### ABSTRACT

*Ginkgo biloba* leaf extract (GBE) considered one of the most effective therapeutic herbs. We evaluated anti-diabetic activities of GBE in rats. Rats were fed highly-fat diet for two weeks and divided into three groups (n=8): Non-diabetic control group (CG), Diabetic group (DG), Diabetic+100mg/kg GBE group (D+GBE). On 14<sup>th</sup> day, the rats were kept in overnight-fasting and administered single intra-peritoneal injection of alloxan-monohydrate (120-130mg/Kg body weight (BW)). BW and blood glucose were measured weekly up to 14<sup>th</sup> week. Fasting/basal blood samples were collected for the biochemical analyses. Liver, skeletal muscle and adipose tissue were also collected for mRNA gene expressions (GLUT-4, IRS-1, IR, PEPCK, SREBP-1c, FAS, PPAR- $\alpha$ , PPAR- $\gamma$ , TNF- $\alpha$ ). Significant reduction in BW was found in D+GBE group at week 14. Glycemia became normalized as an effect of treatment. GBE significantly decreased serum glucose, urea and ALT concentrations. We observed significant higher catalase and lower malondialdehyde levels in D+GBE group. GBE significantly increased HDL-Cholesterol and reduced triglycerides and VLDL-Triglycerides levels. GBE showed up-regulation for hepatic IRS-1 and down-regulation for PEPCK, however, up-regulation for GLUT-4 and PPAR- $\alpha$  found in muscle. Treatment decreased TNF- $\alpha$  expression in liver and adipose tissue. GBE has anti-diabetic mediated by a modulating effect on involved key genes.

**Keywords:** Alloxan, Carbohydrate and lipid metabolism, Diabetes mellitus, *Ginkgo biloba* leaf extract, Rats.

### INTRODUCTION

Overwhelming evidence shows that diabetes mellitus is one of the major public health issue worldwide in the last few decades (Xia *et al.*, 2011). This disease is a cluster of metabolic alterations referred to as 'chronic metabolic syndrome' mainly associated with substantial mortality and morbidity. The cause of diabetes mellitus is insufficient insulin secretion from pancreatic  $\beta$  cells may be due to defect in the insulin secretion, insulin action or both, which results in metabolic disorders syndrome mainly of carbohydrate, protein or fat (Nayak and Roberts, 2006). Oral hypoglycemic agents such as biguanides, thiazolidinediones and sulfonylurea are available along with insulin for the diabetic treatment but these products have adverse effect (Yeo *et al.*, 2011).

*Ginkgo biloba* (GB) has been described as a living fossil, being last remaining member of *Ginkgoaceae* family commonly known as, ginkgo, maidenhair tree, gymnosperm tree and dates back 250 million years in China (Maltas and Yaldiz, 2012). *G. biloba* leaves are used as traditional Chinese herbal medicine to treat asthma, cardiovascular diseases, aging, bronchitis, cancer, impair sexual dysfunction, cancer and

diabetes (Kudolo, 2001; Unger, 2013). The two major fractions present in standardized leaves extract of *G. biloba* are: 6-7% terpenoids and 24-26% flavonoids (Smith and Luo, 2003). Flavonoids present in *G. biloba* are: flavonol-gucoside of kaempferol, flavones, quercetin and isohamnetin with glucose or rhamnose. The terpenoids fraction consist of unique group of diterpenes (ginkgolide A, B, C, J and M) and sesquiterpene bilobalida (Smith and Luo, 2003; Malas and Yildiz, 2012). Very few data on the anti-diabetic molecular mechanism of *G. biloba* is available, so in the present study we investigated the anti-diabetic effect of *G. biloba*, at molecular level in rat model.

### MATERIALS AND METHODS

**Experimental animals:** A total of twenty-four normoglycemic male adult Wistar rats weighing 150-200 g, were selected. Rats were acclimated for a period of 12 days in the animal shed of University of Veterinary and Animal Sciences (UVAS), Lahore, Pakistan, prior to the experiment. All the animals were housed in stainless steel cages, 2 animals per cage, with wood litter bedding, which was changed on weekly basis. The temperature of

animal shed was maintained at  $24\pm 5^{\circ}\text{C}$  with 12-h light: 12-h dark cycle and were given free access to water and food (standard rats chow) (El-Mesallamy *et al.*, 2011). Body weight (BW) was recorded weekly and food intake was measured twice a week for each rat by determining the pre and post-weights of the food jars. The experiment was conducted for 14 weeks under the guidelines of ethical committee for welfare of laboratory animals of UVAS, Lahore, Pakistan.

**Experimental Design:** Rats were allowed to feed on high fat diet fed (HFD: 12.7% maize starch, 6.5% dextrose, 6%, cellulose 3.9% sunflower oil, 31.3% beef tallow, 28.6% casein, 9.7% minerals and 1.3% vitamins by weight) for two weeks and then rats were divided randomly into following three groups (8 rats in each group).

- Group I: Rats of this group were served as non-diabetic or negative control (CG) and given standard diet without any supplementation of *G. biloba* leaves extract (GBE)
- Group II: This group included diabetic control or positive control (DG) rats and given the standard diet without any supplementation of GBE.
- Group III: This group was comprised of diabetic rats with standard diet supplemented with GBE at the dose of 100 mg/kg/day (D+GBE).

On 14<sup>th</sup> day, rats kept in fasting condition and were administered a single dose of alloxan monohydrate (Sigma, USA) at the dose of 120-130 mg/Kg BW intraperitoneally. After 6h of alloxan induction, 20% and 5% oral glucose solution was given to the rats to prevent hypoglycemia (Ebuehi *et al.*, 2010). After 3 days of alloxan injection overnight fasting blood samples were collected from tip of tail and glycemia was measured (ACCU check, Germany). Only rats with fasting blood glucose levels higher than 250 mg/dl were considered diabetic and included in the study (Shankar *et al.*, 2005; Cheng *et al.*, 2013). Supplementation with the standardized ginkgo leaves extracts (terpenoids 6%/flavonoids 24%) was purchased from Hunan Nutramax Inc (COCO CHEN, China) and treatment was started by mixing 100 mg/Kg GBE in the standard diet (40.7% maize starch, 20% dextrose, 5.8% sunflower oil and 22.5% casein, 9.7% minerals and 1.3% vitamins by weight) for 14 weeks.

**Blood sampling and biochemical parameters:** At the end of 14<sup>th</sup> week; blood samples in fasting state, were collected by cardiac puncture and serum was separated by centrifugation (Kumar, 2012). The biochemical analysis of fasting serum glucose (FSG), blood urea, creatinine, alanine aminotransferase (ALT), aspartate aminotransferase (AST), catalase (CAT) and malondialdehyde (MDA) was done by using commercially available kits (Randox, UK).

Serum total cholesterol (TC) and triglycerides (TG) were measured using enzymatic kits (Bio-Merieux, Marcy-l'Etoile, France). Cholesterol (VLDL-C, LDL-C and HDL-C) and TG (VLDL-TG) profiles were performed using fast protein liquid chromatography (FPLC) (AKTA FPLC SYSTEM, GE Healthcare, USA). Lipoprotein isolation was performed as described by Chetiveaux *et al.*, (2002).

#### **Tissue sampling and mRNA expression of genes in the liver, skeletal muscles and visceral adipose tissue:**

Liver, skeletal muscle and adipose tissues were sampled and cleaned with normal saline solution and were stored immediately at  $-80^{\circ}\text{C}$ . RNA was extracted (Laboratoire de Biochimie, MMS, Nantes, France) using trizol reagent (Ambion, USA), according to the manufacturer's instructions. Quantification of total RNA was measured at 260 nm. Total RNA (1  $\mu\text{g}$ ) was converted in to cDNA through the process of revers transcription using Super-ScriptIII Reverse Transcriptase (Invitrogen, France) in a 20  $\mu\text{l}$  reaction volume. Quantitative PCR was performed using SYBR Green Supermix on MyiQ2 Real-Time PCR detecting system (Bio-Rad, Marnes-la-Coquette, France). Primers Sequence was determined by the primer3 website. The mRNA levels were normalized using GAPDH as a housekeeping gene. Relative quantification was performed using the CT method. Primers used for qRT-PCR are listed in Table 1

**Statistical analysis:** Results were expressed as mean  $\pm$  S.E.M. Data was analyzed statistically by One way repeated measure analyses of variance (ANOVA) followed by PLSD Fisher's test using Statview software (SAS Institute Inc, SAS Campus Drive, Cary, NC, USA), to measure ginseng root extracts effects on all physiological and biochemical parameters except mRNA genes expression in studied organs, which were analyzed by Kruskal Wallis, followed by Fisher's test using Stateview.  $P < 0.05$  was taken as significant difference.

## **RESULTS**

**Body weight:** The BW of rats in all the three groups was monitored on 1<sup>st</sup> and 14<sup>th</sup> week of study (Table 2). The BW of DG was found to be significantly ( $P < 0.0001$ ) decreased on week 14. D+GBE group also showed decrease of BW but this decrease was less than that recorded in DG group.

**Blood and fasting serum glucose concentration:** We investigated whether GBE could lower the hyperglycemic activity in diabetic rats. Non-fasting blood glucose was measured at weekly basis throughout the study (data shown for the week1 and week 14). We found no significant differences in the blood glucose concentration between DG and D+GBE group during the first 2 weeks of treatment (data not shown). A significant increase

( $P < 0.0001$ ) in blood glucose level was recorded in DG however, significant ( $P < 0.0001$ ) reduction for non-fasting blood glucose level was recorded with effect to drug between week 1 and week 14 (Table 2).

We further studied the FSG concentration in the alloxan induced diabetic rats at the end of our experimental trial is significantly ( $P < 0.0001$ ) higher in DG than in CG. However D+GBE rats showed significant ( $P < 0.0001$ ) decrease in FSG concentration (Table 3).

**Serum Biochemical parameters:** Serum concentrations of creatinine, urea, AST and ALT in CG, DG and D+GBE groups were shown in Table 3. The GBE showed no change in creatinine and AST levels, but significant decrease in urea ( $P < 0.001$ ) and ALT ( $P < 0.001$ ) levels was observed (Table 3).

**Determination of oxidative stress:** In alloxan-induced diabetic rats, we found a significantly ( $P < 0.0001$ ) decreased in serum CAT level and significant increase ( $P < 0.001$ ) for MDA level. However, D+GBE rats showed significant increase ( $P < 0.05$ ) for CAT and significant reduction ( $P < 0.05$ ) for MDA concentrations.

**Serum lipid Profile:** For lipid profile, GBE treated group showed significant ( $P < 0.0001$ ) enhancement in HDL-C concentration and with no effect on TC, VLDL-C and LDL-C levels. However, D+GBE significantly decrease TG ( $P < 0.0001$ ) and VLDL-TG ( $P < 0.0001$ ) concentrations (Table 3).

**mRNA expression of genes:** In order to understand the underlying mechanisms that how GBE improved the

glucose tolerance in diabetic state, the mRNA expression of key genes were studied in liver, skeletal muscles and adipose tissues in rats. We studied glucose transporter-4 (GLUT-4) insulin receptor substrate-1 (IRS-1), Insulin receptor (IR), Phosphoenolpyruvate carboxykinase (PEPCK), Sterol regulatory element binding protein-1c (SREBP-1c), Fatty acid synthase (FAS), Peroxisome proliferator-activated receptor- (PPAR- ), Peroxisome proliferator-activated receptor- (PPAR- ) and tumor necrosis factor- (TNF- ) in hepatic, skeletal muscle and adipose tissue.

**mRNA genes expression in liver:** For GLUT-4, IR, PPAR- , SREBP1-c and FAS no significant changes were observed in diabetic and GBE treated groups. In parallel, we found significant up-regulation ( $P < 0.05$ ) of IRS-1, and significant down-regulation of PEPCK ( $P < 0.05$ ) and TNF- ( $P < 0.001$ ) in the D+GBE group (Fig 1).

**mRNA gene expression in skeletal muscles:** As shown in Figure 2, significant up-regulation for GLUT-4 ( $P < 0.001$ ) and PPAR- ( $P < 0.001$ ) in D+GBE treated group was recorded, whereas, same genes were down-regulated in diabetic rats.

**mRNA gene expression in adipose tissues:** As shown in Fig 3, GLUT-4 and FAS were not affected in all the studied groups. However, significant decrease in IRS-1 ( $P < 0.0001$ ), IR ( $P < 0.05$ ) and PPAR- ( $P < 0.001$ ) in DG was found. The TNF- showed, significant up-regulation ( $P < 0.0001$ ) in DG and significant ( $P < 0.0001$ ) down-regulation in D+GBE group.

**Table 1. Genes and the primer sequences used.**

Genes	Forward primer (5'-3')	Reverse primer (5'-3')
GAPDH	TCCCATTCCTCCACCTTTGATGCT	ACCCTGTTGCTGTAGCCATATTCAT

## DISCUSSION

Diabetes is a global health problem, becoming more prevalent in the coming few decades (Wild *et al.*, 2004). Diabetes is a pathological condition which is associated with oxidative stress (Ebuehi *et al.*, 2010). In fruits, vegetables and plants phenolic compounds such as flavonoids and phenolic acid are widely distributed have the ability to scavenge active oxygen, hydroxyl radicals and superoxide by donating the electron. The flavonoids present in *G. biloba* leaves extract, exert their action by chelating or scavenging process in anti-oxidant mechanism and terpenes inhibit platelet activation factor (Maltas and Yildiz, 2012). These days, GBE gains attention of many researchers because of its beneficial anti-diabetic effects in diabetic subjects. Many authors reported a daily single dose of 120 mg of ginkgo leaf extracts in the clinical trials (Kudolo, 2001; Kudolo *et al.*, 2006). The aim of the present research is to check the effect of *G. biloba* leaves extract, on alloxan induced diabetes and associated metabolic disturbances in rat.

We found significant reduction in the BW in diabetic rats, but although the BW was less diminished, it was normalized by GBE treatment. Our results for the reduction of BW in alloxan induced diabetic rats are in agreement with previous data (Ebuehi *et al.*, 2010; Cheng *et al.*, 2013). Mechanisms involved in BW reduction in

diabetic condition were reviewed by Swanston-Flatt *et al.*, (1990) and Baynes (1991).

We found significant reduction in hyperglycemic condition concentration in diabetic rats treated with GBE. Other researchers also showed reduction in glycemia with GBE treatment (Shankar *et al.*, 2005; Zhou *et al.*, 2011; Cheng *et al.*, 2013; Ren *et al.*, 2013). This blood glucose reduction could be related either to improvement in the plasma insulin concentration due to positive influence of flavonoids on the pancreatic  $\beta$ -cells or to enhancement in the blood glucose transport to the peripheral tissues (Cheng *et al.*, 2013). To further understand the mechanisms that how GBE act as hypoglycemic agents, we investigated the mRNA gene expressions involved in the carbohydrate/glucose and lipid metabolic activities.

For GLUT-4 expression, significant up-regulation was found only in skeletal muscles after treatment with GBE. Since the expression of GLUT-4 in the skeletal muscles are regulated by metabolism and insulin, thus any dysfunctioning of pancreatic  $\beta$  cells as the case occur in diabetes also impaired the expression of GLUT-4 (Zorzano *et al.*, 2005). Lee *et al.*, (2010) found increase in GLUT-4 protein expression in whole cell lysates in adipose tissues and muscles in mice after treatment with nobiletin flavonoids.

Our data showed significant increase in the expression of IRS-1 only in hepatic tissue after GBE

treatment. Zhou *et al.*, (2011) found significant increase in the expression of IRS-2 in hepatic cells but they did not measure the expression for IRS-1. The mRNA gene expression of IR in the liver did not vary among the groups as did the mRNA expression of IRS-1, indicating that insulin signaling seems little or no effect in liver, since we found no improvement in the expression of IR in any of the studied organ. Evidences show an increase in IR number and mRNA level of the IR in the liver, muscles and adipose tissue in the diabetic rats (Amessou *et al.*, 1999). Despite of increase in blood insulin concentration, increased in PEPCK expression in diabetic animal models were found (Law *et al.*, 2002) as also in our case. Other researchers also found down-regulation for PEPCK after treatment with different flavonoids (Cederroth *et al.*, 2008; Herrera *et al.*, 2013).

The dyslipidemia associated to diabetes condition; an effect of GBE treatment on dyslipidemia was also checked in this study. Although GBE treatment showed no effect on TC, VLDL-C and LDL-C, however, GBE normalized HDL-C, TG and VLDL-TG concentrations in diabetic rats. Dyslipidemia (high TG and Low HDL-C) is commonly observed in diabetes (Briones *et al.*, 1984) and this appears directly correlated with an increased risk of coronary heart disease (Forte *et al.*, 1994). Ebuehi *et al.*, (2010) found significant increase in TC and TG concentration in alloxan induced diabetic rats. Kudolo (2001) found non-significant reduction in TC, TG and LDL-C; however they reported no change in the values of HDL-C after treatment with ginkgo in the non-insulin dependent diabetic mellitus (NIDDM) patients. We studied the genes involved in the lipid metabolism to better understand that how GBE plays a role to correct the dyslipidemia and hypertriglyceridemia in diabetic state.

SREBP-1c plays a pivotal role in lipolytic genes that regulated by insulin and glucose (Yuan *et al.*, 2011). Lipid homeostasis is regulated by SREBPs and directly regulates the expression of more than 30 genes involved in the synthesis and uptake of the TC, TG, phospholipids and FAs (Horton *et al.*, 2002). We reported no change in the expression of hepatic SREBP-1c in treated group and the results are not in agreement with Zhou *et al.*, (2011). The mRNA expression of FAS is markedly down-regulated under metabolic complications, like insulin resistance and diabetes in liver (Real *et al.*, 2010), as also reflected by our data. Flavonoids down-regulates the mRNA expression of FAS (Wu *et al.*, 2011).

Our data showed that *G. biloba* improved lipid metabolism, through up-regulation of PPAR- in muscles. PPAR- also well characterized to increase the circulating amount of HDL level in accordance with measured increase of HDL-C in our study. Dysfunctioning of PPAR- results in TC and TG metabolic abnormalities (Yoon *et al.*, 2003). PPAR- is reported to control insulin sensitivity (Zhou *et al.*, 2011);

they also reported up-regulation of PPAR- expression in hepatic cells after treatment with ginkgo leaves extract.

In the present study, we found the GBE helps the body to overcome the oxidative stress in diabetic state, by reducing MDA and enhancing CAT level in the body. MDA, the final product of lipid break down, is an important biomarker of oxidative stress in the body (Ren *et al.*, 2013) and one of the important indicators used for the free radicals induced lipid peroxidation (El-Khayat *et al.*, 2011). Our data are in accordance with that reported by Ren *et al.*, (2013) and Cheng *et al.*, (2013). This effect could be attributed to the anti-oxidant properties of flavonoids (Shankar *et al.*, 2005; DeFeudis and Drieu, 2000) heavily present in ginkgo (Smith and Luo, 2003; Maltas and Yildiz, 2012).

Recent data showed that oxidative stress and inflammation play major roles in the onset and development of chronic diseases (Camps and Garcia-Heredia, 2014) and that inflammatory state exacerbate insulin resistance (Babish *et al.*, 2010). We measured significant down-regulation for TNF- only in liver and adipose tissue in effect with GBE treatment. There is no data for the tissues for TNF- treated with *G. biloba* to compare with our work. Lee *et al.*, (2010) found non-significant down regulation of TNF- in adipose tissues after treatment with nobiletin: flavonoid found in citrus fruits.

There are strong evidences that flavonoids reduce the blood urea and serum creatinine level in diabetic state (Renno *et al.*, 2008). In clinical trial on (NIDDM) patients, Kudolo, (2001) found no change in AST and ALT levels after 3 months treatment with *G. biloba*.

In conclusion, the leaves extract of *G. biloba* have strong anti-diabetic and anti-oxidative effects. It also led to improve glucose and lipid metabolism by acting on the expression of key genes.
