Abstract:	Bacterial wilt caused by Curtobacterium flaccumfaciens pv. flaccumfaciens is among the diseases that affect Phaseolus vulgaris L. This disease has been frequently detected in bean fields and causes severe production losses in Brazil. The aim of this research was to examine the genetic diversity existing among twenty-four isolates of C. flaccumfaciens collected from their native and alternative host, and a collection of sixty strains belonging to four phytopathogenic pathovars preserved at the French Collection for Plant-associated Bacteria (CIRM-CFBP) by multilocus sequence analysis (MLSA) based on six housekeeping genes (atpD, dnaK, gyrB, ppK, recA and rpoB). A phylogenetic tree with the concatenated sequences of six genes showed high genetic diversity among the strains. For instance, strains belonging to C. f. pv. flaccumfaciens do not cluster together within the species. Similar results were obtained with a minimal MLSA scheme using gyrB and recA, which we propose for reliable identification at the species level of Curtobacterium isolates. No correlation was identified between phylogeny and pathogenicity in the Curtobacterium flaccumfaciens strains analyzed in this work. The specific primers CffFOR2 and CffREV4 designed by Tegli et al. (2002) to detect C. f. pv. flaccumfaciens in naturally infected bean seeds proved to be efficient for the detection of bean-pathogenic strains.				
Response to Reviewers:	We'd like to thank the reviewers for their precise and thorough work on our manuscript. Your work greatly helped us to improve the quality of the manuscript.				

Based on your comments we:
- Reviewed deeply the text according to your remarks.
- Ask a native-English speaker to correct the manuscript to enhance the quality of the text.
- Recalculate the phylogenetic network, and modify the associated Figure 2.
- Corrected the tables and figures needing correction (Table 1, Table 2, Figure 1, Supplemental Figure 2).
- Submitted the complete genome sequences for CFBP 4999 and CFBP 2404 to Genbank. The accession numbers are visible in the text. We ask Genbank for the release og the complete genome sequence of CFBP 3418
- Submitted the sequences obtained for the 6 housekeeping genes to GenBank. The accession numbers are listed in supplemental Table 1 (the sequences were not yet displayed no line on November 15th, still waiting to being processed by Genbank).

14	Abstract
15	
16	Bacterial wilt caused by Curtobacterium flaccumfaciens pv. flaccumfaciens is among the
17	diseases that affect Phaseolus vulgaris L. This disease has been frequently detected in bean fields and
18	causes severe production losses in Brazil. The aim of this research was to examine the genetic diversity
19	existing among twenty-four isolates of C. flaccumfaciens collected from their native and alternative host,
20	and a collection of sixty strains belonging to four phytopathogenic pathovars preserved at the French
21	Collection for Plant-associated Bacteria (CIRM-CFBP) by multilocus sequence analysis (MLSA) based
22	on six housekeeping genes (atpD, dnaK, gyrB, ppK, recA and rpoB). A phylogenetic tree with the
23	concatenated sequences of six genes showed high genetic diversity among the strains. For instance, strains
24	belonging to C. f. pv. flaccumfaciens do not cluster together within the species. Similar results were
25	obtained with a minimal MLSA scheme using gyrB and recA, which we propose for reliable identification
26	at the species level of Curtobacterium isolates. No correlation was identified between phylogeny and
27	pathogenicity in the Curtobacterium flaccumfaciens strains analyzed in this work. The specific primers
28	CffFOR2 and CffREV4 designed by Tegli et al. (2002) to detect C. f. pv. flaccumfaciens in naturally
29	infected bean seeds proved to be efficient for the detection of bean-pathogenic strains.

30 Keywords: gyrB, MLSA, phylogeny, recA, Curtobacterium.

### 32 Introduction

33 Common bean (Phaseolus vulgaris L.) is an important source of nutrients in the human diet. In 34 2013/14, Brazil was the third largest producer, behind Myanmar and India 35 (http://www.fao.org/faostat/en/#data/QC). The common bean has adapted to a wide variety of climatic and 36 soil conditions and in Brazil it is cultivated in three different seasons annually. The widespread production 37 contributes to an increase in the incidence of diseases that can cause significant losses in bean production 38 (Schwartz et al. 2005).

39 Bacterial wilt disease of bean was first recorded in 1920 on a farm in South Dakota (USA), 40 associated with a 90% crop loss that year (Hedges 1922) and in subsequent years, complete crop failure 41 (Hedges 1926). Formerly classified as Corynebacterium (Hedges 1922), the causal agent of bacterial wilt 42 has been reclassified as Curtobacterium flaccumfaciens pv. flaccumfaciens (Hedges 1922; Collins & 43 Jones 1983). Bacterial wilt of common bean was first reported in Brazil in 1995 in the state of São Paulo 44 (Maringoni and Rosa 1997). Since then, this pathogen has become a serious problem in many parts of 45 Brazil, including Santa Catarina, Mato Grosso do Sul, Goiás and the Federal District (Herbes et al. 2008; 46 Theodoro et al. 2010; Uesugi et al. 2003). Curtobacterium flaccumfaciens pv flaccumfaciens was reported 47 in Germany and Iran (Sammer & Reiher 2012; Osdaghi et al. 2016) indicating that this pathogen is likely 48 to spread to other parts of the world in the future.

49 Recently, *C. f.* pv. *flaccumfaciens* was detected in symptomless alternative hosts in Brazil, 50 including barley (*Hordeum vulgare* L.), black oat (*Avena strigosa* Schreb.), canola (*Brassica napus* L.), 51 ryegrass (*Lolium multiflorum* Lam.), wheat (*Triticum aestivum* L.) and white oat (*Avena sativa* L.). When 52 these alternative hosts are grown in succession with bean, they can act as inoculum sources of the 53 pathogen which can infect the bean crop each growing season. (Gonçalves et al. 2017).

*Curtobacterium flaccumfaciens* is currently divided into five pathovars (Young et al. 1978) following the host range of the strains. In addition to pathovar *flaccumfaciens*, pathovar *betae* ((Keyworth *et al.* 1956) Collins & Jones 1983) causes vascular wilt and leaf spot in beetroot (*Beta vulgaris* var. *rubra*); pathovar *oortii* ((Saaltink & Maas Geesteranus 1969) Collins & Jones 1983) causes bulb spot and vascular wilt on the leaves of tulip (*Tulipa* spp.); pathovar *poinsettiae* ((Starr & Pirone 1942) Collins & Jones 1983) causes stem canker and leaf spot in *Euphorbia pulcherrima*; and pathovar *ilicis* ((Mandel *et al.*, 1961) Young *et al.*, 2004) is pathogenic to American holly (*Ilex opaca*). There are also two additional pathovars in this species that have been described but not yet taxonomically approved: *Curtobacterium flaccumfaciens* pv *beticola* (Chen et al. 2007) causing bacterial leaf spot on sugar beet (*Beta vulgaris* var.
 *saccharifera*) and *Curtobacterium flaccumfaciens* pv *basellae*, the causal agent of bacterial leaf spot of

64 malabar spinach (*Basella alba* or *B. ruba*) (Chen et al., 2000).

65 The genetic variability of C. f. pv. flaccumfaciens has been previously studied by pulsed-field 66 gel electrophoresis (PFGE), amplified fragment length polymorphism (AFLP) (Agarkova et al. 2012; 67 Guimarães et al. 2003), rep-PCR (Souza et al., 2006; Agarkova et al., 2012) and BOX-PCR (Guimarães et 68 al. 2003). However, these methods suffer from significant drawbacks such as the incorrect identification 69 of PCR patterns based on subjective gel interpretation, and difficulty to reproduce the results in other 70 laboratories (Tancos et al. 2015). By contrast, multilocus sequence analysis (MLSA) is a powerful and 71 portable molecular technique for population genetics studies, and assignment of strains to defined species 72 (Bishop et al., 2009). This technique has been successfully used, among others, for characterization of the 73 genetic diversity of Clavibacter michiganensis (Jacques et al. 2012) and to assess the diversity of 74 Curtobacterium flaccumfaciens strains isolated from dry beans and other annual crops in Iran and Spain 75 (Osdaghi et al. 2018b).

Studies that increase our knowledge of the diversity of *Curtobacterium flaccumfaciens* strains
will help to generate a minimal MLSA scheme for *C. f.* pv *flaccumfaciens* identification. This will be
useful for plant diagnostic laboratories as well as enabling the improvement of prophylaxis measures and
breeding programs to obtain bacterial wilt resistant cultivars of bean.

80 In this study we chose to assess the genetic relatedness of Curtobacterium flaccumfaciens 81 strains from different pathovars and from diverse alternative host plants. We analyzed twenty-four strains 82 isolated from their native and alternative host in Brazil and sixty Curtobacterium flaccumfaciens strains 83 from the French Collection for Plant-associated Bacteria (CIRM-CFBP) belonging to four 84 phytopathogenic pathovars. The objectives were as follows: 1) to examine the genetic diversity among 85 four pathovars of C. flaccumfaciens strains, 2) to determine the relationship among C. flaccumfaciens 86 strains isolated from alternative hosts and strains isolated from bean, 3) to develop a molecular tool for 87 identifying C. flaccumfaciens strains and 4) to design a molecular tool to test the presence in of bean-88 pathogenic C. f. pv. flaccumfaciens strains in bean seeds and plants.

89

#### 90 Material and methods

#### 91 Bacterial strains and preservation

92 The eighty-four strains analysed in this study are listed in Table 1. Sixty strains were obtained 93 from CIRM-CFBP, the French Collection for Plant-associated Bacteria 94 (https://www6.inra.fr/cirm\_eng/CFBP-Plant-Associated-Bacteria). These strains were isolated over a 95 period of 71 years from Brazil, the United States, Japan and Europe. The remaining 24 strains come from 96 the Brazilian collection at the FCA-UNESP (Faculdade de Ciências Agronômicas - Universidade Estadual 97 Paulista "Júlio de Mesquita Filho", Botucatu, SP, Brazil). These strains were isolated from bean or from 98 diverse alternative hosts in Brazil (Gonçalves et al. 2017) (Table 1). The Brazilian strains were identified 99 as C. f. pv. flaccumfaciens using the specific primers PCR described by Tegli et al. (2002) and by 100 pathogenicity test in common bean plants (under greenhouse conditions).

101 The bacterial strains were stored as lyophilized cultures and maintained in 40% glycerol stock 102 at -80 °C after cell revival. The strains were checked for purity by cultivation on YPGA (also known as 103 LPGA) culture medium (7 g/L yeast extract, 7 g/L peptone, 7 g/L glucose, and 15 g/L agar, pH 7.2) for 104 two days at 25 °C.

105

## 106 Specific detection of C. f. pv. flaccumfaciens

107Bacterial cells, suspended in sterile water, were prepared for PCR by boiling (95 °C/15 min)108and stored at -20 °C before use. These cells were used directly as substrate for PCR reactions.

109 The primers CffFOR2 (5'GTT ATG ACT GAA CTT CAC TCC 3') and CffREV4 (5'GAT GTT CCC

110 GGT GTT CAG 3') described by Tegli et al. (2002) were used to amplify a 306 bp fragment targeting a

111 conserved region of a C.f. pv flaccumfaciens Rep-PCR sequences. The PCR reaction was performed in a

112 mix containing 200µM dNTP, 1.5mM of MgCl<sub>2</sub>, 500nM of each primer, 0.75U of GoTaq Flexi DNA

- 113 polymerase (Promega), and 6µL of the boiled bacterial cell suspension. The thermocycler conditions were
- as follows: initial denaturation at 94 °C for 3 min, followed by 30 cycles of 94 °C for 1 min, 62 °C for 45
- 115 s, and 72 °C for 30 s, and a final extension at 72 °C for 5 min.

116

#### 117 Primer design for housekeeping gene amplification

Primers designed for *Clavibacter michiganensis* (Jacques *et al.*, 2012) were used for the partial amplification of the housekeeping *genes recA*, *gyrB* and *ppK*. Additionally, new primers were designed in this study for partial amplification of the genes *atpD*, *dnaK* and *rpoB* of *Curtobacterium*. The nucleotide sequences of these genes were retrieved from the complete genome sequences of the following strains:

122 CFBP 4999 (Clavibacter michiganensis subsp. michiganensis; GenBank accession number: 123 RDQW00000000), CFBP 2404 (Clavibacter michiganensis subsp. insidious; GenBank accession number: 124 RDQV0000000), NCPPB 2581 (Clavibater michiganensis subsp. nebraskensis; GenBank accession 125 number: NC020891), R1-1 (Clavibacter michiganensis subsp. insidiosus; GenBank accession number: 126 CP011043), DSM20149 (C. f. pv. poinsettiae; GenBank accession number: AM410867.1), DSM20141 (C. 127 f. pv. betae; GenBank accession number: AM410869.1), LMG 7042 (C. f. pv. oortii, GenBank accession 128 number: KF255551.1), CFBP 3418 (C. f. pv. flaccumfaciens; GenBank accession number: 129 PUEZ0000000). The DNA sequences were aligned using MULTALIN 130 (http://multalin.toulouse.inra.fr/multalin/). Based on the consensus generated from the alignments, new 131 sets of primers were designed for Curtobacterium. Specificity parameters of the primer pairs were 132 checked by the Primer-BLAST program at NCBI (http://www.ncbi.nlm.nih.gov/BLAST/), the Primer3 133 tool (http://biotools.umassmed.edu/bioapps/primer3 www.cgi) and the AmplifX software (version 1.7.0) 134 (http://jim.timone.univ-amu.fr/recherche/equipe-t-brue/jullien-nicolas/programmation/amplifx/?lang=fr) 135 in order to ensure that they amplify only one DNA fragment of the target gene from the Curtobacterium

136 genome. Annealing temperatures varying from 52 to 72 °C were tested using a Bio-Rad Gradient 137 Thermocycler to determine the optimal temperature for DNA amplification.

The complete genome sequences of strains CFBP 3418, CFBP 2404 and CFBP 4999 were obtained as described in Merda et al. (2017), using the Illumina technology and HiSeq 2500 (Genoscreen, Lille, France) or MiSeq instruments. Libraries of genomic DNA were performed using the Kit NextEra XT (Illumina, USA). Paired-end reads of 2 x 100 bp were assembled in contigs using SOAPDENOVO 1.05 (Li et al., 2010) and VELVET 1.2.02 (Zerbino & Birney, 2008). Annotation was performed using EuGene-PP (Sallet, Gouzy, & Schiex, 2014).

144

#### 145 Amplification and sequencing of housekeeping genes

The primers used for MLSA are listed in Table 2. The PCR reaction mix contained 200 μM
dNTP, 1.5 mM of MgCl<sub>2</sub>, 500 nM of each primer, 0.75 U GoTaq Flexi DNA polymerase (Promega), and
6 μL of boiled bacterial suspension. The PCR program consisted of an initial hold at 94 °C for 5 min
followed by 35 cycles of 30" at 94 °C, 30" at annealing temperature (60 or 62°C), extension time of 30" at
72 °C, and ending with 7 min at 72 °C. For genes *recA*, *gyrB* and *ppK*, the annealing temperature was 60
°C and 62 °C for *dnaK*, *atpD* and *rpoB*. The PCR products were checked on a 1.5% agarose gel, and

152 forward and reverse sequencing was performed directly on the PCR products by GenoScreen company153 (Lille, France).

154

#### 155 Sequence analysis

156 For each individual gene and for the concatenated dataset the DNA Sequence Polymorphism 157 software (version 5.10.01) was used to calculate haplotype numbers (Hap), haplotype diversity (Hd), 158 nucleotidic diversities ( $\theta\pi$  and  $\theta$ w), and estimated neutrality (Tajima's D, Fu and Li's and Fu's F). The 159 neutrality estimated analysis revealed the evolutionary forces acting on a particular gene (value "0" 160 meaning neutrality; positive values for diversifying selected genes and negative values for conditions of 161 purifying selection).

162 The consensus sequences for forward and reverse sequences for each strain were extracted 163 using Geneious version Pro v. 4.8.5 (http://www.geneious.com/). The sequences were then aligned and 164 trimmed using BioEdit v. 5.0.6. Phylogenetic trees were constructed with MEGA 5.1, using maximum 165 likelihood as the statistical method, and the Jukes-Cantor substitution model with 1000 bootstrap 166 replicates. Trees were constructed for each individual gene, as well as with concatenated alignments of all 167 genes. Sequences of the six genes were extracted from the complete genome sequence of the type strain of 168 Clavibacter michiganensis subsp. michiganensis (CFPB 4999) were used as outgroups in the analyses. 169 Split decomposition analysis was performed with SplitsTree4 v. 4.13.1 (Huson and Bryant, 2006), which 170 allows for the construction of a tree-like network structure if conflicting phylogeny signals are detected in 171 the data set.

172

# 173 Pathogenicity tests on common beans with strains from Brazil

174 Two different bacterial inoculation methods were tested in the greenhouse. For the needle 175 technique, plants were inoculated at the epicotyl (region between cotyledons and primary leaves) by two 176 punctures with a needle, primed with bacterial suspension as described by Maringoni (2002). For the 177 submersion technique, the first trifoliate leaf was inoculated by submersion in a bacterial suspension, 178 adjusted to  $10^8$  CFU/mL (O.D.<sub>550</sub> = 0.14), followed by an incubation period of 72 h as described by 179 Darsonval et al. (2009). In both cases, the bacterial strains were cultivated at 28 °C for 48 h before 180 inoculation. The tests were performed in triplicate using Phaseolus vulgaris cv. 'Pérola'. Plants were 181 cultivated in 3-L pots containing autoclaved soil. For both methods, plants were inoculated when the first trifoliate leaf was fully expanded at approximately 12 days after sowing. The maximum and minimum temperatures inside the greenhouse were of 27 °C and 9 °C, respectively. In both methods, plants were inoculated with sterile water as the negative control. As positive control, plants were inoculated using *C. f.* pv. *flaccumfaciens* type strain (CFBP 3418). Thirty days after inoculation, pathogenic strains were classified as positive (+: when symptoms of mosaic or necrotic lesions were observed on leaves) or highly aggressive (++: when the plant growth was very reduced with low number of chlorotic leaves or led common bean plant to death)

189

190 **Results** 

## 191 Multilocus sequence analysis of *Curtobacterium flaccumfaciens*

192 The concatenated multilocus sequence was constructed by joining six housekeeping genes in 193 alphabetical order 1 – 489: *atpD*; 490 – 957: *dnaK*; 958 – 1686: *gyrB*; 1687 – 2232: *ppK*; 2233 – 2820: 194 recA; 2821 – 3483: rpoB), resulting in a total of 3483 bp.. These sequences are available on Genbank, the 195 accession numbers are listed in Supplemental Table 1. The phylogenetic tree based on the concatenated 196 gene set using maximum likelihood did not cluster strains according to the host species, geographical 197 origin, year of isolation or pathovar (Figure 1). However, on a finer scale, some interesting smaller 198 clusters can be observed, for instance all strains isolated from beetroot in the United Kingdom were 199 grouped in a cluster supported by a high bootstrap value. All Curtobacterium flaccumfaciens strains, with 200 the exception of the strain CFBP 3400, appeared to be clustered in a monophyletic group supported by a 201 100% bootstrap value (Figure 1). Strain CFBP 3400 appears to be highly divergent from the other C. 202 flaccumfaciens strains and thus was subsequently compared to sequences of strains from other species of 203 Curtobacterium in the National Center for Biotechnology Information (NCBI) (Supplemental Figure 1). 204 This analysis showed that this strain actually belongs to the Curtobacterium flaccumfaciens species.

The phylogenetic tree was composed of three main groups supported by high bootstrap values (Figure 1). While the strains of *C.f.* pv *poinsettiae* were all in group G-I and strains from *C.f.* pv *betae* and *C.f.* pv.*ortii* were in group G-III, the strains of *C.f.* pv *flaccumfaciens* were present in all three groups. The strain CFBP 3400 (known as *C. f.* pv. *oortii*) was classified outside of these three groups. Comparing the phenotypic traits from UNESP strains (Table 1) and their distribution along the phylogenetic tree, it was observed that strains with orange colored colonies clustered in the G-I group and strains displaying yellowcolonies were distributed in the G-II and G-III groups (data not shown).

212 The genetic diversity within C. flaccumfaciens strains is around 10% for the concatenated data 213 (353 polymorphic sites out of 3478 sites in total) and varied considerably from gene to gene as follows: 214 4.29% (atpD), 6.94% (rpoB), 9.52% (recA), 11.95% (ppk), 13.25% (dnaK) to 14.19% (gyrB) (Table 3). 215 The number of alleles at each locus varied from 20 for *atpD* to 42 for gyrB. All loci showed 216 polymorphism and polymorphic sites ranged from 21 (*atpD*) to 103 (*gyrB*) (Table 3). Results of neutrality 217 tests (Tajima's, Fu and Li's and Fu's F tests), showed some indication that purifying selection is operating 218 on particular housekeeping genes in Curtobacterium flaccumfaciens strains, as indicated by negative 219 values (Table 3).

A reduced MLSA scheme using *recA* and *gyrB* data, as proposed for *Clavibacter* by Jacques *et* al. (2012) proved to reliably identify the strains of *C. flaccumfaciens* species, with the whole species, and the three internal clusters, being supported by high bootstrap values (Supplemental figure 2).

223

# 224 **Phylogenetic network**

225 All loci showed a number of significant reticulations with the genes gyrB, ppK and recA226 showing the greatest numbers of reticulations (Figure 2). The network for *dnaK* showed that C. f. pv. 227 betae, C. f. pv. oortii and C. f. pv. flaccumfaciens share alleles with each other. The gyrB gene sequence 228 analysis showed that C. f. pv. poinsettiae and C. f. pv. flaccumfaciens share alleles with each other, and 229 that other C. f. pv. flaccumfaciens strains share alleles with C. f. pv. betae and C. f. pv. oortii. The network 230 constructed for ppK showed similar results to those of gyrB. The network for recA revealed strains of C. f. 231 pv. flaccumfaciens sharing alleles with the other three pathovars. The network made with the concatenated 232 genes also presented a significant number of reticulations.

233

### 234 Pathogenicity tests

Symptoms were similar regardless of inoculation techniques used, with mosaic spots appearing on leaves about 10 days after inoculation and developing into necrotic lesions. In the pathogenicity tests, the strains of *C. f.* pv. *oortii*, *C. f.* pv. *betae* and *C. f.* pv. *poinsettiae* were negative for the pathogenicity test (common bean plants were asymptomatic) (Table 1). Symptomatic plants showed a reduced growth compared with asymptomatic plants. Thirty days after inoculation, pathogenic strains were classified as positive (+) or highly aggressive (++) (Table 1). All *C.f.* pv *flaccumfaciens* strains tested using the "needle" technique were pathogenic. Three of them proved to be highly aggressive (CFBP 8371, 3178 UNESP, CFBP 8391), leading to the death of the bean plants. Only these three highly aggressive strains, all isolated from alternative hosts (wheat, oat and cabbage), were capable of causing symptoms on bean using the "submersion" technique.

245

# 246 Specific PCR for Curtobacterium flaccumfaciens pv. flaccumfaciens

247 We tested the accuracy of the PCR primers CffFOR2-CffREV4 described by Tegli et al. 248 (2002), designed specifically to detect C. f. pv. flaccumfaciens strains in bean seeds. The present results 249 showed that the accuracy of these primers was of 96%. Two C.f. pv flaccumfaciens strains isolated in the 250 USA were false negatives (CFBP 3422 and CFBP 3486), confirmed by pathogenicity tests on bean plants. 251 The MLSA analysis showed that these two strains were clustered together in a group of pathogenic strains, 252 which were also positive to PCR amplification assays with the CffFOR2-CffREV4 primers (Table 1). One 253 strain from United Kingdom (CFBP 3401), classified as C. f. pv. betae, and grouped with the other C.f. pv 254 betae strains by MLSA, was false positive, and all other strains of this group gave negative PCR results. 255 Two strains of C.f. pv betae had been tested on bean (type strain CFBP 2402 isolated in United Kingdom 256 and strain CFBP 3404 isolated in Brazil) and were non pathogenic (Table 1). The 306 bp fragment 257 amplified by these specific primers was used in blast search against the complete genome sequence of the 258 type strain CFBP 3418 of C.f. pv. flaccumfaciens and aligned to the intergenic region between two genes 259 coding for trypsin-like cysteine/serine peptidase (data not shown).

260

#### 261 Discussion

A MLSA based on six housekeeping genes (*recA, gyrB, ppK, atpD, dnaK* and *rpoB*) was used to investigate the phylogenetic relationships among 84 strains of *Curtobacterium flaccumfaciens* distributed into four pathovars (*C.f.* pv *flaccumfaciens, poinsettiae, oortii* and *betae*). These strains were isolated from usual or alternative hosts, over a period of 77 years from North America, South America, Europe and Asia. The number of variable sites (3.5 to 12.6%) is comparable to what was found in *Clavibacter michiganensis* (5.0 to 12.8%) (Jacques *et al.*, 2012). Our findings are in agreement with other studies on genetic diversity and phylogenetic relationships in *C. flaccumfaciens* using rep-PCR (Souza et
al. 2006), and MLSA (Osdaghi et al. 2018b).

270 The C. flaccumfaciens strains were grouped in three main clusters. The only correlation we 271 could make was that all the Brazilian orange-colored strains are grouped in the same group (G-I). Some 272 previous studies stated that diverse techniques (AFLP, PFGE, and rep-PCR) used to explore the genetic 273 diversity in C. flaccumfaciens, could separate the strains by their pigments (Agarkova et al. 2012; Osdaghi 274 et al. 2016; Osdaghi et al. 2018a). Colony color aside, the three clusters do not correlate with any of the 275 metadata, that is, pathovar affiliation, isolation date or geographical location, and isolation host. These 276 results are consistents with previous finding. For instance, Souza et al. (2006) reported that the diversity 277 they measured in C. flaccumfaciens using rep-PCR did not correlate either with the country of isolation.

278 In our study, none of the four pathovars (pv. betae, pv. oortii, pv. poinsettiae and pv. 279 *flaccumfaciens*) formed a monophyletic cluster. The cluster G-III contains strains from three pathovars 280 (pv. betae, pv. oortii, and pv. flaccumfaciens), the cluster G-I contains strains from pv. poinsettiae and pv. 281 flaccumfaciens, and the last cluster (G-II) contains only strains from pv. flaccumfaciens. Thus, the pv. 282 *flaccumfaciens* strains, pathogenic on bean, are as diverse as the species and were scattered among the 283 three clusters. Even inside each cluster, there is no phylogenetic structure; strains from different pathovars 284 cluster together, irrespective of their host of isolation or geographical origin. This means that the six 285 genes used for MLSA analysis were not sufficient to discriminate either C. flaccumfaciens, pathovars or to 286 distinguish between C. f. pv flaccumfaciens strains isolated from bean or from other hosts.

287 These results raised the question about the differences in pathogenicity between the pathovars. 288 As the strains are not genetically different based on a six-genes MLSA, the question was whether they can 289 affect plants other than their isolation host and can they be pathogenic on a much larger host range than 290 initially thought. Representative strains of each pathovar were tested for pathogenicity on common bean. 291 Except for C.f. pv flaccumfaciens, which were pathogenic to bean, all strains from other pathovars were 292 non-pathogenic, independent from their hosts. Among the C.f. pv flaccumfaciens strains, some isolated 293 from alternative hosts can be hyper-aggressive, even more aggressive than the type strain. Thus our data 294 reveal no correlation between phylogeny and pathogenicity for C.f. pv flaccumfaciens. Even if the 295 pathogenicity genes are usually contained in the accessory-genome, discrepancy between phylogeny 296 assessed by MLSA and pathogenicity, even if possible, are uncommon. MLSA, even reduced to two 297 genes, has been found to be sufficient to identify taxa determining specific pathology (Hajri et al., 2012; Fischer-Le Saux *et al.*, 2015; Osdaghi *et al.*, 2018a). However, our results were different from that, with these six genes not being sufficient to differentiate the pathovars. A possible explanation is that the different *Curtobacterium* pathovars could be relatively new and the host-driven selection has been too recent to have an effect strong enough on the phylogenetic structure of the population to be detected by MLSA. This is supported by the fact that the phylogenetic network analysis indicates active gene flux inside the *C. flaccumfaciens* species (shared alleles between pathovars and reticulated network).

304 Our results show that strains isolated from bean or from alternative hosts are both pathogenic 305 on bean and not different based on a MLSA analysis, confirming that the alternative hosts can serve as 306 reservoir for this pathogen (Gonçalves et al. 2017). This information should be taken into account when 307 considering management strategies for bacterial wilt disease of bean in the future.

Although the different *C. f.* pathovars could not be differentiated using the six housekeeping genes in the MLSA analysis, the method was effective and reliable for identifying strains of *C. flaccumfaciens*. Downsizing the MLSA scheme to only two genes proved to be enough for reliable identification of *C. flaccumfaciens* strains to the species level. Thus, the use of *recA* and *gyrB* genes in reduced MLSA scheme for strain identification may be used as rapid procedure for the routine identification of *C. flaccumfaciens* species in biological resources centers.

Among the numerous studies carried out to study the diversity of *Curtobacterium flaccumfaciens*, only PFGE (Guimarães *et al.*, 2003) was able to differentiate between the four pathovars. However, the development of a simple and portable screening method for rapidly identification of C. f. pv flaccumfaciens strains among a large number of strains is necessary, for example, for large environmental surveys.

319 The PCR-Based assay developed by Tegli et al. (2002) to amplify a 306bp from an original 320 Rep-PCR DNA fragment of 550bp, efficiently detected C. f. pv. flaccumfaciens in naturally infected bean 321 seeds, and was also effective to separate bean-virulent from non-virulent strains of C. f. pv. flaccumfaciens 322 by amplifying a DNA fragment of the expected size only in pathogenic strains (Osdaghi et al., 2018a). In 323 our study, we have extensively tested this protocol with a large number of strains and the reliability and 324 validity of this procedure to accurately detect C. f. pv. flaccumfaciens strains was confirmed. This simple 325 PCR, could be the basis to design field tests permitting a better crop management. However, false positive 326 and false negative still occur. Thus, the search to improve the available tools and the development of new 327 approaches for C. f. pv. flaccumfaciens identification is still necessary. Further studies using whole328 genome sequencing of different *C*. *f*. pathovars may generate specific and sensitive molecular tools for 329 pathovars discrimination, and PCR-assays targeting the DNA region coding for genes involved in the 330 bean-specificity and bean-pathogenicity.

331 We performed a blast search against the whole-genome of C. f. pv. flaccumfaciens type strain 332 CFBP 3418 using the pair primers developed by Tegli et al. (2002). Like Osdaghi et al., 2018a, we 333 showed that these primers targeted an intergenic DNA region of 306bp between two genes coding for a 334 putative trypsin-like cysteine/serine peptidase (data not shown). Bacterial catalytic proteases are mainly 335 involved in the breakdown of peptide bonds to amino acids required for nutritional purposes or to degrade 336 proteins in the plant cell wall, allowing the bacterial translocation or overcoming plant chemical defenses 337 (Dow et al., 1990; Vignesh et al., 2016). However, the role of these genes and their flanking genes in plant 338 pathogenicity or bean recognition by the pathogen has not been elucidated yet. These findings indicate the 339 necessity of further investigations on the C. f. pv. flaccumfaciens interactions with the common bean, and 340 the mechanisms involved in C. f. pv. flaccumfaciens pathogenicity.

Our research deepens our understanding about the genetic diversity of *Curtobacterium flaccumfaciens*, and confirms the relationship between strains isolated from alternative hosts and bean plants. However, further studies are necessary to better understand the mechanisms involved in *C. f. pv.flaccumfaciens* pathogenicity.

<sup>PT</sup>Pathotype strains.

<sup>T</sup>Type strain.

<sup>1</sup>Inoculation of Cff by needle technique.

<sup>2</sup>Inoculation of Cff by submersion technique.

<sup>3</sup>PCR using specific primers for Cff designed by Tegli et al. (2002).

<sup>4</sup>Not performed.

<sup>5</sup>Positive results.

<sup>6</sup>Negative results.

<sup>7</sup>Highly aggressive strain.

All strains are available at CIRM-CFBP, French Collection for Plant-Associated Bacteria (https://www6.inra.fr/cirm\_eng/CFBP-Plant-Associated-Bacteria).

	Primer			Product

Table 3. Sequence variation at the six housekeeping loci among Curtobacterium strains.

<sup>a</sup> number of analyzed sites. <sup>b</sup> number of polymorphic (segregating) sites.

<sup>c</sup> number of haplotypes. <sup>d</sup> haplotype (gene) diversity.

<sup>e</sup> level of nucleotide diversity.

<sup>f</sup> level of nucleotide diversity from S.

<sup>g</sup> results of neutrality tests performed using the method of Tajima, Fu and Li, Fu's F.

<sup>h</sup> data for six housekeeping genes, concatenated.
