were observed in the SM, in which B pigs had higher CS and HAD  
332 activities and lower LDH activity than LW pigs, which is consistent with their lower  
333 GP, higher pHu and redder meat. In contrast, the LM of B pigs had less oxidative  
334 metabolism, probably due to their older age and greater maturity at a given BW,  
335 since fast-oxido-glycolytic fibers in the LM are converted into fast-glycolytic fibers as  
336 pigs age (Lefaucheur and Vigneron, 1986). Because type I fibers have the lowest  
337 glycogen content (Lefaucheur, 2010), their larger relative area in the LM of B pigs  
338 than in LW pigs can partly explain their lower GP. The redder meat in the LM and SM  
339 of B pigs could be due to their higher muscle myoglobin content with age (Mayoral *et al.*  
340 *et al.*, 1999). The percentage of I fibers was similar in the LM of B and LW pigs, in  
341 agreement with lack of difference for this trait between Meishan and LW pigs  
342 (Lefaucheur *et al.*, 2004). However, other studies reported a higher percentage of I  
343 fibers in the LM of wild pigs or other local breeds (Ruusunen and Puolanne, 2004;  
344 Wimmers *et al.*, 2008). These discrepancies could be explained by differences in  
345 physical exercise, climatic conditions, BW, age and physiological maturity between  
346 the animals in specific studies. As in the LM and SM, B pigs had higher pHu in the

347 RSTM and WSTM than LW pigs. This difference was associated with a higher  
348 percentage of I fibers in the WSTM, and, surprisingly, with a higher glycolytic  
349 metabolism in the RSTM of B pigs than LW pigs, suggesting that different portions of  
350 the same muscle can be influenced differently by breed. The relative areas of the two  
351 STM portions may also have differed between breeds, but they could not be studied  
352 due to the difficulty in delineating the portions (Figure 1).

353 Overall, breed influenced the biological properties of muscle and pork quality traits  
354 more than the rearing system. Within each breed, the A and C systems did not differ  
355 in the IMF content, GP, pHu, lightness or hue angle in the LM and SM, in agreement  
356 with studies that showed no consistent effect of indoor bedding or free access to a  
357 small outdoor area on these traits (Lebret *et al.*, 2002; Millet *et al.*, 2005). Although  
358 the rearing system yielded similar quality traits, it influenced the muscle metabolism  
359 of LW pigs, with higher oxidative metabolism in the LM and SM of LWA pigs than of  
360 LWC pigs. These results agree with the shift from fast glycolytic to fast oxido-  
361 glycolytic fibers in the LM of pigs offered access to an outdoor area (Lebret *et al.*,  
362 2002) and in the SM of free-range pigs during winter, unlike those of pigs housed  
363 indoors (Gentry *et al.*, 2004). No such effects were observed in the LM and SM of B  
364 pigs, or in the RSTM and WSTM of either breed, suggesting greater robustness of  
365 muscle properties of B pigs to environmental factors. Comparing winter free-range to  
366 indoor housing of Swiss LW pigs, Bee *et al.* (2004) also observed higher oxidative  
367 metabolism in the LM but no differences in the RSTM or WSTM. Petersen *et al.*  
368 (1998) observed higher oxidative metabolism in the STM of pigs physically trained or  
369 reared in large pens, but they did not distinguish the RSTM and WSTM portions.

370 Both physical exercise and cold exposure, like for pigs in the A system (Lebret *et al.*,  
371 2014), have been shown to increase muscle oxidative metabolism (Lefaucheur,

2010). In the present study, however, they were not sufficient to modify the metabolic or histological traits of the RSTM or WSTM in either breed.

Among the rearing systems considered, the E system of the Basque pork chain induced the strongest effects on muscle and pork traits. The higher pHu and redness and lower lightness of the LM and SM of BE pigs than of BC pigs agree with the higher oxidative metabolism in the LM and lower glycolytic metabolism in the SM. These results are consistent with the increased IIA:IIB fiber ratio found in the LM of free-range pigs (Petersen *et al.*, 1998; Bee *et al.*, 2004; Gentry *et al.*, 2004). Because BE pigs were older, have more physical activity and encounter colder temperatures, higher oxidative capacity was also expected in their SM, which is involved in locomotion, but this increase was not observed. The redder meat of BE pigs would thus be more likely explained by their greater age at slaughter, which induces higher myoglobin content (Mayoral *et al.*, 1999). The higher pHu in BE pigs than in BC pigs was logically accompanied by a lower GP in the SM, but not in the LM, confirming that muscle properties other than GP determine the pHu (Scheffler *et al.*, 2013).

Unlike our results, extensive pig rearing during winter has been shown to increase GP, especially in muscles involved in movement, such as the SM (Lebret, 2008). This difference may be due to higher pre-slaughter physical activity of BE pigs than BC pigs, despite the high standardization of pre-slaughter handling in the experiment (Lebret *et al.*, 2015).

B pigs had a higher IMF content in all muscles, regardless of their contractile and metabolic profiles, than LW pigs, in agreement with the positive correlation between the IMF content in different muscles in pigs (Quintanilla *et al.*, 2011). Interestingly, the IMF content in both breeds was higher in the glycolytic WSTM than in the oxidative RSTM, with stronger breed differences in the WSTM. Differences in IMF

397 content between Duroc, a breed with high IMF content, and the LW breed were also  
398 stronger in the LM than in the more oxidative psoas major muscle (Wood *et al.*,  
399 2004). Assessing relationships between IMF content and metabolic enzyme  
400 activities, the percentage of type I fibers or mean CSA in the LM, WSTM and RSTM,  
401 revealed no significant correlation between IMF content and these traits, either  
402 between or within muscles (Figure 2). Similarly, IMF content has been shown to be  
403 genetically unrelated to fiber type composition in the LM (Larzul *et al.*, 1997),  
404 suggesting that IMF content and muscular contractile and metabolic characteristics  
405 are unrelated traits that can be manipulated separately by breeding or rearing  
406 factors.

## 408 **Conclusion**

409 Overall, effects of breed on pork quality and muscle biochemical and histological  
410 characteristics were greater than those of the rearing system, among which the E  
411 system induced the greatest changes. Both smaller TNF and CSA of glycolytic fibers  
412 were associated with the lower muscle mass of B pigs than of LW pigs. In all  
413 muscles, B pigs had higher IMF content and pHu and smaller mean fiber CSA than  
414 LW pigs, which likely explains the former's higher pork quality. The expected shift  
415 towards a less glycolytic and more oxidative muscle metabolism in B pigs than in LW  
416 pigs was observed in the SM and, to a lesser extent, the WSTM, but not in the LM or  
417 RSTM, which were more oxidative in LW pigs. Interestingly, the glycolytic WSTM  
418 contained more IMF than the oxidative RSTM, especially in B pigs, supporting the  
419 independence between IMF content and contractile and metabolic muscle properties.

420

## 421 **Acknowledgements**

422 The authors thank the staff of the INRA experimental farm, slaughterhouse and  
423 laboratories, especially Patrick Ecolan and Nathalie Bonhomme, and the breeders  
424 and slaughterhouse staff of the Basque pork chain.

## 426 **Declaration of interest**

427 None.

428

## 429 **Ethics statement**

430 All experimental procedures complied with European Union (Directive 86/609/CEE)  
431 and French legislation (Décret no. 2001-464 29/05/01). INRA UEPR held the pig  
432 experimentation agreement C-35–275–32. All technical and scientific staff involved in  
433 the experiment had an individual agreement for experimenting on living animals,  
434 provided by the Veterinary Services of the French Ministry of Agriculture.
