Background and objectives: Obesity and metabolic syndrome (MetS) are associated with high risk for a variety of chronic diseases. Dietary patterns are critical for development and persistence of obesity and MetS, yet very little information is available on the link between food intake quality and these conditions in Chile. The objective of this study was to evaluate adherence to a Mediterranean diet (MD) pattern -using a locally validated dietary index (Chilean-MDI)- and its correlations with overweight/obesity and MetS prevalence in Chilean adult population.

Methods: We conducted a nationwide, cross-sectional survey using a non-representative, self-selecting sample of 24,882 Chilean adults registered in Aliméntate Sano (www.alimentatesano. cl), an online educational program on MD, healthy lifestyle and chronic disease prevention.

Results: A strong, monotonic inverse association was observed between adherence to MD and both overweight/obesity and MetS. Overweight/obesity prevalence increased across diet categories: 45%, 51% and 61% (p<0.001) from healthy to moderately healthy to unhealthy food intake, respectively. MetS prevalence behaved similarly, increasing from healthy (13%), moderately healthy

(19%) to unhealthy (29%) dietary pattern (p<0.001). Relative risks for overweight/obesity were significantly higher for individuals in moderately healthy (OR=1.58) and unhealthy (OR=2.20) diet groups compared with the high MD adherence group, as well as for MetS (moderately healthy vs. healthy: OR=1.54; unhealthy vs. healthy: OR=1.83).

Conclusions: This study shows a strong inverse relationship between adherence to Mediterranean diet intake and overweight/ obesity and MetS in Chile, corroborating previous findings from other world regions. Increasing MD consumption may represent an effective approach to decrease chronic disease risk in the Chilean adult population. Supported by Fundación Banmédica.

IS PSYCHOLOGICAL WELLBEING ASSOCIATED WITH A HEALTHY LIFESTYLE? CROSS-SECTIONAL SURVEY OF MEDITERRANEAN DIET INTAKE, PHYSICAL ACTIVITY, SMOKING AND WELLBEING IN CHILEAN ADULTS

[1]Rigotti, Attilio; [2]Echeverría, Guadalupe; [3]D'acuña, Sonia; [4]Jiménez, Paulina; [5]Urquiaga, Ines; [3]Nitsche, María Pía; [6]Bitran, Marcela; [7]Pedrals, Nuria; [3]Leighton, Federico.

[1]PhD. MD. Center for Molecular Nutrition and Chronic Diseases, and Department of Nutrition, Diabetes and Metabolism. School of Medicine. Pontificia Universidad Católica de Chile. Chile; [2]MSc. Engineer. Center for Molecular Nutrition and Chronic Diseases. School of Medicine. Pontificia Universidad Católica de Chile. Chile; [3]MD. Center for Molecular Nutrition and Chronic Diseases. School of Medicine. Pontificia Universidad Católica de Chile. Chile; [4]Nutritionist. Center for Molecular Nutrition and Chronic Diseases. School of Medicine. Pontificia Universidad Católica de Chile. Chile; [5]PhD. Biochemist. Center for Molecular Nutrition and Chronic Diseases. School of Medicine. Pontificia Universidad Católica de Chile. Chile; [6]PhD. Biochemist. Center of Medical Education. School of Medicine. Pontificia Universidad Católica de Chile. Chile; [7]Psychologist. Center for Molecular Nutrition and Chronic Diseases. School of Medicine. Pontificia Universidad Católica de Chile. Chile.

Background and objectives: In developed countries, wellbeing indicators are usually associated with healthier lifestyles and reduced cardiovascular risk. However, similar information is very scarce in populations from developing countries. The objective of this study was to evaluate psychological wellbeing and its relationship with Mediterranean diet (MD) intake and other lifestyle components in Chile.

Methods: We applied a cross-sectional internet survey of psychological wellbeing -including measurements of positive mental health (Mental Health Continuum (MHC) questionnaire), optimism, and subjective vitality- and lifestyle habits. We assessed diet quality by a

Chilean Mediterranean Diet Index (Chilean-MDI, range from 0-14 points), physical activity using IPAQ, and current smoking.

Results: In this study sample, 44% of Chilean adults displayed high wellbeing measured by MHC, and higher MHC scores were found among older than younger people. MHC correlated with optimism, but not subjective vitality. Regarding lifestyle, only 21% of the sample exhibited a healthy eating behavior based in high adherence to MD (Chilean-MDI ≥9 points), 27% reported low physical activity and 32% were smokers. Healthy eating -defined as a high Mediterranean diet score- was significantly associated with all wellbeing measures. In addition, people with higher wellbeing showed a healthier overall lifestyle.

Conclusions: Our findings support a link between wellbeing and different components of a healthy lifestyle behavior in Chile. Interventions aimed to increase wellbeing may lead to a better lifestyle as well as reduced risk of chronic diseases. Supported by Fundación Banmédica.

EDOREXY AND CORPORAL COMPOSITION OF SOCCER PLAYERS

[1]Aguilar Rabito, Ana Carolina; [2]Casaccia Torres, Gustavo Gabriel; [2]Méndez Molas, Silvia Lorena; [3]Morínigo Martínez, Macarena.

[1]Nutritionist, MSc. Department of Nutrition Research. Faculty of Chemical Sciences. National University of Asuncion. Paraguay; [2]Nutritionist. Faculty of Chemical Sciences. National University of Asuncion. Paraguay; [3]Nutritionist. Department of Nutrition Research. Faculty of Chemical Sciences. National University of Asuncion. Paraguay.

Background and objectives: Edorexy is a recent term, and refers to episodes of appetite produced by various forms: "addiction" to food, stress or by anxious / depressive episodes. Eating disorders often occur in athletes, and can affect the performance of players. Therefore, we determine the frequency of edorexy, nutritional status and body composition in soccer players.

Methods: We conducted a cross-sectional study of 36 male players from the Intermediate Division, who play soccer at Club Tacuary during May and July 2016. We evaluated edorexia using the self-administered questionnaire of López Morales (2013). We used the ISAK procedure for anthropometric measurements.

Results: We found that median age was of 22 years. The average of fat mass percentage (% FM) was 24.3 ± 4.0% (High) and fat-free mass (% FFM) was 38.1 ± 2.6% (Adequate). Mesomorphic and meso-endomorphic component was the mostly frecuent, not suitable for the type of sport practiced. The psychological data of the Edorexy Inventory showed an overall score of 50.2 ± 7.0pts. Risk of having edorexy syndrome was present in 19/36 of the players surveyed and 8/36 players were diagnosis with edorexy syndrome. The players with edorexy have lower % FFM (difference 2.80%, p = 0.021) and higher % FM (difference 4.40%, p=0.033).

Conclusions: We find that in soccer players the % FM is above the recommendations for this sport.

Keywords: Eating disorder, soccer, somatotype, body composition

CHARACTERIZATION OF THE CONSUMPTION OF BEVERAGES IN THE CLIENTELE IN COMMERCIAL RESTAURANT OF THE TYPE "SELF-SERVICE", RIO DE JANEIRO-RJ BRAZIL

[1]Reino, Alice; [2]Cnop, Mara; [3]Oliveira, Aline; [4]Santos, Vitória; [4]Alves, Iuna; [4]Silva, Merilin; [3]Paula, Nilma; [3]Pereira, Rosangela A; [3]Marins, Vania.

[1]Bsc. Instituto Josué de Castro. Universidade Federal do Rio de Janeiro. Brazil; [2]MSc. Nutricionist. Instituto de Nutrição Josué de Castro. Universidade Federal do Rio de Janeiro. Brazil; [3]PHd. Nutricionist. Instituto de Nutrição Josué de Castro. Universidade Federal do Rio de Janeiro. Brazil; [4]BSc. Nutricionist. Instituto de Nutrição Josué de Castro. Universidade Federal do Rio de Janeiro. Brazil.

Background and objectives: This study aimed to characterize the customers of a self-service commercial restaurant concerning the consumption beverages.

Methods: We investigated individuals of both sexes who have eaten lunch at a self-service restaurant located on a university campus in Rio de Janeiro-RJ. Participants fulfilled a personal data form and semi-quantitative questionnaire on beverage consumption, which was evaluated according to its validity and reproducibility. The consumption of beverages was classified as: did not consume beverages (no-beverage), consumed water, sugar sweetened beverages (SSB), low-calorie beverages. Data were stratified for sex, age, position related to the university, and physical activity. Statistical analyzes were performed using the chi-square test considering the statistical significance p-value <0.05.

Results: 143 individuals were investigated (mean age = 32 years, standard deviation = 11), 59% were men, 44% practiced physical activity regularly, 57% were university students, 26%, university staff or faculty, and 17%, external workers. It was observed that 36% of the participants did not consume any drink at lunch, 28% consumed SSB, 27% consumed water, and 9%, low-calorie beverages. Compared to men, a higher proportion of women did not consume any beverage on the day investigated (45% vs. 30%). The consumption of SSB was more frequent in men than in women (36% vs. 15%, p = 0.04). Individuals over 45 years old had higher consumption of SSB (35%) when compared to those younger than 25 years old (29%). Those who reported regular physical activity practice had higher proportion (49%) of no-beverage at lunch than those who were not active (20%). Conversely, those who did not perform physical activity regularly reported consuming SSB (48%) more frequently than their counterparts (21%). Among the external workers, there was higher frequency of no-beverages

---

(46%) when compared to students (33%) and university staff and faculty (35%).

Conclusions: There was high consumption of sugar-sweetened beverages and the results point out to the need of interventions aiming to healthy beverages consumption in commercial restaurants.

Keywords: beverages, sugar sweetened beverages, university, healthy eating promotion, food consumption.

ASSOCIATION BETWEEN INFLAMMATORY DIET SCORE, OBESITY AND BREAST CANCER IN CÓRDOBA, ARGENTINA

[1]Becaria Coquet, Julia; [2]González, María Florencia; [2]Caballero, Victor Ramón; [2]Camisasso, María Cecilia; [3]Tumas, Natalia; [4]Niclis, Camila; [4]Román, María Dolores; [5]Díaz, María del Pilar; [4]Muñoz, Sonia Edith; [6]Aballay, Laura.

Escuela de Nutrición. Facultad de Ciencias Médicas.Universidad Nacional de Córdoba . Argentina.

Background and objectives: Breast cancer (BC) is a multifactorial disease; several environmental factors have been linked to this pathology. Specifically, obesity and inflammatory diet have been associated with an increased risk of BC in women. Endocrine changes related to these factors trigger an inflammatory response, which favors the occurrence of BC. The aim of this research was to assess the association between the consumption of an inflammatory diet and BC risk, taking into account nutritional status, in Córdoba province (Argentina).

Methods: A case-control study was conducted during 2008-2016 period (346 cases of BC and 566 controls). An inflammatory diet score was developed including 15 dietary variables (nutrients and food groups consumption), obtained through a validated FFQ. A score (0, 0.5 or 1) was assigned for each variable included in the score depending on the compliance of dietary recommendations. A higher score indicated a higher degree of adherence to an inflammatory diet. For each woman an inflammatory score was calculated. A multiple logistic regression model was performed to assess the association between BC occurrence and inflammatory diet, stratifying by nutritional status.

Results: The inflammatory diet score mean was 6.7 (0.9) in all women included in the study. 20% of the women studied were obese. An increased risk of BC of 42% was observed for each unit of increased in the inflammatory diet score in this group (Odds Ratio: 1.42; Confidence Interval: 1.1-1.84).

Conclusions: Obese women with an inflammatory diet have a greater risk of BC in Córdoba (Argentina).

Keywords: Inflammatory diet index - Obesity -Breast cancer- Argentina - case-control study.

EVALUATION OF HYDRATION STATUS OF A BRAZILIAN FLAG FOOTBALL TEAM

[1]Parise Polo, Gabriela; [1]Lekevicius Consolin, Brunna; [2]Marques Rossi, Luciana; [3]Rodrigues, Tânia; [3]Barrella, Ana Beatriz.

[1]Nutrition Student. Centro Universitário São Camilo. Brazil.; [2]PhD. Department of Food Science and Experimental Nutrition. Faculty of Phamaceutical Sciences. University of São Paulo. Brazil.; [3]BSc. Nutritionist. RGNutri Consultoria em Nutrição. Brazil.

Background and objectives: The Flag Football holds many similarities to rugby, but with less contact and with the difference that the play has to stop when a flag is withdraw from the side of the players' bodies. For being an outdoor sport, the body temperature can rise significantly, dissipating more heat to the environment and therefore requiring a greater hydration control. According to the percentage of body dehydration in relation to the weight variation, the physiological effects can lead to compromised performance. Thus, this study aimed to identify the status of hydration after Flag Football training.

Methods: We evaluate 17 female athletes from a Brazilian Flag Football team, aged 26,24 ± 3.8 years. This work was approved by the Ethics and Research Committee of Centro Universitário São Camilo, Brazil. A bioelectrical impedance was use to obtain body mass before and after training. To evaluate the hydration status, it was calculated the percentage of weight variation (%WV). Variables such as self-reported height (m) and percentage of body fat (%BF), calculated by body density (BD) through the sum of three skinfolds, were also collected. The hydration during the training was performed with water ad libitum and the amount ingested was accounted in the %WV.

Results: The average high and body fat was 1,65 ± 0,03 m and 23,23 ± 6,87%. Regarding the weight variation, at the end of training eight athletes has gained weight (0,72 ± 0,51%) and eight has lost (0,50 ± 0,36%). Only one player neither gained nor lost weight. As a weight variation was between ±1%, the athletes finished training normohydrated.

Conclusions: The post training hydration status showed that the fluid replacements strategies were adequate. Given the importance of being adequately hydrated, nutritional counseling and follow-up become essential to avoid detriment to athlete's health and performance.

Keywords: Hydration. Dehydration. Football. Physical Activity.

NUTRITIONAL PROFILE OF PRE-SCHOOL CHILDREN, SCHOOLCHILDREN AND TEENAGERS FROM PUBLIC SCHOOLS IN THE GUARULHOS CITY. BRAZIL

[1]*Nuzzo dos Santos, Letizia;* [2]*Korukian Freiberg, Clara;* [2]*Pelliciari, Maria Christina;* [2]*Toscano Ferreira, Rosana;* [2]*Araujo, Mariangela;* [2]*Gomes Fiore, Elaine;* [2]*Paulino Machado, Adriana.*

[1]MSc. Nutricionist. Guarulhos University. Nutrition Department. Guarulhos. São Paulo. Brazil; [2]MSc. Nutricionist. Nutrition Department. Guarulhos University. Guarulhos. SP. Brazil.

Background and objectives: Front of the epidemiological scenario of Brazil indicating increased obesity in all age groups including children and adolescents, to diagnose the health and nutritional status of schoolchildren in the city of Guarulhos to guide the municipal departments of health and Education in educational programmes and to intervene in possible deviations found. Such a problem is alarming and affects several countries, necessitating effective interventions to minimize the above panorama. The main objective of this study was to identify the health and nutritional status of pre-school children, schoolchildren and teenagers, that attend public schools in Guarulhos City, aged 5 to 12 years.

Methods: Cross-sectional study, approved by the Committee of ethics in research. The study was carried out in 09 schools, located in central and peripheral region of the city, with 3612 students with anthropometric measurements assessment of weight and stature. The nutritional evaluation was based on indicators stature/age and BMI/age, expressed as z-score, and being adopted as the standard reference WHO (2007).

Results: The IMC showed that among the Group of children named preschoolers and schoolchildren, 1.27% are with low weight, while 16.33% and 13.02% showed overweight and obesity respectively. As for teenagers, 1.97% presented low weight, while 18.34% and 12.98% showed overweight and obesity respectively. There were no statistically significant differences between boys and girls in both of groups: children and teens. The data of obesity were more consistent in the schools located at the central region of the city where social conditions are more favorable. Height for age, with 95% confidence, was about 97.76% of children and 97.18% of the adolescents.

Conclusions: The data confirm the decline in child malnutrition and the increasing prevalence of overweight and obesity. The stature of the almost whole population was adequate. The study was presented to the Health and Education Departments of the municipality to corroborate with the public policies of intervention and health promotion, showing the importance of this partnership so that intervention programmes are actually implemented.

Keywords: Nutritional status. Child obesity.

SCHOOL-FOOD ENVIRONMENT REVIEW AND SUPPORT TOOL (SCHOOL-FERST): A NATIONAL SURVEY OF POLICY AND PRACTICE IN NEW ZEALAND SCHOOLS

[1]*D'Souza, Erica;* [2]*Vandevijvere, Stefanie;* [3]*Swinburn, Boyd.*

[1]MCS. PhD candidate. The School of Population Health. The University of Auckland. New Zealand.; [2]Phd. Research Fellow. The School of Population Health. The University of Auckland. New Zealand.; [3]MD. Professor. The School of Population Health. The University of Auckland. New Zealand.

Background and objectives: Research consistently demonstrates the positive links between healthy school environments, educational outcomes and student well-being. Yet New Zealand (NZ) school food and nutrition environments are not consistently monitored and evaluated. A valid, efficient and valuable monitoring and feedback system is needed to show trends in the healthiness of NZ school food environments and to stimulate action.

Methods: Participants from 819 (Response Rate = 33%) primary, intermediate, secondary and composite schools completed a cross-sectional, validated school food survey (School-FERST). Policies were analysed using an adapted version of the Well-SAT tool. Canteen menus were analysed using the national Food and Beverage Classification System for NZ schools, and a sample of menus from Auckland, Taupo, Christchurch and Timaru schools (n=54) were validated using fieldworker observations. Key informant interviews (n=18) were conducted to ascertain the best ways in which to give feedback to schools.

Results: Forty percent of schools stated they had a food and nutrition policy. Most of these policies (n = 146) were vague, lacked comprehensiveness and contained weak statements. Seventy one percent of schools sold food and beverages to students during the school day, with 58% offering only milk and water as beverage options. The average menu score was 2 out of 5, indicating only 20-40% of items on canteen menus were 'healthy'. A large proportion of schools (81%) used food and beverages for fundraising with 90% of these schools using 'unhealthy' items. Most schools had fruit orchards and/or vegetable gardens (80%), included nutrition education in curriculum (90%), are not sponsored by food and beverage companies (94%), and do not have commercial advertising on school grounds (97%). Key informant interviews revealed that schools engaged with comparative, visual feedback with minimal text. They also noted the usefulness of recommendations and positive stories from other schools.

Conclusions: School food and nutrition policies remain weak, and canteen and fundraising menus remain largely unhealthy. Students remain exposed to inconsistent messages and practices across the school that contribute to unhealthy food choices. Therefore a sustainable monitoring and feedback system is required to initiate change and improve outcomes over time.

Keywords: school food, food environment, obesity prevention, food policy

SYSTEMS MAPPING OF UNHEALTHY FOOD ENVIRONMENTS IN AUCKLAND SCHOOLS: A CASE STUDY

[1]D'Souza, Erica; [2]Swinburn, Boyd; [3]Vandevijvere, Stefanie.

[1]MCS. PhD candidate. The School of Population Health. The University of Auckland. New Zealand.; [2]MD. Professor. The School of Population Health. The University of Auckland. New Zealand.; [3]Phd. Senior Research Fellow. The School of Population Health. The University of Auckland. New Zealand.

Background and objectives: Group model building (GMB), a method of systems science, is a systematic process of involving key stakeholders in a structured process to create mental maps of their relevant food systems and combining these into one overall causal loop diagram (CLD). By having multiple stakeholders around the table, this process fosters mutual understanding, shared insights, consensus, motivation for implementing the results and catalyses change. Systems science was used to build a CLD to understand the complexity of school food systems, and identify sustainable, low-burden intervention points that can be easily embedded into an already existing system. This is the first time systems science was used to understand unhealthy food environments in Auckland schools.

Methods: GMB sessions were conducted in two schools. Each session consisted of three workshops spread over 6-8 weeks. Schools nominated a group of representatives (staff, students, parents, canteen providers, etc.) to participate in building a CLD to identify the causes and effects of an unhealthy food environment. Using a set of engagement activities, scripts and software participants created a visual map of their school food environment to build shared understanding, allowing them to better able to identify leverage points for a healthier environment.

Results: Participants developed a CLD that represented their own perceptions of the contributors and causes of unhealthy food environments at their school. Several themes were identified, each unique to the individual school but transferrable to other schools in their community, due to their shared lived environments. Schools identified intervention points, as the dynamic CLD allowed them to envision the possible outcomes of such interventions.

Conclusions: This participatory process empowered schools to take ownership while motivating them to act as agents of change. It allowed them to visualize, process and plan a prevention response that engages with multiple levels of their school food system, allowing for the best possible chance at achieving sustainable positive outcomes.

Keywords: schools, food environment, systems dynamics, participatory research, obesity prevention

AVAILABILITY OF ADEQUATELY IODIZED SALT IN PARAGUAYAN HOUSEHOLDS DURING 2011-2015

[1]Ledesma Solís, Erik Marcelo; [2]Sánchez Bernal, Susana.; [3]Masi, Celia.

[1]Medical Doctor, MD, MSc. Faculty of Medical Sciences. National University of Asuncion. Paraguay; [2]MD, MSc. Institute of Food and Nutrition. Ministries of Public Health and Social Welfare. Paraguay; [3]Nutritionist. MSc. Institute of Food and Nutrition. Ministries of Public Health and Social Welfare. Paraguay.

Background and objectives: Iodine Deficiency Disorders (DDY) has been an endemic problem in Paraguay due to the low Iodine content in its land considering that it's a Mediterranean country. The main strategy for the sustained elimination of IDD has been the universal salt iodization. Determine the availability of adequately iodized salt in Paraguayan households during 2011-2015.

Methods: Descriptive cross-sectional study with secondary data.

Results: 12.126 salt samples distributed in the five year period were included. The fine salt was the most frequently consumed; most samples came from urban areas and the origin was mainly national. Adequate iodine values remained above 52% during the study periods, showing a value of 57, 9% in 2015. During the five year period, iodine deficiency was higher in rural areas and in unregistered salt samples ($\chi 2p<0,05$). According to the geographical area, iodine deficiency was variable across the five year period. Deficiency levels have shown a tendency to increase (4,7% en 2011 vs. 34,3% en 2015, $\chi 2$ p=0,0001), while excessive levels have declined (35,6% en 2011 vs. 7,7% en 2015, $\chi 2$ p=0,0001). Mean values of salt iodine content have decreased showing a median of 23 ppm in 2015, significantly lower than previous years (Kruskal Wallis p=0,0001).

Conclusions: 6 of each 10 households have an adequately iodized salt consumption. Iodine deficiency in salt is mainly concentrated in rural areas and in unregistered samples. This represents a public health problem that needs to be addressed.

Keywords: salt, iodine, iodine deficiency, households

INFANT AND YOUNG CHILD FEEDING PRACTICES AND NUTRITIONAL STATUS OF 6-24 MONTHS-OLD IN GREATER ACCRA REGION, GHANA

[1]Berko Nartey, Eunice; [1]Koryo-Dabrah, Alice; [2]Adedia, David.

[1]MPhil. Registered Dietitian. Department of Nutrition and Dietetics. University of Health and Allied Sciences. Ho. Ghana; [2]MPhil. Mathematician. Department of Nutrition and Dietetics. University of Health and Allied Sciences. Ho. Ghana.

Background and objectives: Good nutrition is the basis for child survival, physical growth, mental development, performance, productivity, health and general well-being throughout human life (WHO, 2016). The research assessed the caregivers' infant feeding practices and nutritional status of their 6-24-month-old children.

Methods: Cross-sectional survey using stratified random sampling technique was used to select 408 children from eight health facilities in the Greater Accra Region of Ghana. Dietary data was collected using the 24-hour recall and analysed using the Esha Fpro for nutrient analysis. The WHO Anthro software (version 3.2.2) was used to generate indices of nutrition (stunting, wasting, underweight, and obesity) from weight (kg) and length/height measurements (cm).

Results: The study showed that caregivers' age (p=0.058), education (p=0.00), employment status (p=0.00), spouse's financial support (p=0.00), alternative means of care (p=0.00), hygiene (p=0.026; p<0.05), and source of knowledge of infant feeding (p=0.017), as well as age of their child (p=0.005), significantly influenced nutritional status. Infant feeding practices that was found to significantly influence nutritional status included, duration of exclusive breastfeeding (p=0.01), safe preparation and storage of food (p=0.00). In comparison to the Dietary Reference Intakes, only children from Osu recorded above the RDA for calories (963.6kcal), fat (48.6g), and Ridge for protein (27.9g). However, about 63% of the infants and young children who participated in the research did not meet their iron and zinc requirements. Food items that significantly contribute to the nutritional status, include cereals (p=0.014), animal protein (p=0.020), vegetables (p=0.004), fruits (p=0.034), and fats & oils (p=0.048). In total, 12.5% of IYC were found to be underweight, 9.4% wasted, and 41.5% stunted, whilst 17% of the infants were overweight. Highest incidences for stunting, wasting and overweight were recorded by children in Adabraka (38.6%), Osu (21.6%), and Tema (33.3%).

Conclusions: Malnutrition is still prevalent in Greater Accra, showing a worrying increase in the double burden of stunting and obesity. The findings of the study will contribute to having targeted interventions to improve IYCF practices in especially the Greater Accra region of Ghana. When malnutrition is minimized through improved infant feeding practices it may lead to better socio-economic development for sustainable quality life.

Keywords: Child Feeding Practices, Nutritional status, Dietary Reference Intakes

KNOWLEDGE, INTERPRETATION AND USE OF FRONT OF PACK LABELLING OF FOODS AND BEVERAGES IN COLLEGE STUDENTS FROM MEXICO CITY

Morales-Zárate, Maricruz; Bahena, Liliana; Tolentino Mayo, María Lizbeth.

Instituto Nacional de Salud Pública. Mexico.

Background and objectives: Several international organizations recognize the Front of Pack Labelling of Foods and Beverages (FoPL) as a Public Health strategy to fight overweight (OW) and obesity (OB), a regulatory measure that has already been implemented in several countries. The objective of this study was to explore and identify the degree of knowledge, interpretation and use of FoPL, mainly from the Guideline Daily Amounts (GDA's) system, in college students.

Methods: Data was obtained from 97 college students from Mexico City who answered a questionnaire. This included previously validated questions divided into four sections: 1) general knowledge of FoPL, 2) interpretation of GDA's, 3) use of GDA's for purchase decision and 4) interpretation and preference of GDA's (Mexican) vs. octagonal labeling (Chilean). In addition, information on height and weight was collected by self-report and the body mass index (BMI) was calculated as kg/m2.

Results: The prevalence of OW or OB in the overall sample was 30.2%. From the total population, 39% answered correctly the amount of daily average calories that should be eaten (2500 kcal). 94% reported consumption of products with FoPL, predominantly of dairy products (73.1%), sweet snacks (72%) and salty snacks (63%); 31.9% reported buying products with FoPL due to nutritional information and 17.5% for claims. The GDA's was familiar mainly to women (65.5%) and subjects with OW (64.9%) and OB (33.3%). However, 86.9% of the women and 85.9% of the men did not interpret correctly the GDA's, and the same happened with 70.4% of the people with OW and OB. The highest GDA's interpretation score was in the age group of >24 years (25%). It was found that 11.4% of the women and 8.3% of the men purchase based on the GDA's. None of the obese respondents uses GDA's to buy their products. Finally, 71% of the respondents preferred octagonal labeling.

Conclusions: Including the FoPL in the Mexican legislation is a good first step. However, it´s necessary a full impact assessment of the labeling regulation, with the intention of developing a tool that supports consumers on having a comprehensible, complete and reliable source of dietary information.

EATING OUT AND THE CONSUMPTION OF UL-TRA-PROCESSED FOOD AMONG BRAZILIAN ADOLESCENTS AND ADULTS

[1]Andrade, Giovanna; [2]Gombi-Vaca, Maria Fernanda; [3]Levy, Renata.

[1]Nutritionist. Departamento de Medicina Preventiva. Universidade de São Paulo. Brazil.; [2]MPh. Departamento de Medicina Preventiva. Universidade de São Paulo. Brazil.; [3]PhD. Departamento de Medicina Preventiva. Universidade de São Paulo. Brazil.

Background and objectives: Background: Eating out has been related to higher consumption of food characterized by high degree of processing, such as soft drinks, sweets and fast foods.

Objectives: To describe food consumption away from home and at home, according to the purpose and extension of industrial food processing. Evaluate the association between eating out and consumption of ultra-processed food.

Methods: Cross-sectional study using the 2008-2009 Brazilian Dietary Survey, carried out with 34,003 individuals aged 10 years or older. Food items were classified in food groups using the NOVA classification. Eating out was evaluated through two indicators: percentage of calories eaten out and frequency of days each individual reported eating out. Both indicators were described according to sociodemographic characteristics. Percentage of food calories per food group was estimated according to location of consumption. Multilevel model was used to evaluate the association between eating out and the participation of ultra-processed food in the diet.

Results: Although most of the calories consumed away from home in Brazil come from the culinary preparations food group, there were a higher contribution of calories from ultra-processed food when away from home, especially from items such as soft drinks and ready-to-eat meals. Compared to consumption at home, eating out increased the consumption of ultra-processed food by 51%.

Conclusions: In Brazil, eating out was associated with ul-tra-processed food consumption. In order to discourage consumption of ultra-processed food away from home, public policies such as food taxation and limitation of sales outlets should be considered.

Keywords: Eating out; Ultra-processed food; Multilevel analysis.

Tai Solarin Univeristy Of Education. Nigeria; [4]Phd Human Nutrition. Federal University Of Agriculture Abeokuta. Nigeria; [5]Msc Chemistry. Tai Solarin University Of Education Ogun. Nigeria.

Background and objectives: Undernutrition among infants has risen to such an extent that it has become a major public health problems especially in the developing countries. In many developing countries, the traditional complementary foods are the gruels prepared from cereals. The gruels from these cereals had been found to be of poor nutritional value, this is majorly responsible for high prevalence of undernutrition, notably protein-energy malnutrition (PEM) in Nigeria. The objective of this study was to formulate and prepare cheap and nutritious local complementary foods that can be used by Nigerian mothers

Methods: The study was an experimental study. Sorghum (Sorghum bicolor), maize, cowpea and (Vigna unguiculata), groundnut and crayfish were obtained from a local market in Ijebu-ode, Nigeria. The sorghum and maize were manually cleaned and were processed into flour using standardized fermentation and germination methods as described by (Ariahu, et al 2009), beans was processed using boiling method, groundnut, roasting method and crayfish drying method. The dried form of the items were dry milled into flour and packed into hermetically sealed container, eighteen samples were derived from the flour and thereafter, proximate and sensory analyses were conducted and results were presented in tables.

Results: The results of the proximate analysis of the complementary foods (CFs) showed that the moisture content of the CFs ranged from 4.00±1.79% for samples 1 to 9.12% for sample 10. The crude protein content ranged from 17.84±1.12% for samples 16 to 25.63v±0.89% for sample 6. The crude fibre content ranged from 1.64±0,36% to 4.63±2.89%. The antinutrient content of the complementary foods (phytate, oxalate and trypsin inhibitor) were determined. The phytate content ranged from 0.09±0.00mg/100g in sample 13 to 4.95±0.41mg/100g in sample 10. The results of the sensory evaluation of the best six complementary foods with the highest protein contents were conducted. In terms of colour and overall acceptability, sample 4 was most acceptable (7.76 and 7.67 respectively) and was more significantly different from others.

Conclusions: The protein content of the complementary foods increased as the content of both legumes increased since the content of the crayfish was constant.

DETERMINANTS OF UNDERNUTRITION AMONG YOUNG CHILDREN IN SOTNIKUM OPERATION DISTRICT, SIEM REAP, CAMBODIA

[1]Blaney, Sonia; [2]Main, Barbara; [3]Chhorvann, Chhea; [4]Vong, Lenin; [5]Hun, Vannary; [6]Menasria, Lylia; [7]Leblanc, Caroline.

[1]Professor or nutrition. Moncton University. Canada; [2]Senior Health advisor. World Vision Canada. Mississauga. Ontario. Canada; [3]Director of National Institute of Public Health of Cambodia. Cambodia; [4]Consultant. World Vision Cambodia. Cambodia; [5]Technical health and nutrition specialiste. World Vision Cambodia. Cambodia; [6]Graduate student enrolled in the programme of Master in Nutrition. Moncton University. Canada; [7]Professor of nutrition. Moncton University. Canada.

Background and objectives: According to the UNICEF framework on the determinants of malnutrition, immediate causes of poor child nutritional status are inadequate dietary intake and poor health status which are, in turn, determined by access to food, to care to health (underlying determinants). To help at improving impact of nutrition programme, a better understanding of causes of malnutrition is essential especially in areas where malnutrition affects a significant proportion of young children. In Cambodia, stunting and wasting affect 32% and 10% of children below five years of age respectively. In Siem Reap province, these proportions are at 36% and 10%. The objective of this study is to assess the relationship between child nutritional status and its immediate and underlying determinants among a population of Cambodian young children.

Methods: Data of a current clinical trial investigating the impact of consumption and promotion of local foods on child nutritional status will be further analysed to respond to the aforementioned objective. The clinical study is a cluster-randomized controlled trial among children 6-23 months old (n=360) living in 14 randomly selected villages. Data on nutritional (anthropometry, haemoglobin, ferritin) and health status (c-reactive protein, intestinal parasites in faeces, occurrence of illnesses), dietary intake (24-hour recalls), food and health practices, household food security, access to health and socioeconomics have been collected at baseline and will be collected at endline. Anthropometry data were analysed using WHO Anthro. Dietary intake are currently assessed using Nutrific software. Household food security (HFI) will be assessed using the HFI Scale. The adequacy of dietary practices will be estimated using WHO indicators. Scores will be developed to assess health practices and health and responsive feeding. Descriptive analyses will be used to assess differences in nutritional status and correlations will be performed to test for association between nutrition status and its determinants. Regressions will be used to identify predictors of nutritional status.

Results: Data are currently analysed since baseline study has been finalized in February. Preliminary results on nutritional status reveal lower rates of undernutrition than expected: 19,5% stunting and 7,9% wasting. Moreover 7 out of 10 children (n=375) had a haemoglobin value below 11g/dl.

Conclusions: To come.

Keywords: young children, undernutrition, determinants, Cambodia

LIVESTOCK OWNERSHIP IS ASSOCIATED WITH INCREASED ODDS OF ANEMIA AMONG PRE-SCHOOL-AGED CHILDREN, BUT NOT WOMEN OF REPRODUCTIVE AGE IN GHANA

[1]Jones, Andrew; [2]Colecraft, Esi; [3]Awuah, Raphael; [4]Boatemaa, Sandra; [5]Lambrecht, Nathalie J.; [6]Adjorlolo, Leonard Kofi; [7]Wilson, Mark L.

[1]PhD. Department of Nutritional Sciences. School of Public Health. University of Michigan.; [2]DrPH. Nutrition and Food Science Department. University of Ghana. Ghana.; [3]PhD. Regional Institute for Population Studies. University of Ghana. Ghana.; [4]MPhil. Regional Institute for Population Studies. University of Ghana. Ghana.; [5]BS. Department of Nutritional Sciences. School of Public Health. University of Michigan. USA.; [6]PhD. Livestock and Poultry Research Center. University of Ghana. Ghana.; [7]ScD. Department of Epidemiology. School of Public Health. University of Michigan. USA.

Background and objectives: Animal agriculture may help to mitigate anemia by providing access to nutrient-dense animal-source foods, but may also increase exposure to infections that increase the risk of anemia. The objective of this study was to determine the association between livestock ownership and anemia among women and children in Ghana.

Methods: We analyzed data from the 2014 Ghana Demographic and Health Survey (GDHS) using information on household livestock ownership that was collected through a quantitative survey. Capillary blood samples from women of reproductive age (15-49 years) (n = 4,798) and preschool-aged children (6-59 months) (n = 2,736) were analyzed using HemoCue photometer systems to assess hemoglobin (Hb) concentrations. Anemia was defined among non-pregnant women of reproductive age as Hb < 120 g/L, and among preschool-aged children as Hb < 110 g/L. In separate multiple logistic regression analyses for women and children we examined the association of household livestock ownership with anemia adjusting for the complex survey design of the GDHS and potential confounding covariates including socioeconomic status and infection indicators.

Results: In unadjusted analyses, household ownership of any livestock was positively associated with the prevalence of anemia among both women of reproductive age (44.3% of women from households with livestock were anemic vs. 40.3% without livestock; 2 = 7.8; P=0.005), and preschool-aged children (74.0% of children from households with livestock were anemic vs. 62.4% without livestock; 2 = 42.5; P<0.001). In multiple logistic regression analysis, household livestock ownership was not associated with anemia among women (OR (95% CI): 1.1 (0.88, 1.3)), but was associated with anemia among children (1.5 (1.1, 2.1)). Household ownership of chickens was associated with anemia in children (1.7 (1.3, 2.4), but ownership of no other animal species was independently associated with anemia risk in children.

Conclusions: Independent of socioeconomic status and infection indicators, livestock ownership in Ghana was associated with increased odds of anemia among young children, but not

among women. The association between livestock and anemia among children appears to be driven principally by ownership of poultry. Further research is needed to understand the potential nutrition- and/or infection-related mechanisms underlying these associations.

Academic Group of Nutritional and Molecular Epidemiology. School of Health Sciences. U Autonoma de Hidalgo. México.; [5]PhD. Research Professor. Department of Psychology. School of Health Sciences. U Autonoma de Hidalgo. México.; [6]MsC. School of Health Sciences. U Autonoma de Hidalgo. México.; [7]PhD. Professor. Departamento de Nutrición. Facultad de Medicina. U de Chile. Santiago Chile.

Background and objectives: Considering the need to have information about the physical activity performed by school children in order to design interventions for the prevention of childhood obesity, the purpose of this study was to describe the physical performance, self-efficacy for physical activity and physical inactivity in Mexican urban schoolchildren by gender and type of school, as well as to determine the differences by nutritional status.

Methods: A cross-sectional study was conducted in 396 schoolchildren from two public and two private schools from urban municipalities in the state of Hidalgo, Mexico. Weight, height and waist circumference (WC) assessments were performed with standardized personnel and calibrated equipment; a six-minute walk test (TM6), physical activity self-efficacy questionnaire (PASQ), and physical activity and inactivity questionnaire for the Mexican population (CAINM) were applied. The nutritional status was classified according to scores Z BMI (BMIZ) with WHO 2007 and school children with values> 90th percentile were diagnosed with abdominal obesity.

Results: In general, schoolchildren registered more than 50% of negative responses regarding the ability to perform physical activity in the PASQ; and an average of 3.2 ± 1.9 hours in front of the screen, being higher in male schoolchildren than in women

$(3.6 \pm 2.1$ vs $2.7 \pm 1.6)$ (p <0.01). Students with abdominal obesity ran a lower total distance compared to non-obese schoolchildren both in public schools $(509.3 \pm 51.5$ vs 541.4 ± 67.5 vs) and private schools $(548.7 \pm 70.8$ vs $526.1 \pm 54.3)$ (p <0.01), without detecting differences by nutritional status with BMIZ. A low correlation of hours of physical inactivity with the nutritional status was found $(r \leq 0.17, p <0.05)$.

Conclusions: Schoolchildren with abdominal obesity showed a lower physical performance compared to normal weight children. Self-efficacy for physical activity in schoolchildren was notoriously low, and the majority did not fulfill the recommendation of spending less than two hours watching TV or playing video games; the above is a challenge to overcome in public policies to promote physical activity in schoolchildren.

Keywords: Physical performance, physical inactivity, childhood obesity, self-efficacy

DETERMINATION OF BODY MASS INDEX, PHYSICAL ACTIVITY LEVELS, PHYSICAL ACTIVITY'S BEHAVIOR AND AUTO-EFFICACY AND THEIR RELATIONSHIP IN ECUADORIAN WORKERS DURING 2006

[1]Mogrovejo, Patricia; [2]Jimenez, Pablo.

[1]MD. MSc. PhD. Directora del Centro de Investigaciones en Enfermedades Crónicas No Transmisibles. Facultad de Ciencias de la Salud Eugenio Espejo. Universidad Tecnológica Equinoccial. Quito. Ecuador.; [2]MD, PhD (c). Profesor investigador de la Carrera de Medicina. Facultad de Ciencias de la Salud Eugenio Espejo. Universidad Tecnológica Equinoccial. Quito. Ecuador.

Background and objectives: Physical inactivity (PI) is a major risk factor for morbidity and premature mortality. However, the prevalence of PI, physical activity's behavior, barriers and auto-efficacy are unknown in Ecuadorian workers. This study aimed to determine Body Mass Index (BMI), Physical Activity (PA) levels, physical activity's behavior, PA barriers and auto-efficacy, and their relationship in Ecuadorian workers during 2006.

Methods: Through a medical story the following information was collected: 1. Sociodemographic information; 2. BMI; 3. PA levels were measured by the International Physical Activity Questionnaire; 4. Stage of Change (SOC) behaviors were measured in accordance to the Trans Theoretical Model; 5. Auto-efficacy and PA barriers were measured by questionnaire. Descriptive statistics, chi- squared test and factorial analysis of multiple correspondences were used.

Results: The prevalence of PI is 65.3%. The prevalence of excess of weight is 50% (40.8% overweight, 9.4% obesity). Overweight is higher in men (p<0.001), married (p=0.000), with primary educa-

tion (p=0.024) and increase with age (p<0.000). Physical activity SOC is associated with PA levels (p=0.000). Sedentary and inactive subjects are classified mainly in lower PA SOC (contemplation, pre contemplation and preparation), whereas active and very active subjects are categorized mostly in PA SOC maintenance. Subjects who are classified in PA SOC action and maintenance are mainly men (39.8%), with high school education (41.8%) and belong to 18-29 group age (41.6%). PA auto-efficacy levels are associated with BMI. Lower PA auto-efficacy is associated with overweight and obesity.

Conclusions: The prevalence of physical inactivity and obesity is high in apparently healthy workers at a private enterprise in Ecuador.. Being obese and lack of time are common barriers for practicing PA. The PA's SOC are associated with PA levels. Research findings were used for designing and implementing a life promotion program at workplace investigated. It includes PA counselling for preventing and managing PI. It includes physical activity SOC and PA auto-efficacy levels.

The George Institute for Global Health. The University of Sydney. Australia.

Background and objectives: Salt reduction is considered one of the most cost-effective and affordable interventions for the prevention of non-communicable diseases, but there are no studies evaluating the effectiveness of national strategies in low or lower-middle income countries. This study aimed to measure the effect of a national salt reduction strategy in Samoa with a view to sharing experiences to enhance future large-scale programs.

Methods: An 18-month multi-faceted salt reduction program was implemented in Samoa comprising of activities designed to influence policy, mobilise the community and raise awareness. Two nationally representative cross-sectional surveys of adults aged 18 to 64 years, measuring salt intake through 24-hour urine and knowledge, attitudes and behaviours related to salt, were conducted before (2013) and after (2015) the intervention to evaluate its impact.

Results: There were 234 participants at baseline (RR 47%) and 479 at 18 months (RR 61%) and samples were balanced in terms of age, gender, area, education and employment. There was no significant change in mean population salt intake between 2013 (7.31g/d) and 2015 (7.50g/d) (0.19, 95% CI -0.50 to 0.88; p=0.588). However, there were significant reductions in the proportion of the population who always or often; use discretionary salt when eating (-16.2%, p=0.002) and consume processed foods (-11.0%, p=0.02), increases in the population who understood the adverse health effects of high salt consumption (+9.0%, p=0.049) and used one or more methods to control their salt intake (+20.9%, p<0.001). 73% of the population reported that they had heard or seen messages from the salt reduction campaign.

Conclusions: Despite some population improvements in salt-related behaviours and knowledge after the intervention, there was no change in 24-hour urinary salt excretion. Inconsistencies in survey methodology, limited intervention dose and duration and the influence of a secular upward trend in salt intake are potential reasons for this. The widespread reach of the salt reduction messages and improvements in knowledge and behaviour suggest that the foundation for further interventions and improvements is in place. Structural policies to lower salt in the food supply and improve the environment are required to achieve a sustained reduction in population salt intake and blood pressure.

Keywords: sodium, public health nutrition, hypertension, NCDs, low and middle income countries.

Conflict of Interest Disclosure: JW is Director of the World Health Organization Collaborating Centre on Population Salt Reduction with a remit to support countries to implement and evaluate salt reduction programs in line with the WHO target for all countries to reduce population salt intake by 30% by 2025. All other authors declare that they have no conflicts of interests related to this study.

The George Institute for Global Health. Australia. Imperial College, London. United Kingdom. Royal Prince Alfred Hospital. Australia.

Background and objectives: The scientific evidence base in support of population wide salt reduction is strong but current high quality data about salt intake levels in India are mostly absent. We sought to establish any associations between estimated daily salt consumption levels measured through 24-hour urinary sodium excretion and knowledge, attitudes and behaviours towards salt in selected communities of Delhi and Haryana in North India and Andhra Pradesh in South India.

Methods: Data were collected through a cross-sectional survey comprising a single 24-hour urine sample, participants' physical measurements and questionnaire data on consumer knowledge, attitudes and behaviour towards salt, in an age-and sex-stratified random sample of 1395 participants in urban and rural areas of North and South India. Measures were made for the overall population of each region and major subgroups by weighting the survey data to the population of Delhi and Haryana, and Andhra Pradesh.

Results: Complete 24-hour urine samples and data on KAB were available for 637 individuals from Delhi and Haryana and 758 from Andhra Pradesh (65% and 68% response rate, respectively). The mean age of participants was 40 years, 47% were women and mean 24-hour urinary salt excretion was 9.3 (8.9–9.7) g/day. Many participants reported favourable knowledge and behaviours to minimise risks related to salt. Several of these behaviours were associated with reduced salt intake—less use of salt while cooking, avoidance of snacks, namkeens (savoury snacks), and avoidance of pickles (all $p < 0.003$).

Conclusions: Salt consumption in India is high, with mean population intake well above the WHO recommended maximum of 5g/day. Several consumer behaviours related to use of salt during food preparation and consumption of salty products were related to actual salt consumption and therefore appear to offer an opportunity for intervention. A national salt reduction programme, including community-wide education as part of a multifaceted strategy, would prevent large numbers of cases of hypertension as well as strokes and heart attacks, averting much premature death and disability

Instituto de Investigaciones en Ciencias de la Salud (INICSA).Universidad Nacional de Córdoba (UNC). Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET). Argentina.; [5]PhD. Instituto de Investigaciones en Ciencias de la Salud (INICSA).Universidad Nacional de Córdoba (UNC). Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET). Argentina.

Background and objectives: Traditional dietary patterns characterized by fatty red meat, processed meat, starchy vegetables, sugars and sweets, candies, fats and vegetable oils in male and by fatty meat, barkery products and vegetable oils in female population, were identified in Córdoba (Argentina). A high adherence to these dietary patterns has been associated with an increased risk of prostate cancer (PC) and breast cancer (BC), in men and women respectively. The aim of this study was to analyze whether the association between adherence to Traditional Pattern and the risk of PC and BC differs according to smoking habit and weight status.

Methods: Two case-control studies were conducted in Córdoba in 2008-2014 including 147/300 cases/controls of PC and

318/526 of BC. Adherence of each subject to Traditional Pattern identified through a principal component factor analysis was estimated. Two level logistic regression models were fitted using interaction terms of smoking habit (smoker-no smoker), weight status (normal weight-overweight) and tertiles of adherence to Traditional Pattern as covariates at level 1, and family history of the disease as clustering variable at level 2.

Results: An increased risk of BC was stronger in smokers with overweight who simultaneously have a high adherence to Traditional Pattern (OR: 2.54; 95%CI: 1.16-5.56). Interaction of high adherence to Traditional Pattern and overweight was significant and associated with an increased risk of PC (OR 2.73; 95%CI: 0.97-7.67). There were no interactions among smoking habit and weight status on PC risk. When stratifying by smoking habit, a greater risk of PC in smokers with overweight and high adherence to Traditional Pattern (OR: 3.52; 95%CI: 0.97–12.76) was found.

Conclusions: A particular emphasis would be made on smoking and other lifestyle conditions, when promoting healthy eating habits.

Keywords: Dietary patterns; breast cancer; prostate cancer; smoking habit; overweight.

THE CO-OCCURRENCE OF ANEMIA AND STUNTING IN YOUNG CHILDREN

[1]Gosdin, Lucas; [2]Young, Melissa; [3]Bartolini, Rosario; [2]Mehta, Rukshan; [4]Srikantiah, Sridhar; [2]Martorell, Reynaldo.

[1]MPH. Hubert Department of Global Health. Rollins School of Public Health. Emory University. USA; [2]Nutrition and Health Sciences. Rollins School of Public Health. Emory University. USA.; [3]Instituto de Investigación Nutricional. Peru.; [4]CARE. India.

Background and objectives: Anemia and stunting are prevalent nutritional problems among children of low- and middle-income countries that have profound effects on child development, morbidity, and mortality. A single conceptual framework is used often to identify the basic determinants of these and other forms of malnutrition. One would expect that problems with matching underlying determinants should co-occur in effected communities and individuals to a greater degree than by chance. We know from ecological analyses that stunting and anemia cluster across types of countries and their regions but is this also the case at the level of individuals, a question seldom asked and which we address.

Methods: In two separate populations of children – ages 6-18 months in Bihar, India (n=5664) and 0-36 months in Lambayeque, Peru (n=840) – we measured the frequency of the co-occurrence of anemia and stunting. We compared this value to the value expected by chance, the product of the prevalence of anemia and stunting using a chi-square test. Using an iterative model selection process, we built explanatory logistic regression models for each condition.

Results: The frequency of co-occurrence in the Indian population was 21.5%, and in the Peruvian population it was 27.1%, which are similar to frequencies expected by chance, 21.3%

(p=0.97) and 28.0% (p=0.87) respectively. In both populations, anemia was associated with sex, while stunting was associated with age, sex, wealth, and social standing (caste or indigenous). In the Peruvian population, anemia was also associated with age, while stunting was associated with dietary diversity over the past month. In the Indian population, anemia was also associated with caste, dietary diversity over one day, and household hunger, while stunting was associated with maternal illiteracy.

Conclusions: These results suggest that the co-occurrence of anemia and stunting in individuals is as expected by chance, despite some shared basic factors (sex, age, and caste). Anemia and stunting should be treated as independent and addressed according to their context-specific causes.

Keywords: anemia, stunting, co-occurrence, infant nutrition

Conflict of Interest Disclosure: The authors have no conflicts of interest to declare. The Bill and Melinda Gates Foundation funded the original trial in Bihar, India. The regional government of Lambayeque, Peru funded its baseline survey.

EVALUATION OF THE NUMBER OF DEATHS FROM MALNUTRITION IN SOUTH AMERICA IN THE PERIOD 1997 TO 2012

[1]Velasquez, John Edinson; [2]Deossa Restrepo, Gloria Cecilia; [3]Restrepo, Luis Fernando.

[1]Nutricionista Dietista, Docente e investigador. Universidad de Antioquia. Colombia; [2]. Magíster en Ciencias de la Alimentación y Nutrición Humana. Profesora Escuela de Nutrición y Dietética, Universidad de Antioquia. Medellín. Colombia.; [3]Estadístico, Especialista en Estadística. Especialista en Biomatemática. Profesor Titular.

Background and objectives: Background: Hunger is one of the main references in world politics, however thousands of people die every year because of the food starvation, South America is a reference of great availability and variety of foods, but it is no stranger to deaths from malnutrition. Objective: To evaluate the number of deaths from malnutrition in South America in the period 1997 to 2012.

Methods: Materials and methods: We used the database reported by the Pan America Health Organization (PAHO) which was accessed in March 2017 and complemented with databases of food availability and GDP from the FAOSTAT. The GENERAL LINEAR MODEL was used in order to carry out the contrasts between countries of South America incorporating the Tukey test, based on a statistical significance level of 5% Additionally the multivariate Biplot technique was carried out, which aims to relate the different years evaluated by projecting the countries and was complemented with cluster analysis, to establish typologies or groups according with the dynamics of the variables. We used statistical packages SAS UNIVERSITY and R version 3.0.0.

Results: The highest number of deaths occur in child under one year, from one to four years and from 65 years of age. Brazil

is the country of South America where more deaths from malnutrition presented, followed by Colombia and Argentina. The countries in which are presented under statistics of deaths from malnutrition are Uruguay, Bolivia, Paraguay, and Chile.

Conclusions: Notwithstanding that the countries of South America have great availability of foods, the deaths from malnutrition are still prevalent in most of the continent.

Keywords: Hunger, malnutrition, Food safety

IN-STORE FOOD ADVERTISING IN BRAZIL: DIFFERENCES BY STORE TYPE AND NEIGHBORHOOD CHARACTERISTICS

[1]Duran, Ana Clara; [2]Khandpur, Neha; [3]Jaime, Patricia.

[1]PhD. Center for Epidemiological Studies in Nutrition and Health. University of São Paulo. Brazil; Department of Epidemiology. School of Public Health. University of São Paulo. Brazil.; [2]PhD. Post-doctoral research fellow. Department of Nutrition. School of Public Health. University of São Paulo. Brazil.; [3]PhD. Associate Professor. Department of Nutrition. School of Public Health. University of São Paulo. Brazil.

Background and objectives: Exposure to advertising within retail food stores may influence food purchase and consumption, and ultimately health conditions. Understanding the nature and heterogeneity of in-store advertising is therefore crucial. The objectives of this study were to: (1) describe the availability of in-store food advertising; and (2) examine differences in the availability of in-store advertising by store type and neighborhood socioeconomic characteristics.

Methods: This was a cross-sectional study conducted in 2010-2011 in Sao Paulo city, Brazil. Our sample included all retail food stores in 52 census tracts, representing neighborhoods of high, medium and low socioeconomic strata. Retail food stores were categorized as (1) grocery stores and supermarkets and (2) limited-service stores [fruit and vegetable (F&V) specialty stores, convenience stores, bakeries/delis, and corner stores]. Data were collected using a reliable Food Store Observational Tool. Counts of different signs/advertisements of F&V, sugar-sweetened beverages (SSB) and snacks (cookies and salty snacks) were recorded. Mixed-effects Poisson regressions with robust variance and clustered at the census tract where each store were located were used to estimate the relationships between recorded foods and neighborhood socioeconomic characteristics (percent black and mixed-race residents and income of the head of the household) and store type.

Results: The sample included 9 grocery stores and supermarkets (2.9%), 229 corner stores (75.1%), 60 convenience stores (10.7%), and 7 F&V specialty markets (2.3%). F&V were advertised in 26.0% of the stores where F&V were sold (23.9% of the total sample of stores), and 19.0% had in-store advertising for SSB/snacks (96.1% of the stores sold these products). Advertising for both F&V and SSB/snacks was 2.5 times more prevalent in grocery

stores and supermarkets than in other store types. Availability of F&V in-store advertising did not vary by neighborhood characteristics. Although stores located in low-income areas were more likely to sell SSB/snacks, no differences were found for advertising.

Conclusions: Advertising for F&V and SSB/snacks was more prevalent in grocery stores and supermarkets. However, availability of advertising for these products did not vary by neighborhood socioeconomic characteristics. Policies aimed at regulating unhealthy foods advertising should include in-store advertising and reach people from different socioeconomic backgrounds.

"HEALTHFULNESS" OF CANADIAN PACKAGED FOOD PRODUCTS WITH AND WITHOUT HEALTH-RELATED CLAIMS: AN INFORMAS-BASED APPROACH

[1]Franco-Arellano, Beatriz; [2]Kim, Min Ah; [3]Vandevijvere, Stefanie; [4]Bernstein, Jodi T.; [5]Labonté, Marie-Eve; [3]Swinburn, Boyd; [5]L'Abbé, Mary.

[1]MSc. Department of Nutritional Sciences. University of Toronto. Canada; [2]BSc. Department of Nutritional Sciences. University of Toronto. Canada; [3]PhD. Department of Epidemiology and Biostatistics. University of Auckland. New Zealand; [4]MPH RD. Department of Nutritional Sciences. University of Toronto. Canada; [5]PhD. Department of Nutritional Sciences. University of Toronto. Canada.

Background and objectives: The increase in diet-related non-communicable diseases (NCDs) is a concern and actions are needed to reduce this health burden. Obesogenic food environments are a key factor and it is therefore important to assess the nutritional quality (e.g., "healthfulness") of the food supply, including health-related labelling on food packages. In Canada, the "healthfulness" of foods is not a criterion required for a product to carry a health-related claim and it is unknown if products carrying health-related claims are "healthier" than those which do not. This study examined the health-related claims displayed on the "healthiest" and "least healthy" food categories in the Canadian food supply using the internationally standardized International Network for Food and Obesity/NCDs Research, Monitoring and Action Support (INFORMAS) taxonomy.

Methods: Cross-sectional analysis of the University of Toronto 2013 Food Label Information Program, a database that contains information on pre-packaged products (n=15,342) of the Canadian food supply. The six "healthiest" and six "least healthy" food categories were determined using the Food Standards Australia New Zealand Nutrient Profiling Scoring Criterion (FSANZ-NP-SC). Health-related claims were classified using the INFORMAS taxonomy.

Results: Analyses included 7055 products in the "healthiest" and "least healthy" food categories. Among these products,

38.6% of products were considered "healthy" (n=2,721). Any type of health-related claim was carried on 63.3% of products classified as "healthy", whereas 45.5% of "less healthy" foods displayed health-related claims on their food labels. Nutrient content claims were the most popular claims used on "healthy" (55.8%) and "less healthy" foods (30.5%). Nutrient-function type claims were the least used: 2.2% and 0.3%, respectively for "healthy" and "less healthy" foods.

Conclusions: A substantial proportion of health-related claims were displayed in "less healthy" foods, potentially misleading consumers towards less nutritious choices.

Keywords: Nutrition labelling, Health-related claims, Public health, INFORMAS

Conflict of Interest Disclosure: Prior this study Beatriz Franco-Arellano was a PepsiCo employee. The company had no connection with the research. The rest of the authors have no conflicts.

IMMIGRATION AND CULTURAL IDENTITY: HOW TO CONSIDER THESE DIMENSIONS IN THE NATIONAL SCHOOL FEEDING PROGRAM

[1]Figueiredo Barata, Mayra; [1]Capezzuto Fernandes Dias, Manuela; [2]Barata, Mayra; [1]Constante Jaime, Patrícia.

[1]Nutritionist. Public Health Faculty. Sao Paulo's University. Brazil.; [2]São Paulo. Brazil.

Background and objectives: The cultural dimension of eating, intricate in the symbolic value of food, is strongly related to the identity and sense of social belonging to a territory. Immigration is a constant movement in Brazil, making the environment changeable and alive. The present work intended to analyze and discuss the normative bases of the National School Feeding Program (Programa Nacional de Alimentação Escolar - PNAE) in relation to the incorporation of the perspectives of cultural identity, culture and immigration and to describe the profile of immigrant students enrolled in 2016 in the municipal education of São Paulo.

Methods: In relation to the incorporation of the cultural identity and immigration perspectives a documentary analysis and a PNAE's normative bases discussion were carried out using a qualitative approach. A description of the immigrant students profiles enrolled in the Sao Paulo's municipal education system in 2016 was also made.

Results: The word culture appears in the selected documents as a guide and reference for food choice, culinary traditions and habits. Regarding immigration and its derivations, no citation was found. In relation to the profile of the immigrant students enrolled in the network, it is noticed that the great majority of these students are Bolivian (58%), followed by Angolans (11%) and the Japanese (5%).

Conclusions: Judging from the numbers found in the databases, the number of immigrants enrolled in the municipal education network is still not significant for measures in the normative bases of the PNAE to be taken. However, discussing cultural identity through experiences among the students themselves and between the educators can represent a more respectful and receptive generation.

Keywords: Immigration, Cultural Identity, Brazilian National School Feeding Program.

RELATIONSHIP BETWEEN VITAMIN K INTAKE AND BODY COMPOSITION INDICATORS

[1]Santos, Elizabete; [2]França, Natasha; [3]Peters, Barbara; [4]Fisberg, Regina; [4]Martini, Lígia.

[1]MD. Nutritionist. Nutrition Department. School of Public Health. University of São Paulo. São Paulo. Brazil; [2]PhD student. Nutrition Department. School of Public Health. University of São Paulo. São Paulo. Brazil; [3]PhD. Nutritionist. Nutrition Department. School of Public Health. University of São Paulo. São Paulo. Brazil; [4]PhD.Associate Professor. Nutrition Department. School of Public Health. University of São Paulo. São Paulo. Brazil.

Background and objectives: In contrast to other fat-soluble vitamins,little is known about the association between vitamin K and adiposity. Is assumed that this vitamin is fat soluble,therefore it can be considering that the adipose tissue may physiologically serve as a storage site for the same. However,the action of vitamin K on adipose tissue as well as the metabolic implications are not yet elucidated.Research into the association between vitamin K intake and body composition may contribute to identifying additional metabolic pathways that relate micronutrient inadequacy to obesity.Thus,the objective of this study is to investigate the relationship between vitamin K intake and body composition indicators between adults and elderly.

Methods: We evaluated 293 individuals of both sexes,adults and elderly participants of the ISA- Capital 2014 survey (cross-sectional study using a population-based household survey). Vitamin K intake was evaluated by means of a 24-hour food recall performed on two non-consecutive days, with an interval of more than one week, in person and by telephone. In order to structure the data collection in detail, the procedures described in the Multiple Pass Method developed by the United States Department of Agriculture were used. Body composition was assessed by means of anthropometry (weight and height) and dual-energy X-ray absorptiometry(DXA) by means of which the absolute values of fat and lean mass were obtained and the Fat Mass Index (FMI) and Appendicular Lean Mass Index (ALMI) by IMC. Linear Person Correlation, Pearson's Chi-Square test and Multiple Linear Regression were used. Significance was set at $P < 0.05$.

Results: 28.86% of the individuals were classified as obese (BMI>30 kg/m²). According to the FMI, 74.83% of the individuals have excess body fat and in relation to the lean mass, 83.89% presented adequate values according to the ALMI (by BMI). Vitamin K intake was associated only with the FMI (p=0.027).There was no correlation between vitamin K intake (p=0.78),BMI (p=0.47), body fat and lean mass in kg (p=0.93 and p=0.85, respectively) and ALMI (p=0.79).

Conclusions: Intake of vitamin K was only associated with FMI.This fact may be related to a better quality of the diet, considering that vegetables are among the main sources of vitamin K.

Keywords: Vitamin K. Food intake. Body composition. Obesity.

AN EVALUATION OF THE HEALTHINESS OF PACKAGED AND PROCESSED FOODS SOLD BY MAJOR MANUFACTURERS IN INDIA

[1]Jones, Alexandra; [2]Dunford, Elizabeth; [3]Taylor, Fraser; [4]Raj, Thout Sudhir; [5]Crossley, Rachel; [6]Rayner, Michael; [7]Neal, Bruce.

[1]LLM. Food Policy Division. The George Institute for Global Health. Sydney. Australia.; [2]Carolina Population Centre. University of North Carolina at Chapel Hill. Chapel Hill. United States.; [3]MEng. Food Policy Division. The George Institute for Global Health. Sydney. Australia; [4]Food Policy Division. The George Institute for Global Health. Bangalore. India; [5]MSc. Access to Nutrition Foundation. Utrecht. The Netherlands.; [6]PhD. Nuffield Department of Population Health. University of Oxford. Oxford. UK.; [7]PhD. Food Policy Division. The George Institute for Global Health. Sydney. Australia.

Background and objectives: India is one of many countries facing a rapid rise in overweight, obesity and diet-related non-communicable diseases. Around 20% of children and adolescents are overweight, and India now ranks third in absolute numbers of obese people after the United States and China. The traditional Indian diet based upon fruits, vegetables, unprocessed cereals and pulses is being eroded by packaged and processed foods high salt, sugar and harmful fats. To contribute to the first India Access To Nutrition Index, our objective was to determine the healthiness of packaged processed foods sold by major manufacturers in India.

Methods: Nutrient information for 943 packaged foods and drinks sold by the 11 largest manufacturers between 2014 and 2016 was obtained from product packaging, company websites or directly from the company. The Australian Health Star Rating (HSR) and the World Health Organization's European Regional Office (WHO EURO) nutrient profile models were used to analyse the nutritional quality of the products. Each company was ranked by the mean HSR of their portfolio, the proportion of 'healthy' products using a HSR cut-off of 3.5 out of 5.0 stars, and the proportion of products meeting WHO EURO criteria. Analysis was undertaken both at the company and food category level; both with and without sales-weighting.

Results: The mean HSR of products was low overall (1.9 out of 5.0) with substantial variation between companies (mean 0.6 to 2.7). Only one in six products were 'healthy' (HSR>=3.5) and only 9% met WHO criteria for marketing to children. There were marked differences in the healthiness of similar products within food categories. There was some variation of company rankings depending upon the metric of healthiness used and whether rankings used estimates that were or were not weighted for sales.

Conclusions: The healthiness of packaged food products made by the largest manufacturers in India was sub-optimal. Improvements in product mix and reformulation of less healthy products should be priorities for companies. The Government of India could support corporate actions by strengthening nutrition labelling requirements and establishing targets for reductions in salt, sugar and fat in packaged foods.

Keywords: public health, packaged foods, nutrient profiling, food manufacturers, India

INTAKE AND DIETARY SOURCES OF CALCIUM AMONG AUSTRALIAN ADOLESCENTS AND YOUNG ADULTS

[1]Rouf, Anika; [2]Sui, Zhixian; [2]Rangan, Anna; [2]Grech, Amanda; [2]Allman-Farinelli, Margaret.

[1]PhD Candidate. School of Life and Environmental Sciences. Australia; [2]School of Life and Environmental Sciences. Australia.

Background and objectives: Adolescence to young adulthood is an important transitional phase, with high requirements for calcium. The Nutrient Reference Values in Australia are 1300 mg for adolescents and 1000 mg for young adults. This study aimed to examine the calcium intake of adolescents and young adults in Australia from food sources and supplements, taking consideration of lifestyle, anthropometry and socio-demographic variables.

Methods: This study utilised dietary data from 490 adolescents (14-18 years) and 561 young adults (19-25 years) from the 2011-12 National Nutrition and Physical Activity Survey. A single 24-hour recall was used to the estimate the mean intake of calcium which included food and supplements. Descriptive statistics were used to report the calcium intake for plausible reporters (energy intake vs. Basal Metabolic Rate ≤0.87 to ≥2.67). Chi-square, trend analysis and linear regression were conducted to identify associations between calcium intake and anthropometric and demographic characteristics and consumption of other food groups.

Results: Total calcium intakes (foods and supplements) were a mean (SD) of 905.5 (501.9) mg for adolescents and 913.1 (504.3) mg for young adults. Calcium supplement use was relatively uncommon, and provided 0.8% and 1.0% of total intake for adolescents and young adults, respectively. Adolescent females had much

lower calcium intakes 775.5 (435.4) mg compared to males 1048.4 (588.7) mg, as did young adults 835.7 (474.6) mg for females and 1014.2 (544.3) for males. The food sources contributing to calcium were similar across age groups and gender, with regular milk (15-24%), cheese (10-12%), refined low fibre bread (10%) and low fat milk (7-9%) as the largest contributors of calcium. Alternative milk beverages contributed <1% to calcium intake. Higher intake of core food groups (vegetables, fruits, dairy) and BMI was associated with higher calcium intakes for adolescents and young adults adjusted for energy intake. For both adolescents and young adults, a higher socio-economic status was associated with greater intakes of calcium.

Conclusions: Mean calcium intake among Australian adolescents and young adults remains below recommendations, especially in females. The findings from this study will be used to inform the development of future interventions.

Keywords: Calcium, dairy, adolescents, young adults, nutrition survey

PROCESSED MEAT CONSUMPTION WAS ASSOCIATED WITH HIGHER BODY MASS INDEX AND POORER DIET QUALITY, COMPARED TO RED MEAT AND POULTRY

[1]Sui, Zhixian; [2]Raubenheimer, David; [3]Rangan, Anna.

[1]PhD. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; [2]Professor. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; [3]Assoc Professor. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia.

Background and objectives: The nature and extent of the relationship between red meat, poultry, and processed meat consumption and obesity and total diet quality has not been clearly established. This study aimed to investigate the associations between red meat/poultry/processed meat consumption and diet quality, taking consideration of demographic and anthropometric characteristic, lifestyle factors, consumption of other food groups and other relevant nutrients and nutrient biomarkers.

Methods: This study utilised 24-hour recalls of 9,113 adults participating in the 2011-12 National Nutrition and Physical Activity Survey and National Health Measures Survey. Red meat, poultry, and processed meat consumption data were captured in detail from all meals and recipes. Chi square analysis and multivariate regression models were conducted to examine the association between red meat/poultry/processed meat consumption and anthropometrics, demographic categories, weight status, intakes of different food groups, nutrients, and nutrient biomarkers.

Results: Approximately 49% of respondents consumed red meat (mean per-capita intake: 57g), 38% consumed poultry (42g), and 39% consumed processed meat (28g). Higher consumption of red meat and processed meat but not poultry was associated

with greater Body Mass Index (BMI). Red meat, poultry, and processed meat consumption all increased with Waist Circumference (WC). Consumption of vegetables was positively associated with red meat but inversely associated with poultry and processed meat consumption. Discretionary foods/beverages consumption was associated with processed meat consumption. Compared with the nutrient intake profiles from red meat and poultry, processed meat consumption was associated with lower protein, long-chain omega 3 fat, niacin equivalents, vitamin C, magnesium, and potassium intakes and vitamin D biomarker, and the highest total fat, saturated fat, and sodium intakes and sodium biomarker.

Conclusions: Processed meat consumption was associated with higher BMI/WC and poorer diet quality, compared to red meat and poultry.

Keywords: Processed meat; red meat; poultry; obesity; diet quality

PRIMARY PREVENTION OF EXCESSIVE FAT GAIN AMONG 2-6 YEAR OLDS. RESULTS FROM THE "HEALTHY START" RANDOMIZED INTERVENTION

[1]Olsen, Nanna Julie; [2]Ängquist, Lars; [3]Mortensen, Erik Lykke; [4]Heitmann, Berit Lilienthal.

[1]Postdoc. Research Unit for Dietary Studies at the Parker Institute. Bispebjerg og Frederiksberg Hospital. Denmark; [2]Postdoc. Department of Clinical Epidemiology. Bispebjerg and Frederiksberg Hospital. Denmark; [3]Professor. Department of Public Health and Center for Healthy Aging, and Section for General Practice. Department of Public Health. University of Copenhagen. Denmark; [4]Professor. Research Unit for Dietary Studies at the Parker Institute. Bispebjerg and Frederiksberg Hospital. Denmark.

Background and objectives: Previous obesity prevention interventions all targeted groups where both normal weight and overweight children were present, e.g. in school settings. Only about 1/4 of these previous interventions were effective in reducing weight gain, and studies have proposed, that the few positive effects were restricted to those already overweight, or to high-risk individuals. The objective of this primary prevention RCT was to examine, if excessive weight and fat gain over on average 1.3 years can be prevented among normal weight, but obesity susceptible, young children aged 2-6 years. ClinicalTrials.gov NCT01583335.

Methods: All children born in 2004-2007 from 11 greater Copenhagen municipalities, with either a high birth weight, maternal pre-pregnancy obesity, or maternal low education, were identified from public registries, and invited to participate. Totally 21% agreed to be included (n=635) and were randomized as interven-

tion or control children. All children who were already overweight or obese were subsequently excluded (n=92). The intervention delivered improvement in diet and activity habits, optimization of sleep quantity and quality, and reduction of stress.

Results: Intention-to-treat analyses showed a lower gain in %-fat mass in the intervention group compared to the control group (difference D=-2.1% (95% CI -3.7; -0.5; p=0.01)), but non-significant differences in BMI z-score gains (p=0.55).

Conclusions: Gain in fat may be prevented among normal weight young children at high risk of future obesity, suggesting not only a more favorable growth, despite a similar weight development, but also that primary prevention of obesity is possible.

Keywords: Primary weight gain intervention, individualized family intervention, pre-school age, sleep optimization, stress management.

ASSOCIATIONS BETWEEN BODY MASS INDEX AND EATING DISORDER SYMPTOMS AMONG ADOLESCENTS IN POLAND

(1)Ostachowska-Gasior, Agnieszka; (2)Zając, Joanna; (3)Kwiatkowski, Jacek; (4)Piwowar, Monika.

(1)PhD. Nutritionist. Department of Hygiene and Dietetics. Dietary Lab Counseling. Medical College. Jagiellonian University of Krakow. Poland.; (2)MSc. Biologist. Department of Hygiene and Dietetics. Medical College. Jagiellonian University of Krakow. Poland; (3)MSc. Computer programmer. Department of Hygiene and Dietetics. Dietary Lab Counseling. Medical College. Jagiellonian University of Krakow. Poland; (4)PhD. Biotechnologist. Department of Bioinformatics and Telemedicine. Medical College. Jagiellonian University of Krakow. Poland.

Background and objectives: Eating disorders are characterized by changes in eating patterns associated with low self-esteem, perfectionism, poor empathy, and an obsession with a body image. The aims of presented study were: 1. Determination of eating disorders risk among Polish adolescents; 2. Evaluation of the relationship between BMI and eating disorder symptoms.

Methods: A cross-sectional survey was performed in a random sample of adolescents from secondary and high schools of Southern Poland, aged between 13 and 19 years old. Information on weight control concerns and behaviors, and eating disorder symptoms (EDI) has been collected using a self-administrated questionnaire. Data obtained from questionnaire were analyzed with using multiple logistic regression model. Differences between categorical variables have been tested by chi-square test. Crude odds ratios (OR) have been calculated to evaluate the risk of independent variables and associated 95% confidence intervals. Statistical analysis has been performed with R software (2.15.3 version), GLM procedure.

Results: A total of 3572 adolescents (average age 16.13±1.54) have been analyzed (1899 girls and 1673 boys). Overweight was stated in 19.7% of examined girls and in 22.6% of boys, and underweight in 27.7% of girls and 6.5% of boys. Symptoms of eating disorders were observed in 11.6% of girls (n=414). There was no significant association between BMI and body dissatisfaction among boys. Weight control behaviors were more characteristic for girls. Overweight and underweight among girls were associated with high score of drive for thinness, body dissatisfaction, bulimia and low self-esteem.

Conclusions: Weight control behaviors may be considered as one of indicators of the association between BMI and eating disorder symptoms. The risk of eating disorders is more characteristic for adolescent girls and more educational and intervention programs is needed especially in this group of teenagers.

Keywords: Eating disorders, adolescents, BMI, self-esteem

"DISCRETIONARY FOODS" VERSUS "ULTRA-PROCESSED FOODS" – COMPARISON OF THE AUSTRALIAN DIETARY GUIDELINES FOOD CATEGORIZATION AND THE NOVA PROCESSED FOOD CLASSIFICATION SYSTEM

(1)Sui, Zhixian; (2)Rangan, Anna; (3)Raubenheimer, David; (3)Gill, Timothy.

(1)Postdoc. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; (2)Assoc Professor. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; (3)Professor. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia.

Background and objectives: The Australian Dietary Guidelines (ADG) categorize foods into core and discretionary foods on the basis of their nutrient contribution, and advises limiting the intake of discretionary choices. A new food classification system (NOVA) has been proposed which categorizes foods by the level of processing, with processed foods, particularly the most highly processed category called ultra-processed foods, being associated with lower overall diet quality. This study aimed to apply the two systems to the current Australian diet and examine the coherence between discretionary food and ultra-processed food.

Methods: All foods, beverages, and recipes in the Australian Food and Nutrient database 2011 (AUSNUT) were categorised: 1) as core or discretionary food according to ADG criteria; and 2) according to the degree of processing based on the NOVA criteria (unprocessed food, culinary ingredient, processed food, ultra-processed food, or mixed dish containing multiple degrees of processing). Both categorisations were applied to dietary data collected using 24-hour recalls of 9,431 adults participating in the 2011-12 National Nutrition and Physical Activity Survey (NNPAS) in order to calculate the proportion of energy contribution from each category.

Results: Of the 1,616 discretionary food items within AUSNUT, 15% were classified under NOVA as processed, 40% as

ultra-processed and 40.5% as mixed dishes containing a large proportion of ultra-/processed food. Data from NNPAS showed discretionary food consumption contributed approximately 33.7% of total energy intake in Australia. In comparison, ultra-processed food (20.7%) and processed food (23.5%) together contributed 44.2% of total energy intake. Among Australian adults, less than a quarter of total energy intake was contributed by unprocessed foods (22.3%).

Conclusions: Ultra-processed foods make up a significant proportion of the discretionary food consumed by Australians. However, the definition of discretionary does not strongly correlate with the degree of food processing. The two food categorization systems thus measure different dietary features within the same population. It remains to establish their relative merits as guides for research, dietary advice and public health policy.

Keywords: Foods; processed; ultra-processed; database; NOVA

144/1456

ADDRESSING THE ROLE OF PROXIMAL DETERMINANTS OF UNDERNUTRITION: COMMUNITY BASED PARTICIPATORY RESEARCH (CBPR) IN BUKOBA RURAL, REPUBLIC OF TANZANIA

Singh, Neeta.

Associate Professor/ Chiar. Nutrition Program. University of the Incarnate Word. San Antonio. Texas. USA.

Background and objectives: In Tanzania, undernutrition among children and mothers, especially in rural areas, is a common phenomenon. Evidence-based strategies for nutrition intervention mainly address direct determinants such as food intake whereas, community based interventions tend to have higher efficacy when combined other proximal determinants such as women's economic and social empowerment. Women's education, access to economic means of production, ownership of assets and ability to purchase inputs are very limited, which increases their income and food insecurity.

Objective: to create cooperative farming project a collective way to cultivate soybean to improve the quality of the existing diet and an infrastructure to effect the women's economic sustainability and empowerment.

Methods: The orientation of this project is Community Based Participatory Research (CBPR) which begin with a research topic of importance to the community with an aim of combining knowledge and action for social change to improve community health. Focus groups of Bukoba Women's empowerment Association (BUWEA) were conducted to share the findings of the first Tanzania Mainland Nutrition Survey. The focus group discussions led to identification of direct determinants of undernutrition as lack of availability; accessibility; and utilization of food whereas identified proximal determinants were women's lack of sustainable purchasing power; decision making power; business acumen; horticultural and technical assistance. These latter implied the lack

of women's social empowerment in their family and community context.

Results: BUWEA members (420) were provided minimal financial resources and technical expertise to grow soybean on 20 acres of land. After this initial harvesting, educational interventions on related topics as benefits and uses of soy in local diets; accounting and business skills; marketing; value added products, and grant writing. Women's Economic Development Personal and Social Impact Survey (WEDIS), administered in Swahili indicated significant consumption of soy in family diets, along with evidence of increased knowledge application in business and farming skills, utilization of technology, greater involvement in family decision-making, and more participation in social/political affairs. These are relevant indicators of women's personal and social empowerment in developing countries.

Conclusions: Recognizing a community as an essential research partner is key element of CBPR

Keywords: Community Based Participatory Research/CBPR, Social Empowerment, Undernutrition

NUTRITION TRANSITION ACROSS FOUR POPULATIONS IN PAPUA NEW GUINEA: DIFFERENCES IN DIETS, FOOD PREPARATION AND EATING BEHAVIOURS

[1]*Vengiau, Gwendalyn;* [2]*Gouda, Hebe;* [3]*Phuanukoonnon, Suparat;* [4]*Marks, Geoffrey.*

[1]MD (PhD Student); [2]PhD. School of Public Health. Faculty of Medicine. University of Queensland and Centre for Mental Health Research. The Park Centre For Mental Treatment, Research and Education. Queensland. Australia.; [3]PhD. James Cook University. Division of Tropical Health and Medicine. Townsville. Queensland. Australia.; [4]PhD. School of Public Health. Faculty of Medicine. University of Queensland. Herstons. Queensland. Australia.

Background and objectives: As with most developing countries Papua New Guinea (PNG) is undergoing rapid economic development which is expected to have an important impact on dietary habits and population health. However, the type and rate of change is expected to vary greatly across cultural groups in PNG and affected by extent of economic development. Understanding these differences is fundamental to developing effective health promotion measures. This study examined dietary patterns in four populations groups in PNG with different exposures to a major project.

Methods: The study applied a cross-sectional design conducted in two phases. Phase one used observation and participatory methods to document diet patterns and validate methods. Phase two used the four step 24-hour recall to collect detailed descriptions of intakes. Study sites included two coastal locations (Hiri, Karkar) and two in the highlands (Hides/Komo, Asaro), with a major project affecting Hiri and Hides/Komo. In phase one, 220 households

and 448 adults were involved, and phase two had 3247 participants selected purposively to reflect SES profile in the populations.

Results: Major components of traditional diets continue to exist in rural areas with more than 70% of participants consuming traditional staples (sweet potato, banana). However, all study sites incorporated store-bought food items. A majority of participants in Komo/Hides, Asaro, and Karkar consumed 20-30% of their diet as rice and tinned fish while it was 70-80% in Hiri. Vegetable oil was widely used in food preparation though used differently across sites - in the Highlands added either when boiling food or after the food is cooked while in Hiri frequently used for frying. Eating behaviours (types of meals, number of meals per day, snacking behaviours) differed by sites reflecting cultural norms.

Conclusions: The level and nature of diet change differed across study sites. Even though traditional diets were common, modern Western foods were essential dietary components with extent of use associated with project exposure. This may predict both favourable and adverse health outcomes. The results show a need to consider differences across populations in the way that the nutrition transition occurs, and to ensure that health promotion measures are suitable.

PhD. Director. Research Institute of Strategy for Prevention. Japan.

Background and objectives: This study aimed to examine the relationship between iron intake and social factors among women of reproductive age in Japan.

Methods: A baseline survey of a prospective cohort study, which is entitled NIPPON DATA2010, was conducted along with the National Health and Nutrition Survey of Japan in November 2010. A total of 486 women aged 20-49 years old participated in the study were included in the analysis after excluding ineligible observations. Adequate iron intake was defined if the amount of iron intake was 9mg and more per day in accordance with the recommendation amount of Dietary Reference Intakes for Japanese (2015). Multivariable logistic regressions were performed to assess the relations between social factors as independent variables and iron intake. Social factors were educational status, marital status, household income, job, regional area and BMI. Total energy and some food groups such as pulses and vegetables were included in this analysis as confounding factors.

Results: The prevalence of adequate iron intake among women of reproductive age was 21.0%. After adjustments for confounding factors, women with lower household income (adjusted odds ratio (OR) 2.28, 95% confidence interval (95%CI) 1.28-4.05) was more likely to have poor iron intake, while women lived in southwest Japan (OR 0.47, 95%CI 0.23-0.95), women with underweight (OR 0.48, 95%CI 0.24-0.99) were less likely to have poor iron intake.

Conclusions: Social factors such as household income, regional area, and BMI were statistically significantly associated with iron intake among women of reproductive age in Japan.

Keywords: Iron intake, social factor, income and regional disparity, women of reproductive age, Japan

GLUTTONY AND GUILT: COMPARING MONTHLY TRENDS IN INTERNET SEARCH QUERY DATA WITH DATA FROM THE AUSTRALIAN NATIONAL NUTRITION AND PHYSICAL ACTIVITY SURVEY

[1]Sui, Zhixian; [2]Coogan, Sean; [3]Raubenheimer, David.

[1]Postdoc. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; [2]PhD. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; [3]Professor. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia.

Background and objectives: Health professionals require contemporaneous information to assess progress and prioritize action relating to overweight and obesity, which is now a global epidemic. Yet, systems for monitoring population-level diet and nutritional intake have been considered insufficient in the majority of countries. The purpose of this study was to investigate whether trends in search query data related to behavioural change associated with obesity can be used to inform actual population nutritional intake and dieting behaviour.

Methods: We first examined long term (2004 to 2016) trends in Australian Google relative search volume (RSV) for the terms

---

"weight loss", "diet" and "fitness" to establish monthly patterns in search term usage. We then examined the monthly energy, macronutrient, and food intake of the Australian population, and the proportion of self-reported dieters, using data collected from the National Nutrition and Physical Activity Survey (NNPAS) 2011/12. Decompositional time series analysis and least squares means contrasts of generalized linear mixed models (GLMMs) were used to examine monthly differences in RSV. Nutritional geometry and ANCOVA was used in the analysis of NNPAS data.

Results: We found that RSV was significantly higher than the mean during January, and lower during December, for all search terms. The decline in RSV was not linear, however, as there was a significantly lower RSV for terms during May to July, and significantly higher from August to October. The pattern of energy intake (kJ) (highest in December and lowest in February) of survey participants, and the percentage of self-reported dieters, closely followed monthly patterns in RSV. The proportion of energy from protein was consistent across months examined; however, energy from lipid and carbohydrate + fiber were variable between months. Likewise, patterns of food-group consumption was variable across months.

Conclusions: Our analysis suggests that search query data can be used to inform the timing of national public health strategies to combat obesity.

MAKING COLLABORATION THE DEFAULT TO DELIVER MULTISECTOR NUTRITION PROGRAMMING - A NEW APPROACH IN TIMOR-LESTE

[1]Grieve, Heather; [2]Da Sousa, Erkulana.

[1]Public Health Nutritionist (Bsc.MND MPH) Australian Embassy. Timor-Leste; [2]Technical Nutrition Lead (BA) Partnership for Human Development. Timor-Leste.

Background and objectives: Despite progress, preliminary data from the 2016 Demographic and Health Survey indicates that undernutrition in women and children continues to be a major development issue, across all municipalities, in urban and rural areas and across all wealth quintiles in Timor-Leste. On the contrary, the prevalence of overweight and obesity is increasing, raising concerns of the emerging double burden of malnutrition.

Global evidence suggests that no single policy or intervention can create sustained reductions in malnutrition. Instead, a mix of coordinated interventions, across sectors is required to address the immediate and underlying causes of malnutrition across the lifecycle .

While integrated multi-sector programming presents great potential, the evidence-base on which to achieve this potential remains weak. In practice, poor program targeting and evaluation has resulted in limited evidence demonstrating the impact of integrated programming on improving nutrition status . The Hamutuk ("together") program is using technology to make col-

laboration the 'default' behaviour and utilising existing platforms to deliver targeting messaging.

The objective is to reduce the prevalence of stunting in children under two years of age through collective multi-sector action

Methods: Hamutuk is taking an evidence based approach to improve the quality and coverage of nutrition promoting behaviours at the household level by:

1. Strengthening nutrition capacity across partners

2. Using m nutrition tools to trigger behaviour change and create a nutrition enabling environment amongst partners

Results: The program is in early implementation. Measured activities to date include partner workshops on behavioural insights, gender, nutrition and the making of a multisector nutrition video for household consumption.

The joint monitoring platforms has sped up the monitoring and evaluation cycle providing faster insights of intervention reach and impact

Conclusions: Hamutuk will allow the Government of Timor-Leste to measure the collective impact of existing nutrition specific and nutrition sensitive interventions on stunting , and model an approach to support effective scale up of multi-sector nutrition programming and m-nutrition interventions.

Keywords: Stunting, multisector nutrition programming, m-nutrition

PEOPLE'S CHOICE – FOOD AND MACRONUTRIENT SELECTION IN AN OBESOGENIC ENVIRONMENT

[1]Sui, Zhixian; [2]Coogan, Sean; [3]Rangan, Anna; [4]Simpson, Steve; [4]Raubenheimer, David.

[1]Postdoc. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; [2]PhD. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; [3]Assoc Professor. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia; [4]Professor. Charles Perkins Centre. School of Life and Environmental Sciences. The University of Sydney. Australia.

Background and objectives: Studying intake of macronutrients and their inter-correlations is complex. People do not have one sum of food intake per day and do not typically plan the macronutrient ratios for their meals. Rather, people have a large variety of meals with variable nutrient ratios and complex dishes comprised by mixed foods throughout the day by spreading nutrient/food intakes into different meals/eating periods. This study aimed to investigate how people regulate their macronutrient intakes under free-living conditions, and whether protein is the regulatory priority, in relation to diet quality.

Methods: This study utilised 24-hour recalls of 9,113 adults participating in the 2011-12 National Nutrition and Physical Activity Survey and National Health Measures Survey. Nutritional Geometry was used to examine how people regulate proportions of macronutrients consumed meal by meal, and over the whole day, while also adjusting for significant anthropometric and demographic features.

Results: Respondents that consumed higher protein density food at the start of the day reduced their proportion of energy from protein during subsequent eating periods; however, their total daily protein intake remained high, and energy intake lower, by the end of the day. In contrast, respondents that consumed lower protein density food at the start of the day increased their proportion of energy from protein in the following meals, but remained low protein density and high energy intake for the day. Over the whole day, the percent protein consumed was inversely associated with total energy intake and positively associated with total diet quality, as indicated by higher consumption of healthy meat and alternatives, vegetable, and dairy products, and lower consumption of discretionary choices. Respondents that consumed a higher proportion of protein energy also reported significantly higher unprocessed food intake and lower processed and ultra-processed food intake.

Conclusions: Total daily energy intake is strongly associated with the proportion of protein in foods chosen early in the day, the proportion of protein over the entire day (daily diet), and the foods available in the environment.

Keywords: Protein; protein leverage hypothesis; energy intake; nutritional geometry; processed food

OVERWEIGHT AND OBESITY IN HEALTH PROFESSIONALS

Palomares, Lita.

MSc. Nutritionist. Professor. Department of Cellular and Molecular Sciences. Cayetano Heredia University. Peru.

Background and objectives: According to World Health Organization in the world there are more than 1900 million adults overweight and obese. Health professionals are not stranger to this reality, and in them the impact is greater because they affect the health behaviors of the patients. The nutritional status of health professionals is important because they serve as health role models and because they are more likely to counsel their patients about health behavior change if they practice healthy habits themselves. Therefore, the objective of this study is evaluate the nutritional status of health professionals in a hospital.

Methods: Descriptive research with a quantitative approach and cross-sectional design was applied. The sample was composed of 106 health professionals from 5 specialties: nursing, medicine, obstetrics, nutrition and medical technology. The anthropometric nutritional status was evaluated according to Body Mass Index (BMI), Waist Circumference (WC), Body Fat Percentage (BFP) and Visceral Fat. The statistical program IBM SPSS Statistics 22.0 was used for the analysis of data.

Results: According BMI of health professionals evaluated, 45.3% were overweight, 20.8% were obese grade I, 1.9% were obese grade II, 2.8 were thin, and 29.2% were normal. About WC, 39.6% had a high cardiometabolic risk, 31.1% had a very high cardiometabolic risk and 29.2% had a low cardiometabolic risk. According to BFP, 58.5% presented a very high level, 30.2% high, 10.4% normal and 1% low. About visceral fat, 34% presented a high level. According to specialties, medical professionals had the highest prevalence of obesity (35.1%), very high percentage of body fat (67.6%) and high visceral fat (54.1%). Midwives had 61.1% of overweight and nurses presented 43.6% of very high cardiometabolic risk. Nutritionists were the only group with normal values of BMI, WC and visceral fat.

Conclusions: 70% of the health professionals evaluated were overweight and obese, in addition to high and very high cardiometabolic risk; also 90% had a high and very high body fat percentage, and 34% had a high level of visceral fat.

Keywords: Overweight, obesity, health professionals, nutritional status.

EXPLORING THE EFFECT OF DIETARY INTAKE TO WEIGHT STATUS OF PREADOLESCENTS IN URBAN SETTING USING A NEW PROPOSED FOOD GROUP CLASSIFICATION – EVIDENCE FROM THAILAND

[1]*Boonchoo, Wannachanok;* [2]*Hayashi, Fumi;* [3]*Takemi, Yukari.*

[1]MAgr. Graduate School of Nutrition Sciences. Kagawa Nutrition University. Saitama. Japan. Ministry of Public Health. Department of Health. Bureau of Nutrition. Nonthaburi. Thailand.; [2]RD. PhD. Faculty of Nutrition. Kagawa Nutrition University. Saitama. Japan.; [3]RD. PhD. Graduate School of Nutrition Sciences. Kagawa Nutrition University. Saitama. Japan.

Background and objectives: The rising trend in the prevalence of overweight and obesity has been recognized as a public health problem in Thailand, particularly in urban settings. However, comprehensive data on the dietary sources of energy and nutrients in Thai obese children are lacking. This study aimed to identify the dietary intake of urban Thai preadolescents by weight status and to determine food contributing to sex-, age-specific BMIz scores (BAZ), by using a new proposed food group classification.

Methods: Dietary intake of 263 children aged 10-12 y in Bangkok Metropolitan Regions, Thailand, was assessed through three non-consecutive 24-h recall interviews. Lifestyle and sociodemographic characteristics were obtained from questionnaires. BAZ was calculated from data obtained from the school health records, and was then classified into non-obese, and overweight/obese groups based on WHO Growth Charts. Differences in dietary intake and contribution to micronutrients were analyzed by analysis of covariance. Individual food items were classified into thirteen groups based on Thai dietary guidelines, and the context of Thailand's food environment around children, including

"street-side snacks". Street-side snacks was defined as a light meal or snack mostly available at a street vendor's, road-side shop, without food label, and included traditional fast food, local dishes, or western fast food and could be eaten between main meals. The relation between food consumption and BAZ was evaluated using multiple linear regression analysis.

Results: After adjustment for sex and misreporting of energy, overweight/obese children had higher intake of daily energy and all primary macronutrients, and consumed more cereal grains, meats/fish, eggs, flavored milk, and street-side snacks. Stepwise multiple regression showed that there were ten food groups that were significantly and positively associated with BAZ. Of these, consumption of street-side snacks had the highest impact to BAZ, and remained at the top even after further controlling for energy intake.

Conclusions: Our finding implies that children's weight status can be affected by the food environment around the school, by showing the association between the consumption of street-side snacks on BAZ. This may help in encouraging future dietary strategies on the prevention of childhood obesity through environmental approach in the Thailand context.

RELATIONSHIP AMONG HYDRATION STATUS AND PHYSICAL ACTIVITY IN ADOLESCENTS. HYDRATION UP & DOWN SUBSTUDY

[1]*Gómez-Martínez, Sonia;* [2]*Rodríguez-Laprast, Juan Alberto;* [3]*Hernández González, Aurora;* [4]*García-Cervantes, Laura;* [5]*Cabanas-Sánchez, Verónica;* [6]*Marcos, Ascensión.*

[1]PhD. Biologist. Institute of Food Science, Technology and Nutrition. Spanish National Research Council. Madrid. Spain; [2]MSc. Nutritionist. Institute of Food Science, Technology and Nutrition. Spanish National Research Council. Madrid. Spain.; [3]PhD. Quemist. Institute of Food Science, Technology and Nutrition. Spanish National Research Council. Madrid. Spain.; [4]MSc. Sports Science Degree. Department of Physical Education, Sport and Human Movement. Autonomous University of Madrid. Madrid. Spain.; [5]PhD. Sports Science Degree. Department of Physical Education, Sport and Human Movement. Autonomous University of Madrid. Madrid. Spain.; [6]PhD. Pharmacist. Institute of Food Science, Technology and Nutrition. Spanish National Research Council. Madrid. Spain.

Background and objectives: Hydration and physical activity are very important concepts on which we must go more deeply since they are essential for the evaluation of the nutritional status and health during adolescence, a key stage in the acquisition of behavioral habits.

The objective was to evaluate the possible relationship between hydration status and physical activity (PA) in adolescents.

Methods: This is a cross-sectional substudy from the Up & Down Study. A total sample of 67 adolescents (39 males and 28 females) was analyzed, with a mean age of 15.9 years ± 0.3. The subjects were grouped according to their sex. The PA level was measured through the Physician-based Assessment and Counseling for Exercise questionnaire (PACE), and the hydration parameters [Total Body Water (TBW) and ExtraCellular Water (ECW)] by bioimpedance.

Results: Adolescents showed normal weight in both sexes (mean BMI = 21 kg/m2). Triceps fold values were higher in girls (16.7 ± 5.6 mm) than in boys (10.3 ± 4.4 mm). Water composition values (TBW and ECW, in litres), were higher in boys than in girls (36.8 ± 5.2 vs 29 ± 2.7 and 15.9 ± 2.5 vs 12.7 ± 1.6), respectively.

Boys were more active than girls according to their score in the PACE questionnaire, obtaining 3.1 ± 1.7 vs 2.1 ± 1.3 days of commitment with PA recommendation of 60 min/day (p=0.028).

82.1% boys and 64.3% girls had an optimal ECW range. However, when evaluating hydration according to TBW, 33.3% boys were within the optimal range while none of the girls met this range.

When studying the relationship among hydration and physical activity, we observed that the subjects who had an optimal hydration range for TBW were the most active ones according to the PACE questionnaire (p=0.011).

Conclusions: Girls were less active than boys in general, and this inadequate habit may be related to a less optimal hydration status. Therefore, physical activity should be taken into account when promoting healthy habits among adolescents, particularly those related to their hydration status.

WHICH DIETARY CHANGES TO MOVE TOWARDS NUTRITIONALLY ADEQUATE DIETS WITHOUT INCREASING THEIR IMPACT ON BIODIVERSITY, WATER AND LAND-USE? THE CASE OF TUNISIA

[1]*Perignon, Marlène;* [2]*El Ati, Jalila;* [3]*Sinfort, Carole;* [4]*Drogue, Sophie;* [1]*Darmon, Nicole;* [1]*Amiot-Carlin, Marie Josephe;* [5]*Group, MEDINA-Study.*

Unité Mixte de Recherche 1110 Markets, Organizations, Institutions and Stakeholders Strategies (UMR MOISA). INRA, CIRAD CIHEAM and Montpellier SupAgro. France.; [5]INRA.

Background and objectives: As several Mediterranean countries, Tunisia has experienced an epidemiological and nutritional transition resulting in an increase in overweight, obesity

and co-morbidities. In the last decades, food consumption departed from traditional diets towards higher consumption of animal-based and sweet products. Tunisia also faces environmental issues such as water scarcity, soil erosion and biodiversity loss. This growing concern for health issues and climate change has emphasized the need to promote sustainable diets, i.e. nutritionally adequate, affordable, culturally acceptable, and with low environmental impact. The objective was to identify dietary changes needed to move towards nutritionally adequate diets without increasing their environmental impact.

Methods: Nutrient intakes were estimated using dietary data from the nationally representative Tunisian study on food consumption (n=7209, 35-70y), and food composition from a Tunisian database and the Food Processor software. Environmental impact of diets was assessed through 6 indicators - water scarcity, biodiversity, and 4 indicators for land-use (erosion resistance, mechanical filtration, groundwater replenishment, biotic production) – estimated for 161 foods. For each gender, two optimized diets respecting all nutritional recommendations from WHO and with minimized departure from the mean observed diet were designed with linear programming under 2 scenarios to fulfill: i) all nutritional constraints (NUTRI) and ii) all nutritional constraints without exceeding observed levels for the 6 environmental indicators (NUTRIENV).

Results: Calcium, copper, iron, magnesium, potassium and vitamin D intakes were below their recommendations in the mean observed diets, while sodium and fats exceeded them. Under the NUTRI scenario, i.e. reaching nutritional adequacy without controlling for the environmental impacts, the main dietary changes were the increases of fruits and dairy products, and decreases of meat and starchy foods. All the environmental indicators were impaired, except erosion resistance and biotic production. Under the NUTRIENV scenario, i.e. when environmental indicators were limited to their observed levels, the changes in fruits, dairy products and starchy foods quantities were lower than in the NUTRI scenario, in favor of vegetables.

Conclusions: Environmental impacts should be assessed when identifying food consumption changes to reach nutritional adequacy. Dietary changes identified to move towards more sustainable diets in Tunisia will be translated into action proposals.

Keywords: Sustainable diet; Nutritional adequacy; Environmental impact; Tunisia; Diet modeling

TREND OF MATERNAL AND CHILD HEALTH AND NUTRITION INDICATORS IN KENYA: IMPLICATION FOR POLICY DEVELOPMENT

Makokha, Anselimo.

Professor. Jomo Kenyatta University of Agriculture and Technology. Kenya.

Background and objectives: The Kenya Demographic and Health Surveys (KDHS) were published in 1989, 1993, 1999, 2003, 2009 and 2014. The objective of the study was to assess changes in key maternal and child health and nutrition indicators in this reports.

Methods: It was a desk study.

Results: Fertility steadily declined from 6.7 births in 1989 to 3.9 in 2014, as the use of contraceptives increased from 27% to 58%. One fifth of teenage girls had either given birth or were pregnant in each of the KDHS reports. By 19 years, 40 – 45% had their first child or pregnancy. Ante natal clinic attendance ranged from 92% to 96%. However, only about one half made the recommended minimum four visits. The proportion of women who delivered in health facilities was below 50%, except in 2014, when it was 61%. By 2014, over a quarter of the women, 28%, were still assisted by traditional birth attendants during birth. Full vaccination coverage among children was at a rate of 79% in 1989 and 2014, but 57% in 2003. Though universal breastfeeding was observed in all the reports, complementary foods were introduced to 25-75% of the babies by the age of two months. Initiation of breastfeeding was done within one hour after birth among only about half of the babies. The proportion of under five children (U5) who had received Vitamin A supplements was 30-33%, except in 2014, when it doubled to 62%. In the five reports from 1989 to 2009, the stunting rates of U5 remained constant, at one third, but reduced to 26% in 2014. The U5 mortality rates increased from 96 to 115 deaths per 1000 between 1993 and 2003, then dropped to 52 in 2014. The infant mortality rate followed a similar trend, increasing from 66 to 77 deaths per 1000, then decreasing to 39 in 2014.

Conclusions: The observed changes in the maternal and child health and nutrition indicators can be evaluated to inform policy and future programme interventions.

Keywords: Maternal, Child, Health, Nutrition, Kenya.

DEVELOPMENT OF A ROADMAP FOR MAIN-STREAMING CONTEXTUAL NUTRITION-SENSITIVE INTERVENTIONS AT KEBBI AND ANAMBRA STATES, NIGERIA

[1]Ezekannagha, Oluchi; [2]Mbhenyane, Xikombiso; [3]Drimie, Scott.

[1]BSc. MPH. PhD Student. Division of Human Nutrition. Faculty of Medicine and Health Sciences. Stellenbosch University. South Africa; [2]Bsc. MSc. PhD. Professor. Division of Human Nutrition. Faculty of Medicine and Health Sciences. Stellenbosch University. South Africa.; [3]BA. MPhil. PhD. Adjunct Professor. Division of Human Nutrition. Faculty of Medicine and Health Sciences. Stellenbosch University. South Africa.

Background and objectives: Continued high prevalence of malnutrition in Nigeria calls for emerging strategies to tackle existing burden and prevent newer incidences. Applying sub-national contextual programming to nutrition-sensitive interventions creates a pathway to sustainable malnutrition reduction. Given the variations at these sub-national levels such as varying malnutrition profiles, political dynamics, state finances and program implementations. This study thus aims to evaluate the epidemiological, operational and socio-political domains of mainstreaming nutrition sensitive interventions in Kebbi and Anambra states, Nigeria to inform the development of roadmap.

Methods: This study employs the Mainstreaming Nutrition Initiative Framework in an explanatory sequential mixed methods design. Kebbi in the North-West geopolitical zone and Anambra in the South-East geopolitical zone was chosen purposively as a high undernutrition state (Stunting – 60.6%) and low undernutrition (Stunting – 18.4%)/emerging overweight state respectively. In Phase 1, the local government area estimates of malnutrition will be sought using Nigeria's Living Standard Measurement Survey. In Phase 2, Firstly, the program documents of ministries of agriculture, welfare, education and environment will be assessed using a nutrition-sensitivity assessment checklist and a potential-to-be nutrition-sensitive checklist. Finally, a program observation site visit will be carried out in which an in-depth interview (Program manager) and two exit interviews will also be conducted on participants that use the program. For Phase 3, a one-day workshop in both states will be conducted with the instrument Political Commitment and Opportunity Measurement – Rapid Assessment Tool (PCOM-RAT). Finally Phase 4 will include synthesis of results from the above phases to develop and validate a roadmap for mainstreaming nutrition-sensitive programming in the study states. The development will use program impact pathway and take cognizance of political, operational and epidemiology findings.

Results: Outcomes of this study will provide a case study to show that the Mainstreaming Nutrition Initiative framework provides a theoretical basis for mixed methods research to enable understanding of epidemiological, operational and socio-political domain of mainstreaming nutrition-sensitive actions.

Conclusions: If the pragmatic roadmap is implemented, this study provides a template for strengthening nutrition-sensitivity and aligning already existing programs in nutrition sensitive sectors.

SALT REDUCTION IN BREAD AMONG MOROCCAN POPULATION

[1]Taboz, Youness; [1]Benkirane, Hasnae; [1]Guennoun, Yasmine; [2]Elammari, Laila; [2]Elberri, Hicham; [2]Mouzouni, Fatima-Zahra; [3]Benajiba, Nada; [1]Elkari, Khalid; [4]Barkat, Amina; [1]Aguenaou, Hassan.

[1]Joint Research Unit in Nutrition and Food. Ibn Tofaïl University. CNESTEN. Kenitra. Rabat. Morocco; [2]Ministry of Health. Morocco; [3]Clinical Nutrition Program. Department of Health Sciences. College of Health and Rehabilitation Sciences. Princess Nourah BintAbdulrahman University. Riyadh. KSA.; [4]Health and Nutrition Research Team of the Mother Child Couple. Faculty of Medicine and Pharmacy. Mohammed V University of Rabat. Morocco.

Background and objectives: To contribute to the achievement of global voluntary targets for non-communicable diseases set by the World of Health Organization and the Second International Conference on Nutrition (ICN2), Morocco has developed a plan of reducing salt consumption to combat the non-communicable diseases. The objective of the present study is to assess acceptance of bread with different percentage reduction of salt by Moroccan population.

Methods: In this study, 201 participants (age >15 y.) were recruited to determine the level of salt reduction in bread. Different salt contents par 100g were tested and compared: 1,74g, 1,62g, 1,56g, 1,46g, 1,34g, 1,21g et 0,81g, corresponding to the reduction of salt of 0%, 7%, 10%, 16%, 23%, 30% and 53%, respectively, compared available bread in local market. Overall liking, "Just About Right" (JAR) and purchase scales was used to score the different salt contents in bread.

Results: Bread with a reduction of 10% and 16% is highly accepted by 76,11% and 78,60% of respondents. Based on JAR score, bread with 10% (1,56g/100g) and 16% (1,62g/100g) of reduction were considered as "just about right" by 50,54% and 56,92% respectively. Best average score of purchase intent is obtained for salt content in bread of 1,62g and 1,56g for a reduction of 10% and 16% respectively.

Conclusions: The results show that reducing salt levels is easily achievable and is acceptable to customers. Bread with a reduction on salt of 10% and 16% is highly accepted by respondents. Food Industry is needed to reduce salt in bread to accompany the national salt reduction strategy in Morocco.

Keywords: Salt reduction, acceptance, bread, Morocco

VALIDITY OF WAIST TO HEIGHT RATIO IN PREDICTING DYSLIPIDAEMIA AMONG SRI LANKAN CHILDREN AGED 8-9 YEARS

[1]Kalaichelvi, Thillan; [2]Samaranayake, Dulani; [3]Ianerolle, Pulani; [4]Thoradeniya, Tharanga; [5]Wickramasinghe, Pujitha.

[1]MSc. Post graduate student. Department of biochemistry and Molecular Biology. Faculty of Medicine. University of Colombo. Sri Lanka; [2]Senior Lecturer. MBBS.MSc.MD.Department of Community Medicine. University of Colombo. Sri Lanka.; [3]BScHons.PhD. Senior Lecturer. Department of Biochemistry and Molecular Biology. Faculty of Medicine University of Colombo. Sri Lanka; [4]BVSc. PhD. Senior Lecturer. Department of Biochemistry and Molecular Biology. Faculty of Medicine University of Colombo. Sri Lanka.; [5]MBBS.DCH.MD.PhD.Professor in paediatrics. Department of Paediatrics. Faculty of Medicine. University of Colombo. Sri Lanka.

Background and objectives: Dyslipidaemia, an important risk factor associated with cardio vascular disease is increasingly observed among paediatric populations. There is a need for a simple and quick screening tool to predict this condition. The present study evaluated the validity of Waist to Height Ratio (WHtR) in predicting dyslipidaemia among 8-9 years old Sri Lankan children.

Methods: Cross sectional study was conducted among 8-9 years old school children within Colombo Municipal area comprising of 146 children with high adiposity (body fat > 28.6% in boys and >33.7% in girls) and 148 children with normal adiposity assessed by bioelectrical impedance analysis (BIA). Weight, height, waist circumference (WC) and serum lipids (Triglyceride-TG, HDL, LDL cholesterol and Total Cholesterol-TC after 12 hours of overnight fasting) were measured. Simple correlation analysis was done to investigate the association between the lipid parameters and anthropometric indices (Body mass index, WC and WHtR). Dyslipidaemia was defined as 2 or more abnormal parameters in the lipid profile. Receiver operating characteristic (ROC) curves were analyzed for WHtR in predicting dyslipidaemia. Youden index was used to determine the optimum cut off values for WHtR predicting dyslipidaemia.

Results: WHtR showed significant correlations with lipids in boys (TC-r=0.216, p<0.01, TG-r=0.362,p<0.001, LDL-r=0.230,p<0.01, HDL-r=-0.208,p<0.05) and in girls (TG-r= 0.329,p<0.001, LDL-r=0.175,p<0.05, HDL-r=-0.349,p<0.001)). The cut off value of WHtR was 0.486 for boys (sensitivity-69.4%, specificity-65.7) and 0.481for girls (sensitivity-61.4%, specificity- 64.5%). The positive and negative predictive values were 66.9% and 68.2% for boys whereas in girls these values were 63.4% and 62.6% respectively.

Conclusions: WHtR can be used as a screening tool to predict dislipidaemia among 8-9 year old Sri Lankan children. These cut off values are similar to the values defined in other populations. Since the WHtR is a simple, quick and non invasive anthropometric technique it could be feasible for use in screening for dyslipidaemia in this population group. A practical cut off for both genders would be 0.5.

Keywords: Dyslipidaemia, Waist-height ratio, Children, Screening tool

College of Health and Rehabilitation Sciences. Princess Nourah BintAbdulrahman University. Riyadh. KSA.; [4]Health and Nutrition Research Team of the Mother Child Couple. Faculty of Medicine and Pharmacy. Mohammed V University of Rabat. Morocco.

Background and objectives: Following the recommendations of the World Health Organization to reduce the average salt consumption in the populations by 30% to reach a target of less than 5 g per day by 2025, Morocco has recently developed a plan of salt reduction in order to reinforce prevention of non-communicable diseases which is a major problem at the national level. The present study is a masterpiece of this national strategy since its objective is to determine the threshold of perception of salt taste in the Moroccan population. The national plan for the reduction of salt consumption will take this into account in order to gradually reduce the salt content in processed foods

Methods: The study involved 201 testers divided into 4 age groups [15-29 years], [30-44 years] [45-59 years] and over 60 years. The pannelists tested NaCl solutions at concentrations of 1, 2, 4, 8, 15, 30, 60, 125, 250, 500 mmol/l in random order using the blind Alternative Forced Choice method. The rinsing between each test was carried out using flat water. Informations on age, sex, height, weight and Body Mass Idex was collected and transcribed on SPSS software for statistical processing

Results: Results show that 38.80% of the testers began to perceive the salty taste from the concentration of 30 mmol/l (1.75 g/l) and 31.84% from the concentration of 15 mmol/l (0.875 g/l), while 10,94% and 13,93% of the testers perceived the salty taste respectively at concentrations of 8 mmol/l (0,46g/l) and 60 mmol/l (3,5g /l). The khi2 test shows a significant correlation between the perception of the salty taste and the sex (p value = 0,035) and the perception of the salty taste and the BMI (p value = 0,034). The age has no significant effect on the threshold of perception of the salty taste (p value 0.500).

Conclusions: The results obtained are very important data that can be used as part of the national salt reduction strategy to convince industrials to reduce salt levels in processed foods

Keywords: Determination, salty taste , perception, Morocco

IMPACT OF NUTRITION EDUCATION ON NUTRITIONAL ADEQUACY AND HAEMOGLOBIN STATUS OF ADOLESCENT GIRLS

Background and objectives: Iron deficiency anaemia is a prominent unsolved problem in India. India has the world's highest prevalence of iron deficiency anaemia among women, with 60 to 70 percent of the adolescent girls being anaemic. Hence, the health of adolescent girls demands special attention. This study was conducted to assess the prevalence of anemia and to study the impact of nutrition education on nutritional and haemoglobin status of adolescent girls aged between 13 to 15 years.

Methods: Three thousand adolescent girls from 10 different locations of 10 states of India were screened out with haemoglobin level below WHO cut off of 12 gm/dl using cyanmethemoglobin method. The samples were further divided into equal sized control and experimental group to conduct the study. Nutrition education was provided for 3 months using various audio-visual aids. Haemoglobin levels at screening stage were considered as pre level and it was assessed again after imparting nutrition education. Food and nutritional adequacy was assessed before and after imparting nutrition education using 24 hour dietary recall and comparing with recommended allowances by Indian Council of Medical Research, India.

Results: Initial screening revealed that the prevalence of anaemia in the population studied was 66.84% with a mean haemoglobin level 10.1 ± 1.11 g/dl. Nutrition education significantly improved the haemoglobin level of experimental group from 10.01 ± 0.51 g/dl to 10.77 ± 0.60 g/dl. However the improvement had not reached the normal cut off level. There was improvement in percent distribution of population with an increase in normal category from 0.94% to 16.64%. Moderately anaemic category fell from 70.05% to 52.41% and also severely anaemic category from 5.99% to 1.49%. Intake of most of the food groups had increased significantly but not up to the recommended amounts. Similarly, mean nutrient adequacy was significantly increased in energy, protein, calcium, iron and folic acid in experimental group after nutrition education although not adequate.

Conclusions: There was increase in haemoglobin level, food and nutrient intake, but the increment did not meet normalcy and the recommended levels. This indicates that more intense nutrition education programme may be included probably through school curriculum.

Keywords: Anaemia, prevalence, adolescent, haemoglobin.

IDENTIFICATION OF GEOGRAPHICAL CLUSTERS OF NUTRITION TRANSITION IN ARGENTINA AND ITS SOCIODEMOGRAPHIC CHARACTERIZATION

[1]Rodríguez Junyent, Constanza; [2]Natalia, Tumas; [3]Graciela Fabiana, Scruzzi; [4]Sonia Alejandra, Pou.

[1]PhD Student. Carrera de Nutrición. Facultad de Medicina Universidad Católica de Córdoba. Argentina; [2]PhD. Centro de Investigaciones y Estudios sobre Cultura y Sociedad (CIECS). Universidad Nacional de Córdoba. CONICET. Carrera de Nutrición. Facultad de Medicina. Universidad Católica de Córdoba. Argentina.; [3]MSc. Escuela de Nutrición. Facultad de Ciencias Médicas. Universidad Nacional de Córdoba y Universidad Católica de Córdoba. Argentina.; [4]PhD. Instituto de Investigaciones en Ciencias de la Salud (INICSA). Universidad Nacional de Córdoba. CONICET. Facultad de Ciencias Médicas. Escuela de Nutrición. Facultad de Ciencias Médicas. Universidad Nacional de Córdoba. Argentina.

Background and objectives: Nutritional Transition (NT) is a process that includes changes in populations' nutritional profile, determined by convergent socioeconomic, demographic, environmental, and sociocultural factors. The geographical context and its sociodemographic characteristics emerge as potential underlying factors of the populations' epidemiological and nutritional profile. This work proposes to identify the geographical clusters based on the contribution of NT indicators in Argentina (2005-2013) and distinguish the sociodemographic scenarios that characterize them.

Methods: Multi-group, ecological design (23 provinces and the Autonomous City of Buenos Aires). A cluster analysis was conducted to identify clusters by proximity among geographical units, based on similarities among NT indicators (nutritional state, physical activity, and food intake), obtained from official sources of information: Nationwide Nutrition and Health Surveys (2005), Risk Factors of Non-Transmissible Diseases (2005, 2009, 2013), and Population, Household, and Housing Census 2010. Summary measures of these indicators and of sociodemographic variables were calculated (based on the 2010 census), with the aim of characterizing each cluster identified. These were incorporated into a GIS (Geographical Information System) to draw up maps using the ArcGIS 10.2 software

Results: Three NT clusters were identified in Argentina: 1) provinces in the Pampas region, Cuyo and part of Patagonia; 2) the Autonomous City of Buenos Aires and the south of Patagonia; 3) the provinces in the northwest and northeast of Argentina. Cluster 2 displayed the highest levels of adult (19.99%) and child (11%) obesity, use of computers (71.3%), frequent salt consumption (23.63%) and consumption of at least 5 daily portions of fruit and vegetables (5.28%), while cluster 3 recorded the highest prevalence of low weight, low height and anemia in children (2.69%, 9.69%, 19.06%; respectively). Physical inactivity, alcohol intake and overweight in adults were similar in the clusters identified. Cluster 3 showed the worst relative situation concerning indicators of socio-economic level, health coverage, education, and degree of urbanization.

Conclusions: There are geographical clusters in Argentina with specific nutritional and sociodemographic characteristics. This might indicate different NT processes in the interior of the country.

URINARY SODIUM EXCRETION AND RISK OF ISCHEMIC STROKE

[1]Kieneker, Lyanne; [2]Eisenga, Michele; [3]Gansevoort, Ron; [4]de Boer, Rudolf; [3]Navis, Gerjan; [5]Muskiet, Frits; [3]Dullaart, Robin; [6]Joosten, Michel; [3]Bakker, Stephan J.L.

[1]MSc. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; [2]MD. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; [3]MD, PhD. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; [4]MD, PhD. Department of Cardiology. University Medical Center Groningen. The Netherlands.; [5]PhD. Department of Laboratory Medicine. University Medical Center Groningen. The Netherlands.; [6]PhD. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.

Background and objectives: Results: **Methods:** We studied 7,330 subjects free of cardiovascular events at baseline in the Prevention of Renal and Vascular End-stage Disease (PREVEND) study, a prospective, population-based cohort of Dutch men and women aged 28-75 years. UNaV was measured in two 24-hour urine specimens at baseline (1997-1998) and two specimens during follow-up (2001-2003).

Results: Baseline median UNaV was 137 mmol/24h (IQR: 106-171 mmol/24h). During a median follow-up of 12.5 years (IQR: 11.9-12.9 years), a total of 131 ischemic stroke events occurred. In primary analyses, we observed an inverse association between UNaV and risk of ischemic stroke (HR per 1 SD [51 mmol/24h] decrement, 1.53; 95% CI, 1.17-2.02) after adjustment for lifestyle and dietary variables. The association of UNaV with risk of ischemic stroke was modified by smoking status (Pinteraction=0.017), in such a way that the association was only observed among current smokers (HR per 1 SD decrement, 2.58; 95% CI, 1.60-4.15; n=53) and not among former/never smokers (HR per 1 SD decrement, 1.08; 95% CI, 0.77-1.52; n=78). In secondary analyses, we found that current smoking was associated with a higher hematocrit (st.β=0.11, P<0.001), particularly in subjects with low sodium intake (Pinteraction<0.001).

Conclusions: In this population-based study, lower UNaV is associated with an increased risk of ischemic stroke, particularly among current smokers. We found indications that – analogous to the increased risk of stroke observed on treatment with erythro-poietin-simulating agents – adverse rheological effects exaggerated by low sodium intake may play a role.

COMPARISON OF TWO PREGNANCY NUTRITIONAL EVALUATION STANDARDS USING NATIONAL DATA FROM URUGUAY

[1]Mardones, Francisco; [2]González, Nely; [3]Bove, Maria Isabel; [4]Rosso, Pedro; [5]Villarroel, Luis; [6]Bacallao, Jorge; [7]Farias, Marcelo.

[1]MD. MSc. Department of Public Health. Pontificia Universidad Catolica de Chile. Chile.; [2]Nutrionist. MSc. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.; [3]Nutritionist. PhD. Instituto de Salud y Bienestar. Universidad Católica del Uruguay. Uruguay.; [4]MD. Department of Pediatrics. Pontificia Universidad Católica de Chile. Chile.; [5]PhD. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.; [6]PhD. Universidad de Ciencias Médicas. Cuba.; [7]MD. PhD. Department of Obstetrics and Gynecology. Pontificia Universidad Católica de Chile. Chile.

Background and objectives: The USA Institute of Medicine (IOM) and the Rosso-Mardones maternal weight gain guidelines are widely used in Latin America. The purpose of this study was to compare some indicators of fetal growth related to the use of each chart at the beginning of pregnancy with national Uruguayan information.

Methods: Data of 23,832 healthy pregnant women and their term single newborns registered at the national level in the maternity hospitals between 2010 and 2012 were considered. Maternal nutritional status was classified at the beginning of pregnancy ac-

---

cording to both guidelines. The diagnostic ability of both instruments regarding inadequate fetal growth was compared using sensitivity and specificity values. Inadequate fetal growth was defined as birth weight < 3000 g, birth weight > 4,000 g, and birth length < 50 cm.

Results: Proportions of BL < 50 cm and both BW < 3000 g and > 4000 g were similar at each nutritional category of both charts; absolute figures for at risk newborns were much higher in the RM underweight and obese women. The RM chart showed higher sensitivity values than the AEA chart at the beginning of the pregnancy.

Conclusions: The higher sensitivity of the RM chart would support its use for prevention purposes in countries such as Uruguay.

Keywords: Nutrition during pregnancy, maternal body mass index, birth length, birth weight.

INNOVATIVE HOME GROWN SCHOOL FEEDING LINKED TO FAMILY FARMING: FAO SCHOOL FOOD AND NUTRITION APPROACH IN SUB-SAHARAN AFRICA

[1]Polo Galante, Andrea; [2]Mireles, Mauricio; [3]Kiamba, Josephine; [4]Mamadoultaibou, Aissa; [5]Sablah, Mawuli; [6]Boitshepo, Giyose; [4]Sanou, Dia.

[1]PhD Nutritionist Senior Consultant. FAO. Nutrition and Food Systems Division. Rome. Italy; [2]Regional Project(s) Coordinator. FAO Regional Africa; [3]PhD Consultant. FAO Regional Africa; [4]Nutrition Officer. FAO Sub Regional Office for Central Africa; [5]Chief Technical Adviser. FAO Regional Africa; [6]Senior Nutrition Officer Nutrition and Food Systems Division. Rome. Italy.

Background and objectives: Home Grown School Feeding (HGSF) has been considered a simple win-win scenario for countries seeking to promote greater levels of school attendance, school performance economic integration of local family famers and increased access to a diversified school meals for improved nutrition and educational outcomes. However, the complex policy and programmatic design required in order to ensure efficient inter-ministerial as well as inter-sectoral collaboration (often between the ministries of Education, Social Protection, Agriculture and Health) in the implementation and in particular the procurement and delivery of home grown school meals, the constant challenges to ensure that local family farmers can cope with the production needs of a diversified nutritionally balanced school meals.

Methods: FAO in partnership with the Government of Brazil have been working in the implementation of comprehensive sustainable pilots HGSF in diverse Sub-Saharan African countries in order to identify the strategic needs as well the most common bottle-necks for effective implementation of HGSF programs.

Results: As a direct result of this partnership, two countries (Sao Tome and Principe and Malawi) have been provided with technical support in the areas of policy & legal frameworks, agricultural mapping assessments for identification and design and local school meals menus as well as tailor-made nutrition education

materials for the promotion of behavioural change and lifelong life skills for good nutrition.

Conclusions: Preliminary results support the conclusion that long-term investments for the organization of the family farming sector remains a fundamental bottleneck for the majority of countries. Findings have indicated the need for efforts to concentrate on ensuring greater participation of the Ministries of Agriculture and other stakeholders in the development, implementation and management of HGSF programs in Africa. The development of family farming specific support programs, the re-orientation of rural extension services for this purpose, and the facilitation of innovative procurement mechanisms to allow local purchases and sustainable and reliable supply of diversified food for school food and nutrition initiatives in Africa are critical parameters that should be combined with nutrition education at all levels.

THE ROLE OF THE NUTRITIONIST IN AN INTERDISCIPLINARY APPROACH OF COGNITIVE STIMULATION IN PEOPLE OVER THE AGE OF 60

[1]Ragusa, Marina; [2]Andracchi, Rita; [1]Billaud, María de los Angeles; [3]Cantisani, María Isabel.

[1]Nutritionist. Instituto Nacional de Servicios Sociales para Jubilados y Pensionados. Argentina.; [2]Neurologist. Instituto Nacional de Servicios Sociales para Jubilados y Pensionados. Argentina.; [3]Social psychologist. Instituto Nacional de Servicios Sociales para Jubilados y Pensionados. Argentina.

Background and objectives: People over the age of 60 can have several functional limitations. Depression, neurodegenerative diseases, arthritis and osteoporosis can increase obstacles to developing and maintaining daily activities. Environmental and psychological factors can reinforce or relieve this situation (Olazarán-Rodríguez, 2012). Therefore poor nutrition can lead to malnourishment.

The advancements of knowledge into neurological, vascular and degenerative diseases highlight the need for an integral approach through interdisciplinary work (Allegri, 2013) (Demey, 2010).

Using this model, PAMI has been offering a program of cognitive stimulation by using an holistic approach to the over 60's in the La Matanza district since 2011. By providing weekly activities such as music, games, art and physical exercise, we aim to improve the quality of life for this client group.

The multidisciplinary team includes a neurologist, psychologists, nutritionists, a physical education teacher, and a music therapist.

Nutritional objectives:

• Encouraging healthy nutrition.

• Promoting independence by adapting utensils, and food preparation

• Stimulating preserved cognitive functions.

• Encouraging satisfaction during meal times.

Methods: The program is aimed at people over 60 with physiological aging or initial to moderate stage of cognitive impairment; additionally we provide support groups for care givers.

Activities carried out in the Nutrition area:

• Cooking workshops with creative recipes of pureed foods, finger food.

• Healthy modifications of Argentine recipes

• Practice with adapted kitchen utensils.

• Specialist talks.

• Evoking an emotional value of food

• Identifying correct meals to eat at certain times in the day

• A memory recollection game with matched cards

Results: Using qualitative evaluation we observed:

• A decrease in caregiver's workloads.

• Feedback from family members of an increase in pleasure derived when eating.

• A need to quantify results, which will be used with the Mini Nutritional Assessment

• Attendance at the workshops has been maintained while the number of new attendees has increased.

Conclusions: Nutrition is not only the mechanical activity of incorporating substances into the body, but also involves emotions, evokes memories, and generates pleasure. Food is a useful vehicle when working with cognition and emotions, maintaining or improving people's independence.

Keywords: Elderly, Nutrition, Cognitive

WEIGHT CONCERNS SCALE (WCS): VALIDATION OF THE ONLINE VERSION APPLIED TO NUTRITION STUDENTS

[1]Chioda Ribeiro Dias, Juliana; [2]Olivati de Sarro, Isabela.

[1]PhD. Nutricionist. Centro Unviversitário Unifafibe. Bebedouro. Brasil; [2]Graduation student. Centro Universitário Unifafibe. Bebedouro. Brasil.

Background and objectives: The body image is a multidimensional construct. One aspect of this construct is weight concerns. The Weight Concerns Scale (WCS) aims to evaluate the degree of concern with body weight. The aim of this study was estimate the reliability and validity of WCS's online version in female Nutrition students.

Methods: 102 students from a Brazilian private university completed the WCS in the online format. Information about the age, economic level, weight and height were also collected. The validity of the scale was measured by means of factorial and convergent validity. Confirmatory factor analysis of scale was carried by using goodness-of-fit indices: the chi-square by degrees of freedom ratio (c2/df), Comparative Fit Index (CFI), Normed Fit Index (NFI) and Root Mean Square Error of Approximation (RMSEA). Convergent validity was estimated by Average Variance Extracted (AVE) and Composite Reliability (CR) and the internal consistency by standardized Cronbach's alpha coefficient (α).

Results: The average age was 22.61±5.04 years, 4.90% were underweight, 66.67% eutrophic, 18.63% were overweight and 9.80% were obese. The WCS showed adequate factorial adjustment in the total sample (l=0.49-0.84; c^2/gl=1.832; CFI=0.969; NFI=0.936; RMSEA=0.091). The convergent validity (AVE=0.43; CR=0.78) was bellow recommendations and the internal consistency was adequate (α=0.77). The prevalence of eating disorder risk was 33.33%.

Conclusions: The online version of WCS showed satisfactory validity and adequate reliability. When it comes to the developing of eating disorders, the sample has presented a high prevalence of risk.

PLASMA VITAMIN C AND THE RISK OF GASTRIC CANCER RISK IN THE EURGAST STUDY

[1]Jakszyn, Paula; [2]Lujan, Leila; [3]Aranda, Nuria; [4]Sarrats, Ariadna; [5]Agudo, Antonio.

[1]Unit of Nutrition and Cancer. Catalan Institute of Oncology. Spain; [2]Biostatistitian . Unit of Nutrition and Cancer. Catalan Institute of Oncology. Spain; [3]Reseacrher. Unitat de Nutrició i Salut Pública. Facultat de Medicina i Ciències de la Salut. Universitat Rovira i Virgili. Spain; [4]Researcher. Spain; [5]Epidemiologist.Unit of Nutrition and Cancer. Catalan Institute of Oncology. Spain.

Background and objectives: Vitamin C is an antioxidant and inhibitor of carcinogenic N-nitroso compound production in the stomach. Higher dietary vitamin C consumption is associated with decreased risk of gastric cancer (GC) in numerous case-control studies, but data from prospective studies are limited. Recently the WCRF have included citrus fruit as a protective factor with limited–suggestive evidence specifically for gastric cardia cancers. Our previous analysis based on 256 cases and using a fluorometric method has an inverse association between GC and serum vitamin C .The objective of this study was to re-assess the association of plasma vitamin C levels with the risk of GC in a case-control study nested within the European Prospective Investigation into Cancer and Nutrition (EPIC) including a larger sample size and a more accurate methodology.

Methods: Serum vitamin C was measured using liquid chromatography coupled to mass spectrometry in 456 GC cases and 456 matched controls (sex, age and blood collection) form teh nested case control study EURGAST . Conditional logistic regression models adjusted smoke, education, BMI, helicobacter pylori infection , red meat, processed meat, alcohol, and energys were used to estimate relative cancer risks .

Results: After adjusting by potential counfounders , No association with plasma vitamin C and gastric cancer risk was found (HR 20 microg/l: 0.947, 95 CI: 0.82-1.08). When results were analyzed by tumor localization, comparing highest vs. lowest tertiles of serum vitamin C results have shown a negative association for cardia cancer site (HR 0.482, 95 % CI: 0.235- 0.99). No association was found for non cardia site.

Conclusions: Plasma vitamin C levels may play a role decreasing the risk of cardia gastric cancer . More prospective studies, including a larger number of cardia cancers are needed to confirm these findings.

Keywords: Gastric cancer, biomarkers , vitamin C, risk, cohort study

COMPARISON OF DISORDERED EATING SCALES ON A HEALTHY POPULATION

[1]*Inan-Eroglu, Elif;* [2]*Ozdemir, Aslihan;* [2]*Madali, Berna;* [1]*Dikmen, Derya.*

[1]PhD. Nutrition and Dietetics Department. Hacettepe University. Turkey.; [2]MSc. Nutrition and Dietetics Department. Hacettepe University. Turkey.

Background and objectives: Since their publication, the Three Factor Eating Questionnaire and the Eating Attitude Test 26 (EAT 26) have become the most widely used psychometric tools identifying individual differences in eating attitudes in studies of human eating behaviour. In this context the objective of this work was to examine the association between TFEQ and EAT 26 in adults.

Methods: In order to determine participants' eating behaviours, the eating attitude test 26 (EAT 26) and three factor eating questionnaire (TFEQ) were administered by intern dietitians. The TFEQ evaluates 3 dimensions of eating behavior: cognitive restriction (CR), uncontrolled eating (UE), and emotional eating (EE). The responses are measured on a Likert scale ranging from 1 (completely true) to 4 (completely false). Questions on socio-demographic characteristics were also included. The sample comprised 32 women and 14 men, ranged from 19 to 40 years. The questionnaires were analyzed with the statistical program SPSS.

Results: According to EAT 26, 8.9% participants had eating disorder. The mean TFEQ score of the participants was 40.59 ± 6.85. There was a significant difference between TFEQ total scores and TFEQ uncontrolled eating scores of participants with and without eating disorders ($p < 0.05$). When this difference was investigated by gender, there was a difference between TFEQ total scores, TFEQ emotional eating scores and TFEQ uncontrolled eating scores of women with and without eating disorder ($p < 0.05$), while no difference was found in men with and without eating disorder. Also there was a positive correlation between EAT 26 scores and TFEQ total scores and TFEQ cognitive restriction scores of women ($r=0.409$ $p=0.020$ and $r=0.493$ $p=0.004$, respectively).

Conclusions: This study showed a positive association between the TFEQ and EAT 26 in participants, especially in women. However, further studies are needed to explore the causes of this association. It would be interesting to investigate genetic and sociocultural causes that effect eating behavior in a larger sample.

Keywords: EAT 26, TFEQ, eating behaviour

PELLAGRA-A FORGOTTEN ENTITY

[1]*Rao, Amruth;* [2]*Upputuri, Brahmaiah;* [2]*Hemalatha, R.*

[1]Scientist. National Institute of Nutrition. Tarnaka. Hyderabad. India.; [2]National Institute of Nutrition. Tarnaka. Hyderabad. India.

Background and objectives: Pellagra is a niacin or tryptophan deficiency disorder.. Not long ago, the disease was endemic in several parts of the world; including India. The patients affected by the deficiency of Vit-B3 generally suffer from dermatitis. The symptoms begin as an acute eczematous rash distributed over the photo-exposed areas and in chronic situations, the skin becomes rough and chronic eczematous lesions are found. Pellagra is characterized by the three D s. i.e., Diarrhea, Dermatitis and Dementia. Over the past two decades, only a few pellagra cases have been reported. By the year 2011, Pellagra had almost disappeared due to Public Distribution System but, the clinical features still prevail in Indian subcontinent to some extent. This study clearly recommends that general ration should be regularly distributed.

Methods: The case records of patients with clinical diagnosis of pellagra attending the Nutrition Unit of Osmania General Hospital, Hyderabad were retrospectively reviewed between 1992 and 2012. The inclusion criteria were (a) clinical findings consistent with pellagra (photosensitive rash in sun-exposed areas). (b) resolution of symptoms with administration of niacin and (c) exclusion of other diseases. The medical records were reviewed for age, sex, seasonal variation, cutaneous examination findings and associated symptoms. Chronic energy deficiency was calculated based on $BMI < 18.5 kg/m2$.

Results: 335 patients were included in the study. Table 1 shows the corresponding descriptive data. Mean (SD) age of the study patients was 42.76 ± 11.6 years. CED was present in 63.8% of patients. Over-weight and obesity was uncommon in the study. The commonest age groups affected were middle aged patients and was highest in 30-40years age group followed by 40-50years of age group. Patients <20 years and >60years were uncommon in the study. Peripheral neuritis was present in 3.88% of patients, followed by Protein energy malnutrition, glossitis and tuberculosis in 1.49%, 1.49% and 1.19% of cases

Conclusions: Pellagra is a historically old disease, which is not completely eradicated. The decline in the proportion of pellagra patients over the past few decades may be attributed to the implementation of national nutritional programs, National product distribution system and improved nutritional status.

Keywords: Pellagra, Dermatitis, niacin, tryptophan deficiency

THE IMPACT OF REPLACING COW'S MILK WITH GROWING UP MILK ON VITAMIN D AND IRON INTAKES AND ADEQUACY IN IRISH CHILDREN AGED 12 – 36 MONTHS

[1]Kehoe, Laura; [2]Walton, Janette; [3]McNulty, Breige A.; [4]Nugent, Anne P.; [5]Flynn, Albert.

[1]BSc. MSc. Research Nutritionist. School of Food and Nutritional Sciences. University College Cork. Republic of Ireland.; [2]BSc. MSc. PhD. Research Fellow. School of Food and Nutritional Sciences. University College Cork. Republic of Ireland.; [3]BSc. PhD. Lecturer in Nutrition. University College Dublin Institute of Food and Health. University College Dublin. Republic of Ireland.; [4]BSc. PhD. Lecturer in Nutrition. University College Dublin Institute of Food and Health. University College Dublin. Republic of Ireland.; [5]BSc. PhD. School of Food and Nutritional Sciences. University College Cork. Republic of Ireland.

Background and objectives: Growing up milks (GUM) are milk-based drinks with added vitamins and minerals intended for children aged 12 – 36 months. We have previously shown that intakes of vitamin D and iron are low in Irish children and that fortified milks (in particular GUM) are a key determinant of higher intakes. Studies in other countries have shown that replacing cow's milk (CM) with fortified milks can help to improve intakes, adequacy and status of vitamin D and iron in both chidren and adults.

The objective of this analysis was to investigate the impact of replacing CM with GUM on intakes, adequacy and risk of excessive intakes of vitamin D and iron in young Irish children.

Methods: Analyses were based on a sample of children (aged 12 – 36 months) from the Irish National Pre-School Nutrition Survey (www.iuna.net). The sample included children with a daily CM intake ≥300ml (n 146). Dazult software DaDiet© was used to simulate the replacement of 300ml of CM with an equivalent volume of GUM (composition per 100ml: vitamin D; 3.1μg, iron; 1.2mg). The composition of any milk intake >300ml was unchanged from that consumed. Usual intakes were calculated via the NCI-method and the proportion (%) of the population with intakes below the estimated average requirement (excluding energy under reporters) and above the tolerable upper intake limit were calculated.

Results: Replacing 300ml of CM with an equal volume of GUM would increase mean intakes of vitamin D (from 6.3 to 13.6μg/d) and iron (from 7.7 to 10.6mg/d). The proportion of the population with inadequate intakes would be significantly reduced from 82 to 17% for vitamin D and from 14 to 0% for iron with no risk (0%) of excessive intakes of either nutrient.

Conclusions: This study has shown that replacing 300ml of CM with GUM would result in a substantial reduction in the prevalence of inadequate intakes of vitamin D and completely eliminate inadequate intakes of iron in Irish children aged 12 – 36 months.

Keywords: Vitamin D, iron, growing-up-milk, adequate intakes

PREVALENCE AND FACTORS ASSOCIATED WITH STUNTING IN PRIMARY SCHOOL CHILDREN AND ADOLESCENTS IN THE BURKINABE SAHEL

[1]Ouedraogo, Ousmane; [2]Coulbaly, Soumaila; [2]Millogo, Tieba; [2]Garanet, Franck; [3]Kabore, Saidou; [4]Zoma, Robert; [5]Kouanda, Seni.

[1]MPH. Institut Africain de Santé Publique. Ouagadougou. Burkina Faso; [2]MD MPH. Institut Africain de Santé Publique. Ouagadougou. Burkina Faso; [3]Msc. Nutrition Direction de la Nutrition. Ouagadougou. Burkina Faso; [4]Msc. Demographie Direction des Statistiques Sectorielles. Ministère de la Santé. Ouagadougou. Burkina Faso; [5]MD Ph D. Institut Africain de Santé Publique. Ouagadougou. Burkina Faso.

Background and objectives: Stunting within students is a real public health and development issue.

However, there are few studies in pupils and adolescents in developing countries.

The objective of the study was to determine the prevalence and factors associated with stunting in primary school children and adolescents in the Burkinabe Sahel.

Methods: Descriptive and analytical cross-sectional study carried out in 13 public primary schools in Dori commune in June 2016. Sampling was random in two-stage clusters. The data were collected through anthropometric measurements, blood sampling and the administration of a questionnary to the students. Individual interviews were conducted at the household level. Prevalences were calculated using the 2007 WHO Growth Standards for Adolescents aged 5-19 years and the associated factors were studied using a multivariate logistic regression on STATA 14.

Results: A total of 568 pupils aged 5-15 years were involved. Nearly 50.62% of students were between 10 and 15 years of age. Girls accounted for 52% of students. The prevalence of stunting was 32.92% (95% CI). The coexistence of stunting and acute malnutrition accounted for 13.56% of students - and the cumulative chronic malnutrition and anemia was 29.40%.

Age (OR =1,20), sex (OR =1,53) and anemia (OR =0,61) were statistically associated with stunting (p <0.05). There was no difference between schools. The student's individual dietary diversity and level of household food insecurity were not statistically associated with significant growth retardation.

Conclusions: The study shows a high prevalence of stunting within elementary students in Dori.

Age, sex and anemia play major roles.

Keywords: Associated factors, stunting, pupils, prevalence, Burkina Faso

WORKING IN NUTRITION: HUMAN RESOURCE CONSTRAINTS THAT AFFECT ACHIEVEMENT OF NATIONAL NUTRITION PLAN GOALS

[1]Pomeroy-Stevens, Amanda; [2]Lamstein, Sascha; [3]Biradavolu, Monica; [4]Adero, Nancy.

[1]MSc. Research and Evaluation Advisor. SPRING Project. John Snow Inc. United States.; [2]Phd. Nutrition Advisor. SPRING Project. John Snow Inc. United States.; [3]Phd. Sociologist. QualAnalytics. United States.; [4]MPH. Technical Advisor. SPRING Project. John Snow Inc. Uganda.

Background and objectives: Though countries acknowledge the importance of strengthening human resources to deliver on national nutrition action plans (NNAPs), it is often hard to create sustainable improvements in the nutrition workforce. The USAID-funded Strengthening Partnerships, Results, and Innovations in Nutrition Globally (SPRING) Project produced evidence on why this may be in two countries, Uganda and Nepal.

Methods: As part of SPRING's Pathways to Better Nutrition Case Studies, qualitative data were collected in Uganda and Nepal over two years (2013-2015 and 2014-2016, respectively). Six stakeholder groups, six nutrition-related sectors, and three levels of governance were studied through key informant interviews, direct observation, and news content analysis. These data were analyzed in NVivo to identify common themes, including nutrition workforce.

Results: Several nutrition workforce issues were mentioned as constraints to successful implementation of Uganda and Nepal's NNAPs. Stakeholders in both countries noted high turnover in key government, donor and UN nutrition positions; for instance approximately 50 percent of all NNAP sector focal positions turned over during the study, with several positions remaining vacant through the end of the study period. Turnover at every level was regularly cited as why planning and spending stalled for nutrition activities. Funding for nutrition coordination positions was also ad-hoc, which may have encouraged transience. Another nearly universal concern was lack of implementing staff trained in nutrition, especially in non-health sectors. The few available district and sub-district nutrition staff were often overwhelmed by responsibilities. Barriers to increasing implementation-level nutrition staff were lack of mentoring and recruitment for district nutritionists (Uganda) and difficulties recruiting for hard-to-reach areas (Nepal).

Conclusions: Our recommendations for overcoming these constraints include improving handover protocol for transitions of nutrition focal positions; securing funding for nutrition positions; including nutrition in civil service curricula; and innovating incentives to staff hard-to-reach areas. Recognizing the universality of this challenge, SPRING has developed several resources to help strengthen the nutrition workforce. Our workforce mapping toolkit is designed to identify gaps in training, recruitment, and planning for nutrition services. SPRING's community health worker advocacy toolkit can be also be used to advocate for increased nutrition workforce training and recruitment.

PLASMA METABOLOME ASSOCIATED WITH OBESITY IN COMMUNITY DWELLERS: TSURUOKA METABOLOMIC COHORT STUDY

[1]Kurihara, Ayako; [2]Harada, Sei; [3]Takebayashi, Toru; [2]Okamura, Tomonori; [4]Tomita, Masaru.

[1]R.D. MSc. Department of Preventive Medicine and Public Health. Keio University School of Medicine. Japan.; [2]MD. PhD. Department of Preventive Medicine and Public Health. Keio University School of Medicine. Japan.; [3]MD. PhD. MPH. Department of Preventive Medicine and Public Health. Keio University School of Medicine. Japan.; [4]PhD. Keio University Institute for Advanced Biosciences. Japan.

Background and objectives: There has been growing evidence of the importance of amino acids for obese metabolism change using metabolome analysis. The aim of this study is to examine the associations of amino acids and other polar metabolites with obese in the Japanese population.

Methods: Subjects are 35 to 74 years-old residents enrolled into our cohort study from April to July 2012, as a part of three-year baseline. Of the 11,002 participants, we had performed plasma global metabolomic profiling by capillary electrophoresis–mass spectrometry (CE/MS) in 8414 of the participants by the end of August 2016. We excluded 668 participants for the following reasons: missing information, previous history of cancer, the energy intake above 3,500 kcal or under 500 kcal. The remaining 7,726 participants (3,444 males, 4,282 females) were included in the analysis. 73 polar metabolites were identified and absolutely quantified using CE/MS; amino acids, amines, organic acids, purines and the others (detection rate >90%). Diet, including alcohol intake, was assessed with a semiquanitative food-frequency questionnaire (FFQ). Body mass index (BMI) was calculated with measured height and body weight at recruitment. According males and females, the participants were divided into four categories according to the quartile of the BMI, we compared the obese group (Q4) to the normal range group (Q2) by partial least squares discriminant analysis (PLS-DA) and pathway analysis using MetaboAnalyst 3.0.

Results: The PLS-DA model was fairly developed in both of males and females. The levels of six metabolites in plasma including glutamic acid were associated with obesity (VIP score>1.5), higher in the obese group. The results in the pathway analysis indicated that five pathways were associated with obesity; alanine, asparate and glutamate metabolism, arginine and proline metabolism, pyruvate metabolism, taurine and hypotaurine metabolism and citrate cycle.

Conclusions: We found six plasma metabolites and five pathways related to obesity among community-dwelling adults in the north of Japan, with applying metabolomics to a large population-based study. We continue our survey to clarify the causality between the found biomarkers and development of obesity related to diet intake and exercise, and contribute reducing the health risk due to the obesity in future.

Faculty of Nutrition Sciences and Food Technology. Shahid Beheshti University of Medical Sciences. Iran.; [3]MD. PhD. Health policy and management. Department of Health Management and Economics. School of Public Health. Tehran University of Medical Sciences. Iran.; [4]PhD. Sociologist. Department of Community Nutrition National Nutrition and Food Technology Research Institute. Faculty of Nutrition Sciences and Food Technology. Shahid Beheshti University of Medical Sciences. Iran.; [5]PhD. Economist. Department of Economics. Alzahra University. Iran.; [6]BS. Nutritionist. Department of Community Nutrition. National Nutrition and Food Technology Research Institute. Faculty of Nutrition Sciences and Food Technology. Shahid Beheshti University of Medical Sciences. Iran.

Background and objectives: In Iran, multidisciplinary program for improvement of nutritional status of children was initiated in 2005. In supportive section of this program, monthly food ration has been distributed for nourishment of growth retarded/malnourished children living in deprived family. This study aimed to evaluate the effectiveness of the supportive section of this program on nutritional status of children in two provinces of Iran (Qazvin and Semnan).

Methods: An effectiveness evaluation was conducted using mixed methods. Qualitative data gathered from twelve focus group discussions by mothers to determine factors that affect distributed foods consumption by the target child and their nutritional status. Quantitative data collected by quasi-experimental design.

362 children aged 6-72 months under coverage of the program selected as intervention group via multistage sampling. Comparison group included 409 children selected from children 6-72 months under coverage of Primary Health Care System using convenience sampling method. After 6 months, 332 in intervention and 324 in comparison group completed the study. Anthropometric indices of the children were measured at the baseline and 6 month thereafter. Data on child health and household demographic characteristics were collected by a questionnaire. Effectiveness was estimated using difference-in-difference (DiD) estimator.

Results: At the end of the study, mean of WAZ, HAZ, and WHZ was increased compared to the baseline in both groups (P<0.001). Differences in WAZ, HAZ and WHZ between two groups were not significantly differ at the end of the study (P=0.62, P=0.91, and P=0.94, respectively). The percentage of children who became normal in underweight, stunt, and wasting increased in both groups after 6 months (34.8% to 41.7%, 57.2% to 57.8%, and 40.1% to 49.6% respectively in intervention children; 58.2% to 66.3%, 65.8% to 69.4%, and 60.4% to 69.9% respectively in comparison children). Mothers reported low income, intra-household food sharing, irregular distribution, quantity and quality of distributed foods, and lack of training and education as the main factors affected distributed food consumption by the target child.

Conclusions: Providing foods for nourishment of malnourished children living in low income family could prevent the worse nutritional status. However, it is not effective in improvement of nutritional status without empowerment strategies.

ANALYSIS OF THE PRESENCE OF FOOD ADDITIVES IN LABELS OF INDUSTRIALIZED FOOD PRODUCTS WITH HOMEMADE TERM COMMERCIALIZED IN BRAZIL

[1]Kanematsu, Liege Regina Akemi; [2]Uggioni, Paula; [3]Schvartz, Aline; [3]da Silva, Brenda Francisco.

[1]Nutritionist. Graduate Student. Nutrition Postgraduate Programme of Federal University of Santa Catarina. Brazil; [2]PhD. Assistent professor. Department of Nutrition. Nutrition Postgraduate Programme. Federal University of Santa Catarina. Brazil; [3]Graduation student. Department of Nutrition. Federal University of Santa Catarina. Brazil.

Background and objectives: Contemporary food has been characterized by the increase in the consumption of industrialized food and the increase in the consumers' interest in traditional food products. Most food products contain additives, which are generally included to increase the shelf life of foods or make them attractive. Term such as homemade and others similars are present in labels of food products commercialized in Brazil. However, according to the Brazilian legislation, food labeling shouldn't have terms that cannot be demonstrated, since they may induce

the consumer to error in relation to its real nature or composition. The study aimed at investigating of the presence of food additives in the labels of packaged foods that contain the term homemade.

Methods: To reach such a goal, a cross-sectional, descriptive and analytical study of the type census was carried out (n=5506). All industrialized food products available for purchase in a supermarket from one of the ten largest supermarket chains in Brazil were analyzed. For this purpose, the lists of ingredients of 75 packaged foods (with term homemade) were analyzed. It was also observed the function of the additive and the number of these. Total frequency of the additives by food groups according to the Collegiate Directive Resolution was observed.

Results: From the sample, 80% (n = 60) of food analyzed had food additives. The most commonly found additives were flavorings, leavens and dyes, and the lowest were the humectant, acidity regulator and the sequestrant. The group of foods with the highest number of homemade terms was group I (baking, cereals and others) being also the group with the highest presence of additives (n= 23). The group that contained the highest average additives (9,25) was group VI (oils and fats). The food with the highest number of additives (n=14) was present in group VIII (sauces and prepared food). It has been found that most packaged foods with homemade term have food additives in their list of ingredients.

Conclusions: It should be noted that consumers do not expect these food segments to contain food additives or other ingredients that are not part of their cultural or historical context.

PREVALENCE OF THE DOUBLE BURDEN OF MALNUTRITION IN HOUSEHOLDS IN THE CITY OF LAMBARÉ, PARAGUAY, DURING THE PERIOD OF APRIL TO JUNE 2016

Bareiro Arce, Alberto.

MSc. Nutricionista. Instituto Privado de Nutrición Integral. Asunción. Paraguay.

Background and objectives: In Paraguay, it has been considered as the most important nutritional problem to malnutrition, preferably in children under 5 years of age. At the moment a problem is emerging, the increase of the overweight and the obesity. The WHO is drawing attention to the emergence of the nutritional phenomenon known as the Double Burden of Malnutrition (DBM), a situation in which both nutritional conditions coexist in the same household. The present study determines the prevalence of double burden of malnutrition in homes in the city of Lambaré through a survey conducted during the months of April to June 2016.

Methods: An observational, descriptive, analytical, cross-sectional study was performed. With probabilistic sampling, taking all the neighborhoods of Lambaré, then the blocks were selected by simple random draw and the households were chosen for convenience. In each household, parents and all children under 5 years of age were included in the study, where anthropometric and socioeconomic data were collected. We used a confidence level (Z) of 95% and an allowed margin of error (e) of 10%. 96 households comprising 617 individuals were included in the study.

Results: The results show a prevalence of obesity in adults of 36.3% and overweight of 15.2%, being higher in women. In the under-5 age group, 4.3% were obese, 6.9% overweight, 60.8% eutrophic, 23.1% at risk of malnutrition and 4.9% undernourished. In addition 9.2% with low stature. The prevalence of the DBM in the city of Lambaré during the months of April to June 2016 was determined to be 7.3%; in 28.6% of these households income was lower than the current minimum wage.

Conclusions: The prevalence of DBM in homes in the city of Lambaré during the months of April and June of 2016 is 7.3%. The socioeconomic status of households with DBM is largely the middle class. The nutritional status of the population studied has similarities with existing official data.

SOCIOECONOMIC CHARACTERISTICS INFLUENCE ADHERENCE TO DIETARY PATTERNS DURING PREGNANCY

(1) Barros Gomes, Caroline; (2)Barreto Malta, Maíra; (3)Justina Papini, Silvia; (4)Benício, Maria Helena D' Aquino; (5)Corrente, José Eduardo; (3)Carvalhaes, Maria Antonieta.

(1)PhD student. Nutricionist. Department of Public Health - Botucatu Medical School. Univ Estadual Paulista. Brazil.; (2)PhD. Nutricionist. Department of Nutrition - Public Health School. São Paulo State University. Brazil.; (3)PhD. Nutricionist. Department of Nursing - Botucatu Medical School. Univ Estadual Paulista. Brazil.; (4)PhD. Physician. Department of Nutrition - Public Health School. São Paulo State University. Brazil.; (5)PhD. Statistician. Department of Biostatistics - Botucatu Biosciences Institute. Univ Estadual Paulista. Brazil.

Background and objectives: The assessment of food consumption by dietary patterns is a methodology not limited to traditional assessment of nutrient intake, enabling a global analysis of the diet and creation of more viable guidelines. Our objective was to investigate the food consumption during pregnancy determining dietary patterns and its association with socioeconomic characteristics of pregnant women.

Methods: We prospectively followed two groups of pregnant women (n = 353) and collected in each trimester two 24-hours food records: one face-to-face and another by phone, with one of them for weekend/holiday. The determination of patterns was performed by principal component analysis with all groups and gestational trimesters together. We investigated the association between adherence to patterns with the maternal characteristics in logistic regression model adjusted for potential confounders (group, tri-

mester and maternal characteristics with p<0.20 in crude analysis), considering p<0.05 as significance level. All analysis were performed in SPPS v. 20.0.

Results: We identified three patterns: Traditional Brazilian (P1); Predominantly Ultra-processed and beef (P2); Integral, fruits, legumes, low fat milk and derivatives (P3). Pregnant women who work outside home had 36% more likely to be in the tercil of greater adherence to P1 (OR 1.36; 95%CI: 1.01-1.82); chance similar to those non-white color (OR 1.35; 95%CI: 1.01-1.82). Not living with a partner increased in 71% the chances of greater adhesion to P2 (OR 1.71; 95%CI:1.20-2.44). On the other hand, pregnant women with intermediate schooling (8|-11 years of study), front those with 11 or more years, showed 41% less chances of greater adherence to P3 (OR 0.59; 95%CI: 0.42-0.84); when compared to the economic class B, pregnant women from class C and D/E showed, respectively, 40% and 50% less chances of greater adherence to this pattern (OR 0.60; 95%CI: 0.37-0.95 and OR 0.50; 95%CI: 0.28-0.90).

Conclusions: We found associations between work outside home, non-white skin color, not living with a partner, education and socioeconomic classification with adherence to different dietary patterns identified. This knowledge is of extreme importance to the formulation of dietary education interventions with potential for positive impact on maternal and child health.

MONITORING OF TELEVISION ADVERTISEMENTS FOR BREASTMILK SUBSTITUTES AND COMMERCIALLY PRODUCED COMPLEMENTARY FOODS IN PHNOM PENH, CAMBODIA AND DAKAR, SENEGAL

[1]*Champeny, Mary;* [2]*Kroeun, Hou;* [3]*Sy Gueye, Ndeye Yaga;* [4]*Boren, Ly;* [5]*Diop, El Hadji Issakha;* [1]*Pries, Alissa;* [1]*Zehner, Elizabeth;* [4]*Huffman, Sandra.*

[1]Helen Keller International; [2]Helen Keller International. Phnom Penh. Cambodia; [3]Helen Keller International. Dakar. Senegal; [4]Consultant to Helen Keller International; [5]Helen Keller International. Africa Regional Office. Dakar. Senegal.

Background and objectives: Promotion of breastmilk substitutes (BMS) can negatively affect breastfeeding and is prohibited by global minimum standards. Promotion of complementary foods is inappropriate if it encourages feeding to children <6 months of age. This study was undertaken to assess the prevalence and content of BMS and complementary food advertisements on selected television channels in Phnom Penh, Cambodia and Dakar, Senegal.

Methods: Sixteen television channels were monitored daily from 6:00 a.m. to midnight for 13 months in Phnom Penh, Cambodia, while 20 channels were monitored 24 hours a day for three months in Dakar, Senegal. The number, frequency and duration of advertisements for BMS and commercially produced complementary foods which aired during this time were reported, along with the proportion of advertisements with nutrition/health claims and instructions for age of use.

Results: Ten television channels in Phnom Penh and four in Dakar aired advertisements for BMS. Three and five channels, respectively, aired advertisements for complementary foods. All channels that aired advertisements in Phnom Penh were local, however only international cable channels aired advertisements in Dakar. All BMS products advertisements in Phnom Penh were for children over one year of age. Products for children over one year and 6+ months of age were advertised in Dakar.

BMS advertisements were shown on average 382 times per month in Phnom Penh and 95 times per month in Dakar. Average air time was 189.5 and 29.7 minutes per month, respectively. Advertisements for complementary foods were aired 11 times per month on average in Phnom Penh and 33 times in Dakar, and air time averaged 3.2 minutes per month and 13.6 minutes.

Fewer than half of BMS advertisements and only one-third of complementary food advertisements explicitly stated an age of use for products. Nutrient content, nutrient function, and/or health claims were common in BMS advertisements.

Conclusions: This study illustrates the need to adopt, monitor, regulate and enforce legislation prohibiting BMS promotion. Advertisements for complementary foods often fail to state that products should not be fed to infants less than six months of age; this should be done to protect optimal infant and young child feeding.

IS FISH CONSUMPTION RELATED TO LOWER RISK OF MORTALITY IN CHINA AND US? A JOINT CHNS-NHANES STUDY

[1]*Zhang, Yu;* [2]*Jiao, Jingjing;* [3]*Zhuang, Pan;* [4]*Wang, Wenqiao.*

[1]PhD. Nutritionist. Department of Food Science and Nutrition. College of Biosystems Engineering and Food Science. Zhejiang University. China.; [2]PhD. Nutritionist. Department of Nutrition. School of Public Health. Zhejiang University School of Medicine. China.; [3]BSc. Department of Food Science and Nutrition. College of Biosystems Engineering and Food Science. Zhejiang University. China.; [4]MD. Department of Nutrition. School of Public Health. Zhejiang University School of Medicine. China.

Background and objectives: Fish intake has been associated with a reduced risk of major chronic diseases, particularly cardiovascular disease. However, data linking fish consumption and mortality are lacking and conflicting. The aim of this study is to examine whether fish consumption is associated with lower risk of mortality in Chinese and US adults.

Methods: We investigated the proposed association separately for US and Chinese adults using data from the China Health

and Nutrition Survey (CHNS, n=14,113) and National Health and Nutrition Examination Survey (NHANES, n= 31,021), including NHANES III conducted in 1988-1994 and continuous NHANES 1999-2010 for this prospective cohort study. Participants with cardiovascular disease or cancer at baseline were excluded.

Results: During a median follow-up of 14 and 9.8 years for CHNS and NHANES, 1009 (CHNS) and 4205 (NHANES) deaths were documented. The fish consumption level was higher in China than in the United States. Among Chinese adults, increased fish intake was significantly associated with lower all-cause mortality. As compared with the lowest level of fish intake, the hazard ratios (HRs) across increasing intake levels were 0.44 (95% CI, 0.36-0.56), 0.66 (95% CI, 0.55-0.79), 0.76 (95% CI, 0.63-0.91; P<0.001 for trend), after adjusting for potential confounders. However, fish intake was not associated with total mortality among US adults. The multivariable-adjusted HRs across increasing intake levels were 1.04 (95% CI, 0.92-1.18), 0.91 (95% CI, 0.79-1.05), 0.96 (95% CI, 0.82-1.12; P=0.28 for trend), as compared with the lowest level. We only detected a borderline inverse association between fish intake and risk of death from stroke in NHANES (P=0.06 for trend). Moreover, a positive association with risk of death from diabetes was observed in certain category of fish intake in NHANES. Subgroup analysis showed that the inverse association of fish with all-cause mortality was stronger among participants living in rural compared with those in urban areas in CHNS.

Conclusions: In these two independent but similar national cohort studies, fish consumption is associated with a reduced risk of total mortality for Chinese rather than US adults. Future studies may clarify the heterogeneity across races.

AGGREGATION OF CHRONIC DISEASES AND ASSOCIATED FACTORS IN THE MIDWEST REGION OF BRAZIL IN 2012

[1]*Pereira, Lídia Pitaluga;* [2]*Muraro, Ana Paula;* [3]*Ferraz Moreira, Naiara;* [4]*Rodrigues, Paulo Rogério Melo;* [5]*Ferreira, Márcia Gonçalves.*

[1]Msc. Nutritionist. Institute of Public Health. UFMT. Mato Grosso. Brazil.; [2]PhD. Nutritionist. Institute of Public Health. UFMT. Mato Grosso. Brazil.; [3]PhD. Nutritionist. Faculty of Health Sciences. UFGD. Mato Grosso do Sul. Brazil; [4]PhD. Nutritionist. Faculty of Nutrition. UFMT. Mato Grosso. Brazil.; [5]PhD. Nutritionist. Institute of Public Health and Faculty of Nutrition. UFMT. Mato Grosso. Brazil.

Background and objectives: Noncommunicable diseases (NCDs) are recognized as a public health issue bringing great impact to the health system in Brazil. Individually, each disease contribute to increased mortality and when aggregated they can multiply this risk. The aim of the study was estimate the aggregation of self-reported chronic diseases and to identify the associated factors.

Methods: Cross-sectional study with data from 6,695 individuals aged ≥18 years-old, both sex, collected by Surveillance System

for Protective and Risk Factors for Chronic Diseases by Telephone Survey (Vigitel), at Midwest Region of Brazil in 2012. One resident of each household, with at least one fixed telephone line, was randomly selected from probability samples, subsequently answering the questionnaire. Hypertension, diabetes and obesity were used to create the aggregation of chronic diseases which was classified in zero - individuals with no disease, 1 - individuals with at least one disease and 2 - those with two or more diseases. Sociodemographic and economic data, lifestyle and self-assessment of health status were analyzed such as independente variables. Chi-square test was used in the bivariate analysis. Multinomial logistic regression models were used to evaluate the associated factors with aggregation levels. The complexity of the sample and the effect of the study design were considered in the estimates.

Results: The aggregation of two or more diseases was observed in 10.4%, higher among women compared to men (p=0.03) and it was positively associated with increased age (p<0.01). After adjustments, the factors that remained associated with the aggregation were age (p=0.03), formal work p<0.01, alcohol consumption (p=0.05), worsening of self-reported health status (p<0.01), and living at Cuiabá city (p=0.01) and Campo Grande city (p=0.02).

Conclusions: The aggregation of chronic diseases in the Midwest Region in Brazil was associated with lifestyle related behaviors, sociodemographic and economic characteristics.

PREVALENCE OF METABOLIC SYNDROME IN A GHANAIAN POPULATION

[1]*Ellahi, Basma;* [2]*Agbozo, Faith;* [3]*Dikmen, Derya;* [4]*Darrah, Samuel;* [5]*Zotor, Francis.*

[1]PhD. Nutritionist. Faculty of Health and Social Care. University of Chester. UK.; [2]MPhil. University of Health and Allied Sciences. Ghana; [3]PhD. Department of Nutrition and Dietetics. Hacettepe University. Turkey; [4]BSc. University of Health and Allied Sciences. Ghana.; [5]PhD. University of Health and Allied Sciences. Ghana.

Background and objectives: Abdominal obesity assessed by waist circumference is one of the most important predictor for metabolic syndrome and obesity-related diseases mortality (1). Metabolic syndrome (MetS) prevalence has increased and affects 25% of populations in developed countries (2). However, there is paucity of data on rates in African populations (3,4). The present study aimed to determine the prevalence of the MetS and the associated risk factors among adults living in Ghana.

Methods: Adult males (n=354) and females (n=496) above 18 years were recruited using multistage cluster-randomized sampling method in urban and rural areas of Hohoe municipality in the Volta region of Ghana. All subjects had anthropometric variables (BMI, waist circumference, waist hip ratio) related with abdominal obesity measured, in addition to dietary intake, physical activity and blood pressure. Additionally, blood glucose was assessed from a blood sample after overnight fasting. WHO recommendations for body mass index (BMI), waist circumference

cut-off points for overweight and obesity, and factors associated with MetS risk were utilised for analysis.

Results: The mean age for the 850 participants was 47.26±16.13 years. Fasting blood glucose levels were higher in men (5.4±1.46 mmol/L) when compared with women (5.2±1.37mmol/L) (p>0.05). Mean waist circumference was 79.8 cm in men and 85.5 cm in women (p=0.00). BMI was significantly higher in women (26.10 kg/m2) when compared with men (22.46 kg/m2). The subjects' diastolic and systolic blood pressure levels were high in both genders (normal 26.6%, pre-hypertensive 37.4% and hypertensive 36%). The prevalence of MetS was 8.7 % and significantly higher (p<0.05) in women (13.5% versus 7.9% in men). Increased age, waist circumference, raised blood pressure, and BMI were all correlated with MetS (p<0.05).

Conclusions: This is among the few studies which highlights the prevalence of MetS in Ghana. Abdominal obesity predictors, in particular waist circumference, are the main causative factor for MetS. Dietary adjustments, regular physical activity and weight loss should be the main focus points for MetS management.

PANORAMA OF NUTRITION LANDSCAPE IN EAST AFRICAN COMMUNITY

Ouma, Cyprian.

WFP.

Background and objectives: The focus of nutritional challenges in the East African region has been on under nutrition measured through stunting, wasting and underweight levels in young children. There has been little correlational analysis on the emerging globalization and diet shifts, with the nutritional deficiencies the region faces. We explored the inter-relationships and trends of nutritional outcomes in children under 5 years.

Methods: We investigated the availability of food and nutrition data collected in DHS surveys for the last 20 years. The data was aggregated, standardized and harmonized. Assessment of the Quality of data and analysis was done in SPSS vs 24.

Results: Kenya registered an improvement in prevalence of wasting t from 7% to 4% over 6 years with Rwanda having the lowest levels .Highest proportions of mothers who practiced exclusive breastfeeding was in Rwanda while Kenya showed an improvement from 31.9% to 61.4% over 6 years. The levels of stunting in Burundi decreased from 63% in 2000 to 57.5% in 2010, wasting levels rose to 9% in 2005 but fell to 6.1% in 2010. In Kenya, Stunting levels decreased from 35% to 26%; and the proportion of underweight children dropped from 16% to 11%. In Rwanda, percentage of stunted children decreased from 57% to 38% from1992 to 2015 and wasting reduced from (8%) in 2000 to 2.2% in 2015 and prevalence of underweight children gradually decreased to 9% from 23.7%.

In Uganda over 10 years, stunting and underweight prevalence levels in children decreased to 33% from 45% in 2000. Tanzania's stunting levels in the last 5 years remained the same but alongside Rwanda reported a spike in the number of overweight cases while Kenya recorded a positive trend with the number of overweight cases reducing by 36,000.

Conclusions: Multiple forms of malnutrition coexist in EAC and vary across countries, regions and groups. Malnutrition is not decreasing at the required rate and is affecting the majority of the EAC population. The changing burden of disease should be tracked and included in development plans.

Keywords: EAC, Malnutrition

NUTRITION INEQUALITIES IN EAST AFRICA

Ouma, Cyprian.

World Food Programme (WFP). Kenya.

Background and objectives: Food and nutrition inequalities in the East Africa Community region are characterized by high prevalence rates of malnutrition. Although the region is characterized by high rates of undernutrition, the nutrition dynamics are rapidly shifting into obesity, making th region to face a double burden of malnutrition.

Methods: Country profiles data sources, indicators and dimension of inequality data were sourced from publicly available demographic and health Surveys (DHS), localized SMART assessments, NGO and UN reports, multiple indicator cluster surveys (MICS) and institutional websites WHO, EAC, AU. The use of large-scale, nationally representative household surveys that collect data through standardized, face-to-face interviews in low- and middle-income countries was applied. Inequality Nutrition data was disaggregated into three dimensions, economic status, sex and place of residence. The wealth index was used to calculate the economic status at household level by using country specific indices to show the ownership of certain assets and access to certain services, after which quantiles were created.

Results: Disaggregation by place of residence shows that high levels of stunting in all the EAC countries are found in rural areas than in urban dwellings. Low levels of stunting are seen among wealthy families and high prevalence's are reported among the poor households. Rural living children are more likely to be underweight in comparison to urban children. Overall these shows that

more nutrition inequality if found among poor rural households who have low access to essential health services, suffer chronic food insecurity and have low purchasing power that leads to inadequate food consumption and insufficient dietary diversity .

Conclusions: Nutrition inequalities exists in the region and because of the harmful effects of malnutrition over the life cycle, inequalities exemplify other household and communal disadvantages creating a circular relationship. Identifying the data gaps that hinder action on equity and inequalities and ttargeting expansions in services specifically towards the most disadvantaged may be more successful and cost effective than using limited resources to create across-the-board increases in services.

DEVELOPING THE NEXT GENERATION OF PACK-AGED FOODS: A FRAMEWORK TO ADDRESS MULTI-STAKEHOLDER REQUIREMENTS

[1]Masset, Gabriel; [2]Vlassopoulos, Antonis; [2]Gomez Alvarez, Pilar; [2]Potter, Monika; [2]Lehmann, Undine.

[1]PhD Nutritionist. Consumer Science & Applied Nutrition. Institute of Material Sciences. Nestle Research Center; [2]Nutrient Profiling. Consumer Science & Applied Nutrition. Institute of Material Sciences. Nestle Research Center.

Background and objectives: The demand for foods and beverages with improved nutritional composition has increased in the past decade. Governments, academics, and consumers have different expectations of what is a 'healthy' product. Here we present the development of a 'nutrition innovation framework' which could be used as a guidance to improve the nutritional composition of a product category and its application in two case studies: breakfast drinks and sweet biscuits.

Methods: The framework is divided in three steps: 1. Definition of product positioning, i.e. the targeted food category or eating occasion. 2. Definition of nutritional targets/requirements based on the latest dietary recommendations and regulated definitions of 'healthy' (e.g. front-of-pack labeling). 3. Testing the extended to which the proposed targets identify best-in-class nutritional composition using the Mintel Global New Product Database branded food composition data.

Results: The framework was applied to two product categories, breakfast drinks and sweet biscuits, falling respectively under the 'breakfast' and 'snacks' eating occasions. In both cases, food based dietary guidelines and regulatory definitions of 'healthy' focused on low sugar content (added and total), no addition of salt, low saturated fat content and a high nutrient density. Wholegrain, protein, complex carbohydrates and fruit and vegetable content were clearly prioritized. For breakfast drinks a Mintel extract showed that only 10% (n=9/95) of the existing products would meet external definitions of 'healthy'. In the case of biscuits, no products would meet all external definitions and there was a need for interim nutritional targets to successfully stimulate innovation.

Proposed interim targets were achieved by 7 products out of 2072 products analyzed.

Conclusions: This novel framework uses the latest available evidence and data to guide the food industry towards more nutritious products while addressing the requirements of public health officials and regulators. Further research is needed to assess the applicability/ feasibility of this framework across companies' portfolios. In particular, there is a need to clearly define the product categories in which such (re)formulation guidelines could operate and to develop a comprehensive scoring algorithm to track improvements in nutrient composition and compare between products.

PLASMA MAGNESIUM AND RISK OF DIABETES. THE PREVENTION OF RENAL AND VASCULAR END-STAGE DISEASE STUDY

[1]Schutten, Joelle; [2]Gomes Neto, António; [3]Gansevoort, Ron; [3]de Borst, Martin; [3]Navis, Gerjan; [3]Bakker, Stephan J.L.

[1]MSc. Department of internal medicine. University Medical Center Groningen. The Netherlands.; [2]MD; [3]MD-PhD.

Background and objectives: Low circulating magnesium has been found to be associated with prevalence of diabetes in cross-sectional studies. Such associations can be due to reverse causation. We therefore aimed to investigate the association of plasma magnesium with risk of developing diabetes.

Methods: We examined 5673 subjects aged 28-75 years without diabetes at baseline in the Prevention of Renal and Vascular End-Stage Disease (PREVEND) study, a prospective population-based cohort study. Diabetes was defined as fasting glucose level ≥7.0 mmol/l, non-fasting glucose level ≥11.1 mmol/l or anti-diabetic drug use. The association of plasma magnesium with risk of diabetes was studied using Cox models. We adjusted multivariable models for age, sex, race, body mass index, educational level, smoking, alcohol consumption, cholesterol, hypertension, history of stroke and coronary heart disease, family history of diabetes, kidney function (eGFR CKD-EPI), plasma levels of potassium, calcium, sodium and albumin, and use of diuretics and proton pump inhibitors.

Results: During a median follow-up of 11.2 (IQR: 7.1-11.8) years, 448 (7.9%) subjects developed diabetes. Mean age was 49.1±12.1 years, 48.1% were male. Mean plasma magnesium was 0.81±0.05 mmol/L, and plasma magnesium was inversely associated with risk of diabetes after multivariable adjustment (HR 0.79; 95% CI 0.63-0.99 per 0.1 mmol/L). We observed a significant interaction by age (Pinteraction<0.01). In age-stratified analyses (based on equal number of events in both groups), we observed no association of plasma magnesium with risk of diabetes in subjects

aged <55 years (HR 0.94; 95% CI 0.67-1.32 per 0.1 mmol/L). In contrast, we observed an inverse association of plasma magnesium with risk of diabetes in subjects aged ≥55 years (HR 0.65; 95% CI 0.52-0.83 per 0.1 mmol/L). Adjustment for potential confounders did not materially alter the association (HR 0.66; 95% CI 0.48-0.90 per 0.1 mmol/L).

Conclusions: Plasma magnesium is inversely associated with risk of diabetes. This association appears particularly present in subjects aged ≥55 years. Magnesium might therefore play a role in the prevention of diabetes, in particular in the older population.

A CARBON TAX ON FOOD MUST BE ETHICALLY NUANCED

[1]Fox, Elizabeth; [1]Downs, Shauna; [2]Fanzo, Jessica; [1]Rieder, Travis.

[1]Berman Institute of Bioethics. Johns Hopkins University. USA; [2]Berman Institute of Bioethics. Johns Hopkins University. School of Advanced International Affairs. Johns Hopkins University. USA.

Background and objectives: With global food production accounting for 19-29% of total global carbon emissions, it is reasonable to ask whether we could eat more sustainably than we currently do. A carbon tax on food is estimated to reduce greenhouse gas emissions by 8.6-9.3% and has been proposed as a way to encourage consumers to adopt a more sustainable diet. However, the details of such a proposal are morally significant.

Methods: We used an ethics framework to assess the moral risks of a carbon tax on food commodities, and particularly on red meat. We completed a policy analysis to develop carbon tax scenarios that could ethically mitigate carbon emissions from foods.

Results: A carbon tax on foods does not meet a justice requirement. It exacerbates the burden on those who have contributed the least to the problem and who would be most negatively affected from the perspectives of nutrition, socioeconomics and vulnerability to climate change. Additionally, insufficient attention has been placed on evaluating meat alternatives, the amounts of those alternatives that would be needed to account for energy and nutrient loss associated with not eating meat, and the production requirements and environmental impacts of those alternatives. However, there are ways that a carbon tax could be implemented in an ethically just way. It could be implemented in wealthy countries with strong social protections and in countries that have disproportionately high levels of red meat consumption. A carbon tax on food could also be ethically applied to specific foods (e.g. red meat), instead of all foods or all animal-sourced foods. This would allow for alternatives with a lower environmental footprint to remain available and affordable to certain populations to meet their dietary needs.

Conclusions: The discussion moving forward should focus on how to make environmental gains from altering consumption habits without exacerbating existing vulnerabilities. A food tax must be carefully constructed so as to not benefit the privileged at the expense of the vulnerable. We cannot permissibly tackle the injustices of climate change by creating and exacerbating injustices elsewhere.

GENDER DIFFERENTIALS IN ADULT EXCESS WEIGHT IN THE ARAB WORLD: A REVIEW

[1]Akik, Chaza; [2]Ghattas, Hala; [3]Sharara, Eman; [4]Makhlouf Obermeyer, Carla.

[1]DrPH. Research Associate. Center for Research on Population and Health. American University of Beirut. Lebanon.; [2]PhD. Assistant Research Professor. Center for Research on Population and Health. American University of Beirut. Lebanon; [3]MPH. Research Assistant. Center for Research on Population and Health. American University of Beirut. Lebanon; [4]DSc. Professor. Center for Research on Population and Health. American University of Beirut. Lebanon.

Background and objectives: Some of the highest prevalences of overweight and obesity have been reported in the Arab region; a consequence of the global nutrition transition, and ensuing alterations in diet and lifestyles. Globally, increases in weight have been shown to be greater among women, and it is likely that cultural factors exacerbate these gender differentials in the Arab region. We therefore aimed to review evidence for the female excess in weight among adults in countries of the Arab world.

Methods: We searched MEDLINE and Social Sciences Citation Index (SSCI) databases for articles published between January 2000 and October 2016, and hand-searched bibliographies of retrieved articles. We included studies that reported adult overweight or obesity prevalence; were conducted among residents of Arab League countries; described study design and methods and specified sample size. Data on prevalence of overweight, obesity and central obesity were extracted by gender. Male- to-female ratios (M/F) of each excess weight indicator were computed. Qualitative data on cultural factors that contribute to excess weight were also extracted.

Results: Out of 1,734 articles retrieved, 339 articles met inclusion criteria and 213 provided data. Data from nationally representative studies showed high overall prevalence of overweight (ranging between 28.2% to 37.9%) and obesity (ranging between 14.5% and 43.7%). A clear gender difference in overweight was observed, with 41/56 studies having M/F ratio exceeding 1. However, females were more likely to be obese and centrally obese with M/F ratios of less than 1 in 72/77 studies and 35/37 studies respectively. Explanations for these gender differences included higher levels of physical inactivity among females due to cultural barriers, reduced efforts from women to take care of their body shape after getting married and having children, and preference for plumpness as a sign of feminine beauty among traditional societies.

Conclusions: In a region where overall levels of obesity are among the highest globally, we find that prevalence of overweight is higher among men, whereas obesity and abdominal obesity are more prevalent among women. It is likely that gender norms specific to the region amplify these differentials.

TEMPORAL TRENDS IN FOOD GROUP AVAILABILITY AND CANCER INCIDENCE IN AFRICA: AN ECOLOGICAL ANALYSIS

[1]Aglago, Elom Kouassivi; [2]Bray, Freddie; [3]Zotor, Francis; [4]Slimani, Nadia; [5]Ferrari, Pietro; [5]Gunter, Marc.

[1]Nutrition and Metabolism Section. International Agency for Research on Cancer (IARC). France; [2]PhD. Scientist. Cancer Surveillance Section. International Agency for Research on Cancer. Lyon. France; [3]PhD. Nutritionnist. University of Health and Allied Sciences. Ho. Volta Region. Ghana; [4]Independent researcher. France.; [5]PhD. Scientist. Nutrition and Metabolism Section. International Agency for Research on Cancer. Lyon. France.

Background and objectives: Many African countries are experiencing an unprecedented epidemiological transition characterized by an increase in incidence of non-communicable diseases including various cancers, and fueled by the uptake of a Western-type diet and increased sedentary behavior. Nevertheless, data linking specific changes in diet and lifestyle with cancer incidence in Africa are extremely limited and there are few population-based cancer studies available. We aimed to evaluate at the country level the relation between food group availability as a proxy for individual level consumption and trends in cancer incidence across Africa.

Methods: Recent age-standardized rates for breast, prostate, colorectal, oesophageal, thyroid and pancreatic cancer were obtained from the African Cancer Registry Network, for 18 countries. National availability data for red meat, animal fats, cereals, starchy roots, vegetables/fruits, alcoholic beverages in kg/capita/year, and energy in Kcal/capita/day were retrieved from the Food and Agriculture Organization of the United Nations (FAO) databases. Food availability values were considered for four hypothetical times of exposure: time of collection of cancer incidence data (T0) and 5, 10, 15 and 20 preceding years (T-5, T-10, T-15, T-20). Ecological partial correlation coefficients with adjustment for potential confounders were calculated for the relation between cancer incidence and food availability.

Results: There was a significant increase in the availability of energy and all the major food groups for over the 20 years considered in this analysis (T-20 vs. T0, $p<0.05$). In multivariate analyses, red meat (r-5=0.495, $p=0.002$) and animal fats (r-10=0.450, $p=0.007$) availability were significantly positively correlated with colorectal cancer incidence in both men and women.. In contrast, starchy roots were negatively correlated with colorectal cancer (r-10=-0.359, $p=0.034$) and thyroid cancer (r-20=-0.331, $p=0.052$). Alcoholic beverages were also positively correlated with colorectal cancer (r-20=0.314, $p=0.066$) and oesophageal cancer (r-15=0.624, $p=0.001$).

Conclusions: This analysis provides ecological support for an impact of Westernization, marked by higher consumption of animal products and lower consumption of starchy roots, on the development of certain cancers in Africa over the past decades. Further research on the impact of diet and lifestyle with cancer development in Africa through high-quality epidemiological studies are urgently needed.

Keywords: Cancer. Food availability. Nutrition transition. Africa. Ecological analysis

ENVIRONMENTAL SUSTAINABILITY IN FOOD AND NUTRITION UNITS - ROLE OF NUTRITIONIST?

[1]Oliveira, Halsia Stefane; [2]Martins da Silva, Háquila Andrea; [3]da Silva Neves, Sherida; [4]dos Santos, Antônio Marcos.

[1]MSc. Nutritionist. Federal Institute of Education Science and Technology of Ceará campus Crato. Crato. Brazil; [2]MSc. Nutritionist. Federal University of Ceará. Fortaleza. Brazil; [3]MSc. Nutritionist. University of Fortaleza. Fortaleza. Brazil; [4]MSc. Docent. . Federal Institute of Education Science and Technology of Ceará campus Crato. Crato. Brazil.

Background and objectives: Studies indicate that only few undergraduate courses in nutrition include disciplines focused on environmental issues in their curricular matrices, in despite of the fact that food production be responsible for the considerable generation of solid waste and consumption of water, energy and raw materials. The objective was to know the opinion of responsible technical nutritionists (RT) of food and nutrition units (UANs) about the role of the nutritionist in implementation of the sustainability practices focused on the production of meals.

Methods: This is a qualitative study, with intentional sampling. Online questionnaires sent to RT of different UANs. There were interviewee nutritionists from hospital cooking, school meals, both representatives of the municipal public service, federal educational institutions and private companies. Professionals should answer the questions: "Have you received any training on sustainability practice at UAN?" and "Is the nutritionist the most appropriate practitioners working in environmental sustainability at UAN?".

Results: 11 nutritionists answered the questions. Regarding their participation in training aimed at sustainability practice at UAN, 63.6% of nutritionists denied, 18.2% confirmed and two (18.2%) professionals reported their participation in generalized content training. Regarding their opinion on nutritionists as the most appropriate practitioners working in this issue, 36.4% disagreed and 63.6% favored it. Disagreement was justified by the large number of attributions of the RT nutritionist and the lack of training / capacity building for this responsibility, suggesting

the partnership with a trained professional. Those agree said that nutritionist knows and keep up with the whole routine of the unit, establishes procedures, plans menus and supervises the execution process. They must to be trained in this area.

Conclusions: Among the researched nutritionists, most of them reported that they did not have the training to work for sustainability at UAN and acknowledged that the nutritionist was the most suitable professional for this task, showing the need for changes in the training of this professional.

France; [3]PhD. INRA MOISA UMR1110. France; [4]PhD. Nutrition Obésité et Risque Thrombotique (NORT). Inserm UMR S 1062. Inra 1260. Aix Marseille Université. France; [5]PhD. Paris School of Economics and INRA. UMR1393 PjSE. France; [6]MD. PhD. Service d'Endocrinologie. Diabétologie. Maladies Métaboliques. Hôpital Avicenne. France; [7]MD. PhD. Equipe de Recherche en Epidémiologie Nutritionnelle. Centre de Recherche en Epidémiologie et Statistique Sorbonne Paris Cité. Inserm 1153. Inra 1125. Cnam. Université Paris 13. France.

Background and objectives: Organic food intake has risen in many countries during the past decades. Even though motivations associated with such choice have been studied, psychological traits preceding these motivations have rarely been explored. Consideration of future consequences (CFC) represents the extent to which individuals consider future versus immediate consequences of their current behaviors. Consequently, a future oriented personality may be an important characteristic of organic food consumers. The objective was to analyze the association between CFC and organic food consumption in a large sample of the adult general population.

Methods: In 2014, a sample of 27,789 participants from the NutriNet-Santé cohort study completed the CFC questionnaire and an Organic-Food Frequency questionnaire. For each food group (17 groups), non-organic food consumers were compared to organic food consumers across quartiles of the CFC using multiple logistic regressions. Moreover, adjusted means of proportions of organic food intakes out of total food intakes were compared between quartiles of the CFC. Analyses were adjusted for socio-demographic, lifestyle and dietary characteristics.

Results: Participants with higher CFC were more likely to consume organic food (OR quartile 4 (Q4) vs. Q1 = 1.84, 95% CI: 1.58, 2.15). Overall, future oriented participants were more likely to consume 15 food groups. The strongest associations were observed for starchy refined foods (OR = 1.75, 95% CI: 1.60, 1.91), fruits and vegetables (OR = 1.71, 95% CI: 1.55, 1.88), and non-alcoholic beverages (OR = 1.70, 95% CI: 1.58, 1.84). The contribution of organic food intake out of total food intake was 33% higher in the Q4 compared to Q1. More precisely, there was a significant increase of the contribution of organic food consumed for 16 food groups. The highest relative differences between Q4 and Q1 were observed for starchy refined foods (22%), non-alcoholic beverages (21%), and dairy products (20%). Seafood was the only food group without a significant difference.

Conclusions: This study provides information on the personality of organic food consumers in a large sample of adult participants. Consideration of future consequences could represent a significant psychological determinant of organic food consumption.

PHYSICAL ACTIVITY IN THE CLASSROOM TO PREVENT CHILDHOOD OBESITY: A PILOT STUDY IN SANTIAGO, CHILE

[1]Arnaiz, Pilar; [2]Soto-Sanchez, Johana; [3]Saavedra, Juana; [4]Dominguez De Landa, Angélica; [5]Rozowski, Jaime; [6]Iriarte, Laura; [7]Cantwell Wood, Jennifer; [8]Mardones, Francisco.

[1]MD. Department of Pediatrics. ontificia Universidad Catolica de Chile. Chile.; [2]PhD. Department of Physical Education. School of Exercise Science and Sport. University of Playa Ancha. Chile.; [3]BSc. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.; [4]BSc. MSc. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.; [5]PhD. Department of Nutrition. Pontificia Universidad Católica de Chile. Chile.; [6]Nutritionist. MSc. International Life Sciences Institute (ILSI Sur Andino). Santiago. Chile.; [7]Nutritionist. MSc. Family Nutrition of the Triad. LLC. Greensboro. NC. USA.; [8]MD. MSc. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.

Background and objectives: Chile is in an advanced stage of the nutritional transition, which means that there is an increased prevalence of obesity, notably in children. A 4-month pilot study tested the suitability of a physical activity intervention for first graders (children ages 6 and 7) in a public school in Santiago, Chile.

Methods: This intervention was done in the classroom twice a day. Teachers were trained to deliver the program in the classroom during the school day. Teachers were surveyed to determine if this intervention fit within their curriculum and classroom routines

and they reported in a focus group that it was suitable for them. All children actively participated in the program and positive changes in their attitudes towards physical activity were observed by their teachers. Anthropometrics, blood pressure, and hand grip strength were measured in the students.

Results: Of the 89 students studied, 54 were male and 35 were female, with an average age of 6.44 years (SD±0.39, 5.82- 8.00 years). A significant reduction was observed in children with high waist circumference ≥90th percentile, and in mean systolic blood pressure. However, statistical power values for those comparisons were rather low. Anthropometry and hand grip strength were not modified.

Conclusions: The latter calculations and the lack of a control group are showing the weaknesses of this pilot study and that further research with a larger sample size and an experimental design are strongly needed.

Keywords: children, physical activity, blood pressure, waist circumference

Conflict of Interest Disclosure: This study was funded by the International Life Sciences Institute (ILSI Sur Andino). which had no influence in the presented results.

ARE NUTRIENTS INTAKE ASSOCIATED WITH COPD?: A CROSS SECTIONAL SURVEY IN MOROCCO

[1]Benslimane, Abdelilah; [2]Najdi, Adil; [3]Kinany, Khaoula; [3]Khalis, Mohammed; [3]Mint Sidi Deoula, Meimouna; [4]Nejjari, Chakib; [5]Benjelloun, Mohammed Chakib; [6]Bour, Abdellatif; [7]Garcia Larsen, Vanessa; [8]Elrhazi, Karima.

[1]PhD Student. Nutritional epidemiology. Department of epidemiology, clinical research and public health. Faculty of Medecine of Fez. Morocco; [2]Assistant Professor. public health. School of Medecine of Tangier. Morocco; [3]PhD student. Nutrition and public health. Department of epidemiology, clinical research and community health. Faculty of Medicine. Fez.; [4]Professor. public health. Mohammed VI international University. Casablanca. Morocco; [5]Professoren. Pneumology. Head of Department of Pneumology. Hassn II Hospital School of Fez. Morocco; [6]Professor. Nutritional and dietary Transition team. Laboratoiry of Biologic & health assay. Departement of Biology. Faculty of Sciences. University Ibn Tofaïl Kenitra. Morocco; [7]PhD. Assistant Professor. International Health (Primary). Division: Human Nutrition. Imperial College London. London; [8]Professor. Public health. Department of epidemiology. Clinical research and community health. Faculty of Medicine. Fez.

Background and objectives: Diet represents an important source of micro and macronutrients. Several studies demonstrated the existing evidence that they have a series of antioxidant, anti-allergic and anti-inflammatory properties, which can have a protective effect against COPD risk in the population.

Objective: to investigate the dietary intake of micro and macronutrient with the COPD prevalence in a representative sample of adults Moroccan in Fez City.

Methods: A cross-sectional study carried out in Fez as part of the BOLD study. The relationships between dietary intake and spirometrically defined chronic obstructive pulmonary disease (COPD) were investigated in 767 adults. Post-bronchodilator spirometry was performed for all participants using a Micro Spirometer. The dietary information was obtained by food frequency questionnaire(FFQ). From the food diary results, nutrients and energy intake were calculated using Food composition table analysis. Comparison of micro and macro nutrient intake between two subgroups with an without COPD was performed using Mann-Whitney and kruskal-wallis non parametric test.

Results: From 767 subjects. 56.7% were female. Mean age was 55.6±10.9 years old. The prevalence of COPD was 12.6%. 38.1% of the participants were overweight, and 31.2% were obese. Among all subjects, 25% were current or ex-smokers. Intakes of Vitamin C, Vitamin A, Carbohydrate, Calcium, Protein and total Energy Intake were low in person with COPD (P=0.03; P=0.04 ; P=0.02; P=0.02 ; P=0.05; P=0.05 ; P=0.02 respectively)

Conclusions: This study has shown the lower intake in several macro and micronutrients as a potential risk factor of COPD. Appropriate trials are needed to establish the real impact of nutrient intake on COPD in Morocco

Keywords: Micronutrient, macronutrients, COPD, Morocco

BODY MASS INDEX TRAJECTORIES OF INDIGENOUS INDIAN ADULT POPULATION AND IN RELATION TO DIET, PHYSICAL ACTIVITY AND SOCIOECONOMIC FACTORS

[1]Laxmaiah, Avula; [2]Balakrishna, Nagalla; [3]Arlappa, Nimmathota; [3]Meshram, Indrapal; [4]Harikumar, Rachakulla.

[1]MBBS. MPH. PhD. Scientist F. Division of Community studies. National Institute of Nutrition. ICMR. Hyderabad. India; [2]PhD. Scientist E. Division of Biostatistics. National Institute of Nutrition. ICMR. Hyderabad. India; [3]MD. Scientist E. Division of Community studies. National Institute of Nutrition. ICMR. Hyderabad. India; [4]MBBS. DPH. Scientist E. Division of Community studies. National Institute of Nutrition. ICMR. Hyderabad. India.

Background and objectives: Indigenous population in India constitutes 8.6% of the total population. Limited cross sectional studies indicate increase in the prevalence of overweight and obesity even in Indian indigenous population, which were known for high physical activity and low body mass index (BMI) levels. The objective of the study is to quantify BMI trajectories among indigenous Indian adult population 20 years and above and also to identify factors associated with increase of overweight and obesity in this population.

Methods: It was a periodical longitudinal National study on 'diet and nutritional status of indigenous population', carried out by the National Nutrition Monitoring Bureau (NNMB) during the years

---

1985-87, 1998-99, and 2008-09 by covering 9,753, 21,334, 28,730 adults in the respective years. The BMI trajectories among adult indigenous population was assessed by mixed models and according to BMI categories for both men and women and multiple Logistic regression analysis was computed to identify associated factors.

Results: The prevalence of overweight and obesity among Indian indigenous adult population at baseline was 1.2% and 1.6% among men and women, respectively in 1985-87 and it was increased to 3.6% and 3.8% in 1998-99 and 7% and 8% in 2008-09. The trajectories of BMI was 0.52kg/m2 (CI: 0.47 - 0.56) in men and 0.47 (CI: 0.43 – 0.51) in women. The trajectories were more in normal BMI categories than CED and overweight and obesity categories. The results were consistent with less rapid increased rates of BMI for adults who had lower intakes of sugar and sugar sweetened beverages, oils and fats and those engaged in moderate and severe physical activities and it was more rapidly increased in adults who belonged to high socioeconomic and high per capita monthly income.

Conclusions: The overweight and obesity is a significant problem even among indigenous tribal population and there is an urgent need educate the population on the rapid increase and consequences of overweight and obesity on health of the individuals.

INFLUENCE OF FOOD CONSUMPTION IN GLYCEMIC CONTROL AND THE CARDIOMETABOLIC RISK OF CHILDREN AND ADOLESCENTS WITH DIABETES MELLITUS TYPE 1

Dias, Marcia Regina Messaggi Gomes; Fritz, Camilla Kapp; Porchat de Leão, Andreia Araújo; Mascarenhas, Luis Paulo; França, Suzana Nesi.

Federal University of Paraná.

Background and objectives: Type 1 diabetes mellitus (DM1) is a disease characterized by the destruction of the beta cells, which can lead to an insulin deficiency. Through a balanced diet, one can obtain better glycemic control. Objective: To investigate the influence of dietary intake patterns on glycemic control and cardiometabolic risk in children and adolescents.

Methods: Descriptive cross-sectional study with children and adolescents between 9 and 17 years of age, with DM1. Anthropometric parameters (body weight, height (h), waist circumference (WC), body mass index (BMI), score z (h/age) and (BMI/age), blood pressure measurement and biochemical tests (lipid profile, fasting glycemia and glycated hemoglobin). A questionnaire was used to evaluate the level of physical activity and food consumption was estimated by a 3-day food diary. Patients were classified as having metabolic syndrome (MS) or not, when more than 3 risk factors were identified.

Results: The sample consisted of 31 individuals (55% female). Inadequate food intake was identified, regardless of gender, age or disease duration. Only 14% of the population reached the daily energy requirement and only 10% of the children had adequate intakes

of protein, carbohydrate and lipid. The population consumed in excess carbohydrate and cholesterol and presented low consumption of monounsaturated fats. The mean value of glycated hemoglobin was high (Hb1Ac 9.49%) and there was a better glycemic control in the population that presented higher energy expenditure and lower lipid consumption. Of the total sample, 25% of children and adolescents had MS. However, this was not related to food quality and physical activity level. The most prevalent factors were fasting glycemia; high triglycerides and low HDL levels, and large abdominal circumference than expected. Both the MS and non-MS groups presented inadequate diet and sedentary lifestyle.

Conclusions: The present study showed an inadequate dietary intake of the sample and that these DM1 individuals tend to present an elevated cardiovascular risk. The findings suggest that strategies should be created to promote healthy eating and continuous follow-up, favoring the link between health professionals and patients and increasing adherence to prescribed treatments.

Keywords: diabetes mellitus, cardiometabolic risk, metabolic syndrome, glycemic control, food consumption.

Nutrition Innovation Lab. Helen Keller International.Nepal; [6]Country Director. Helen Keller International. Nepal; [7]MD.Professor.Patan Academy of Health Sciences. Nepal; [8]MD.Head of Department. Kanti Children's Hospital. Nepal; [9]PhD. Director.Nutrition Innovation Lab. Tufts University. United States; [10]PhD. Associate Director. Nutrition Innovation Lab.Tufts University. United States.

Background and objectives: Dating gestational age (GA) of pregnant women is essential for assessing age of pregnancy and intra-uterine fetal growth. Obstetric ultrasound (USG), the gold standard for establishing GA, is not available in most low -income countries. Dating last menstrual period (LMP) and measuring symphysis pubis-fundal height (SFH) offer potential as cheaper alternatives.

The objective is to compare the accuracy of gestational age (GA) estimated by reported last menstrual period (LMP) and measured symphysis-pubis fundal height (SFH), with the ultrasound estimates (USG) as a reference, in a cohort of pregnant women in rural Nepal.

Methods: Data derive from pregnant women and their newborn infants from a USAID-supported birth cohort study in Banke district of Nepal. GA was assessed using three separate methods between 18 to 26 weeks of pregnancy. A total of 717 women were assessed using USG, 712 with reported LMP, and 614 women with SFH. Paired t-tests were used to assess differences in GA estimated by LMP or SFH compared to USG. A concordance correlation coefficient (CCC) was calculated to quantify agreement among the three methods.

Results: The median GA using USG was 275 days, 278 days by LMP (p<0.0003 compared to USG) and 268 days by SFH (p<0.0000 compared to USG). The concordance correlation coefficient for GA estimates for LMP and US was 0.35, and between SFH and USG was 0.40. Percent women with GA estimates at delivery within +/- 7 days comparing LMP to USG were 18%, and 77% within +/- 14 days. In contrast, the percent women with GA estimates within +/- 7 days at delivery comparing SFH and USG were 19%, but only 62% within +/- 14 days.

Conclusions: There were small but significant differences in the median GA estimates obtained by the three methods. The degree of agreement between LMP and SFH were poorly concordant. No significant differences in accuracy between the measures were observed. However, GA estimates were found to be more accurate than SPH in LMP compared to USG (within +/-14 days). This finding suggests that LMP should be used instead of SFH in the absence of USG.

Keywords: gestational age estimates, pregnant women

FACTORS ASSOCIATED WITH LOW BIRTH WEIGHT IN RURAL MALI USING BIRTH WEIGHT RECALLED FROM MOTHER'S MEMORY OR BIRTH WEIGHT REPORTED FROM A HEALTH CARD. (2013)

[1]Fortin, Sonia; [2]Moya Alvarez, Violeta; [1]Kameli, Yves; [3]Le Port, Agnes; [1]Adubra, Laura; [4]Kodjo, Niamke Ezoua; [5]Martin-Prével, Yves; [2]Savy, Mathilde.

[1]MSc. UMR 204 Nutripass – IRD-UM-Supagro. Institut de Recherche pour le Développement (IRD). Montpellier. France.; [2]MSc, PhD. UMR 204 Nutripass – IRD-UM-Supagro. Institut de Recherche pour le Développement (IRD). Montpellier. France.; [3]MSc, PharmaD, PhD. Poverty, Health and Nutrition Division (PHND). International Food Policy Research Institute (IFPRI). Dakar. Senegal.; [4]MSc. World Food Programme. Bamako. Mali.; [5]MSc, MD, PhD. UMR 204 Nutripass – IRD-UM-Supagro. Institut de Recherche pour le Développement (IRD). Montpellier. France.

Background and objectives: It is widely known that low birth weight (LBW) is associated with increased risk of neonatal death and impaired cognitive development. However, in developing countries, estimating LBW can be challenging due to the absence of official documents. Moreover, causes of LBW are multifactorial. The objectives of the present work are: (1) to compare the profiles of mothers reporting birth weight from memory vs.

mothers who provide a document indicating birth weight in rural West Mali; (2) to identify the determinants of LBW depending on the method birth weight is reported.

Methods: In 2013, we conducted a cross-sectional survey among randomly selected mothers of 12-42 months old children (n = 1254) in the district of Kayes, Mali. We collected birth weights during the survey from either an official health card (HC) or from mother's memory (MM), as well as potential determinants of LBW such as socioeconomic characteristics, pregnancy details, mother's anthropometry and household food insecurity. Definition of LBW was a weight under 2500g. Relationships between LBW and potential determinants were assessed using logistic regressions.

Results: The prevalence of HC-LBW was significantly lower than the MM-LBW prevalence (11% vs. 16%, p = 0.04). Mothers reporting birth weight from memory were less educated (p < 0.01), poorer (p = 0.03) and attended fewer prenatal visits (p < 0.01) than mothers who reported birth weight from HC.

Factors associated with MM-LBW included mother's profession, skilled person who attended delivery and household food insecurity (respectively: p <0.01, p <0.01, p = 0.03). Factors associated with HC-LBW were mother's education, antenatal care and place of delivery (p < 0.01). House occupancy status was associated with both HC-LBW and MM-LBW (p < 0.01), while mother's anthropometry was not, neither with HC-LBW nor MM-LBW.

Conclusions: LBW prevalence estimates and determinants depend on the method used to report birth weight data (HC vs. MM); the method of reporting is itself highly influenced by socioeconomic characteristics of mothers.

Keywords: Memory reported birth weight, documented birth weight, low birth weight, Rural Mali.

EFFECTIVENESS OF A CULTURALLY APPROPRIATE LIFESTYLE MODIFICATION PROGRAMME IN IMPROVING BODY COMPOSITION IN URBAN SRI LANKAN WOMEN WITH PREDIABETES

[1]Waidyatilaka, Indu; [2]lanerolle, Pulani; [3]Wickramasinghe, Rajitha; [4]Atukorala, Sunethra; [5]de Silva, Angela.

[1]MBBS, MSc, PhD. Department of Biochemistry and Molecular Biology. Faculty of Medicine. University of Colombo. Sri Lanka.; [2]BSc, PhD. Department of Biochemistry and Molecular Biology. Faculty of Medicine. University of Colombo. Sri Lanka.; [3]MD, PhD. Department of Public Health. Faculty of Medicine. University of Kelaniya. Ragama. Sri Lanka.; [4]BSc, MSc, PhD. Department of Biochemistry and Molecular Biology. Faculty of Medicine. University of Colombo. Sri Lanka.; [5]Department of Physiology. Faculty of Medicine.University of Colombo. Sri Lanka.

Background and objectives: Lifestyle interventions are the keystone of prevention and treatment for non-communicable diseases. Effectiveness of interventions rests on cultural relevance. Increased fat mass (FM) and abdominal obesity has been suggested as a possible cause for increased cardiometabolic risk

---

and improvement of body composition status may have a positive effect on dysglycemic status. This abstract presents data on the effectiveness of a lifestyle modification programme in improving body composition among newly diagnosed prediabetic Sri Lankan women.

Methods: Urban women (n=1500) aged 30-45 years from Colombo Municipal Council area were screened for prediabetes and 130 newly diagnosed prediabetics were recruited randomly to intervention and control groups. Using a participatory approach an intervention progaramme was developed and implemented for 4 months in the intervention group (goal: 5% weight loss and 150 minutes of physical activity/week). Control group received regular advice and print material only. Weight, waist, glycosylated haemoglobin (HbA1c), body composition (bioelectrical impedance analysis using a population specific equation) were assessed. Independent sample t- test and paired t- test were used.

Results: The final sample was 101 women (intervention n=51, control n=50) with no significant difference in baseline parameters between responders and non-responders or between groups. Following intervention, 52.9% of the intervention group achieved the weight loss goal compared to the control group (2%) and a significant (P < 0.001) reduction in mean waist circumference (0.88 ± 1.2 cm) was observed in the intervention group. In the intervention group, there was a reduction in both FM and fat free mass (FFM) post intervention compared to baseline (P < 0.05) and also a reduction in weight (2.6 ± 2.0 kg) (P < 0.001). Hence a concurrent reduction in FM% and an increase in FFM% were observed. In the intervention group, there was a reduction (P < 0.05) in HbA1c (0.2±0.24%) and FPG (20.6±11.6 mg/dl) and 37.3% became normoglycaemic, with none among controls. In the control group no changes were seen in any parameter post intervention.

Conclusions: Improvement in body composition and reversal of dysglycaemia were achieved through a goal- based, culturally sensitive intervention programme of four months duration.

COMPLEMENTARY FEEDING INTERVENTIONS AND ITS EFFECT ON MORBIDITY OF CHILDREN UNDER 5 YEARS

[1]Mahamadou, Tanimoune; [2]Ouma, Cyprian; [3]Oman, Allison; [4]Kimani, Alex.

[1]Eng. Phn. Nutritionist World Food Programme; [2]Nutritionist World Food Programme; [3]Senior Nutritionist World Food Programme; [4]Intern Nutritionist World Food Programme.

Background and objectives: Complementary feeding using fortified blended food supplements in poor households is one of the intervention for improving nutrients intakes and reducing the incidence of diseases in children under 5 years. We assessed the impact of this vital child survival programme in Rutsiro and Nyamagabe districts.

Methods: A cross-sectional study was conducted to collect data on the targeted population in the two districts between August and September 2016. Two stage sample stratification by district and wealth category was done. Final sample size was 3700 aged 6-59 months. Morbidity was assessed based on two weeks recall questionnaire. The child caretaker was the main respond. Key indicator symptoms assessed were cough, fever and diarrhoea.

Results: Children enrolled in the complementary feeding receiving fortified food supplement were slightly less likely to be affected by combination of 2-3 symptoms (46.5%) as compared to those not enrolled in the programme (48.4%).

Conclusions: The complementary feeding using fortified blended food supplement reduces the prevalence of morbidity and reinforces the impact of the nutrition infection cycle on child malnutrition. Undertaking appropriate food supplementation is encouraged for future nutrition programmes.

Keywords: complementary feeding, fortified blended food, Morbidity

MAPPING OF SCHOOL MEAL NUTRITION GUIDELINES AND STANDARDS IN LOW AND MIDDLE-INCOME COUNTRIES

[1]Vargas Araya, Melissa; [2]Hernandez-Garbanzo, Yenory; [3]Islas Ramos, Ana.

[1]MSc. International Nutrition Consultant. Food and Agriculture Organization of the United Nations. Italy.; [2]PhD. Nutrition Officer. Food and Agriculture Organization of the United Nations. Italy.; [3]EdD. Nutrition Officer. Food and Agriculture Organization of the United Nations. Italy.

Background and objectives: Poverty eradication, health, education, food security and nutrition continue to be the pillars of sustainable development. Schools can make a sizeable, lasting impact on these determinants through various access points. One such access point is the provision of meals through globally widespread school-based programmes. Key actors have proposed that many of these programmes can benefit from a stronger emphasis on the quality, adequacy and nutritional composition of the meals provided, primarily through the enforcement of nutrition guidelines and standards (NGS). The objective of this study was to conduct a mapping of school meal NGS in low and middle-income countries, and to identify implications from school food programmes (SFP).

Methods: This study used a triangulation of methods for data collection and analysis including survey administration, complemented with official laws, regulations and policies, scientific articles, and through direct follow-up with key respondents. The inclusion criteria to select countries, encompassed being classified as a low or middle-income country, and having a government-owned or transitioning SFP targeting primary schools.

Results: Survey responses were received from 33 countries (59% response rate). A further 10 countries, which did not re-

spond to the survey, were then included, using information from the above-mentioned sources. Overall, identified SPF nutrition objectives, beneficiaries, food procurement and preparation modalities, varied widely between countries as they obey to different nutrition priorities, possibilities and contexts. Out of the 43 sample countries, 17 were found to have some general recommendations to guide the composition of the SFP meals, while 13 (mostly from Latin America) had official NGS for school meals and 10 were in the process of development. The majority of the identified NGS included both nutrient (great emphasis on energy and protein) and food-based standards, determined by using different nutrition requirements. Food-based standards were not always explicitly aligned with national food-based dietary guidelines. Many tend to be complex and change according to SPF modality.

Conclusions: These preliminary results underscore that SFP characteristics have important implications which should be considered for the development and feasibility of NGS. More attention is needed to the development process, context, easiness and flexibility of application, and training for end implementers.

Keywords: nutrition guidelines and standards; school meals; school food programmes

THE ADOLESCENTS IN THE SOURTHERN CONE WITH LESS CONSUMPTION OF FRUITS AND VEGETABLES ARE LESS ACTIVE?

[1]Delgado D'Agostini, Silvia Mónica; [2]Kristeller, Jean; [3]Bove, Maria Isabel.

[1]; [2]MCs. Nutricionista. Facultad de enfermería y tecnologías de la salud. Unviersidad Católica del Uruguay. Uruguay; [3]PhD. Nutricionista. Instituto de Salud y Bienestar. Universidad Católica del Uruguay. Uruguay.

Background and objectives: During the adolescence, they acquire and consolidate stylelife habits. Physical inactivity and low fruit and vegetables consumption are frequent habits in all age. These represent health risk factors and for NCDs.

The objetive was evaluate the association between fruits and vegetables consumption with being physically active in adolescents in the Southern Cone, based on of the Global School Based Student Health Survey (GSHS) of Uruguay and Argentina (2012) and Chile (2013).

Methods: Cross-sectional descriptive study with an analytical component in adolescents between 13 and 17 years of age based (GSHS). The association between being physically active and consumption of five fruits and vegetables was studied. Control variables were age, sex, alcohol consumption, smoking habit, sedentary lifestyle, and condom use. Relative frequencies and means with 95% CI were used. The comparison of categorical and dichotomous variables was performed using the Pearson Chi square hypothesis test (2 א). The risk of being physical inactive was estimated with a multivariate analysis that was expressed in Odd Ratios with a 95% CI. An alpha (α) was considered of 0.05.

Results: Only 29.4% (28.9 - 29.9) of the adolescents were active. Males in the Southern Cone were more active than females 37.6 (36.8 - 38.4) and 22.4 (21.8-23.1), respectively. (P <0.001) The consumption of 5 servings or more of fruits and vegetables was low (18.7%); only 13.5% consumed more than 3 vegetables and about one third (38%) 2 or more fruits daily. Consumption of less than 2 fruits, less than 3 times vegetables and less 5 or more servings of fruits and vegetables was significantly associated with being less active. (P<0.001) The risk of being less active was 1.50 times higher in those who did not consume the 5 or more servings of vegetables and fruits per day. The condition of being a woman also double this risk OR: 2.06 (1.96 -2.17).

Conclusions: The low fruits and vegetables consumption, and increased risk of being physical inactivity that have these adolescents; it reveals need to consider strategies that to address both issues together to achieve synergies to improve health in the short and long term

Keywords: Physical activity. Fruits. Vegetables. Adolescence.

ASSOCIATION OF MONOUNSATURATED FATTY ACIDS INTAKE WITH MORTALITY IN CHINA AND UNITED STATES

[1]Zhuang, Pan; [2]Jiao, Jingjing; [3]Wang, Wenqiao; [1]Chen, Jingnan.

[1]BSc. Department of Food Science and Nutrition, College of Biosystems Engineering and Food Science. Zhejiang University. China.; [2]PhD. Nutritionist. Department of Nutrition. School of Public Health. Zhejiang University School of Medicine. China.; [3]MD. Department of Nutrition. School of Public Health. Zhejiang University School of Medicine. China.

Background and objectives: Recent dietary guidelines for Americans recommended replacing saturated fats with plant-derived monounsaturated fats as evidence showed the preventive effect of monounsaturated fatty acids (MUFA) on cardiovascular diseases. However, studies investigating the association of MUFA intake with mortality are limited. We aim to assess and compare the association between dietary intake of MUFA and mortality between Chinese and US adults.

Methods: We used data from the China Health and Nutrition Survey (CHNS, n=14,113) and National Health and Nutrition Examination Survey [NHANES, 1988-1994 (III), continuous 1999-2010 (n=36,032)]. Dietary intake of MUFA was assessed using a 24-h dietary recall in NHANES and 3-day 24-h dietary recalls in CHNS.

Results: A total of 4826 deaths occurred during 378,359 person-years of follow-up in NHANES and 1009 deaths accrued during 199,091 person-years in CHNS. Total MUFA intake was significantly associated with lower risk of overall mortality in CHNS. After adjustment for confounders, the hazard ratios (HRs) across increasing quartiles of MUFA intake were 0.85 (95% confidence interval [CI], 0.70-1.02), 0.69 (95% CI, 0.55-0.87), 0.83 (95% CI, 0.60-1.15); P=0.02 for trend), as compared with the first quartile.

Total MUFA intake was also inversely but weakly associated with mortality in NHANES. As compared with the first quartile, the HRs across increasing quartiles of MUFA intake were 1.00 (95% CI, 0.90-1.11), 0.89 (95% CI, 0.77-1.04), 0.83 (95% CI, 0.67-1.02; P=0.06 for trend). Importantly, increased MUFA intake was related to lower risk of death from stroke [fourth quartile versus first quartile: 0.25 (95% CI, 0.12-0.52); p=0.02 for trend] in NHANES. Analyses of specific MUFA showed that the association of palmitoleic acid with mortality was inverse in CHNS (P=0.002 for trend) but null in NHANES. As the main type of MUFA, oleic acid intake was also weakly associated with mortality in NHANES (P=0.06 for trend) whereas the association seemed U-shape in CHNS.

Conclusions: Total MUFA intake was associated with reduced risk of mortality for both Chinese and US adults, though the association was strong in CHNS but weak in NHANES. Our findings provide epidemiological evidence for formulating the recommended nutritional intake of MUFA for Chinese and American people.

Keywords: Monounsaturated fatty acids, Palmitoleic acid, Mortality, CHNS, NHANES.

ACTUALIZATION OF THE CONTENT OF ADDED FOOD SUGARS IN THE SPANISH FOOD COMPOSITION DATABASE (BEDCA).

[1]Martínez-Burgos, Mª Alba; [2]Moreno, Ángela; [2]Martínez de Victoria Muñoz, Ignacio; [3]Yago, Mª Dolores; [3]Mañas, Mariano; [3]Martínez de Victoria Muñoz, Emilio.

[1]PhD. Institute of Nutrition and Food Technology. Center of Biomedical Research. Technological Park of Health Sciences. Department of Physiology. Faculty of Pharmacy. University of Granada. Granada. Spain; [2]MSc. Institute of Nutrition and Food Technology. Center of Biomedical Research. Technological Park of Health Sciences. University of Granada. Granada. Spain. [3]PhD. Institute of Nutrition and Food Technology. Center of Biomedical Research. Technological Park of Health Sciences. Department of Physiology. Faculty of Pharmacy. University of Granada. Granada. Spain.

Background and objectives: Food composition databases (FCDB) are important tools for food and nutrition professionals (Pennington, 2007). Food composition data can be obtained from various sources. Different proposals to evaluate the quality of these data (Martínez-Victoria, et al., 2015).

The necessity of distinguish from added sugar (AS) and naturally occurring sugars (NS) in foods has been growing since there are a lot of scientific information that shows the connection between AS and metabolic syndrome, as well as other related diseases. Because of that, the FDA has implemented the new Nutrition Facts label for packaged foods. Due to changes in some recipes provided by food companies, the sugar data added in the USDA database have been withdrawn.

This situation generates a growing interest in information on the content of sugars in food, in the consumer and in health pro-

fessionals. The content in sugars will serve for the new nutritional labeling, mandatory in accordance with European Union legislational ready, so it is important to have this data in the Spanish FCDB (BEDCA) (www.bedca.net).

Methods: We were implemented the method proposed by JCY Louie et al. (2015) in order to establish a differentiation of sugar content of most of food that make up BEDCA and has searched analytical data from primary sources like scientific papers and laboratories associated with intent to add it up to the nutrients list of foods that do not have sugar content previously.

Results: The foods in BEDCA have been divided in two groups: "100% AN" or "100% NS" and added sugar data that our group found in their search for foods that does not have any sugar data.

The next step (already started) is to compile a recipe list of all food that have a mix of AS and NS to obtain the real sugar content of that to include in our database.

BEDCA is currently the only FCDB developed in Spain with compiled and documented date, according to EuroFIR (www.eurofir.org).

Conclusions: BEDCA (950 foods, 48 components, 310 methods and associated references) will allow users and professionals of Nutrition and Public Health to use online quality food composition data.

Keywords: Sugar; added sugars; food composition; nutrition label; food composition database.

SETTING OF CUT-OFF SCORE FOR ASSESSING THE COUNSELING COMPETENCY OF FILIPINO VILLAGE NUTRITION WORKERS ON INFANT AND YOUNG CHILD FEEDING (IYCF) BASED ON SENSITIVITY AND SPECIFICITY

[1]Sacdalan-Africa, Leila Sacdalan-Africa; [2]Mansyur, Muchtaruddin; [3]Muslimatun, Siti; [4]Barba, Corazon.

[1]Associate Professor. Institute of Human Nutrition and Food. College of Human Ecology. University of the Philippines Los Baños. Philippines; [2]Director. Southeast Asian Ministry of Education Organization. Regional Center on Food and Nutrition. Universitas. Indonesia; [3]Faculty Member, Indonesia International Institute for Life Sciences. Indonesia; [4]Professor Emeritus. Institute of Human Nutrition and Food. College of Human Ecology. University of the Philippines Los Baños. Philippines.

Background and objectives: Five instruments for assessing the counselling competency of Filipino village nutrition workers on infant and young child feeding (IYCF) were developed and

validated. These included: (1) 28-item knowledge test(KNO); (2) 10-item attitude test(ATT); (3) 18-item worker's skills self-assessment(CSW); (4) 18-item supervisor's instrument for assessing worker's skills(CSS); and (5) 17-item activity checklist for IYCF counselling client(CSM). These were combined into competency assessment instruments KAS-COM(1,2,3,4,5); KAS-WOR(1,2,3); KAS-SUP(1,2,4) and KAS-MOM(1,2,5). To establish the composite distribution for knowledge(KNO), attitude(ATT), and skills(CSW, CSS, CSM) in the competency score calculation and to set the cut-off score based on sensitivity and specificity, this study was undertaken.

Methods: Using the receiver operating characteristic(ROC) analyses, 28 possible combinations of composite distributions (30-30-40; 25-25-50; 20-20-60; 15-15-70; 25-15-60; 25-10-65; 20-10-70) for knowledge, attitude and skills, with corresponding passing score of 60%, 65%, 70%, 75% were tested.

Results: The best area under curve (KNO=0.86; ATT=0.81; CSW=0.77; CSS=0.94; CSM=0.81) was the 20-10-70 percent distribution for knowledge, attitude and skills, respectively with 75% cut-off score. Among the constructs, CSS had the highest area under curve (0.94) and using 51% as cut-off score, it was a good test (0.92) to identify the skilled workers on IYCF counselling. The tests for knowledge, attitude, CSW, and CSM with 63%, 79%, 80%. and 89%, respectively as cut-off scores were fair enough in identifying the knowledgeable workers, those with better attitude; and were skilled to do the IYCF counselling. The setting of cut-off score for each assessment instrument (KAS_WOR, KAS_SUP, KAS_MOM and KAS_COM) resulted to areas under curve ranging from 0.83 (good) to 0.92 (excellent). Using 50% and 80% as cut-off values, the sensitivity for the instruments with supervisor and client as assessors of skills was excellent (1.0 and 0.96) while specificity was fair (0.78 and 0.76). The cut-off score for self-assessment instrument KAS_WOR (75%) was fairly sensitive and specific. The cut-off score for the combined instrument (KAS_COM) is 65%.

Conclusions: The use of ROC curve in identifying the cut-off score and the composite distribution for knowledge, attitude and skills provided a sound basis for identifying competent BNS in terms of IYCF counselling.

Keywords: composite distribution of competency score, setting of cut-off score, ROC curve, sensitivity and specificity, IYCF counselling

ASSESSING THE RELATIONSHIP BETWEEN HOUSEHOLD WATER QUALITY AND ENVIRONMENTAL ENTERIC DYSFUNCTION (EED) IN YOUNG CHILDREN LIVING IN SOUTHWESTERN UGANDA

(1)Lauer, Jacqueline; (2)Duggan, Christopher; (3)Ausman, Lynne; (4)Griffiths, Jeffrey; (3)Webb, Patrick; (5)Ghosh, Shibani.

(1)MS MPH. PhD Candidate. Gerald J. and Dorothy R. Friedman School of Nutrition Science and Policy. Tufts University. Boston, MA. United States.; (2)PhD MPH. Professor. Department of Nutrition. T.H. Chan School of Public Health. Harvard University. Boston, MA. United States.; (3)PhD. Professor. Gerald J. and Dorothy R. Friedman School of Nutrition Science and Policy. Tufts University. Boston, MA. United States.; (4)MD MPH&TM. Professor. Department of Public Health and Community Medicine. Tufts University School of Medicine. Boston, MA. United States.; (5)PhD. Assistant Professor. Gerald J. and Dorothy R. Friedman School of Nutrition Science and Policy. Tufts University. Boston, MA. United States.

Background and objectives: Environmental enteric dysfunction is defined by abnormal intestinal morphology resulting in reduced absorptive capacity, inflammation, and poor growth. While the causes of EED warrant further investigation, it has been linked to unsanitary environmental conditions, especially repeated exposure to enteric pathogens. The main objective of this study is to determine if household water quality is a risk factor for EED in children living in southwestern Uganda.

Methods: This cross-sectional assessment was a sub-study of the Uganda Birth Cohort study, undertaken from 2014-2015. 385 children who met the inclusion criteria were randomly selected for participation. Data on water quality and sex of the household head, mother's education level, and mother's age were extracted from the 6 month infant age time point. Water quality was assessed using the Aquagenx CBT for detecting and quantifying E.coli bacteria. EED was assessed at 12-16 months using a lactulose: mannitol (L:M) test. For the L:M test, children consumed 20 ml. of solution containing 5 grams of lactulose and 1 gram of mannitol. All urine was collected for a minimum of four hours, and 1.5 ml. aliquots were stored at a minimum of -20°C. Levels of the two sugars were analyzed using validated LC-MS methods. Funding was provided by USAID (grant AID-OAA-L-1-00006).

Results: Of the 385 children, 49.4% were male and 50.7% were female, and the median age was 15.0 months [14.1, 15.7]. Among the households, 43.8% had "safe" water, 13.5% had "probably safe" water, 12.2% had "probably unsafe" water, and 30.5% had "unsafe" water. The median L: M score was 0.27 [0.16, 0.41], with 20.26% having no EED (L:M <0.15), 57.4% having moderate EED (0.15 <= L: M <= 0.45), and 22.34% having severe EED (L:M > 0.45). The association between water quality and EED was assessed using linear regression. The L:M scores of children consuming water deemed "unsafe" were 0.08 points higher (99% confidence interval [CI]: 0.02, 0.15) compared to water deemed "safe".

Conclusions: Household water contamination may be an important risk factor for EED, which is consistent with previous findings but requires further study.

Keywords: environmental enteric dysfunction, malabsorption, water quality, child health

ENVIRONMENTAL IMPACTS OF NATIONAL DIETS: COMPARISON OF LAND USE AND WATER DEPRIVATION IMPACTS IN FRANCE AND TUNISIA

[1]*Perignon, Marlène;* [2]*El Ati, Jalila;* [3]*Drogue, Sophie;* [1]*Darmon, Nicole;* [1]*Amiot-Carlin, Marie Josephe;* [4]*Sinfort, Carole.*

[1]PhD. Nutritionist. Unité Mixte de Recherche 1110 Markets, Organizations, Institutions and Stakeholders Strategies (UMR MOISA). INRA, CIRAD CIHEAM and Montpellier SupAgro. France.; [2]PhD. Nutritionist. Institut National de Nutrition et de Technologie Alimentaire. Tunisia.; [3]PhD. Economist. Unité Mixte de Recherche 1110 Markets, Organizations, Institutions and Stakeholders Strategies (UMR MOISA). INRA, CIRAD CIHEAM and Montpellier SupAgro. France.; [4]PhD. Environmental Physician. Unité Mixte de Recherche « Information, Technologies, environnemental Analysis, agricultural Processes » (UMR ITAP). Montpellier SupAgro. France.

Background and objectives: Environmental impacts of national diets are often analyzed through Carbon emissions. Nevertheless, with a life cycle vision, other impacts are to be considered and new methods and data are now available to compute water deprivation and land use impacts (Pfister et al., 2016; Vidal-Legaz et al., 2016). The objective of this study was to use an hybrid method combining economical statistics data to production ones and compute environmental potential impacts due to water deprivation and land use for the French and Tunisian diets.

Methods: National nutritional enquiries were merged with the international custom data base UNComtrade and the FAOstat one. For animal products, feed composition and origin were also considered. Characterization factors for the water deprivation were the WSI factors from Pfister et al. (2009). Land use impacts were computed from the occupied surface including land occupied by animal feed crops. Then LANCA characterization factors (Beck et al., 2011; Bos et al., 2016) were applied to compute land use potential impacts. Biodiversity impacts from land use were obtained from Chaudhary et al. (2015).

Results: Potential impacts were computed for the total equivalent amount of food of one person during one year in France and Tunisia. Impacts are generally one order higher (roundly 5 to 15 times) for the Tunisia diet than for the French one but food production in Tunisia has positive impacts on erosion and biotic production. Comparing food groups show the prevailing importance of the group "meat/fish/eggs".

Conclusions: The hybrid approach allowed to consider the origin of each product in the French and Tunisian diets and to differentiate environmental potential impacts due to water deprivation and land use for each country and for each food family.

Keywords: national diet, life cycle assessment, land use, water deprivation

EPIDEMIOLOGY OF TYPE II DIABETES MELLITUS IN URBAN POPULATION

[1]*Modem, Sai leela;* [2]*Vadarevu, Sony.*

[1]Associate Professor. St.Joseph's college for Women (Autonomous). Visakhapatnam. India.; [2]Assistant Professor. St.Joseph's college for Women (Autonomous). Visakhapatnam. India.

Background and objectives: Diabetes Mellitus proves to be major cause of morbidity and mortality around the world and contribute largely to healthcare costs. Deshpande (2008) points that the risk of death of patients with DM is twice that of the population of the same age without DM . Seema et al (2010) opine that DM poses significant healthcare burdens on both families and society. Adiseshiah (2005) suggests that multidisciplinary interventions help in management of DM patients and delay the onset of complications which are usually life threatening and affect the quality of life.

Objective: To understand and trace out the critical factors haunting the DM patients selected from an urban population.

Methods: The study of 51 hospitalised DM patients was undertaken in Visakhapatnam city in the Andhra Pradesh state of India. The secondary data in the form of patients' case history was collected and primary data of family, socio-economic status, anthropometry, diet and physical activity were obtained. BMI was calculated.

Results: The hospitalised DM patients were aged from 41 to 90 years, that is late middle age to old age. The males and females were equally affected by the disease and its complications. The maximum affected were in the age group 61-70 years. The disease had a toll on people of all walks of life and with active lifestyle. The diet followed by the affected over a period of time was analysed. However no concrete diet pattern could be arrived at as causative factor. The diet counselling was undertaken.

Conclusions: The study revealed very pathetic situation as the people affected with DM were in productive age. The burden of the disease the quality of life and the economic condition of the patients.

Conflict of Interest Disclosure: The co-author was my Grad student and the work is a dissertation undertaken in my supervision.

DIETARY PATTERNS IDENTIFIED BY LATENT PROFILE ANALYSIS (LPA) AMONG BRAZILIAN SCHOOLCHILDREN: USING DATA FROM THE WEB-CAAFE SURVEYS

[1]Lobo, Adriana; [2]Assis, Maria Alice Altenburg De; [2]Leal, Danielle; [2]Hinning, Patrícia; [3]Kupek, Emil; [4]Bellisle, France.

[1]MSc. Nutritionist. Postgraduate Program in Nutrition. Health Sciences Center. Federal University of Santa Catarina. Florianopolis. Santa Catarina. Brazil.; [2]PhD. Postgraduate Program in Nutrition. Health Sciences Center. Federal University of Santa Catarina. Florianopolis. Santa Catarina. Brazil; [3]PhD. Postgraduate Program in Public Health. Health Sciences Center. Federal University of Santa Catarina. Florianopolis. Santa Catarina. Brazil; [4]PhD. Université Paris 13. Equipe de Recherche en Epidémiologie Nutritionnelle. Centre de Recherche en Epidémiologie et Statistiques. Inserm (U1153). Inra (U1125). Cnam. COMUE Sorbonne Paris Cité. F-93017 Bobigny.rm.s Cité. F-93017 Bobigny. France.

Background and objectives: Although the identification of dietary patterns is important to support dietary interventions, there are few studies in Brazilian children, none of them using Latent Profile Analysis (LPA). The aim of this study is to apply LPA to identify dietary patterns in pupils of public schools participating in the Web-CAAFE 2013-2015 surveys, in Florianopolis, Brazil.

Methods: The Web-CAAFE Survey is an annual cross-sectional school-based survey designed to help public health and education professionals to evaluate schoolchildren from 2nd to 5th grade regarding nutritional status, food consumption and physical activity. Data for the present study were collected in the years 2013, 2014 and 2015 and included 6,379 schoolchildren from Florianopolis (southern Brazil). Data was obtained using the questionnaire Web-CAAFE (Food Intake and Physical Activity of Schoolchildren), a web-based self-administered questionnaire that examines food consumption and physical activity during the previous day. Latent profile indicators were the frequency of consumption of 32 food/beverages items, in number of times per day. LPA was used to assign the children to the most likely latent profiles based on their food consumption.

Results: Three latent profiles were identified: 1) Traditional pattern (39.7% of the children), with a significantly elevated probability of consuming rice, vegetables, green leaves, beans, manioc flour, meat, fruits, bread and biscuits and dairy products; 2) Monotonous pattern (39.3% of the children), with a significant probability of consuming pasta, instant noodles and pizza/hamburger/hot-dog, and 3) High diversity pattern (21% of the children), with a significantly higher probability of eating a variety of foods, healthy or not, such as corn and potatoes, French fries, breakfast cereals, soda, sweets, chips snacks, vegetables, green leaves, milk, yoghurt and fruits. A higher proportion of boys presented a Monotonous dietary pattern (43.6% CI 95% 41.9-45.3 vs 35.0% CI 95% 33.3-36.6) and a higher proportion of girls presented a Traditional pattern (45.0% CI 95% 43.2-46.7 vs 34.5% CI 95% 32.9-36.2).

Conclusions: The present study offered insights about the use of LPA for describing the eating patterns of Brazilian schoolchildren. Three patterns were identified: Traditional, Monotonous and High diversity.

Keywords: dietary patterns, Latent Profile Analysis, schoolchildren.

Universidad de Zaragoza. Zaragoza. España. CIBERobn (Biomedical Research Center). Spain.

Background and objectives: Overweight and obesity have achieved high rates in children and adolescents across the world. A diet quality index (DQI) is a useful tool that provides an overall

score of an individual´s dietary intake when assessing compliance with food-based dietary guidelines. Moreover, family life plays an important role in developing eating behaviors and dietary intake in children and adolescents. This study was aimed to assess the associations between DQI and family meals in adolescents included in a comprehensive therapy for obesity.

Methods: Multi-intervention approach (diet, physical activity and psychological support in a family-group-based treatment-EVASYON) was implemented within a one-year intervention in 13-to-16-year-old overweight or obese Spanish adolescents. A total of 67 adolescents, 31 females, were included in the present study, whose energy intake and BMI had been measured at baseline. In the EVASYON study, diet quality index was calculated from food frequency questionnaire at baseline, 6 and 13 months of follow-up. Family meal was assessed from dietary history reported from parents at baseline, 2, 6 and 13 months of treatment. In the present study, we evaluate the diet quality index and family meals after 6 months of intervention. Data are shown as means and SD for continuous variables and frequency and percentages for categorical variables). U-Mann Whitney and Chi-squared tests were performed. Signification level was established at p<0.05. All statistical analyses were performed by using SPSS STATISTICS v.20 (IBM Corp., New York, NY, USA, 2010).

Results: 67.2% adolescents had family meals and showed DQI score of 71.16±8.94 after 6 months. Males had lower DQI values than females, meanwhile similar percentage of family meals was observed (69.4% vs 64.5%). However, there was only a significant relationship between DQI and family meal in females (p=0.036).

Conclusions: It is important to create a comfortable atmosphere in order to reach a better diet quality index in adolescents with obesity. Males need to be instructed in food and health related issues. The efforts in obese adolescents should be directed to really achieve healthier behavioral changes, including family, in order to improve their DQI.

Keywords: Adolescents, family-involvement, family-group-based, multi-intervention approach, diet quality index

UMR204 'Nutripass' - IRD-UM-Supagro. Institut de Recherche pour le Développement (IRD). France.; [5]UMR204 'Nutripass' - IRD-UM-Supagro. Institut de Recherche pour le Développement (IRD). Mali.; [6]MSc. Poverty, Health and Nutrition Division (PHND). International Food Policy Research Institute (IFPRI). Senegal.; [7]MSc. World Food Program (WFP). Bamako. Mali.; [8]MSc, MD, PhD. UMR204 'Nutripass' - IRD-UM-Supagro. Institut de Recherche pour le Développement (IRD). France.; [9]MSc, PhD. Poverty, Health and Nutrition Division (PHND). International Food Policy Research Institute (IFPRI). USA.

Background and objectives: The "Cash for Nutrition Awareness" (CNA) component of the community-based intervention "Santé Nutritionnelle à Assise Communautaire à Kayes" (SNACK) was implemented in Mali by the World Food Program (WFP-Mali) in 2013 for a duration of 3 years. The conditional cash transfer program aimed at improving child nutrition outcomes by increasing maternal and child attendance at community health centers (CHCs) through the distribution of a small amount of cash (~$3.00-$12.00 USD), during antenatal visits, delivery, vaccination and monthly growth monitoring visits starting at 6 months, covering the "1000 days" period (i.e. from pregnancy to 23 months of age of the child). The objective of this study was to explore the incentive value of the cash for beneficiaries to attend CHCs.

Methods: We conducted a process evaluation two years after the start of the program, using a purposive sample of 12 CHCs and their catchment area. We collected data using semi-structured interviews with frontline workers (n=76) and mothers (n=24), semi-structured observations of cash distributions and services delivered in 11 CHCs (twice for each CHC, n=22), and free listing with groups of up to 10 mothers gathered outside the CHCs (n=24 groups). Data were analyzed using thematic analysis along the program impact pathway (from service delivery to beneficiaries' receipt and use of cash).

Results: We identified various implementation issues, including difficulties for program workers to supply the cash to the CHCs due to a challenging implementation environment (namely long travel distances to deliver cash to the CHCs and high workloads). In addition, some mothers returned home empty-handed, as the total amount of cash available was often insufficient to pay all women attending the CHC in the same day. In some CHCs, cash was also delivered on different days than the days they provided services. Beneficiaries identified maternal and child health

as their main motivation to attend activities at the CHCs and cash only as a benefit, mainly used to buy food.

Conclusions: Implementation issues and a potentially insufficient amount of cash may have decreased the incentive value of the cash to increase attendance at CHCs. The research was funded by UNICEF, EC (IFAD) and CGIAR (A4NH).

A GLOBAL FOOD FORTIFICATION DATA REPOSITORY: ENSURING THE AVAILABILITY OF DATA FOR PROGRAM MONITORING, ACCOUNTABILITY, ADVOCACY, AND STRATEGIC DECISION MAKING

[1]*Luthringer, Corey L.;* [2]*Codling, Karen;* [3]*Garrett, Greg S.;* [4]*Martinez, Homero;* [5]*Pachón, Helena;* [6]*Gorstein, Jonathan.*

[1]MPH. Food Fortification. Global Alliance for Improved Nutrition. USA.; [2]Iodine Global Network. Thailand; [3]MSc. Director. Food Fortification. Global Alliance for Improved Nutrition. Switzerland; [4]MD, PhD. Micronutrient Forum. Micronutrient Initiative. Canada; [5]Food Fortification Initiative; [6]PhD. Executive Director & Associate Professor. Iodine Global Network & Department of Global Health. University of Washington. USA.

Background and objectives: While multiple agencies maintain databases with a variety of programmatic data, there is a need for greater alignment and harmonization to achieve more uniform global monitoring of the state of, and progress in fortification; programmatic decision making and accountability; and advocacy. A global repository of key program-related indicators for multiple food vehicles (maize flour, oil, rice, salt, wheat flour) will help fill this niche and will provide a resource for governments, donors, and implementing agencies to make data-driven decisions about fortification policies and programs.

Methods: We implemented a process that entailed reviewing existing databases, developing a core set of indicators, and outlining a process for continuous collection and aggregation of updated data. These processes and outcomes were reviewed at each stage through a consultative process implemented in a food fortification community of practice comprising over thirty organizations/actors operating at national and global levels [the Global Fortification Technical Advisory Group (GF-TAG)].

Results: A set of core indicators covering aspects related to demand, supply, and the enabling environment for fortified staple foods were defined based on data available within existing databases. Examples include the status of fortification legislation, regulations, monitoring, compliance, and coverage. Proxy indicators were also crafted where the ideal indicator is not available across all countries and fortified food vehicles. Data stewards were identified for each food vehicle to serve as gatekeepers to ensure optimal data inclusion and quality. A repository prototype was developed with assistance from Camber Collective and TenPoint7

that includes existing data from the core indicators within an interactive data visualization platform and was publically launched in June 2017. Data stewards streamlined data collection processes with countries and technical partners to ensure timely data updates and inclusion of additional indicators over time to address user needs.

Conclusions: As food fortification programs are scaled up in countries, it is imperative to track progress and establish standard indicators to assess performance, impact and sustainability. This effort has underscored the need for broader improvements in fortification data, including improvements in data collection that require continued collaboration across all GF-TAG member organizations.

SUPERMARKET SHOPPING AND NUTRITIONAL OUTCOMES: A PANEL DATA ANALYSIS FOR URBAN KENYA

[1]*Demmler, Kathrin Maria;* [2]*Ecker, Olivier;* [3]*Qaim, Matin.*

[1]PhD. Agricultural Sciences. RTC; [2]PhD. Research Fellow. Development Strategy and Governance Division. International Food Policy Research Institute. Washington, DC. USA.; [3]Prof. International Food Economics and Rural Development. University of Goettingen. Germany.

Background and objectives: Overweight and obesity are growing health problems in many developing countries. Rising obesity rates are the result of changes in people's diets and lifestyles. Income growth and urbanization are factors that contribute to these changes. Modernizing food retail environments may also play a certain role. For instance, the rapid spread of supermarkets in many developing countries could affect consumer food choices and thus nutritional outcomes. However, concrete evidence about the effects of supermarkets on consumer diets and nutrition is thin. A few existing studies have analyzed related linkages with cross-sectional survey data. To our knowledge, we are the first to use panel data in this setting.

Methods: Panel data from households and a total of 1,199 adult individuals was collected in urban Kenya in the years 2012 and 2015. Panel regression models with individual fixed effects plus other controlling factors were employed.

Results: Our results show that shopping in supermarkets significantly increases adults' body mass index (BMI). Regarding impact pathways we did not find that supermarkets contribute to net increases in total calorie consumption. However, our panel data models revealed significant shifts in dietary composition. Supermarket shopping contributes to a sizeable decrease in energy consumption from unprocessed staples and from fresh fruits and vegetables. We found significant increases of supermarket shopping on energy consumption from dairy, vegetable oil, processed meat products (sausages etc.), and highly processed foods (bread, pasta,

snacks, soft drinks etc.). These shifts towards processed and highly processed foods lead to less healthy diets, with higher sugar, fat, and salt contents, and probably lower amounts of micronutrients and dietary fibers.

Conclusions: The observed changes in dietary composition could explain the increasing effect on BMI, even without a rise in total calorie consumption. These results confirm that the retail environment affects people's food choices and nutrition. However, the effects depend on the types of foods offered. Rather than thwarting modernization in the retail sector, policies that incentivize the sale of more healthy foods – such as fruits and vegetables – in supermarkets may be more promising to promote desirable nutritional outcomes.

Keywords: Dietary choices, overweight, supermarkets, panel data, developing countries

THE ROLE OF THE NUTRITIONIST IN THE PUBLIC HEALTH SYSTEM OF SPAIN

[1]López-Plaza, Bricia; [2]Bermejo, Laura M; [3]Morato-Martinez, Marina; [3]Valero-Perez, Marlhyn; [4]Palma-Milla, Samara; [5]Gomez-Candela, Carmen.

[1]PhD. Nutrition Researcher. Nutrition Department. La Paz University Hospital. Hospital La Paz Institute for Health Research (IdiPAZ). Autonomous University of Madrid (UAM). Spain; [2]PhD. Nutrition Researcher. Nutrition Department. La Paz University Hospital. Hospital La Paz Institute for Health Research (IdiPAZ). Autonomous University of Madrid (UAM). Spain.; [3]BSc. Nutritionist. Nutrition Department. La Paz University Hospital. Hospital La Paz Institute for Health Research (IdiPAZ). Autonomous University of Madrid (UAM). Spain.; [4]MD. Endocrinologist. Nutrition Department. La Paz University Hospital. Hospital La Paz Institute for Health Research (IdiPAZ). Autonomous University of Madrid (UAM). Spain.; [5]MD. PhD. Endocrinologist. Nutrition Department. La Paz University Hospital. Hospital La Paz Institute for Health Research (IdiPAZ). Autonomous University of Madrid (UAM). Spain.

Background and objectives: The figure of the nutritionist is well recognized around the world. The nutritionist's intervention not only improves the health of the patient but also reduces the associated health cost. Even though there is accumulated evidence of the role of the nutritionist in the prognosis of a person's health status, in Spain, its inclusion in health systems has not been achieved. For this reason the main objective is introduce the role of nutritionist in the public health system of Spain and the strategies to give visibility to these health professionals.

Methods: It is now known that for every euro spend on dietary counseling from Nutritionists, society gets a net 63€ in return: 56€ in terms of improved health, 3€ net savings in total health care costs and 4€ in terms of productivity gains. However in the Spanish Health System, the nutritionist is not considered. Taking into account the importance of the incorporation of nutritionists in the

health system, the Autonomous University of Madrid through the Clinical Nutrition Education and Research the Chair of the Teaching Sponsorship (UAM-VEGENAT) have set in motion measures to spread the importance of nutritionists in health institutes.

Results: As a result of this necessity, the first congress of Dietitians-Nutritionists, an absent health professional, has been done. This congress has been supported by the Nutrition Department of La Paz University Hospital, in order to give more visibility to this group of professionals. Topics of special interest as the current situation of this collective and its functions within a hospital have been presented. Nutritionists from Spain and other countries put in evidence the urgent need to carry out national policies that promote the incorporation of the nutritionist in the Public Health Systems of Spain. There was an exploration through the different areas, besides the sanitary one, where the role of the nutritionist takes on special importance as in research centers, universities, companies, etc.

Conclusions: The lack of nutritionists in the Spanish Public Health System should be resolved. Events of diffusion such as this Congress serve to give visibility of these health professionals.

Keywords: Nutritionist, Spanish Public Health System

DRIVERS AND BARRIERS OF SCHOOL FEEDING PROGRAMS IN THE PHILIPPINES

[1]Glas, Maria Gracia; [2]Funke, Anette; [2]Breyhan, Barbara; [3]Chávez Zander, Ursula; [3]Krawinkel, Michael.

[1]M.Sc.Nutrionist.Institute of Nutritional Sciences. Justus-Liebig-University of Giessen; [2]Kindermissionswerk. Die Sternsinger. Germany; [3]Institute of nutritional sciences. Justus-Liebig-University of Giessen. Germany.

Background and objectives: School feeding programs (SFP) are an important strategy to prevent and tackle malnutrition in low and middle income countries. The SFP intervention studied was implemented in ten public elementary schools in the Victorias City, in the province of Negros Occidental (Philippines), an area with an estimated 40% of children (5-10 years) being underweight. The objective of the study was to identify drivers and barriers of the SFP.

Methods: A qualitative research approach was applied to gain insights into participants' experiences with the SFP. The participant groups consisted of school authorities, teachers, and mothers or caregivers. Six focus group discussions, two for each participant group, were conducted with question guides and analyzed with a QDA-Software. Additional data were collected through informal conversations and observations while visiting the schools.

Results: Drivers as well as facilitators of the SFP were the motivation of the participants, awareness, promotion for parents and caregivers, good management, including monitoring activities, adequate targeting, and the implementation of hygiene education as part of the school curriculum. Awareness promotion through the SFP activities enhanced hygiene and nutrition practices of parents and children, however this was limited to environments with

supportive infrastructure. Further, school vegetable gardens were important drivers for a successful SFP. Identified barriers were lack of parental involvement and of linkages between SFP and national policies and related activities. Another aspect that hindered the effectiveness of the SFP was the lack of complementary nutrition sensitive activities aligned to the SFP as well as insufficient infrastructure and equipment.

Conclusions: Participant motivation and active participation of community members, parents, and school staff members played a key role in the success and sustainability of the SFP. School vegetable gardens displayed an important part of the SFP, but they cannot sustain stable food production for the SFP throughout the whole school year. Improvement in management skills, funding, and investments in adequate infrastructure and necessary conditions such as kitchen equipment, handwashing and toilet facilities, and separate dining spaces, are required to enhance the effectiveness of the SFP in the study area.

Keywords: school feeding, focus-groups, school health, motivation, participation

OBJECTIVELY MEASURED LEVELS OF PHYSICAL ACTIVITY IN FIRST GRADE CHILDREN OF BUENOS AIRES. DATA FROM MINISALTEN STUDY

[1]Indart Rougier, Paula; [2]De Gregorio, Maria Jose; [1]Zonis, Luciana Noemi; [1]Favieri, Andrea Lorena; [3]Rausch Herscovici, Cecile; [4]Kovalskys, Irina.

[1]BSc. Nutritionist. Nutrition and Health Area. ILSI Argentina (International Life Sciences Institute). Buenos Aires. Argentina.; [2]Bsc. Sociologist. Department of Anthropological Sciences. University of Buenos Aires. Buenos Aires. Argentina.; [3]PhD. Nutrition and Health Area. ILSI Argentina (International Life Sciences Institute). Buenos Aires. Argentina.; [4]MD. Nutrition and Health Area. ILSI Argentina (International Life Sciences Institute). Buenos Aires. Argentina.

Background and objectives: Global Recommendations on Physical Activity for 5-17 years old, of the World Health Organization (WHO), are to invest at least 60 minutes a day in moderate to vigorous physical activity (MVPA). The study aim was to objectively assess levels of physical activity (PA) in a sample of first grade children of Buenos Aires and to examine differences according to gender.

Methods: This data correspond to the baseline assessment (June to November 2015) of MiniSALTEN Study (obesity prevention program targeting first grade children at public primary schools). All children of first grade attending to the 12 public primary schools from the city of Buenos Aires participating in MiniSALTEN were invited to participate. The levels of PA were measured using ActiGraph wGT3X-BT accelerometers for 7 consecutive days (24 hours). Outcomes were: time in light, moderate and vigorous PA and sedentary time (minutes/day) determined by Evenson et al.'s cut points. Time in MVPA (minutes/day) was also

determined. Accelerometer data were analyzed using the ActiLife 6.11.8 software. Descriptive statistical analyzes of the variables measured for the total and by sex were made. Data were processed using IBM SPSS Statistic 18.

Results: 185 children (mean age = 6.7 years, 94 girls and 91 boys) wore accelerometers. The total sample spent 354.4 minutes/day in PA light, 47.9 minutes/day in PA moderate, 17.8 minutes/day in PA vigorous and 937.7 minutes/day in sedentary time. Children spent 65.7 minutes of the day in MVPA. 55.7% of the total sample don´t meet the PA guidelines of the WHO. According to gender, boys invest significantly more time in MVPA than girls (74.7 vs. 57.1 minutes/day) (p = 0.000). 60.6% of the girls don´t meet the recommendation while 72.5% of the boys exceed the recommendation.

Conclusions: This is the first Argentine study that objectively describes the PA levels in a sample of children starting primary school from Buenos Aires. Considering it shows that the majority of children don´t meet the PA recommendation, nor for active time neither for sedentary time, lots of preventive efforts should be considered when planning public health policies.

Keywords: Physical activity, Sedentary time, Accelerometer, Children.

Conflict of Interest Disclosure: The source of funding for the research is the Coca-Cola Foundation. The authors declare that they have no competing interests. The funding source had no role in study design, data collection and analysis, decision to publish, or preparation of manuscripts.

NEW MULTISECTORAL TOOLS TO ADDRESS ANEMIA AT THE NATIONAL AND DISTRICT LEVELS

[1]Fisseha, Teemar; [2]Sakar, Danya; [3]D'Agostino, Alexis; [4]Harvey, Philp; [5]Moorthy, Denish; [6]Namaste, Sorrel.

[1]MPH. Monitoring and Evaluation Officer. SPRING Project. John Snow Inc. USA.; [2]MHS. Nutrition Specialist. SPRING Project. John Snow Inc. USA.; [3]MPP. Monitoring and Evaluation Specialist. SPRING Project. John Snow Inc. USA.; [4]PhD. Nutritionist. Independent Consultant. USA; [5]MBBS. MS. Nutritionist. SPRING Project. John Snow Inc. USA.; [6]MHS. DrPH. Nutritionist. SPRING Project. Helen Keller International. USA.

Background and objectives: Anemia is caused by multiple factors, and it can be difficult for decision-makers to prioritize anemia actions for their context. Collaborating with country implementers, the SPRING Project developed two tools for use at the national and district level, to encourage stakeholders to gather and interpret data related to anemia and anemia programs. We cover the theoretical rationale, design, and testing of the tools.

Methods: The "Guidance for Conducting a Landscape Analysis for Anemia" was designed to help provide stakeholders a broad understanding of the national anemia situation, and the "District

---

Assessment Tool for Anemia (DATA)" to enable districts to understand anemia and prioritize actions. The anemia landscape tool was developed based on experiences assessing the anemia situation in Ghana, Uganda, and Sierra Leone and validated by receiving input from 34 content-specific experts. The DATA tool was also developed with input from multiple stakeholders and field tested in a district in Ghana. A revised tool was piloted in a district in Nepal and Uganda.

Results: The landscape analysis tool guides the user through a four-step process to assess the anemia situation: characterize anemia prevalence, establish causes of anemia, and review and assess existing anemia policies and interventions. An accompanying Excel-based tool allows users to aggregate and present data. Using similar content as the national tool, the DATA tool is an Excel-based tool that guides a two-day facilitated workshop. During the workshop district-level stakeholders from multiple sectors discuss and complete questionnaires and the data generated is automatically translated into output dashboards. The DATA tool underlines the importance of local contextual factors, identifies enablers and barriers to address these factors, and assists district stakeholders to prioritize anemia actions.

Conclusions: An effective multisectoral effort to combat anemia requires insights from multiple data sources and an understanding of data gaps and their implications for implementation. These resources guide stakeholders through the collection and use of such information. The extent to which the findings generated from using these tools will be used to inform planning and program design remains to be seen. An important next step will be to scale-up and evaluate these tools.

ASSOCIATION BETWEEN HOUSEHOLD CULTIVATION OF NUTRIENT-DENSE CROPS AND MATERNAL AND CHILD DIETARY DIVERSITY IN SELECTED RURAL COMMUNITIES IN THE UPPER MANYA KROBO DISTRICT OF GHANA

[1]Colecraft, Esi; [2]Marquis, Grace; [3]Aryeetey, Richmond; [4]Bannerman, Boat; [5]Thompson-Colon, Theresa; [6]Atuobi-Yeboah, Afua.

[1]University of Ghana. Ghana; [2]PhD. Nutritionist. School of Dietetics and Human Nutrition; [3]PhD. Nutritionist. School of public Health. University of Ghana. Ghana; [4]MSc. Data Analyst. Nutrition Links Project. University of Ghana. Ghana; [5]PhD. Research Associate. School of Dietetics and Human Nutrition. McGill University. Canada; [6]MPhil. Nutritionist. Nutrition Links Project. University of Ghana. Ghana.

Background and objectives: Households with restricted income may sell nutrient-dense produce they cultivate at the expense of their own nutrition. We assessed whether household cultivation of nutrient-dense vegetables was associated with mothers and children's dietary diversity indicators.

Methods: This analysis used data from cross-sectional baseline survey of 184 mothers with children (6 to 36 mo) participating in Nutrition Links, a 5-y project to improve rural health and economic well-being in the Upper Manya Krobo district of Ghana. The survey included questions regarding socio-demographic characteristics, agriculture production (including dark green leafy vegetables, orange-flesh sweet potatoes and fruits), and maternal and child dietary intake. Dietary diversity score (DDS), computed as consumption of up to eight food groups for mothers (7-day recall) and up to seven food groups for children (24-hour recall), were dichotomized as "good" (met recommendation of ≥5 for women and ≥4 for children) or as "poor" (did not meet recommendation). Bivariate analyses and linear regression were used to determine associations and predictors, respectively of child dietary diversity.

Results: The mean ages of mothers and their children were 27.2 ± 7.2 y and 12.4 ± 6.3 mo, respectively. Approximately 60% of households cultivated at least one type of nutrient-dense vegetable or fruit on their farms. The mothers' mean DDS was 4.5 ± 1.2 and children's mean DDS was 3.2 ± 1.9, with a significant positive correlation (r=0.36, P<0.01) between the two DDS. Younger children (6-12 mo) were more likely than older children (12-36 mo) to have a "poor" DDS (70.5% vs. 29.5%; P<0.001). Children from households cultivating at least one nutrient dense crop were more likely to have "good" DDS compared to those from households not cultivating these crops (57.7% vs. 42.3%: P=0.03) but no association was noted with mothers' DDS. Mothers' DDS (P=.002), household nutrient dense crop cultivation (P=0.025) and child age (P<0.001) independently predicted child DDS.

Conclusions: Mothers need support to improve their children's diet diversity during early complementary feeding. The positive association between household crop cultivation and child DDS supports use of agricultural interventions focused on nutrient rich crops to improve child nutrition.

Keywords: dietary diversity, children, maternal, agriculture, dietary intake

FOOD-BASED DIETARY PATTERNS AND NUTRITIONAL QUALITY OF MEALS IN BRAZIL (2008-2009)

[1]Machado, Priscila Pereira; [2]Louzada, Maria Laura da Costa; [3]Andrade, Giovanna; [3]Ricardo, Camila; [4]Levy, Renata.

[1]PhD candidate. Graduate Program in Nutrition in Public Health, School of Public Health. University of São Paulo. Brazil. Center for Epidemiological Research in Nutrition and Health (NUPENS/USP). School of Public Health. University of São Paulo, Brazil.; [2]PhD. Nutrition Course. Federal University of São Paulo. Brazil. Center for Epidemiological Research in Nutrition and Health (NUPENS/USP). School of Public Health. University of São Paulo, Brazil.; [3]MSc. Department of Preventive Medicine. School of Medicine. University of São Paulo. Brazil. Center for Epidemiological Research in Nutrition and Health (NUPENS/USP). School of Public Health. University of São Paulo, Brazil.; [4]PhD. Department of Preventive Medicine. School of Medicine. University of São Paulo. Brazil. Center for Epidemiological Research in Nutrition and Health (NUPENS/USP). School of Public Health. University of São Paulo, Brazil.

Background and objectives: It has been observed the declining in the consumption of traditional meals based on freshly prepared dishes, and its replacement by the ultra-processed food and drink products. However, evidence on the composition and nutritional profile of each main meal from low and middle-income countries is still scarce. This study aimed to identify food-based dietary patterns at lunch and dinner and assess the nutritional quality of these patterns in Brazil.

Methods: Cross-sectional analysis based on individual-level dietary data from 32,898 individuals aged ≥10 years in Brazil, collected as part of the 2008–2009 National Household Budget Survey. Food consumption was evaluated by two 24-hour food records. Lunch and dinner were identified as the most caloric meals in the periods between 11 a.m. and 5:59 p.m. and between 6 p.m. and 11:59 p.m., respectively. Food items were classified into three food groups and subsequent subgroups according to the extent and purpose of the processing they undergo. Exploratory factor analysis was applied to identify food-based meals patterns. We used linear regression analyses to evaluate the association between quintiles of the foods patterns' scores and nutritional indicators of the meals.

Results: We identified three food-based meals patterns for lunch and dinner. The first pattern, labeled 'ready meal', was positively associated with bakery products, ready meals and other processed and ultra-processed products, and negatively associated with unprocessed and minimally processed food such as rice, beans and meats. The second pattern, labeled 'snack', included butter, milk, coffee and tea, processed breads and margarine. The third pattern, labeled 'traditional meal', was positive for unprocessed or minimally processed foods (like fruits/fruit juices, roots/tubers and fish), and negative for meats and soda. For lunch and dinner, the nutritional indicators of unhealthy diet increase significantly across quintiles of the ready meal and snack patterns, while nutritional indicators for healthy diet increase significantly across quintiles of the traditional meal pattern.

Conclusions: This study suggests that the adherence of traditional meals and the avoidance of ready meals and snacks patterns may be an effective way to improve the nutritional quality of Brazilian diets.

Keywords: Dietary pattern. Diet quality. Meals. Food processing. Household Budget Survey.

OBESITY, INSULIN RESISTANCE AND TYPE 2 DIABETES MELLITUS IN FEMALE ADOLESCENTS, LIMA – PERÚ

[1]Pajuelo Ramírez, Jaime; [2]Bernui, Ivonne; [3]Sánchez González, José; [3]Arbañil Huamán, Hugo; [4]Miranda Cuadros, Marianella; [5]Cochachin Henostroza, Omaira; [5]Aquino Ramírez, Anthony.

[1]MSc.Medical Doctor. Instituto de Investigaciones Clínicas. Universidad Nacional Mayor de San Marcos. Perú. MSc.Medical Docotr. Instituto de Investigaciones Clínicas. Universidad Nacional Mayor de San Marcos. Perú; [2]MSc. Biologist. Centro de Investigación de Bioquímica y Nutrición. Universidad Nacional Mayor de San Marcos. Perú; [3]MD. Servicio de Endocrinología. Hospital Nacional Dos de Mayo. Perú; [4]MSc. Nutritionist. Centro Nacional de Alimentación y Nutrición. Instituto Nacional de Salud. Perú; [5]Pre-graduate student. School of Nutrition. Universidad Nacional Mayor de San Marcos. Perú.

Background and objectives: The prevalence of obesity in adolescents at the national level was 3,2% in 2010 and this figure was more than double for the year 2014 (7,5%). This increase is alarming because of the complications obesity causes, including type 2 diabetes mellitus (DM2), dyslipidemia and hypertension. The objective was to determine the prevalence of IR in an obese adolescent population and to identify the presence of DM2.

Methods: In 1206 female adolescents were evaluated with BMI for age. Obesity at BMI/A ≥ 95p was defined using the WHO standards. In the obese patients, insulin, glucose, and lipid profile were determined using the Matthew equation (Insulin uUI/mL * glycemia mmol/dL/22.5). HOMA-I was calculated using a value ≥ 3,16 , to define insulin resistance (RI). To identify dyslipidemia the cut-off points were: hypercholesterolemia ≥ 200 mg/dL, low HDL-C ≤40 mg/dL, high LDL-C ≥ 130 mg/dL and hypertriglyceridemia ≥ 150 mg/dL. Obese women with IR were given a glucose tolerance test (PTG) by choosing the criteria of the American Diabetes Association, between 140 and 199 mg/dL intolerant to glucose and 200 mg/dL and more as diabetics.

Results: Obesity was present in 25.1% of the study population. In this group of obese adolescents, 28.1% had IR. When comparing the group of obese with RI with obese without RI, it was observed that the difference of the means of the biochemical variables presented statistical significance, except the HDL-C.

In the same way the differences between the prevalences of the dyslipidemias were significant with the exception of HDL-C. RI had an OR of 16.2 (6.3-41.9), 12.1 (4.9-30.1), and 7.6 (3-19.5) with hypertriglyceridemia, hypercholesterolemia, and C -LDL, respectively. PTG showed 3.3% intolerant and none diabetic.

Conclusions: Obese adolescents were identified with a high risk of becoming diabetic over time and presenting with cardiovascular problems and that this is exacerbated by the presence of them at a young age.

Keywords: Obesity; Insulin resistance; glucose tolerance; adolescent

THE LATIN AMERICA AND THE CARIBBEAN INTERVENTIONS THAT FOSTERING NUTRITIONAL WELL-BEING: OPPORTUNITIES TO STRENGTHEN NUTRITION PUBLIC POLICIES

[1]Rios-Castillo, Israel; [2]Molina, Veronika; [2]Mejicano, Gabriela; [2]Alfaro, Norma; [3]Rivas, RoseMarie; [4]Hernandez-Garbanzo, Yenory.

[1]MSc. Nutritionist. Regional Nutrition Officer for Latin America and the Caribbean. Sub Regional Office for Mesoamerica. Food and Agriculture Organization of the United Nations (FAO). Panama; [2]MSc. Nutritionist. Institute of Nutrition for Central America and Panama (INCAP). Guatemala City. Guatemala; [3]Nutrition Specialist. Food and Agriculture Organization of the United Nations (FAO). FAO Representation in El Salvador. San Salvador. El Salvador; [4]PhD. Nutritionist. Nutrition Officer. Food and Agriculture Organization of the United Nations (FAO). Headquarter. Rome. Italy.

Background and objectives: Latin America and the Caribbean Region is currently in a transition between two key periods in its development. In the last 20 years, the region has made progress in hunger and undernutrition control and prevention. However, overweight and obesity as well as non-communicable chronic diseases are rapidly increased affecting across the entire region. The present study aimed to identify and analyze national experiences to support nutritional well-being in Latin America and the Caribbean.

Methods: The Information was obtained from primary and secondary sources in the 33 participating countries, from February through August 2016.

Results: Two hundred and four interventions were identified in the three sub-regions covered by the study. Most interventions seek to prevent or reduce malnutrition due to deficiencies, or promote healthy lifestyles among vulnerable groups. Seventeen interventions were selected to conduct in-deep interviews in Chile, Colombia, Costa Rica, Dominican Republic, Guatemala, Jamaica, Mexico, Paraguay, Trinidad and Tobago, and Uruguay. According to the results, the main success factors for the interventions were: political endorsement; targeting actions for the identification of beneficiaries and coverage at the national level; adequate and timely budget; sufficient, trained and committed staff; monitoring and evaluation; work in partnerships with the public and private sector as well as international cooperation; community participation and empowerment of beneficiaries.

Conclusions: There is significant potential for the strengthening of nutrition public policies to promote comprehensive interventions that foster nutritional well-being in LAC that is currently facing the double burden of malnutrition and the NCD epidemic. Implementation of a regional nutrition public policies framework could complement the UN Decade of Actions on Nutrition ongoing commitment to fight against the double burden of malnutrition in LAC.

METABOLIC SYNDROME AND RISK FACTORS ASSOCIATED WITH LIFESTYLE

[1]Pistoni, Martha Pistoni; [2]Cappelen, Liliana Cristina; [2]Cejas Rey, Valeria.

[1]Msc Nutritionist. National Center for Nutrition Research. Salta. Argentina; [2]Nutritionist. National Center of Nutrition Research. Salta. Argentina.

Background and objectives: Metabolic syndrome (MS) is a term that has been used to define a group of risk factors that include: visceral obesity, hypertension, hyperglycemia and atherogenic dyslipidemia, which predispose the individual to develop cardiovascular disease and type 2 diabetes mellitus, becoming one of the main problems of public health in the 21st century. The objective of this study was to determine the prevalence of metabolic syndrome in the adult population and its relationship with some risk factors related to lifestyle.

Methods: Case - control study nested in a cross - sectional study of a representative sample of adults (175) from households of Salta city, Argentina. Weight, height, waist circumference, blood pressure measurement, food consumption, physical activity (IPAQ) and laboratory tests were performed. Metabolic syndrome was diagnosed according to the criteria of Adult Treatment Panel III (ATP-III). Excel, WHO software Antro v.1.0.4 Plus, EPI 7 programs were used.

Results: MS prevalence was 21.1%, significantly higher in males (28%) than in females (17.8%); OR = 1.95; 95% CI: 1.15 to 3.3. MS risk is higher in the overweight population (OR = 179; 95% CI: 11.1 to 2884); it is 2.6 times higher when the energy adequacy is excessive compared to normal caloric intake (95% CI: 1.58 to 4.43); Is 5.5 times higher with daily intake of sugary beverages (95% CI: 3.1 to 9.7) and 65 times higher when fiber adequacy in the diet is deficient (95% CI: 16.1 To 262.7). The consumption of saturated fatty acids was higher in the population with MS (21.5 ± 20.7 vs 17.6 ± 13.9) but without statistical significance. High cho-

lesterol intake (> 200 mg / day, according to ATPII) triples the risk of MS (95% CI: 1.87 to 4.8) and low levels of physical activity increase 1.5 times the risk of developing it .

Conclusions: The composition of the diet: high in calories, saturated fat, cholesterol and reduced in fiber added to low levels of physical activity, are predisposing risk factors of MS.

Keywords: metabolic syndrome, diet, physical activity

EXPLORING THE FOOD AND NUTRITION SECURITY IMPACT OF THE SOCIAL PROTECTION POLICY "PROSOLI" AMONG ELDERLY BENEFICIARIES IN DOMINICAN REPUBLIC

[1]Rios-Castillo, Israel; [2]Hernandez-Garbanzo, Yenory; [3]Mota-Modeste, Sevil; [4]Fulcar, Altagracia Maria; [5]Then-Paulino, Amarilis; [6]Medina-Disla, Hector; [7]Suriel, Altagracia.

[1]MSc. Nutritionist. Regional Nutrition Officer for Latin America and the Caribbean. Sub Regional Office for Mesoamerica. Food and Agriculture Organization of the United Nations (FAO). Panama; [2]Phd. Nutritionist. Nutrition Officer. Food and Agriculture Organization of the United Nations. Headquarter. Rome. Italy; [3]MD. Nutrition Consultant. Food and Agriculture Organization of the United Nations. Representation in the Dominican Republic. Santo Domingo. Dominican Republic; [4]Nutritionist. World Food Programme of the United Nations. Country Office in the Dominican Republic. Santo Domingo. Dominican Republic.; [5]MPH. MD. Nutrition Division. Ministry of Public Health; and Public Health Division. Universidad Autonoma de Santo Domingo (UASD). Santo Domingo. Dominican Republic.; [6]Statistician. Cabinet of the Social Policy Coordination "Progresando con Solidaridad (PROSOLI)". Vice Presidency of the Dominican Republic. Santo Domingo. Dominican Republic.; [7]Directorate. Cabinet of the Social Policy Coordination "Progresando con Solidaridad (PROSOLI)". Vice Presidency of the Dominican Republic. Santo Domingo. Dominican Republic.

Background and objectives: Food security and nutritional well-being are important elements for elderly people living in social and economic vulnerable situations in the Dominican Republic. The present study aimed to compare food security and nutritional outcomes at household and individual level of elderly beneficiaries and non-beneficiaries of the Dominican Republic social protection policy "Progresando con Solidaridad (PROSOLI)".

Methods: A cross-sectional study of 335 elderly people (50% beneficiaries) was conducted to compare food security and nutritional outcomes in beneficiary and non-beneficiary groups. Data was collected from June-December 2016 in ten geographically-dispersed regions at national level in the Dominican Republic. The Latin America and the Caribbean Food Security Scale (ELCSA) and the food diversity index at household level were conducted. Data analysis included anthropometric, dietary intake and socio-demographic data and rand univariate parametric or non-par-

ametric statistical analyses using Wilcoxon Mann-Whitney, t tests and proportional test.

Results: Median age and interquartile range (iqr) of participants was 74.1(13.0) years; 51% were women. Sixty percent reported moderate or severe household food insecurity, however, the prevalence was significantly higher in non-beneficiaries (65%) compare to beneficiaries (55%) (Proportional test, p<0.05). A significantly higher prevalence of wasting (BMI<23kg/m2) was also found in non-beneficiaries (44%) compare to beneficiaries (34%) (Proportional test, p<0.05). For dietary intake, geometrical mean and standard deviation of dietary calcium intake was 396 mg (125-1255) in beneficiaries and 292 mg (74-1146) in non-beneficiaries (ttest, p=0.0280); and saturated fatty acids were 8.5mg (2.7-27.0) in beneficiaries and 6.2mg (1.6-23.9) in non-beneficiaries (ttest, p=0,0241); no such difference was observed with other macro or micronutrient intake.

Conclusions: Results suggest that nutrition-sensitive social protection policies such as PROSOLI may significantly influence the food security situation and nutritional status of their elderly beneficiaries. This underscores the need of capitalizing on the strengths of nutrition sensitive social protection policy and program measures to support in an integrated manner efforts that aim to promote healthy eating habits and better nutrition among elderly.

SIMULATIONS OF THE IMPACTS OF BIOFORTIFIED CROPS ON VITAMIN A INTAKE OF YOUNG CHILDREN AND IRON INTAKE OF WOMEN OF REPRODUCTIVE AGE IN CAMEROON

[1]Luo, Hanqi; [2]Stewart, Christine; [3]Vosti, Stephen; [4]Guintang Assiene, Jules; [5]Brown, Ken; [6]Engle-Stone, Reina.

[1]PhD candidate. Program in International and Community Nutrition. University of California Davis. USA.; [2]Associate professor. Department of Nutrition. University of California Davis. USA.; [3]Adjunct Professor. Agricultural and Resource Economics. University of California Davis. USA.; [4]MS. Nutrition Deputy Program Manager. Helen Keller International. Cameroon.; [5]Senior Program Officer and Initiative Lead. Nutrition Global Development. Bill & Melinda Gates Foundation; [6]Assistant professor. Department of Nutrition. University of California Davis. USA.

Background and objectives: Biofortification to increase the micronutrient content of staple crops may reduce the burden of micronutrient deficiencies, but effectiveness relies on food con-

sumption patterns, which may vary spatially. Dietary intake data can be used to estimate the potential impacts of biofortification.

Methods: We completed 24-hour dietary recalls among women (n = 912) and children 12 - 59 month of age (n = 883) during a national survey in Cameroon, with representative sampling for three geographic strata (North, South, and Yaoundé/Douala). We simulated the impacts of pro-vitamin A biofortified sweet potato, maize, and cassava on the adequacy of vitamin A intake of children, and the impacts of iron-biofortified rice, beans, millet, and sorghum on adequacy of iron intake of women, under optimistic assumptions of full replacement of the non-biofortified varieties. We calculated "reach" as the proportion of the population that consumed a biofortified food on the previous day, and "effective coverage" as the proportion of the population with inadequate micronutrient intake that achieves dietary adequacy following biofortification.

Results: The baseline prevalence of inadequate vitamin A intake among children varied by region (South: 33%; North: 71%; Yaoundé/Douala: 48%). Effective coverage was the highest for maize (~20%), which had the greatest reach in the North region, and the lowest for sweet potato (~8%), because of infrequent consumption of sweet potato. Inadequate iron intake was common among women (South: 88%; North: 63%; Yaoundé/Douala: 82%; adjusted for absorption). Millet and sorghum were only consumed in the North (~45% and ~8% reach, respectively); hence, effective coverage was only 17% and 2%, respectively, in the North and near zero elsewhere. Beans and rice were consistently consumed in all regions (~15% and ~30% reach, respectively). However, amounts consumed and estimated iron absorption were low, so the effective coverage was less than 5% for both.

Conclusions: Among children, maize was consumed more commonly in regions with the highest prevalence of vitamin A inadequacy, so biofortified maize may be more effective than other crops for increasing dietary adequacy. Among women, several iron-biofortified crops would increase iron intake, but the prevalence of inadequacy is likely to remain high.

Keywords: biofortification, dietary modeling, vitamin A, iron

HOUSEHOLD FOOD INSECURITY AND DIETARY DIVERSITY INDEX AMONG MOTHERS OF CHILDREN UNDER TWO YEARS OLD IN PANAMA

[1]Escala, Lisbeth; [2]Rios-Castillo, Israel; [3]Jimenez-Acosta, Santa; [4]Vergara, Eira; [5]Gonzalez, Elka; [6]De Leon, Jose.

[1]MBA. Nutritionist. Sub Regional Office for Mesoamerica. Food and Agriculture Organization of the United Nations (FAO). Panama; [2]MSc. Nutritionist. Regional Nutrition Officer. Food and Agriculture Organization of the United Nations. Sub Regional Office for Mesoamerica. Panama City. Panama.; [3]MD. pediatrician. Nutrition Division. National Institute of Hygiene. Epidemiology and Microbiology (INHEM) of Cuba. Havana. Cuba.; [4]MPH. Nutritionist. Nutrition and Dietetic Department. Medicine School. University of Panama. Panama City. Panama; [5]MSc. Nutritionist. Nutrition Division. Ministry of Health. Panama City. Panama; [6]MPH. Nutritionist. Nutrition Division Head. Ministry of Health. Panama City. Panama.

Background and objectives: Food security exists when all people in all social and economic contexts have capacity to get enough and of high quality nutrient foods to cover their nutritional needs. There are clear evidences about the relation of food security and dietary diversity with a better nutritional status. The present study aimed to evaluate household food insecurity and dietary diversity index (HDDI) among mothers of children under two years old in Panama.

Methods: A cross-sectional study of 273 household was conducted in four geographically dispersed health regions (San Miguelito, Panama Centro, Cocle and Veraguas). This study was part of a national project aimed to develop Food Based Dietary Guidelines for children under two years in Panama. Household food insecurity was assessed using the Latin America and the Caribbean Food Security Scale (ELCSA) considering the previous three months, and dietary diversity index, which included twelve food groups in the last 24 hours. The statistical data description comprehend frequency and percentage, mean and standard deviation (SD), and median and interquartile range (iqr).

Results: Mean age and SD for mother was 27.3 ± 7.4 years, for children was 9.1 ± 5.7 months (51% female). Nineteen percent of households reported moderate or severe food insecurity; the median HDDI and iqr was 8 (7 – 10) points. The less-consumed food groups were fish (19%), eggs (56%), vegetables (56%), fruits (64%) and pulses (66%).

Conclusions: Moderate and severe food insecurity is mainly present in families with children under two years at risk of poverty and social exclusion, which remains as concern for public health and agricultural sectors in Panama; HDDI shows lowest consumption of high quality nutrients foods such as fish, vegetables and fruits. Comprehensive nutritional interventions should be put in place to fight against malnutrition, especially in early stage of life.

EVALUATION OF A SCHOOL FEEDING PROGRAM IN A REAL SETTING

[1]Chichizola, Nuria; [2]Saravi, Agustina; [3]Moyano, Daniela; [4]Perez, Laura; [5]Arroyo, Susana; [6]Mario, Virgolini; [2]Britos, Sergio.

[1]Centro de Estudios sobre Políticas y Economía de la Alimentación. Universidad Nacional de Entre Ríos. Argentina; [2]Centro de Estudios sobre Políticas y Economía de la Alimentación. Universidad Nacional de Buenos Aires. Argentina; [3]Universidad Nacional de Córdoba. Argentina; [4]Universidad Nacional de Salta. Argentina; [5]Nutritionist Universidad Isalud. Argentina; [6]BSc. Ministerio de Salud. Argentina.

Background and objectives: School age is an opportunity to build lasting healthy habits. In Argentina, overweight and multiple deficiencies of essential nutrients, affects 34.5% and 38%, respectively.

The objective of the study was to characterize the nutritional quality of school feeding in six jurisdictions of Argentina and the contribution of the school cafeteria and kiosk in it.

Methods: A team of nutritionists made 24-hour food records in a sample of 1108 scholars and registered two days of food service in 61 schools and the sale in 24 school kiosks. Intake of Kcal and critical nutrients was compared to FAO/WHO 2004 requirements and WHO 2003 recommendations. Adequacy indicators, main dietary sources and quality nutritional of school feeding program were analyzed.

Results: The median energy intake was 1958 kcal; 31% comes from the school meals, 10% from the kiosk and 59% from home. The 97% of children exceed the recommendation of discretionary calories and 79% of added sugars; 99% of school breakfasts are high in sugars and 24% of lunches in saturated fats. Almost half of the discretionary calories and sugars are provided by school. Home diet is monotonous and the school meal reinforces this monotony. Breakfast is the more inadequate school offer; only 15% of them contain at least one portion of dairy. Home diet and breakfasts are the most responsible of the observed inadequacies.

Conclusions: The nutritional redesign of school feeding programs is urgently needed, prioritizing breakfast and the provision of food nutritional quality.

Keywords: evaluation, nutritional quality, school feeding.

A NEW INSTRUMENT TO MONITOR GLOBAL DIET QUALITY

[1]Herforth, Anna; [2]Ballard, Terri; [3]Rzepa, Andrew; [4]Diego-Rosell, Pablo; [5]Webb, Patrick.

[1]PhD. Nutritionist. Agriculture and Food Security Center. Columbia University. USA.; [2]DrPH. Independent Consultant. Italy.; [3]JD. Gallup, Inc. UK.; [4]PhD. Gallup, Inc. Spain.; [5]PhD. Friedman School of Nutrition Science and Policy. Tufts University. USA.

Background and objectives: Dietary risks have been identified as the most significant contributor to the global burden of disease. However, there is no global mechanism for monitoring dietary quality in a standardized way across countries. This paper defines the need for monitoring dietary quality on a global basis, and outlines steps needed for the design and testing of a survey module suitable for global implementation.

Methods: A review commissioned by Gallup, Inc. was carried out to identify, characterize, compare and contrast widely-used definitions of diet quality (DQ) and dietary recommendations at global and national levels. An expert consultation was held to discuss results and identify possible mechanisms for data collection at global level, with the aim of defining what should be measured and how.

Results: Based on assessments of international and national dietary recommendations/food based dietary guidelines and epidemiological meta-analyses, there are several operational definitions of DQ. The technical advisory group (TAG) came to a consensus that in all contexts, a healthy diet (a) achieves sufficient nutrient adequacy and (b) reduces the risk of diet-related NCDs such as cardiovascular disease and type II diabetes. Key elements of a universal definition and set of metrics linked to these positive health outcomes across countries and regions are (a) adequate dietary diversity, (b) abundant consumption of diverse plant foods, such as fruits, vegetables, legumes, nuts, seeds and whole grains; and (c) low consumption of ultra-processed foods (UPFs), such as sugar-sweetened beverages and processed meat products. In order to operationalize the nutrient adequacy and health-protective diet components into a concise questionnaire module, the TAG recommended modifying the questionnaire for the minimum dietary diversity for women (MDD-W) to include 23 items. The TAG affirmed that Gallup World Poll (GWP), which implements a nationally representative survey in 160 countries annually, would be an appropriate mechanism for implementing a diet quality survey.

Conclusions: Diet quality is a critically important health and nutrition policy issue that should be measured globally. There is concordance on the key elements of diet quality that could feasibly be monitored on a regular basis, and survey modules are under preparation for piloting within the context of GWP.

Keywords: Diet quality, dietary assessment, diet-related non-communicable diseases (NCDs), MDD-W

NUTRIENT PROFILE, GAPS AND DIFFERENTIAL PRICING OF PROCESSED FOODS IN ARGENTINA

[1]Borg, Ayelén; [2]Simonetti, Cecilia; [3]Oliver, Emilce; [3]Britos, Sergio.

[1]Bsc. Nutritionist. Centro de Estudios sobre Política y Economía de la Alimentación. Universidad de Buenos Aires. Argentina; [2]Nutritionist Student. Centro de Estudio sobre Política y Economía de la Alimentación. Argentina; [3]Bsc. Nutritionist. Centro de Estudio sobre Política y Economía de la Alimentación. Universidad de Buenos Aires. Argentina.

Background and objectives: In a context of high prevalence of overweight and obesity the discussion about the incidence of food in the high intake of critical nutrients has gained relevance. The purpose of this study is to analyze the nutritional profile of processed food which have significant contribution in saturated fat, free sugar and sodium intake to know their quality gaps and the difference in the price between different nutritional qualities.

Methods: A sample of 1179 products grouped in 11 categories of foods which represent around 42% and 47% of the total intake of nutrients to limit was analyze. The nutrient content of each category was compared with a corresponding standard which was were determined according to the critical nutrient density value of the category adjusted to total calories of a healthy diet with preponderance of high nutrient density foods

It was calculated a nutritional score with the NRFI method to compare the price per kcal according to nutritional quality. The price of the products were registered from the website "Precios Claros".

Results: The 15% of the products of the sample have a higher content than the standard for saturated fat, 27% for free sugar and 29% for sodium. Processed meats, Sausages, salty cookies and dressings are the categories with the greatest inadequacy in sodium. Sodas and sweet snacks have the most inadequacy in free sugar.

The price per calories is 47% higher in products of the two quintiles with better nutritional quality in relation to the two of lower quality.

Conclusions: The excesses in the consumption of critical nutrients are concentrated in eight categories of products. Nevertheless there are a lot of processed products which their content in critical nutrition does not have an incidences in the excesses intake. It is necessary to design an appropriate nutrient profile system at the local level.

Keywords: Nutritional profiles; Critical nutrients; Nutritional quality; Price of food; Processed food.

Chile; [6]Escuela de Nutrición y Dietética. Universidad de Antioquia. Colombia; [7]Facultad de Ciencias Químicas y Farmacia. Universidad de San Carlos de Guatemala; [8]Departamento de Salud Nutricional. Ministerio de Salud de Panamá; [9]Faculdade de Ciências da Nutrição e Alimentação da Universidade do Porto. Portugal; [10]Asociación de Nutricionistas y Dietistas del Uruguay.

Background and objectives: The sale of food on the street is a common practice around the world. The nutritional quality of food and hygienic-sanitary conditions of street food stalls varies between countries, and may have implications for certain health-related events. The objective of this study was to characterize the consumption of street food and the perception of the hygienic-sanitary conditions of the street food stalls in Paraguay.

Methods: As part of a multicenter study conducted in 11 Iberoamerican countries (Argentina, Brazil, Chile, Colombia, Costa Rica, Guatemala, Panama, Paraguay, Peru, Uruguay and Portugal), we applied a structured online survey with 12 questions related to sociodemographic characteristics, the street food consumption frequency, perception of hygiene of the street food stalls and episodes of vomiting or diarrhea following after the consumption of these foods.

Results: 525 people were surveyed, 51.8% (n = 272) reported consumption od street food in the last 3 months. We found that 79% were women, 61,8% were between 18 and 30 years old, 49,3% had university studies and 36,8% were postgraduates, also 66.5% worked or studied in the health or food area. During the last 3 months 33.8% consumed some type of food on the street every week. The most frequently consumed foods were: chipa (cassava flour bread) (40.6%), meat patties (40%), brochets (36.8%), sandwich (36.7%) and fruits (40%). The availability of these foods (38.6%), lack of time to prepare meals (25%) and the fact that they are tasty foods (23.5%) are the main reasons for consumption. Only 11.4% of people had the perception that the food street stalls were clean or hygienic and 14.7% reported having diarrhea or vomiting after consuming some food at these stalls.

Conclusions: Despite the high educational level of the population surveyed and the perception of poor hygienic-sanitary condi-

tions in the street food stalls, the consumption of unhealthy food on public places is highly frequent. Given that availability is a key conditioning factor of consumption, promotion of fruit consumption could be a valid strategy.

Keywords: Street food. Consumption. Public Health Policies. Hygienic-sanitary conditions

PHYSICAL ACTIVITY, NUTRITIONAL STATUS AND METABOLIC SYNDROME IN ADULTS

[1]Pistoni, Martha Pistoni; [2]Cappelen, Liliana Cristina; [2]Gomez Augier, Virginia.

[1]Msc Nutritionist. National Center for Nutrition Research. Salta. Argentina; [2]Nutritionist. National Center of Nutrition Research. Salta. Argentina.

Background and objectives: Physical inactivity is the fourth most important risk factor for mortality in the world according to the World Health Organization and its prevalence is increasing in many countries, which has a significant influence on the increase of chronic nontransferable diseases and on health of the world's population. The objective of this study was estimate levels of physical activity and its association with metabolic syndrome and nutritional status in the adult population.

Methods: Cross-sectional study, descriptive of a representative sample of households in the capital of the province of Salta, Argentina. The short version of the International Physical Activity Questionnaire (IPAQ) was used as a valid measure to estimate the categories of physical activity. Nutritional status was assessed through Body Mass Index and Metabolic Syndrome classification was performed according to ATP-III. Excel, WHO software Antro v.1.0.4 Plus, EPI 7 programs were used.

Results: The sample was 175 people. The mean age of the studied population was 44.4 ± 13.6 years. 21.1% of adults had metabolic syndrome. Regarding the categories of physical activity: 27.4% were low, 40.6% moderate and 32% intense. In the evaluation of nutritional status, only 23.4% of the population were anthropometrically normal, 4.6% presented underweight, 29.7% were

overweight and 42.3% were obese. This high prevalence of altered nutritional status allows us to assume that the intensity of physical activity declared is only of the last time, so no association was observed between levels of physical activity, nutritional status and metabolic syndrome.

Conclusions: In the linear correlation there is no statistically significant finding, among the levels of self-reported physical activity, with anthropometric and biochemical variables.

Keywords: Physical activity. Metabolic Syndrome. Nutritional status

A GLOBAL OVERVIEW OF FOOD-BASED DIETARY GUIDELINES

[1]Herforth, Anna; [2]Arimond, Mary; [3]Coates, Jennifer; [4]Álvarez, Cristina; [5]Christianson, Karin; [6]Muehlhoff, Ellen.

[1]PhD. Nutritionist. Agriculture and Food Security Center. Columbia University. USA.; [2]MSc. Nutritionist. UC Davis. USA.; [3]PhD. Associate Professor. Friedman School of Nutrition Science and Policy. Tufts University. USA; [4]MSc. Nutritionist. FAO. Italy.; [5]MSc. Friedman School of Nutrition Science and Policy. Tufts University. USA; [6]PhD. Nutritionist. FAO. Italy.

Background and objectives: Food-based dietary guidelines (FBDG) are an attempt to translate the evidence base regarding relationships between foods, diet patterns, and health into specific and culturally appropriate recommendations. This objective of this study is to assess similarities in FBDG across countries in order to identify whether there are commonalities that could serve as the basis for global dietary guidelines.

Methods: Recently, FAO completed a major update of their online repository of FBDG and associated resources. All FBDG available in this repository as of 2016 were reviewed. Organization of messages into themes involved an iterative and primarily inductive process. Key messages were organized by major food group/type, and analyzed for their relationship to existing WHO dietary recommendations. The main graphics were organized into a typology, globally and by region.

Results: FBDG were available for 82 countries (Africa: 5; Asia and the Pacific: 15; Near East: 3; Europe: 32; Latin America and the Caribbean: 25; North America: 2). Graphics showed that most countries divide foods into 3-5 food groups (starchy staples; fruits, vegetables; dairy, and other "protein foods"). Few countries specified recommended amounts or types of "protein foods." Messages about fats were mixed, some countries advocating less fat consumption in general, and others specifying healthy vs. unhealthy fats. The single most common type of message (95% of countries in key messages; 100% of countries in graphic images) was encouragement of consumption of fruits and vegetables. A majority of countries also had messages on limiting salt (70%), various fats/fatty foods (63%), and sugars (51%).

Conclusions: While countries vary in their groupings of foods and the specific foods included in food groups, there is widespread

---

concordance on encouraging consumption of fruits and vegetables, and limiting foods high in salt, sugar, and certain fats. Multiple ways are recommended across countries to meet protein needs in accordance with food culture. These points are aligned with existing WHO global guidance (including the lack of guidance about optimal ways to achieve protein intake), as well as other epidemiological evidence about diet patterns that reduce risk of diet-related diseases. This review underscores international agreement about some universal components of a healthy diet.

PREVALENCE OF OVERWEIGHT, OBESITY AND PHYSICAL ACTIVITY IN CHILDREN FROM ASUNCIÓN, CENTRAL AND CAAGUAZÚ AND FLUID INTAKE PATTERNS

[1]Sanabria, Marta; [2]Aguilar, Gloria; [2]Estigarribia, Gladys; [2]Sanabria, Gabriela; [2]Muñoz, Sergio; [2]Kawabata, Anibal; [3]Feferbaum, Rubens; [2]Rolon, Rolando; [2]Rios, Patricia.

[1]MsD; [2]National University of Caaguazu. Paraguay; [3]University of Sao Pablo. Brazil.

Background and objectives: Introduction: Obesity is a multifactorial disorder. According to the survey of cardiovascular risk factors in 2011, the percentage of physical inactivity in the population is 74.5%. There are no previous studies in Paraguay about the pattern of consumption of these beverages in children.

Objective: To estimate the prevalence of overweight obesity and physical inactivity and to evaluate the pattern of consumption of energetic beverages in children and adolescents from Asuncion, Central and Caaguazú in 2015.

Methods: We used a probabilistic cohort stratified by age (7-19 years) and by conglomerates (schools in Asunción, Central and Caaguazú). Size sample: 2.300 subjects. A 24 hours reminder used for repeat samples. Cluster (schools). INTA Questionnaire was applied for measuring physical activity. Overweight and obesity was calculated with BMI Z score (WHO). Analysis by ANOVA and T Test. Significance: $p < 0,05$.

Results: Entered the study 2300 children and adolescents, average age was 11 years (2,89 years SD). The prevalence of overweight was 26.81% and obesity was 18.60% in Asuncion, Central and Caaguazú. The 50% of the study population said to spend 60 min daily sitting in front of the TV, with a rank from 0 to 120 minutes, 50% performed physical activities. The pattern of beverages consumption was: Volume. Median 1950 ml (RQI 1450-2600): Water 766 ml (RQI 491-1191); Milk and derivatives: 362 (RQI 255-471), Infusions 200 (RQI 141-450), Natural juices: 425 (RQI 300-600), Artificial juices 300 (RQI 200-500), Nectar 200 (RQI 200-350), Carbonate beverages 416 (RQI 300-616). %

Conclusions: The prevalence of malnutrition by excess is high. Half the population stated to performed physical activities outdoors for 30 minutes per day. The consumption pattern of these beverages

in children and adolescents is characterized by a less consumption of dairy products and more consumption of sugared beverages.

Keywords: obesity, physical activity, fluids intake, children

CREATING HEALTHY FOOD ENVIRONMENTS THROUGH THE BENCHMARKING OF NUTRITION-RELATED GOVERNMENT POLICIES IN SOUTH AFRICA: LOCAL EXPERT RECOMMENDATIONS FOR IMPROVED PRACTICE

[1]Spires, Mark; [2]Sanders, David; [3]Swart, Elizabeth Catherina.

[1]MPH. Researcher. School of Public Health, University of the Western Cape. South Africa; [2]MBChB. Emeritus Professor. School of Public Health. University of the Western Cape. South Africa.; [3]PhD. Professor. Department of Nutrition and Dietetics. University of the Western Cape. South Africa.

Background and objectives: Worldwide, rates of non-communicable diseases (NCDs) are on the rise. Dietary risk factors increasingly contribute to this surging global burden. This is also more and more the case in low- and middle-income countries, including South Africa. Since unhealthy diets are predominantly driven by unhealthy food environments, comprehensive actions by governments are crucial. Although a detailed plan currently exists for achieving specific NCD-related targets in South Africa, this has yet to be translated into concrete actions and/or policies.

The aim of this study is to benchmark public sector policies impacting food environments in South Africa by assessing government policies on food environments against achievable, well-defined benchmarks.

Methods: 1. Collection of relevant policy documents and policy scan to gather evidence

2. Validation of evidence document with government officials

3. Expert rating workshops: rating the extent of government policy implementation, identify gaps in these policies, and proposing concrete actions

4. Prioritization of proposed policy actions by experts

5. Feedback of results to experts, government officials, and the public

Results: An evidence report that was validated by a low number of government officials was generated. Workshops with experts were convened during which the evidence was rated and actionable steps identified. Ratings were generally low, with the lowest ratings being given to policies in the areas of 'food trade & investment' (1.00/5) and 'food retail' (1.03/5). Gaps in these areas included the absence of regulation of trade and investment in unhealthy foods, and the lack of consideration of informal vendors, respectively; with proposed actionable steps including policies to support investment in healthier food options, and the relaxation of zoning restrictions and provision of subsidies for the provision of healthy foods for informal vendors. The highest ratings were given in the areas of 'leadership' (2.71/5), 'food consumption' (2.26/5), and 'governance' (2.11/5).

Conclusions: Although South Africa is making great strides towards improving the nutritional intake of its citizens, and seems to providing the leadership and governance to this end, there is still a great deal more that the government can do as far as policy development and, especially implementation goes.

FOOD BEHAVIORS OF RISK AND NUTRITIONAL STATUS IN PRETEENS

[1]Cappelen, Liliana Cristina; [2]Pistoni, Martha Pistoni; [3]Gomez Augier, Virginia; [4]Cejas Rey, Valeria.

[1]Nutritionist. National Center for Nutrition Research. Salta. Argentina; [2]Msc Nutritionist. National Center for Nutrition Research. Salta. Argentina; [3]Nutritionist. National Center of Nutrition Research. Salta. Argentina; [4]Nutritionist. National Center of Nutrition Research. Salta. Argentina.

Background and objectives: Documenting the development of altered eating behaviors and attitudes at an early age can help identify at-risk cases and improve intervention strategies. Therefore, the objective of this research was to analyze risky dietary behaviors in preadolescents of public and private school institutions, according to gender and nutritional status.

Methods: Descriptive, cross-sectional study of a sample of students aged 10 to 13 years of both sexes belonging to public and private establishments in the capital of Salta. The nutritional status was evaluated anthropometrically through the body mass index and the EAT 26 test (Maloney 1988) was used to measure dietary risk behaviors, which evaluates diet, bulimia and oral control.). Excel, WHO software Antro v.1.0.4 Plus, EPI 7 programs were used.

Results: 288 students belonging to public schools (51.7%) and private schools (48.3%) were evaluated with a even distribution by sex. In public schools, 50.4% presented risky dietary behaviors while in private schools only 17.8%, a highly significant difference (p 0.0000001). The percentage of overweight and obese pupils is high in the total sample (52.5%), predominantly in males, both in private establishments (47%) and in public schools (66.2%). It's worrisome the low percentage of children in normal situations, corresponding to 24.6% and 37.7% of women and men respectively in public schools. These figures increase in private establishments, reaching 48.2% in women and 47.6% in men.

Conclusions: We found a statistical association between risky dietary behaviors, type of school establishment (public and private) and overweight and obesity.

Keywords: Dietary behaviors. Nutritional status. Schoolchildren

MOBILE TECHNOLOGY TO IMPROVE TREATMENT, REPORTING, AND MONITORING FOR ACUTE MALNUTRITION

[1]Emary, Colleen; [2]O'Leary, Melani; [3]Roschnik, Natalie; [4]Keane, Emily; [5]Frank, Tine; [6]Snyder, Laura.

[1]World Vision International; [2]MSc. Nutrition Technical Specialist. World Vision Canada. Canada; [3]MSc. Senior Nutrition Advisor. Save the Children; [4]MSc. Nutrition Advisor. Save the Children; [5]Consultant; [6]Design and Development Manager. World Vision Canada. Canada.

Background and objectives: Community-based Management of Acute Malnutrition (CMAM) is a proven approach for treating acute malnutrition. Its effectiveness is undermined by poor adherence to clinical protocols, inaccurate record keeping and weak supervision systems. A mobile application (app) for CMAM was developed to provide health workers (HWs) with case management tools and job aids, including response-triggered decision tree algorithms, automated referral initiating and tracking, integrated media for counselling, and automated reporting. The app was contextualized and deployed in Afghanistan, Mali, Chad, Niger, and Kenya in 2014 to determine the effectiveness and impact of the technology.

Methods: Evaluations were conducted in 2016 to assess the effect of the app on protocol adherence, monitoring, reporting, user acceptability and competency. Data was collected from a sampling of one third of implementation health centers and was matched with health centers using the traditional paper-based system for comparison. Evaluation tools included: Observational Checklist, Focus Group Discussions with HWs and beneficiaries, and Key Informant Interviews with project staff, Health District officials and Community health committee members. Monitoring tools administered quarterly, provided information on user acceptability and competency.

Results: Data completeness, protocol adherence, and treatment outcomes were improved across all 5 countries and HW acceptability was high if they were given enough time, training and support. The main challenges to HW uptake were battery life, screen size, network speed/coverage, and requirement to complete dual reporting (electronic and paper-based). The app prevented skipping steps in treatment protocol, resulting in longer case management times.

Conclusions: The app has demonstrated the potential to transform the delivery of CMAM, improving the ability to more efficiently and effectively treat acute malnutrition in humanitarian settings. However, developing 'global specifications' was not feasible given the differences between national protocols; country contextualization was complex and time consuming; field testing with users was vital; working with a technology partner who can accommodate timeline flexibility and works in fragile contexts would be beneficial; weak CMAM services in some countries affected uptake of the app. The app has also highlighted the need to better understand what is feasible in terms of capacity and time for HWs in low resource settings, with high patient caseloads.

Keywords: Acute Malnutrition; Technology; Nutrition; Child

NUTRITIONAL RISK FACTORS AMONG ADOLESCENTS FROM A CITY IN THE NORTHEAST REGION OF BRAZIL

(1)Vergara, Clarice; (2)Gonzalez, Ricardo; (3)Machado, Márcia; (1)Sampaio, Helena; (1)Bezerra, Ilana; (4)Almeida, Paulo César; (5)Moreira, Thereza; (6)Carioca, Antonio Augusto; (1)Arruda, Soraia; (1)Maia, Carla Soraya.

(1)PhD. Nutritionist. Center for Health Sciences. Ceará State University. Brazil.; (2)MSc. Physical Education. Institute of Physical Education and Sports. Federal University of Ceará. Brazil.; (3)PhD. Nursing. Department of Public Health. Federal University of Ceará. Brazil.; (4)PhD. Statistical. Center for Health Sciences. Ceará State University. Brazil.; (5)PhD. Nursing. Center for Health Sciences. Ceará State University. Brazil.; (6)PhD. Nutritionist. Center for Health Sciences. University of Fortaleza. Brazil.

Background and objectives: To describe the prevalence of nutritional risk in adolescents from a city in the Northeast Region of Brazil.

Methods: This is a school-based cross-sectional epidemiological study. Nine hundred and twenty adolescents aged 12 to 17 years old were randomly selected from six schools in different six geographic regions, in the city of Fortaleza, Ceará, Brazil. All eligible students in the selected classes were surveyed. Nutritional status, gender, economic level, body perception, diet and physical activity were included as variables.

Results: The evaluated group consisted of 49.2% boys and 50.8% girls. Twenty-one percent of students (n = 193) were underweight; 57.4% (n = 528) presented eutrophy; 15.5% (n = 143) were overweight, and 6.1% (n = 56) presented obesity (p<0.001). The majority of the students (51.7%, n = 476) presented intermediate economic level and 39.5% (n = 363), low economic level (p<0.001). Body perception presented discrepant results comparing to nutritional status: 34.5% (n = 317) of students wanted to lose weight and 24.1% (n = 222) wanted to gain weight (p<0.002). The frequency of the consumption of milk (62.8%; n=578), fruit (73.2%; n=673), fruit juices (65.1%, n = 599), vegetables (45.2%, N = 416), green salads (38.9%, n = 358), Potatoes (49.5%, n = 455) and soft drinks (79.3%, n = 730) demonstrated inadequate eating habits. Regarding the practice of physical activity, 44.3% (n = 408) of students did not practice any physical activity (60 minutes/day) in the last week evaluated. It was also observed that 15.3% (n = 141) used video game or computer for more than 5 hours a day and 15.5% (n = 143) watched television for more than 5 hours daily.

Conclusions: It is possible to verify the existence of nutritional risk among the evaluated adolescents, evidencing the need to implement education and health actions with this age group.

Keywords: Adolescent, risk factors, nutrition, epidemiological surveys

PALM OIL: WHAT ARE WE TALKING ABOUT?

(1)Gesteiro, Eva; (2)Galera-Gordo, Jesús; (3)González-Gross, Marcela.

(1)ImFINE Research Group. Department of Health and Human Performance. Universidad Politécnica de Madrid. Spain; (2)MSc. ImFINE Research Group. Department of Health and Human Performance. Universidad Politécnica de Madrid. Spain; (3)PhD. Professor. ImFINE Research Group. Department of Health and Human Performance. Universidad Politécnica de Madrid. Spain.

Background and objectives: The lack of distinction in fatty acid (FA) composition in palm oil (PO) and its fractions may induce misleading conclusions regarding the effect on lipid metabolism. We aimed to analyze the FA concentrations in percentage for PO, palm kernel oil (PKO) and their fractions.

Methods: Data were extracted from CODEX-2015 for PO, PKO, palm olein (POL), palm kernel olein (PKOL), palm stearin (PS), palm super olein (SO) and palm kernel stearin (PKS). Saturated fatty acid (SFA) percentage was calculated for lauric (C12:0), myristic (C14:0), palmitic (C16:0), and stearic acids (C18:0). Unsaturated fatty acid (USFA) percentage was calculated for palmitoleic (C16:1), oleic (C18:1) and linoleic (C18:2) acids.

Results: Ratio (SFA/USFA) was lower for PO (1:1.2), POL (1:1.3), PSO (1:1.5), and higher for PS (2.1:1), PKOL (3:1), PKO (4.3:1) and PKS (10.3:1). Palmitic acid concentration was highest in PS (60.46%) followed by PO (38.84%), POL (38.41%) and PSO (34.62%), being lower in PKS, PKO and PKOL (8.08%, 7.84% and 8.22%, respectively). Palm kernel oils showed higher values for lauric (42-54%) and myristic (21-13%) acids. Stearic acid was about 4% in PO and its fractions while 2% in PKO and its fractions. Oleic acid was higher in PSO (46.41%), POL (40.43%) and PO (35.79%) when compared to PS (25.52%). It was lower in PKOL (19.08%), PKO (14.73%) and PKS (5.86%). Palmitoleic acid concentration was 4.25%, 4.01%, 2.30%, 1.90% and 1.93% in PO, POL, PKOL, PKO and PKS, respectively. It was barely detected in PSO (0.25%) and PS (0.10%). Linoleic acid concentration was two-folded in PO (14.77%), PSO (12.79%) and POL (11.07%) when compared to PS (6.44%), yet lower in PKOL (3.28%), PKO (2.14%) and PKS (0.97%).

Conclusions: Our study highlighted the large variation in FA composition for different palm oils and their fractions, which may explain different effects on lipid metabolism. Recently, a new fraction rich in oleic acid (48-60%) has been considered to be included in the CODEX. An adaptation of labelling is needed in order to clarify the FA composition of palm oil used by the food industry.

Keywords: Palm oil, Palmitic acid, Food labelling, Cardiovascular risk

HEALTH RELATED QUALITY OF LIFE IN OBESE, OVERWEIGHT AND NO OVERWEIGHT CHILDREN FROM PUBLIC SCHOOLS OF CORDOBA CITY (ARGENTINA)

[1]*Mamondi, Verónica; [2]Lavin, Julieta; [3]Román, María Dolores; [4]Berra, Silvina.*

[1]MSc. Nutritionist. School of Nutrition. National University of Cordoba. Argentina.; [2]Nutritionist. Institute of Research in Health Sciences INICSA. CONICET. National University of Cordoba. Argentina.; [3]PhD. Nutritionist. School of Nutrition. INICSA. CONICET. National University of Cordoba. Argentina.; [4]PhD. MSc. Nutritionist. INICSA. CONICET. National University of Cordoba. Argentina.

Background and objectives: The prevalence of childhood obesity have steadily increased since more than four decades. Measures of health related quality of life (HRQoL) may contribute to know the impact of overweight on physical, social, and emotional well-being. Objective: to know the HRQoL in children according to their condition of excess weight.

Methods: Cross-sectional study conducted in a representative sample of 1577 children attending Municipal primary schools in the city of Cordoba, Argentina, in 2011. Children completed the KIDSCREEN-52 questionnaire measuring 10 dimensions of HQRoL. Body weight and height were measured to calculate BMI and to categorize excess weight according to IOTF and WHO definitions. Associations between variables were assessed using ANOVA, adopted 5% as the significance level. Between-group differences were assessed using Cohen's "d" as a measure of effect size (ES). ES of 0.2–0.5 were considered small, those between 0.51 and 0.8 moderate, and those over 0.8 were considered large.

Results: The prevalence of obesity was 11.1% using the IOTF definition and 16.5% using the WHO definition. The prevalence of overweight resulted in 20.7% and 22.7%, respectively. Obese children scored lower than no overweight children in dimension of Physical well-being, both girls (mean=49.2 versus 52.1; p<0.05; ES=0.31) and boys (50.6 vs 55.3; ES=0.47). As well, obese girls (means=49.4 versus 52.2; p<0.05; ES=0.27) and boys (means=51.3.4 versus 54.1; p<0.05; ES=0.27) scored worse than no overweight children in Self-perception. Nevertheless, score of School environment were higher in obese girls (mean=60.0) compared with no overweight (mean=56.6; p<0,05; ES=-0.31). No differences were found in the other dimensions of HRQoL. No differences in HRQoL were observed between overweight and no overweight children These analyses were carried out with IOTF definitions, but similar results were obtained when WHO definition was used as reference.

Conclusions: Obesity was associated to a worse Physical well-being and Self-perception, both in girls and boys, when comparing with no overweight children. HRQoL should be an outcome to be measured in overweight preventive interventions.

Keywords: Children. Obesity. Health related quality of life.

THE COMMUNITY FOOD ENVIRONMENT IN COSTA RICA FAVORS HIGH INTAKES OF SODIUM

Department of Nutritional Sciences/University of Toronto. Canada.

Background and objectives: The availability of foods within the environment greatly influences nutrient intake. Understanding access to foods lower in sodium is essential to prevent and control non-communicable diseases (NCD) associated with excessive sodium consumption, such as hypertension, cardiovascular and renal diseases.

To characterize the community food environment in Costa Rica by (i) assessing the sodium content declared on the nutritional label of 7570 processed and ultra-processed products and from company websites for 311 commercial fast foods, and (ii) describing the types of fast foods available within key communities.

Methods: Nutrition information on packaged and restaurant foods was collected through a systematic scan of packaged foods sold on supermarkets and online information, respectively. Sodium content of packaged foods was evaluated using the nutritional criteria from 3 systems: a. PAHO Nutrient Profile Model, b. UK Traffic Light, and c. US FDA criteria for "nutritional" claims. In the qualitative study, social ecological, health beliefs and trans-theoretical change models were used. Data were collected from 2013 to 2016.

Results: 79% of processed and ultra-processed products (n=6005) declared nutritional information on the label, and of these, 77% (n=4642) provided the sodium content. Processed, ultra-processed and fast foods reported varying amounts of sodium, even within a single food category. However, in most categories, regardless of the system used, there were classified as medium to high sodium sources. In rural areas, there was less variety of ultra-processed foods and less expensive compared to urban areas. Those with low socioeconomic status had less access to a healthier food supply, except for fresh items. Likewise, cultural diversity and stage of life influenced preferences and use of processed and

ultra-processed foods. A wide and varied supply of foods high in sodium, was observed in all the places visited (supermarkets, parks, markets, macrobiotics, "pulperías", fairs, outside educational centers), conditioned by socioeconomic, cultural and geographical factors. With globalization, urbanization and the use of mass media, the availability, variety and marketing of affordable foods high in sodium increases.

Conclusions: The community food environment in Costa Rica favors a high intake of sodium, which increases risk of NCDs associated with excess sodium consumption.

Keywords: Salt, sodium, food environment, community food environment, Costa Rica.

ANALYSIS OF THE PRESENCE OF GENETICALLY MODIFIED ORGANISMS' INFORMATION ON FOOD LABELS

[1]Franzini Severiano, Larissa; [2]Paranhos Quinta, Fernanda; [3]Tarricone Garcia, Mariana; [4]Amaral Mais, Laís; [3]Bortoletto Martins, Ana Paula.

[1]Undergraduate student. Nutrition. Brazilian Institute for Consumers Defense. Brazil; [2]Undergraduate student. Nutrition. Universidade de São Paulo. Brazil.; [3]PhD. Instituto Brasileiro de Defesa do Consumidor. Brazil.; [4]MSc. Instituto Brasileiro de Defesa do Consumidor. Brazil.

Background and objectives: Transgenic organisms, also called genetically modified organisms (GMOs), have its genetic material modified by the inclusion of genes through molecular biology, to promote improvement of the product's quality and higher productivity. In Brazil, GMOs came clandestinely in 1997. Nowadays, Brazil is the second biggest producer of GMOs in the world, having as transgenic food 94.2% of its soy and 84.6% of its corn cultivated in its land. In 2003, a decree was published stipulating that all foods containing GMOs have to present in its label a "T" black symbol in a yellow triangle, with a sentence and the scientific name of the donor species of the responsible gene for the GMO modification. Still, many companies do not identify the presence of GMOs in their products. The aim of this study was to evaluate the presence of GMOs' information on food labels.

Methods: Products, collected in four supermarkets, that contained soy or corn as one of the first five items from the ingredient list were included. We analyzed the labels of 83 products. Soy products were considered: soy oil, soy protein, isolated soy protein, texturized soy protein, hydrolyzed soy protein, vegetal soy protein, soybean extract, and soy lecithin emulsifier. Corn products were considered: corn flour, corn groats, corn starch, corn meal, and corn oil. Food labels were classified as "adequate" or "inadequate". Those that did not present information about the presence or lack of GMOs were classified as "questionable".

Results: From the 83 food labels that were analyzed, 24.1% were classified as "adequate", 8.5% as "inadequate", and 67.5% as "questionable". Among the 20 food labels considered "adequate", we verified that 60% were from products with corn, while 40% were from products with soy. We cannot confirm if the food labels without information were adequate or inadequate, because of the current lack of legislation compliance from food industries.

Conclusions: Most of the food labels did not present any kind of information regarding the presence of GMO's. Therefore, it is necessary to prioritize monitoring and punishment actions for the companies that do not ensure essential information for the consumers to make conscious choices.

Keywords: Genetically modified organisms, label, soy, corn, consumer's rights.

REPRODUCIBILITY OF A MINI FOOD CONSUMPTION QUALITY ASSESSMENT (MINI-ECCA) IN MEXICAN ADULTS

[1]Bernal Orozco, María Fernanda; [2]Macedo Ojeda, Gabriela; [3]Badillo Camacho, Nayeli; [3]Orozco Gutiérrez, Jaime Fernando; [4]González Gómez, Montserrat; [1]Márquez Sandoval, Yolanda Fabiola; [4]Altamirano Martínez, Martha Betzaida; [5]Vizmanos Lamotte, Barbara.

[1]PhD. Nutritionist. Department of Clinics of Human Reproduction, Growth and Child Development. University of Guadalajara. Mexico.; [2]PhD. Nutritionist. Department of Public Health. University of Guadalajara. Mexico.; [3]BSc. Nutritionist. Department of Clinics of Human Reproduction, Growth and Child Development. University of Guadalajara. Mexico.; [4]MSc. Nutritionist. Department of Clinics of Human Reproduction, Growth and Child Development. University of Guadalajara. Mexico.; [5]PhD. Doctor. Department of Clinics of Human Reproduction, Growth and Child Development. University of Guadalajara. Mexico.

Background and objectives: The assessment of population's food consumption quality allows the development of food aid programs, public policies for fortification or for food labelling and the elaboration of nutritional recommendations. However, in Mexico, there are not reproducible and validated short/quick screening tools to evaluate this characteristic. For this reason, our aim is to develop a Mini Food Consumption Quality Assessment (Mini-ECCA) in Mexican adults and determine its reproducibility.

Methods: A longitudinal study was carried out from March to December 2016 in a sample of apparently healthy workers from the Intermunicipal System of Water Services (SIAPA for its initials in Spanish), who voluntarily agreed to participate and signed informed consent form. The Mini-ECCA is conformed by 12 items

with visual support. It was built upon national and international recommendations and reviewed by experts. Its application lasts 5 minutes. Each question scores 0 or 1; the higher the score, the better the food consumption quality. Besides, it allows a classification of four categories of food consumption quality according to final score (10-12: very good; 7-9: good; 4-6: low; 1-3: very low). It was applied twice with a 15-days interval between them. Spearman correlation (reproducibility) and intraclass correlation coefficient (concordance) were calculated from the total scores, and for the concordance between categories (SPSS v.20 for Windows, p<0.05 significant).

Results: One hundred fifty five subjects were included; the average age was 40.2 (standard deviation (SD) 7.4) years. The average of Mini-ECCA´s total score was: first application 6.0 (SD 2.2), and second application: 6.3 (SD 2.3). Spearman correlation between the total scores of the first and second applications was ρ=0.713 (p<0.001) and intraclass correlation coefficient (ICC) was 0.841 (95% CI 0.779, 0.885).

Conclusions: Mini-ECCA's reproducibility was good (ρ=0.713) and its concordance was excellent (ICC of 0.841). Therefore, Mini-ECCA is a tool that, once validated, could be used in public health, to carry out focused food consumption assessments and orientation.

Keywords: Diet quality index, food consumption quality, reproducibility.

PUBLIC POLICY IN MEXICO FOR THE FIGHT AGAINST OVERWEIGHT AND OBESITY IN SCHOOL CHILDREN

[1]Morales-Ruán, María del Carmen; [1]Jiménez Aguilar, Alejandra; [2]Shamah-Levy, Teresa; [1]López Olmedo, Nancy; [3]Théodore, Florence; [1]Tolentino Mayo, María Lizbeth; [1]Moreno Saracho, Jessica; [4]Bonvecchio Arenas, Anabelle.

[1]MSc. Nutritionist. Center for Nutrition and Health Research. National Institute of Public Health. México.; [2]PhD. Research. Center for Nutrition and and Health Research. National Institute of Public Health. Mexico.; [3]PhD. Research. Center for Nutrition and Health Research. National Institute of Public Health. México.; [4]PhD. Nutritionist. Center for Nutrition and Health Research. National Institute of Public Health. México.

Background and objectives: The excess weight in school-children in Mexico is a serious health problem that has increased at an alarming rate. In 2010, the government established General Guidelines for the Dispensing or Distribution of Foods and Beverages at School Food Establishments (SFE) in Elementary Schools whose objective is to stop the epidemic of overweight and obesity.

Objective: To evaluate the compliance with the Guidelines during two scholar periods (2011-2012 and 2012-2013), that correspond to stages II and III of their implementation, with regard to the availability and compliance with the established criteria for the sale of foods and beverages at SFE of public elementary schools.

Methods: Cross-sectional study carried out in 39 schools that were randomly selected, from the national census of schools in Mexico. The foods and beverages available at schools were recorded in two school years, and their nutritional characteristics were compared to those established in the Guidelines. Linear, logistic or Poisson regression models were developed, according to the type of variable of interest, to make comparisons between the stages, within each food category.

Results: A broad availability of energy dense foods that are not allowed in the SFE such as cookies, desserts and sweetened beverages, was found at the schools in both stages of the study. Less than 7% of the foods and drinks were vegetables, fruits and plain water.

The food categories that met fewer of the nutritional criteria established in the Guidelines were prepared foods (fried and non-fried), as well as snacks.

Conclusions: No changes were observed between stages in the compliance with the Guidelines for the availability of foods in schools. These results suggest that Guidelines must be promoted and provided with legal basis, to make its accomplishment mandatory.

Keywords: Public policy, schools, obesity, food and beverages, Mexico

PREVALENCE OF CARDIOVASCULAR RISK FACTORS AMONG ECUADORIAN WORKERS AT A PRIVATE ENTERPRISE

[1]Mogrovejo, Patricia; [2]Jimenez, Pablo.

[1]MD. MSc. PhD Centro de Investigación en Enfermedades Crónicas No Transmisibles. Facultad de Ciencias de la Salud Eugenio Espejo. Universidad Tecnológica Equinoccial. Quito. Ecuador.; [2]MD. PhD(c). Profesor e investigador de la Carrera de Medicina Centro de Investigación en Enfermedades Crónicas No Transmisibles. Facultad de Ciencias de la Salud Eugenio Espejo. Universidad Tecnológica Equinoccial. Quito. Ecuador.

Background and objectives: Cardiovascular diseases (CVDs) are the leading cause of morbidity and mortality worldwide. Cardiovascular diseases are among the main causes of mortality in Ecuador. However, the prevalence of Cardiovascular Risk Factors (CVRF) is unknown in Ecuadorian workers. This study aimed to determine the prevalence of obesity, overweight, physical inactivity, hypertension, central obesity, dyslipisdemia history, tobacco use, alcohol and low fruit and vegetable intake among Ecuadorian workers at a private enterprise.

Methods: A cross sectional study was conducted on 917 Ecuadorian private workers (663 men and 254 women). Surveys were conducted to obtain life style information, hypertension and dyslipidemia stories, tobacco and alcohol use; anthropometric data (waist circumference, waist/hip ratio and Body Mass Index), fruit and

vegetable intake and physical activity levels (International Physical Activity Questionnaire). Statically, descriptive statistics, chi-squared test and multiple correspondence factorial analysis were used.

Results: The prevalence of CVRF are: 87,9% low fruit and vegetable intake, 65.3% physical inactivity, 50% excess of weight (40.8% overweight and 9.4% obesity); 36.4% alcohol, 25.6% central obesity, 14.8% tobacco use, 14% hypertension and 6.9% dyslipidemia history. Hypertension coexisted with obesity (38.4%), overweight (15%) and central obesity (p=0,000). Overweight and central obesity increases with age (p=0,000). Being obese and lack of time are the most common barriers to practice physical activity.

Conclusions: There is a high prevalence of cardiovascular risk factors in apparently healthy workers at a private enterprise in Ecuador. This exposes the need of preventive strategies against cardiovascular disease at workplace by making lifestyle modifications. The preventive strategies against CVDs would help in decreasing employee absenteeism, as well as hospital and drug costs which burden the health care system.

Keywords: Cardiovascular risk factors, physical inactivity

EVALUATION OF LEFTOVERS OF PREPARATIONS WHICH MAKE UP THE MENU OF A FOOD AND NUTRITION UNIT IN THE CITY OF SÃO PAULO

[1]*Toscano Ferreira, Rosana;* [1]*Korukian Freiberg, Clara;* [2]*Lyra, Carolina.*

[1]MSc. Nutritionist. Nutrition of Department. São Camilo University Center. São Paulo. Brazil.; [2]Nutritionist. Nutrition of Department. São Camilo University Center. São Paulo. Brazil.

Background and objectives: The Food and Nutrition Unit (UAN) consists of an area dedicated to the preparation and distribution of meals, with the objective of guaranteeing the provision of balanced meals according to hygienic-sanitary and dietary standards, guaranteeing food safety since the preparation and production until distribution to the final consumer. The waste of food in a UAN occurs both in the transformation of food into ready-to-eat meals, leftovers, which are all ready-to-eat foods that have not been distributed, as in the distribution stage, interpreted as food remains. Waste reduction can bring a number of benefits to a UAN, such as reducing production costs by using less inputs and energy. The main objective of this study was to Identify the amount of leftovers from the preparations that make up a menu in a food and nutrition unit.

Methods: Cross-sectional, observational descriptive study with primary data collection, developed at a UAN of a financial institution located in the southern region of the city of São Paulo, administered by a service provider in the food and nutrition segment. All items belonging to the menu were weighed in the five days of collection, between May and June 2016. For the data collection, the quantities of food produced were considered, from the gender requisition of the stock, calculating if the correction factor and cooking index, besides weighing the leftovers of the days of

collection for later calculation of percentage of leftovers and grams per capita. The analysis was made according to parameters stipulated by Lanzillotti, 10% as the maximum acceptable limit, and Vaz, 7 to 25 g per capita, respectively.

Results: The mean total food preparation during the five days of weighing was 105.5 kg, with 26.77 kg were of leftover food, totaling a percentage of 25.37% and a mean per capita of 33g .

Conclusions: The average total percentage of leftovers as per capita leftovers are high when compared to those proposed in the literature.

NUTRITIONAL QUALITY OF A SELECTED SAMPLE OF PACKAGED FOODS IN ARGENTINA

[1]*Tiscornia, María Victoria;* [2]*Castronuovo, Luciana;* [3]*Allemandi, Lorena Andrea;* [4]*Nessier, Celeste;* [5]*Gijena, Julieta;* [6]*Ferenc, Marina;* [6]*Crinó, Agustina.*

[1]Bsc. Nutritionist. Fundación InterAmericana del Corazón Argentina. Argentina.; [2]PhD. Sociology. Fundación InterAmericana del Corazón Argentina. Argentina.; [3]BSc. Public Health. Fundación InterAmericana del Corazón Argentina. Argentina.; [4]MSc. Nutritionist. Universidad Catolica de Santa Fe. Argentina.; [5]BSc. Nutritionist. Universidad Catolica de Santa Fe. Argentina.; [6]Student. Instituto Universitario CEMIC. Argentina.

Background and objectives: One of the major causes of the global increase in the prevalence of obesity, and other diet-related chronic diseases has been the increased intake of foods high in sugar, salt, and fats. This study analyzed the nutritional quality of packaged foods highly consumed or targeted to children in Argentina.

Methods: Data for breakfast cereals, cookies and milk desserts were collected at a major supermarket chain in Argentina in June 2016. Pictures were taken of the Nutrition Information Panel (NIP) of all products.

NIP of all products was analyzed using the PAHO and the WHO Europe Nutrient Profile (NP) Models.

Results: A total of 301 products were collected, 42 (14%) breakfast cereals, 209 (69%) cookies and 50 (17%) milk desserts. According to the PAHO NP model, most products (87%, n=262) showed high critical nutrient levels in at least one nutrient: 27% (n=82) were "excessive" in one nutrient, 25% (n=74) in two nutrients, 22% (n=65) in three nutrients, and 14% (n=41) in four nutrients. From the total sample, 58.8% (n=177) had excessive levels of sodium, 56.4% of saturated fats (n= 170), 53% of free sugars (n=159), 49.8% of total fats (n=150), and 2.3% (n=7) had other sweeteners. For each food category, 94% (n=196) of cookies, 92%(n=46) of milk desserts and 47% (n=20) of breakfast cereals contain elevated levels of at least one critical nutrient. For the WHO Europe NP model, most products (91%, n=292) exceeded the nutritional thresholds.

Conclusions: Most of the products analysed have high levels of sugars, fats and/or sodium. Policy considerations need to be

made regarding marketing regulation directed to children, the use of nutrient and health claims and front of package warning labels, according to the nutrient profile of products in order to inform adequately to consumers empowering them to make healthy choices

IS INEQUALITY AFFECTING THE NUTRITIONAL STATUS OF ADULT CHILEAN POPULATION? NUTRITIONAL STATUS IN ADULT CHILEAN POPULATION: INEQUALITIES IN A POST-TRANSITIONAL COUNTRY

[1]Mujica, Maria Fernanda; [2]Navarro-Rosenblatt, Deborah; [3]Lopez-Arana, Sandra; [3]Corvalan, Camila.

[1]Faculty of Land and Food Systems. The University of British Columbia. Canada; [2]School of Public Health. University of Chile. Santiago. Chile; [3]Institute of Nutrition and Food Technology (INTA). University of Chile. Santiago. Chile.

Background and objectives: Previous research in Latin America shows that socioeconomic status (SES) influences dietary patterns and obesity distribution. However, it is unclear how SES impacts overall nutrition status, in a post-transitional country such as Chile. The objective of this study was to assess the relationship between nutritional status (overweight, short stature and anemia), and two key aspects of SES-income and educational level in adult Chilean population.

Methods: Nationally representative data of 1,413 women (20-49y) and 819 men (>49y) from the 2003 and the 2009-2010 Chilean National Health Surveys were included in these secondary analyses. Body mass index (BMI) was categorized as underweight, overweight and obesity according to WHO criteria. Overnutrition was defined as BMI ≥ 25 kg/m2. Short stature (height <1.49m) and anemia (hemoglobin concentration <12 mg/L) data were assessed only for women. Descriptive statistical analysis and Chi square tests were used to compare prevalence (%; 95% CI) by educational level (low=0-7 y, middle=8-12y, and high>12y) and income tertiles.

Results: Overweight [(34.0% (30.1%-38.2%) in women] and [47.8% (41.5-54.1) in men] and, as well as, obesity [(27.1% (23.5%-30.9) in women] and [28.9 (23.7-34.8) in men], were high while underweight was negligible. Less educated women had higher prevalence of overnutrition (80.2%; 68.8%-88.1%) and short stature (14.9%; 8.5%-13.7%) than higher educated women (49.2%; 40.9%-57.5% and 3.7%; 2.0%-6.9%, respectively) (P<0.05 for both). Poorer women had higher prevalence of short stature (10.1%, 7.4%-13.8%) than richer women (2.2%, 1.0%-5.0%) (P<0.05). Anemia did not differ by SES. In men, nutritional status did not vary by income or educational level (all p>0.05).

Conclusions: In a post-transitional country such as Chile we observed SES and gender inequalities in adult nutritional status; this poses important challenges for future nutrition policies.

Keywords: Chile, Malnutrition, Inequalities, Obesity, Anemia

APPLYING A FEASIBILITY LENS TO AN INTEGRATED NUTRITION PROGRAM IN PERI-URBAN AND URBAN SENEGAL

[1]Zongrone, Amanda; [2]Le Port, Agnes; [1]Becquey, Elodie; [3]Vanderkooy, Anna; [4]Huybregts, Lieven; [5]Diatta, Ampa D; [5]Sessou, Eric; [4]Leroy, Jef; [1]Rawat, Rahul; [4]Ruel, Marie.

[1]PhD. Poverty, Health and Nutrition Division (PHND). International Food Policy Research Institute (IFPRI). Senegal.; [2]PharmD. PhD. Poverty, Health and Nutrition Division (PHND). International Food Policy Research Institute (IFPRI). Senegal.; [3]BES. Markets, Trade and Institutions (MTID). International Food Policy Research Institute (IFPRI). Senegal.; [4]PhD. Poverty, Health and Nutrition Division (PHND). International Food Policy Research Institute (IFPRI). USA.; [5]MSc. Poverty, Health and Nutrition Division (PHND). International Food Policy Research Institute (IFPRI). Senegal.

Background and objectives: The PROMIS program, implemented by HKI, integrated a package of preventive services with monthly screening and referral for acute malnutrition (AM). A one-month supply of small-quantity lipid-based nutrient supplements (SQ-LNS) for children 6-23 months of age served as an incentive to attend screening and behavior change communication (BCC) on nutrition, health, and hygiene. In peri-urban and urban Senegal, we assessed the feasibility of using neighborhood nutrition sites run by community volunteers as the program platform. Feasibility evaluation provides insights to improve implementation and increase potential for impact.

Methods: We evaluated feasibility within Bowen's (2009) seven "key areas of focus" along the program's theory of change with individual semi-structured qualitative interviews with purposively selected beneficiary mothers (n=40), volunteers (n=37), and program staff (n=12); and group free listing with 40 opportunistic groups of 5-15 beneficiary mothers.

Results: Results across feasibility domains showed that PROMIS was perceived as acceptable by beneficiaries and volunteers. SQ-LNS added value to the program for mothers and demand for program services was also increased by proximity of sites and effective communication on timing of services. Implementation of screening, BCC, and SQ-LNS was overall successful, however, barriers to program utilization included limited motivation, lack of interest in BCC topics, and time constraints. In an effort to reach more beneficiaries with SQ-LNS, some volunteers conducted home visits and/or dropped the requirement of screening and BCC. These modifications limited program practicality. PROMIS' design was inadequately adapted to the time constraints faced by mothers. Sites were affiliated with a health center and integration was ensured through referral of children with AM, health agent supervision and SQ-LNS management. Mothers' recollection of BCC messages revealed that child feeding and hygiene were the most salient, 75% of what they recalled was consistent with recommendations (limited efficacy).

Conclusions: We conclude that providing SQ-LNS without the conditionality of screening and BCC indicated a lack of understanding of the program theory of change among volunteers. However, program modifications made by volunteers to reach beneficiaries also

---

indicated that the program delivery platform requires further adaptation to a peri-urban and urban setting. Feasibility evaluation provided valuable insights not easily obtained through other methods.

Keywords: feasibility study, small-quantity lipid nutrient supplement, prevention of malnutrition, Senegal

FRONT-OF-PACK SYMBOLS AS INDICATOR OF NUTRIENTS LEVEL IN ULTRA-PROCESSED FOODS: A BRAZILIAN PROPOSE

(1)Thieme, Rubia Daniela; (2)Thomaz, Ana Cláudia; (3)Czajkowski Jr., Sérgio; (4)Bertoni de Oliveira, Lucimara; (4)Franco, Gabriela; (5)Marchesini, João Caetano.

(1)MSc. Nutritionist. Nutrition Department. Universidade Positivo. Brazil.; (2)Nutritionist. Master student of Postgraduate Program in Food and Nutrition. Universidade Federal do Paraná. Brazil.; (3)MSc. Advertising Professional. Business School. Department Universidade Positivo. Brazil.; (4)BSc. Nutrition Department. Universidade Positivo. Brazil.; (5)MD. Hospital Marcelino Champagnat. Brazil.

Background and objectives: Ultra-processed foods contribute excessively to the energy, fat, sugar and sodium intakes. Nutrition information included in ultra-processed packaged foods may be confusing. Nutrition labels and front-of-pack (FOP) food labelling are proposed to provide more accessible and comprehensible nutrition information to consumers and may help consumers to make more healthy food choices. The objective of this study was to create a symbol to identify nutrients level in Brazilian ultra-processed foods and to verify consumer understanding of this information.

Methods: Cross-sectional study from Jun 2016 to Dec 2016 with the development of FOP food labelling, and verification of the consumer understanding of it and influence on food choice. The FOP labelling contained nutrition information for total fats, saturated fats, addition sugars, sodium and fiber in packaged beverages and foods. Heathy and unhealthy levels of each particular nutrient were based in United Kingdom and Brazilian legislation for packaged foods. A questionnaire to verify the consumer understanding of nutritional information in the symbol in FOP food labelling and the food choice was applied in a Retail Lab to participants aged >18 years recruited from an university in south of Brazil. Data was shown how means, standard deviation and frequencies.

Results: The FOP symbol for identification was a single stamp. The stamp was based in Multiple Traffic Light system: red, yellow and green. The text in each FOP symbol indicated the relative health value of each nutrient in the front-of-pack label: red – Be careful with your heath; yellow – Pay attention with your health; and green – Heathy choice. The questionnaire was answered by 54 individuals, 30.42 ± 13.12 years, 57.41% (n = 31) were women. All participants identified the FOP single stamp and answered that were easier to understand the ultra-processed packaged foods nutritional information with the FOP single stamp. The FOP stamp may influence 88.9% (n=48) of the participants in their food choices.

Conclusions: FOP single stamp was create to identify nutrients level in Brazilian ultra-processed foods and was based in Multiple Traffic Light system, and facilitate consumer understanding of nutritional information. However, FOP stamp does not assurance totally change in food choices.

Keywords: Ultra-processed foods. Nutritional Labelling. Front-of-pack labelling. Consumer survey.

NUTRITION OF WOMEN IN CHILE

(1)Olagnero, Gabriela; (2)Mardones, Francisco; (3)Rosso, Pedro; (4)Passi Solar, Álvaro; (5)Torres-Robles, Romina; (6)Rozowski, Jaime; (7)Cantwell Wood, Jennifer.

(1)Nutritionist. BSc. Research and Development. Danone Nutricia. Buenos Aires. Argentina.; (2)MD. MSc. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.; (3)MD. Department of Pediatrics. Pontificia Universidad Católica de Chile. Chile.; (4)BSc. MSc. Chile. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.; (5)Sistema de Bibliotecas. Pontificia Universidad Católica de Chile. Chile.; (6)PhD. Department of Nutrition. Pontificia Universidad Católica de Chile. Chile.; (7)Nutritionist. MsC. Family Nutrition of the Triad. LLC. Greensboro. NC. USA.

Background and objectives: The advanced stage of Chile's nutritional transition implies the increase of obesity prevalence, coexisting with problems caused by underweight, especially in pregnancy. The objective was to diagnose the nutritional and health status of Chilean women of reproductive age and contrasting findings with current nutritional programs.

Methods: A comprehensive literature review from the last 15 years, including articles published in peer-reviewed journals and official reports, produced a final list of 85 references.

Results: Ultra-processed foods intakes are rising. Changes in food intake play a role in obesity epidemic. Overweight and obesity prevalence are growing in pregnant women population accounting for 29% in early pregnancy, increasing the risk of perinatal complications and metabolic syndrome later in child's life. Furthermore, the beginning of obesity epidemic in the population under 6 years is well documented.

Several micronutrients and omega-3 fatty acids are cited as deficient. Pregnancy complications including anemia, diabetes, hypertension, cesarean section and inadequate fetal growth are frequently found in malnourished women. Implementation of recent national policies might be important to address the situation. Those policies include micronutrient fortified food supplement distribution to pregnant women, food labeling changes, sugar sweetened beverages taxes, and a secondary prevention program for overweight non-pregnant girls and women.

Conclusions: The current study proposes to implement policies that use a more accurate weight gain chart during pregnancy, improves in the current fortified food supplements and include a secondary prevention program for overweight pregnant and nursing women.

THIAMINE-FORTIFIED FISH SAUCE IN RURAL CAMBODIA: VITAMIN STABILITY AND ORGANO-LEPTIC PERCEPTIONS

[1]Whitfield, Kyly C; [2]Karakochuk, Crystal; [3]Moore, Kirsten; [3]Chan, Benny; [4]Kroeun, Hou; [5]Borath, Mam; [6]Sophonneary, Prak; [2]Li-Chan, Eunice CY; [2]Kitts, David D; [7]Green, Timothy J.

[1]Department of Applied Human Nutrition. Mount Saint Vincent University. Canada.; [2]PhD. Food, Nutrition and Health. University of British Columbia. Vancouver. Canada.; [3]BSc. Food, Nutrition and Health. University of British Columbia. Vancouver. Canada.; [4]MPH. Helen Keller International Cambodia Country Office. Phnom Penh. Cambodia.; [5]MMgt. National Sub-Committee for Food Fortification. Ministry of Planning. Phnom Penh. Cambodia; [6]MD. National Nutrition Programme of Maternal and Child Health Centre. Ministry of Health. Phnom Penh. Cambodia; [7]PhD. South Australian Health and Medical Research Institute. Adelaide. Australia.

Background and objectives: Background: In Cambodia and throughout Southeast Asia, potentially fatal infantile beriberi occurs because thiamine-deficient mothers produce thiamine-poor breast milk. To prevent this thiamine deficiency in breastfed infants, we developed a novel thiamine-fortified fish sauce with the aim of improving maternal thiamine intake during pregnancy and lactation. We formulated two thiamine-fortified fish sauces: low concentration (low; 2 g thiamine hydrochloride (THCl)/L) and high concentration (high; 8 g/L).

Objective: To test the stability of thiamine in fish sauce during typical storage and use in rural Cambodian households, and after exposure to sunlight, oxygen, and heat in the laboratory. Also, to examine consumer acceptability through sensory evaluation of thiamine-fortified fish sauces compared to a control sauce containing no thiamine.

Methods: Thiamine-fortified fish sauce was exposed to sunlight, oxygen, and sunlight + oxygen for up to 21 days, and heat (100°C) for up to 35 minutes. Sensory evaluation was conducted among 90 women (18-45 y) in Prey Veng, Cambodia using the Triangle Test, Paired Preference Test, and a Nine Point Hedonic Scale.

Results: Mean ± SD THCl in low and high fish sauce household samples was 2.3 ± 0.4 and 9.7 ± 1.0 g/L (n=53 each), respectively. Sunlight, oxygen, sunlight + oxygen, and heat exposure caused ≤10% degradation in samples. Women enjoyed the taste of all fish sauces, and only 30 (33%) correctly identified the different sample in the Triangle Test, suggesting that the fish sauces were not discernible. More than 65% of women liked the sauces (scores ≥6 on a Nine-Point Hedonic Scale).

Conclusions: Thiamine is stable in a fish sauce matrix, and thiamine-fortified fish sauce is acceptable to rural Cambodian consumers, highlighting the potential of fish sauce as an ideal thiamin fortification vehicle to increase maternal thiamine intake to combat infantile beriberi.

THE ECONOMIC BURDEN OF NOT MEETING FOOD RECOMMENDATIONS IN CANADA

[1]Lieffers, Jessica; [2]Ekwaru, John Paul; [3]Ohinmaa, Arto; [3]Veugelers, Paul.

[1]PhD. RD. Postdoctoral Fellow. Population Health Intervention Research Unit. School of Public Health. University of Alberta. Canada; [2]PhD. Biostatistician. Population Health Intervention Research Unit. School of Public Health. University of Alberta. Canada; [3]PhD. Professor. Population Health Intervention Research Unit. School of Public Health. University of Alberta. Canada.

Background and objectives: Healthy lifestyles (e.g., healthy eating, smoking cessation, physical activity) can often prevent chronic diseases (CD) (e.g., type 2 diabetes, cardiovascular diseases, cancers). Public health professionals have difficult choices to make when deciding on resource allocation for CD prevention programs. Estimates of the economic burden of CD due to lifestyle factors are insightful for these professionals and exist for smoking, obesity and physical activity; however, only a few estimates exist for healthy eating. The purpose of this study was to estimate the economic burden of CD attributable to not meeting food recommendations in Canada.

Methods: Foods identified by the Global Burden of Disease Study (GBD) as being either protective (1. vegetables; 2. fruit; 3. whole grains; 4. milk; 5. nuts and seeds) or detrimental (6. processed meat; 7. red meat; 8. sugar-sweetened beverages) in terms of CD risk were included. Risk estimates were obtained from the GBD. Usual intake distributions for these foods were obtained from the 2004 Canadian Community Health Survey 24-hour dietary recalls (n=33,932 respondents). Canada's Food Guide (or other relevant) recommendations were used. Population attributable fractions (PAF) that accounted for both independent risk factor contributions and multiple exposure levels were calculated. Annual direct health care (hospital, drug, physician) and indirect (human capital approach) costs in 2014 for relevant CDs were obtained from the National Health Expenditure Trends and Economic Burden of Illness. PAF outcomes were multiplied by these costs to estimate those attributable to diet.

Results: Not meeting recommendations for the eight foods is responsible for ~CAD$17.4 billion/year (direct health care costs:

~CAD$6.5 billion; indirect costs: ~CAD$11.0 billion). Males were responsible for ~2/3 of these costs. The top contributors to these costs were inadequate nuts and seeds, inadequate whole grains, excess processed meat, and inadequate fruit.

Conclusions: In Canada, the costs of not meeting food recommendations are similar to smoking and higher than physical activity. These findings also suggest prioritization to dietary factors such as nuts and seeds and whole grains is potentially warranted. This research will ultimately help public health professionals make better-informed decisions to improve population health, reduce health care costs and protect workforce productivity.

Keywords: chronic disease, burden of disease, economics, population attributable fraction

THE RELATIONSHIP OF FOOD INSECURITY AND THE NUTRITIONAL STATUS OF MEXICAN MOTHER-CHILD PAIRS

[1]Shamah-Levy, Teresa; [2]Mundo Rosas, Veronica; [2]Morales-Ruán, María del Carmen; [2]Cuevas Nasu, Lucía; [3]Méndez Gómez-Humarán, Ignacio.

[1]PhD. Researcher. Center for Nutrition and Health Research. National Institute of Public Health. México.; [2]MSc. Nutritionist. Center for Nutrition and Health Research. National Institute of Public Health. México; [3]MSc. Statistician. Mathematics Research Center. Aguascalientes Unit. México.

Background and objectives: Previous studies have suggested a link between obesity and HFI (Household food insecurity); especially among adult women [8-10]. Specifically, it has been documented that women who experience food insecurity are more likely to be obese when compared with those from households with food security. HFI has been associated with overweight mothers and underweight children living in the same households. Adult obesity has been linked to both obesity and undernutrition in children.

The objective was to examine the association between HFI and child stunting risk and to determine if maternal-child overweight/obesity modifies the relationship between HFI and stunting risk.

Methods: We assessed the association of HFI with the nutritional status of mothers and their <11-year-old children based on data from the Mexican National Health and Nutrition Survey (ENSANUT 2012). The study included 5,087 mother-preschool child pairs and 7,181 mother school aged child pairs. HFI was measured with the Latin American and Caribbean Food Security Scale (ELCSA). We calculated the prevalence (95% CI) of each HFI category by socioeconomic characteristic and maternal-child nutritional status. Multiple logistic regressions were used to examine the associations of interest adjusting by pertinent covariates.

Results: There was a higher prevalence of stunting among preschool children with moderate HFI (16.2%) or severe (16.8%) (p=0.036 and p=0.007, respectively), compared with mild or no HFI (13.2 and 10.7%). A significant interaction was found between maternal obesity status and HFI on stunting among pre-

school children (p<0.05). HFI severity increased the risk of school aged children stunting among non-obese mothers but not among obese mothers.

Conclusions: An intriguing finding from our study is that among preschoolers HFI severity increased their risk of stunting if their mothers were not obese. However this was not the case if their mothers were obese. The double burden of malnutrition in Mexico occurs most notably among mother child pairs living with HFI. Food security government policies and programs need to take into account these complex relationships in the context of an advanced nutrition transition.

Keywords: Food insecurity; obesity, under nutrition; nutrition transition; Mexico

PREVALENCE OF UNHEALTHY LUNCHBOXES IN PERUVIAN PRIMARY SCHOOL

[1]Tarqui-Mamani, Carolina; [2]Alvarez-Dongo, Doris; [2]Espinoza-Oriundo, Paula.

[1]Doctora en Salud Publica. Centro Nacional de Alimentación y Nutricion.Instituto Nacional de Salud. Departamento de Medicina Preventiva y Salud Publica. Universidad Nacional Mayor de San Marcos. Peru; [2]Nutricionista. Centro Nacional de Alimentación y Nutrición. Instituto Nacional de Salud. Peru.

Background and objectives: The consumption of unhealthy food has increased in the world and Peru.

Objective: To determine the prevalence of unhealthy lunchboxes in Peruvian schoolchildren at the primary level.

Methods: Cross-sectional study. Probabilistic sampling, stratified and multistage. The calculated sample size was 5223 students. Unhealthy lunchbox defined as the missed of a fruit, drink and healthy complement (low in sugar, salt and oil) according to Peruvian law, it was evaluated by observation. The analysis was performed using complex samples adjusted by weighting factor. It was calculated percentages, confidence interval of 95% and chi square. The formal authorization from the principal, teachers, parents were requested, additionally refer consent was requested to students ≥ 9 years.

Results: The 100% of children carried drinks, 68.2% food complements, 38.6% fruit y 6.4% candies. The prevalence of unhealthy lunchboxes was 94.6%. The percentage of children bringing unhealthy drinks was 89.6 and 44.7% carried unhealthy complements. In the urban area, the highest prevalence of unhealthy drink was 82.2% and 89.9% of unhealthy complements. The schoolchidren who resided in Lima Metropolitan had 33.4% of unhealthy drinks and 45.9% of unhealthy complements. Children who resided in the cost had 27.7% of unhealthy drinks and 26.8% of unhealthy complements. The drink most consumed were soda or artificial nectar (15.8%), water or sugar-free drink (10.4%), and

natural fruit soda with sugar (10.1%). The complement most consumed were the Sandwich with jams, butter, cheese, chicken, hamburger (21.6%), cookies (17.2%) and preparation make in home as Steak (14.9%) and yogurt (9.5%).

Conclusions: The prevalence of unhealthy lunchboxes in Peruvian schoolchildren is high, predominating in urban areas, Metropolitan Lima and the Peruvian coast

NUTRITIONAL STATUS AND FAMILY SOCIOECONOMIC LEVEL OF CHILDREN ATTENDING A SELECTED SCHOOL

[1]Araujo Pino, Silvia Stella; [2]Ruiz Díaz Quintana, Edith Victoria; [2]Velázquez López, Wilma Noelia; [1]Morínigo Martínez, Macarena.

[1]Nutritionist. Department of Nutrition Research. Faculty of Chemical Sciences. National University of Asuncion. Paraguay; [2]Nutritionist. Faculty of Chemical Sciences. National University of Asuncion. Paraguay.

Background and objectives: The growth and development of a child and its health trajectory are closely linked to its nutritional status (NS), suggesting that the latter could reflect the family socioeconomic and cultural level. Therefore, we set out to identify the NS and the socioeconomic level (SEL) of children Basic School No. 264 of the city of San Lorenzo, Paraguay.

Methods: The research was framed in the Institutional Project "Healthy Child Healthy Country" of the Faculty of Chemical Sciences, which in 2015 helped school No. 264. The sample consisted of 41 students between 5 and 12 years old. We evaluated the NS of the children through the Body Mass Index for age (BMI / E) and height for age (T / E) from the WHO 2007 standart. We used the SEL index of the Mexican Association Of Market Intelligence and Opinion (AMAI). We collected the anthropometric data in the school and the socioeconomic survey we do it to the heads of the home in their respective houses.

Results: Children had a mean age of 9.3 ± 1.7 years, mean weight of 27.4 ± 9 kg, mean height of 121.1 ± 13.7 cm and mean BMI of 17 ± 2.7 kg / m2. According to IMC / E, 68.3% of the children were eutrophic and 24.4% were overweight or obese, while for age (T / E), 75.6% of the children were of normal height. 58.5% of the families were of the low SEL. We found that in the high NSE 73.1% of the children were eutrophic vs 60% in the low NSE, the excess weight was higher in the high NSE than in the low NSE (33.3% vs 19.2%). Finally, 6.7% of the children had low stature in the high SES vs. 3.8% in the low SES.

Conclusions: We found that cases of excess weight and risk of stunting coexist in children in the high NSE of the school No. 264.

Keywords: Nutritional status, socioeconomic level, children, double burden

THE HEALTHY KITCHENS, HEALTHY CHILDREN STUDY; A COMMUNITY-BASED SCHOOL NUTRITION INTERVENTION IMPROVES DIET DIVERSITY IN PALESTINIAN REFUGEE SCHOOLCHILDREN IN LEBANON

[1]Jamaluddine, Zeina; [2]Ghattas, Hala; [3]Choufani, Jowel; [4]Sahyoun, Nadine.

[1]M.S.Research assistant. Center for Research on Population and Health. American University of Beirut. Lebanon; [2]PhD. Assistant Research Professor. Center for Research on Population and Health. American University of Beirut. Lebanon; [3]MPH. Senior Research Assistant. Environment and Production Technology Division. International Food Policy Research Institute. US; [4]PhD. Professor. Department of Nutrition and Food science. University of Maryland. US.

Background and objectives: Palestinian refugees in Lebanon are protracted refugees with high rates of food insecurity and low diet quality. In this context we implemented a school nutrition intervention that consisted of a subsidized nutritious snack, plus nutrition education in two elementary schools. We assessed the impact of this intervention on diet diversity and nutritional status of schoolchildren receiving the intervention as compared to children attending two neighboring schools who only received the nutrition education component.

Methods: We collected socio-demographic and nutrition status data from 1433 students (aged 5-15y) and their parents at baseline, and 1362 at 8-months follow-up in 4 schools. Snacks were sold at a subsided price, 5 days a week in two intervention schools. We conducted a difference in difference analysis for diet diversity and hemoglobin levels of children who participated in the intervention at least 50% of the time (high-participation) as compared to those who participated less than 50% (low-participation), or who only received nutrition education (control). Analyses were adjusted for child age and gender, maternal education, household expenditure and school cluster effect.

Results: There were 648 children in the control group, 260 children in the low-participation group, and 454 in the high-participation group. After adjusting for co-variates, there was a significantly greater increase in overall diet diversity score in the high-participation group than in controls (p=0.016), but not in the low-participation group. However, both low and high-participation groups had higher odds of consuming meat or chicken as compared to control; OR=1.8; p=0.000 and OR= 2.1; p=0.006 respectively. The high-participation group also had higher odds of consuming dairy (OR = 1.22; p=0.000), and lower odds of consuming sweetened beverages (OR= 0.73; p=0.015) and desserts (OR= 0.57; p=0.011) than control. Both low and high-participation groups had inversely and significantly changes in hemoglobin (Δ=+1.6mg/dl) as compared to the control group (Δ = -1.0mg/dl); p=0.05.

Conclusions: A community-based school nutrition intervention improved diet diversity and hemoglobin levels of refugee children that had participation level above 50%.

BASELINE AND PROCESS EVALUATION ANALYSIS OF A RURAL NUTRITION-SENSITIVE INTERVENTION WITHIN THE FIRST 1000-DAY WINDOW OF OPPORTUNITY IN CENTRAL AMERICA AND DOMINICAN REPUBLIC, 2016-2019

[1]Perez, Wilton; [2]Roman, Ana Victoria; [3]Roldan, Evelyng; [4]Siu, Carolina.

[1]PhD. Epidemiologist. Department of monitoring and evaluation. Institute of Nutrition of Central America and Panama. Guatemala; [2]PhD. Food Science and Technology. Institute of Nutrition of Central America and Panama. Guatemala; [3]MSc. Nutritionist. Nutrition and Micronutrient Department. Institute of Nutrition of Central America and Panama. Guatemala; [4]MSc. Public Health. Direction. Institute of Nutrition of Central America and Panama. Guatemala.

Background and objectives: The first 1000-day window of opportunity is a crucial period for largest and efficient impact of food and nutritional interventions to reduce malnutrition in poor-resourced settings. Nutrition-sensitive interventions as agriculture have the potential to improve several determinants of food and nutrition status through the promotion of dietary diversity, household income improvement and women's empowerment. However studies that assess the impact in rural settings of Central America and Dominican Republic are lacking. In this study the aim is to determine the baseline level of food insecurity, agricultural food production capacity that will allow to generate evidence to support the implementation of an intervention focused on pregnant women and mothers with children less than 24 months old in rural areas of Central America and Dominican Republic.

Methods: A multi-component intervention was designed to increase agricultural management production of foods and improve family economy and to assess the impact on food and nutrition security for a three-year period, 2016-2019. Target communities were randomly selected from high-cluster of child growth retardation in seven countries. Around 850 rural families are expected to enrol. For baseline, food insecurity scale and socio-demographics factors were determined. An adequacy approach was used to evaluate the level of implementation of the project in areas of home gardening, educational activities on health and nutrition, agricultural practices, nutritional policy advocacy.

Results: One-third of the enrolled participants have a primary education level. Access to safe drinking water is reported in almost half of the households. Wood is the main fuel for cooking. Almost all families perform agricultural activities, but formal agricultural training to use local production for consumption is almost null.

Climate risk management training was found scarce and food insecurity affects almost one-fifth of the rural families.

Conclusions: Rural families in Central America and Dominican are highly vulnerable to food and nutritional insecurity. This situation may be worse in rural communities where lack of climate mitigation strategies is limited. Baseline information has been useful to design and strengthen capacities and enhance local food production of high nutritional value for self-consumption.

A SYSTEMATIC REVIEW AND META-ANALYSIS EXAMINING THE EFFECT OF DIET ON COGNITIVE FUNCTION IN COGNITIVELY HEALTHY ADULTS

[1]McEvoy, Claire; [2]Leng, Yue; [3]Peeters, Geeske; [4]Krup, Allison; [2]Allen, Isabel; [5]Yaffe, Kristine.

[1]PhD. Visiting Research Fellow. Department of Psychiatry. University of California San Francisco. USA; [2]1)PhD. Department of Psychiatry. University of California San Francisco. USA; [3]1) PhD. Global Brain Health Institute. Trinity College Dublin. Ireland; [4](3)PhD. Department of Psychiatry. University of California San Francisco. USA; [5]1)MD. Departments of Psychiatry, Neurology, and Epidemiology and Biostatistics. University of California. San Francisco. USA.

Background and objectives: Cognitive impairment is a major public health concern due to increasing prevalence, high morbidity and rising socioeconomic burden. Modifying dietary behaviour could be a promising way to reduce age-related cognitive decline, however findings from clinical trials have reported inconsistent results. The objective of this systematic review was to examine the effectiveness of diet interventions on domains of cognitive function in adults without known cognitive impairment.

Methods: PubMed, EMBASE and PsycINFO were systematically searched to December 2016 to identify randomised controlled trials (RCTs) that examined the effect of diet on cognitive function or dementia events in cognitively healthy adults > 18 years. Data extraction and Cochrane risk of bias for included RCTs were performed by two independent reviewers. Standardized mean differences (95% CI) were combined, using a random-effects meta-analysis.

Results: Fourteen RCTs in 6370 participants (3333 diet intervention and 3037 control) were included. Diet significantly improved performance on measures of global cognition (SMD = 0.16; 95% CI 0.02, 0.30, P = 0.02), executive function (SMD = 0.11; 95% CI 0.04, 0.18, P = 0.003) and information processing speed (SMD = 0.12; 95% CI 0.05, 0.19, P = 0.001) compared to control. Significant heterogeneity (I2 = 79%) and funnel plot asymmetry was detected only for global cognition. RCTs were graded as low (n =1,7%), moderate (n = 7, 50%) or high (n = 6, 43%) risk of bias.

Conclusions: The pooled analysis of available RCT data showed small positive effects of diet on non-memory cognitive domains in adults without known cognitive impairment. Further studies are required to determine the therapeutic potential of diet on rate of cognitive decline and for dementia prevention.

Keywords: Diet, cognitive function, meta-analysis

Unité Mixte de Recherche en Nutrition et Alimentation. Université Ibn Tofaïl. Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [(4)]PhD. Unité Mixte de Recherche en Nutrition et Alimentation. Université Ibn Tofaïl. Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [(5)]Prof. Unité Mixte de Recherche en Nutrition et Alimentation . Université Ibn Tofaïl.Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.

Background and objectives: Physical activity (PA) in childhood plays an important role in reducing the risk of cardiovascular health diseases, diabetes and obesity in adulthood. According to this evidence, it has been recommended for children to participate in at least 60 minutes per day in Moderate-to-Vigorous PA (MVPA).The present study examined gender differences in objectively measured sedentary behavior, physical activity, and physical activity guideline attainment among Moroccan children.

Methods: In total, 173 children 49.1% are boys, aged between 8 to 14 years old participated in this study. To asses PA, children wore triaxial accelerometer for 7 consecutive days and had at least 4 days wearing with minimum 10 h-wearing time per day.

Results: Participant spent 533.16± 87.82(min/day) in sedentary behavior accounted for 62.8% of average daily wearing time. Boys were more physically active and took more steps/day than girls,(11632.88±3713.41 vs 9526.05±2870.84 min/day, p <0.001). Girls spent equal time in sedentary than boys (258.65±51.18/day vs 258.54±50.70min/day; p=0.421). Boys were eight times more likely to meet physical activity guidelines than girls (OR: 8.06, 95 % CI: 4.03–16.13) p<0.0001.

Conclusions: Boys engaged in more physical activity and were more likely to attain guidelines than girls. These findings highlight the need for effective and sustainable strategies and programs aiming to promote physical activity and to reduce sedentary behavior among Moroccan children, specially for girls.

Keywords: Accelerometery. Children. Physical activity. sedentary time.

HEALTH BENEFITS AND COST SAVINGS OF TWO WEIGHT LOSS INTERVENTIONS: DIETARY COUNSELLING BY PRACTICE NURSES AND PROMOTING SMARTPHONE WEIGHT LOSS APPS

[(1)]Cleghorn, Christine; [(2)]Wilson, Nick; [(3)]Nair, Nisha; [(4)]Kvizhinadze, Giorgi; [(4)]Nghiem, Nhung; [(3)]McLeod, Melissa; [(5)]Blakely, Tony.

[(1)]PhD. Research Fellow. Department of Public Health. University of Otago. Wellington. New Zealand.; [(2)]MPH. Professor. Department of Public Health. University of Otago. Wellington. New Zealand; [(3)]MPH. Senior Research Fellow. Department of Public Health. University of Otago. Wellington. New Zealand; [(4)]PhD. Research Fellow. Department of Public Health. University of Otago. Wellington. New Zealand; [(5)]PhD. Professor. Department of Public Health. University of Otago. Wellington. New Zealand.

Background and objectives: Obesity is an important risk factor for many chronic diseases which cause premature death, reduce quality of life and are expensive for health systems. Dietary counselling by practice nurses and mHealth interventions are two approaches which can offer information and support to those attempting to lose weight. Here we model the effect of these two interventions on health gain (quality-adjusted life-years (QALYs)) and health system costs.

Methods: The modelled interventions were a mHealth promotion intervention using currently available smartphone apps and dietary counselling by dietician trained practice nurses. A multi-state life-table model was used to project all-cause mortality and morbidity rates by sex and age for the New Zealand population (including Māori, indigenous population). It includes 14 Body Mass Index related disease life-tables, where proportions of the modelled population simultaneously reside. The change in incidence in these disease life-tables flows through to impact on mortality and morbidity to change QALYs and associated health system costs.

Results: The smartphone app promotion intervention was estimated to generate 150 QALYs (95%UI: 100 to 210) over the lifetime of the population. It also generated US$2.7 million [m] (95%UI: 1.7 to 4.0m) in savings to the health system. Greater impacts were seen from dietary counselling by practice nurses with 1350 QALYs gained (95%UI: -230 to 3110) and cost-savings of US$22.1m (95%UI: -4.0 to 51.7m), however the uncertainty interval includes zero indicating that this intervention may not generate health gains. Those individuals receiving the intervention could expect to increase their average number of days lived in good health by approximately 1 day for the mHealth intervention and 2 days for the counselling intervention.

Conclusions: In this modelling study, these two weight loss interventions were associated with relatively small health gains at a population level. Nevertheless, these are likely to be cost-saving interventions, especially the mHealth one, and could therefore still form a small component of a wider obesity reduction strategy (especially if app quality and uptake increases in the future). However, other strategies to change the obesogenic environment (marketing controls, taxes/subsidies etc.) are more effective in controlling obesity in this type of developed country.

Keywords: Weight loss; Cost-effectiveness modelling; Smartphone apps; Dietary counselling.

Department of Preventive Medicine and Public Health. University of Navarra. Pamplona, Spain.; [5]Prof. Biologist. Department of Biochemistry and Molecular Biology II and Institute of Nutrition and Food Sciences. University of Granada. Granada. Spain; [6]Prof. Pharmacist. ImFINE Research Group. Department of Health and Human Performance. Technical University of Madrid. Spain; [7]Prof. Pharmacist. Department of Nutrition. Faculty of Pharmacy. Madrid Complutense University. Madrid. Spain; [8]PhD. Physician. Research Institute of Biomedical and Health Sciences. University of Las Palmas de Gran Canaria. Las Palmas de Gran Canaria. Spain.; [9]Prof. Pharmacist. Department of Pharmaceutical and Health Sciences. Faculty of Pharmacy. CEU San Pablo University. Madrid. Spain.

Background and objectives: Background: The increase in obesity prevalence is well known and many factors can play an important role in its development. The relative contributions of energy intake and expenditure to the obesity epidemic, however, remain poorly defined in Spain. Moreover, few studies in our country undertake the investigation of subject's perception on their nutritional status and its relation with socioeconomic status in the Spanish population.

Objectives: To analyse the relevance of perception, attitudes and socioeconomic status in relation to body composition

Methods: A total de 2009 individuals (1,013 men, 996 women), aged 9–75 years from the ANIBES cross-sectional Study using a nationally-representative sample from the Spanish population

was studied. The following variables were investigated: age groups, gender, geographical distribution, locality size, unemployment rate, percentage of foreigners, education or economic level, anthropometric factors Anthropometry measurements (weight, height, body mass index, waist circumference, % body fat, % body water), perceived health, quality of life and diet.

Results: Body fat percentage (%) decreases with increasing habitat size, population density (χ^2 =0,042) and socioeconomic status (χ^2 =0,000). Individuals have a clearer perception of their weight (χ^2 =0,000) as well as their diet (χ^2 =0,000) related to body fat composition. A better health status perception is observed in subjects with lower BMI values, while higher BMI subjects declare a higher effort to improve their diets (χ^2 =0,004). At normal BMI values, better perception of weight and diet (χ^2 =0,000) and at lower BMIs, subjects declare higher number of hours of sleep (χ^2 =0,000).

Conclusions: Self-reported perception on diet and health status are associated with an adequate body image in the Spanish population. In addition, subjects living in cities with higher population density and having a better socioeconomic status present lower obesity prevalence.

Keywords: Body Mass Index, Obesity, perception, socioeconomic status

THE PARTICIPATION OF NUTRITIONISTS AS A SOURCE OF INFORMATION FOR PRESS ARTICLES RELATED TO OBESITY, PUBLISHED DURING THE YEARS 2008-2013 IN COLOMBIA

[1]*Correa-Madrid, María Camila;* [2]*Isabel Cristina, Carmona Garcés;* [3]*González-Zapata, Laura Inés.*

[1]Nutritionist. Universidad de Antioquia. Colombia.; [2]Nutritionist. MSc Educación. Profesora Asistente. Escuela de Nutrición y Dietética. Universidad de Antioquia. Grupo de Investigación Interdisciplinaria en Educación para la Salud y Educación Nutricional. GIIESEN. Universidad de Antioquia. Colombia; [3]PhD. Nutritionist. School of Nutrition and Dietetics. University of Antioquia. Medellín. Colombia.

Background and objectives: Overweight and obesity are a public health problem in Colombia. By 2010 one in two colombians had one of these problems. One of the functions of the mass media is to mobilize society around this topics and is very important the participation of nutritionists as a part of the nutrition education in these kind of communication channels. The aim of this paper is to describe the participation of nutritionists as a source of information supporting the publication of articles about obesity in newspapers during the years 2008-2013.

Methods: Cross-sectional study. 163 news were selected from two newspapers; 48 from El Espectador and 115 from El Colombiano. A descriptive analysis was performed using X2 tests to establish the relationship between the variables of interest. α = 0.05. SPSS v.18.

Results: During the study period a gradual increase in news related to obesity was found. The most used source of information in the news was scientific-academic (42.3%) and only 6.7% of the articles used nutritionist as a source. When a nutritionist was used as a source to produce the news, there is not an association between the topic and the source.

Conclusions: The newspaper articles related with obesity increased in Colombia. The challenge for nutritionists is to gain participation in mass media like press, in order to achieve the objectives around the prevention and control of this issue.

Keywords: Obesity; press; mass media; health communication.

USE OF MARKETING TECHNIQUES ON A SELECTED SAMPLE OF FOOD PACKAGES IN ARGENTINA

[1]Allemandi, Lorena Andrea; [2]Castronuovo, Luciana; [3]Tiscornia, María Victoria; [4]Gutkowski, Patricia; [5]Nessier, Celeste; [5]Gijena, Julieta.

[1]Bsc. Public Health. Fundación InterAmericana del Corazón Argentina. Argentina.; [2]PhD. Sociology. Fundación InterAmericana del Corazón Argentina. Argentina.; [3]BSc. Nutritionist. Fundación InterAmericana del Corazón Argentina. Argentina.; [4]BSc. Communication Science. Fundación InterAmericana del Corazón Argentina. Argentina.; [5]MSc. Nutritionist. Universidad Catolica de Santa Fe. Argentina.

Background and objectives: Marketing of unhealthy foods plays an important role in the rising prevalence of childhood obesity. Product packaging is a significant marketing method. The objective of our study was to investigate marketing techniques (characters and premium offers) used on food packages of a selected sample of products.

Methods: Data for breakfast cereals, cookies and milk desserts was collected at a major supermarket chain in Argentina in June 2016. Pictures were taken on the front, sides and back of all products, including Nutrition Information Panel (NIP) and ingredient list. We translated and adapted the internationally standardised International Network for Food and Obesity/Non-Communicable Diseases Research, Monitoring and Action Support (INFORMAS) protocol. Pictures and nutrient data from the NIP were entered into a food database designed and tested for this study. For the analysis of nutritional quality we used the PAHO and the WHO Europe nutrient profiles (NP) models. Statistical analysis were conducted using R Statistical software.

Results: We analyzed 301 food packages: 42 breakfast cereals, 209 cookies and 50 milk desserts. Premium offers were found in 18% (n=55) of all products, 45% of this were found on the front side of the packages (n=25). Promotional characters appeared on 32% (n=95) of all products, of those 69% (n=56) appeared on the front side of the package.

In each category, 62% (n=31) of breakfast cereals, 25% (n=52) of cookies and 62% (n=31) of milk desserts featured promotion-al characters, and 2% (n=1) of breakfast cereals, 16% (n=33) of cookies and 42% (n=21) of milk desserts included premium offers.

Products with one excess nutrient (PAHO NP model) had significantly more promotional characters and premium offers (p<0.0005). Only 23% (n=9) without excess nutrients included promotional characters and 3% (n=1) included premium offers.

Conclusions: Promotional characters and premium offers are used to promote unhealthy food products in Argentina. Evidence-based public health policies should restrict the use of these marketing techniques on products with high levels of sugars, fats and/or sodium, especially when children are exposed to them.

NUTRITIONAL STATUS OF THE PEOPLE ASISTED IN THE PRIMARY LEVEL HEALTH SERVICES IN MONTEVIDEO AND INLAND OF URUGUAY

[1]Elichalt, Marta; [2]Gronros, Diana.

[1]MSc. Nutritionist. Nutrition School. University of the Republic. Uruguay.; [2]Nutritionist. Nutrition School. University of the Republic. Uruguay.

Background and objectives: To characterize the nutritional status (NS) of the assisted population in primary care services in Montevideo and inland between April and November 2016. To compare the type and magnitude of the nutritional problems between services of Montevideo and it's inland, and between services of Montevideo, according to municipal grouping based on the proportion of poor families (PF).

Methods: The information collected by the students in the last year of the Nutrition Degree was systematized, and they applied a survey with Google forms. The information collected was: sex, age, reason for referral, anthropometric diagnosis and service. The NS in children was assessed by anthropometric indicators and compared with WHO standard on 2006. In adults, the body mass index was used and compared with the WHO reference on 1998. The services were grouped by location considering the municipal division of Montevideo according to the proportion of FP by level of income.

Results: The assisted population was 1982 corresponding to 17 services. Of all, 75% were women and almost half were over 18 years of age. 50% of referral reasons were Non-Communicable Diseases. Over-malnutrition exceeded the value identified in studies at the national level in one-third of services. Deficit malnutrition varied in services between 5% and 20%. In children under 18, the prevalence of malnutrition due to deficit and excess was bigger than in other national studies. There are important differences in malnutrition due to deficit and excess in adults and children among services with a higher proportion of PF.

Conclusions: There are problems of excess and deficit that surpass the national data. The nutritional stage in which the user is captured and the proportion of PF are probably determinants

---

of the type and magnitude of the nutritional problems found in nutritional care.

THE EFFECT OF PEER SUPPORT ON CARDIOVAS-CULAR RISK FACTORS: A META-ANALYSIS

[1]McEvoy, Claire; [2]McAuley, Emma; [3]Moore, Sarah; [4]Cupples, Margaret; [5]Kee, Frank; [6]Young, Ian; [3]McKinley, Michelle; [3]Woodside, Jayne.

[1]PhD. Centre for Public Health. Queen's University Belfast. UK; [2]Medical Student. Centre for Public Health. Queen's University Belfast. UK; [3]PhD. Centre for Public Health. Queen's University Belfast. UK; [4]MD. Centre for Excellence in Public Health. Queen's University Belfast. UK; [5]MD. Centre for Excellence in Public Health. Queen's University Belfast. UK; [6]MD. Centre for Public Health. Queen's University Belfast. UK.

Background and objectives: Diet interventions are effective for prevention of cardiovascular disease (CVD) but are generally resource intensive and prohibitively expensive to scale-up for wider public health benefit. Social support provided by lay people (peer support) is an alternative low-cost approach to facilitate self-management of diet behaviour, but the effect of peer support on health outcomes is not clear. This systematic review aimed to evaluate the effect of peer support on CVD risk.

Methods: PubMed, EMBASE and CINAHL were systematically searched to identify randomised controlled trials (RCTs) addressing the effect of peer support on CVD risk factors including, obesity, markers of diabetes risk, blood pressure and blood lipid levels in adults > 18 years. Data extraction and assessment of bias were performed by two independent reviewers and data were pooled using a random-effects meta-analysis.

Results: Twenty-six RCTs were included in the review. Peer support showed significant improvements in glycaemic control (HbA1c -0.22% [95% CI -0.40, -0.04] P = 0.02) and obesity (BMI -0.83kg/m2 [95% CI -1.58, -0.07], P = 0.03) in comparison to control, with evidence of significant heterogeneity across studies (I2 = 49%, and 59% respectively) and funnel plot asymmetry. There was no significant effect of peer support on blood pressure or lipid levels. Most RCTs (n =18, 69%) were graded as high risk of bias.

Conclusions: Despite some evidence supporting a beneficial effect of peer support for established vascular risk factors, trials were heterogeneous with poor methodological quality, which limits the ability to draw firm conclusions. There is a need for further well-designed RCTs to evaluate the effect and sustainability of peer support on cardiovascular disease risk.

Keywords: peer support, cardiovascular risk factors

ENERGY EXPENDITURE BY DOUBLY LABELED WATER COMPARED TO PHYSICAL ACTIVITY MEASURED BY TRIAXIAL ACCELEROMETER IN MOROCCAN CHILDREN

[1]Baddou, Issad; [1]El Harchaoui, Imane; [2]Benjeddou, Kaoutar; [3]El Kari, Khalid; [1]Saeid, Naima; [4]Elmzibri, Mohamed; [3]El Hamdouchi, Asmaa; [5]Aguenaou, Hassan.

[1]PhD Student. Unité Mixte de Recherche en Nutrition et Alimentation. Université Ibn Tofaïl. Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [2]PhD Student. Unité Mixte de Recherche en Nutrition et Alimentation. Université Ibn Tofaïl. Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [3]PhD. Nutrition reseracher. Unité Mixte de Recherche en Nutrition et Alimentation. Université Ibn Tofaïl. Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [4]PhD. Unité Mixte de Recherche en Nutrition et Alimentation. Université Ibn Tofaïl. Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [5]Prof. Unité Mixte de Recherche en Nutrition et Alimentation . Université Ibn Tofaïl.Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.

Background and objectives: A large numbers of methods are used for the assessment of physical activity. The ability to assess accurately physical activity (PA) in free-living conditions is extremely important in the global context of non-communicable diseases. The purpose of the study is to examine the association between physical activity Energy Expenditure (PAEE) measured using triaxial accelerometer (GT3X+) and energy expenditure (EE) measured using the doubly labeled water (DLW) method in free-living of 11-14y old Moroccan children.

Methods: Total Energy Expenditure (TEE) was measured in 21children over a fourteen-day period during the school year. Physical activity was measured simultaneously using accelerometry over seven consecutive days. TEE was also calculated from the Actigraph using a published equation.

Results: 21 children (mean z-score BMI (-0.45± 1.47 kg/m2), mean age (12.10± 0.80 year) participated in this study. TEE measured using (DLW) was significantly higher than TEE estimated by accelerometry ((10.03± 2.14 MJ /day) vs (8.12± 1.08 MJ /day); p <0.001), also PAEE measured using (DLW) was significantly higher than PAEE estimated by accelerometry (3.66 ± 1.59 MJ /day) vs (1.95 ± 0.87 MJ/ day) ; p <0.001). Positive correlation between DLW outcomes and physical activity intensity measured by accelerometry was only observed with light intensity physical activity, specifically with PAEE (Rho =0.468 (p=0.025)) and PAL (Rho =0.621 (p=0.002).

Conclusions: PAL and PAEE were influenced by time spent in light-intensity activities. This study suggests that in this sample of children, light activity seems to contribute mainly to free-living PAEE and PAL. Further studies to assess these variations are needed particularly in low- and middle-income countries.

Keywords: Accelerometry, Doubly labeled water, Energy expenditure, Physical activity

NUTRITIONAL INTERVENTION PROGRAM "PANI" OF BENEFICIARY CHILDREN ATTENDING THE REGIONAL HOSPITAL OF CONCEPCIÓN

[1]Nuñez, Ninfa; [2]Sanabria, Marta; [3]Aguilar, Gloria; [3]Sanchez, Raquel; [3]Arguello, Brunilde.

[1]MsC. Paraguay; [2]Universidad Nacional de Asuncion. Paraguay; [3]Universidad Nacional de Caaguazu. Paraguay.

Background and objectives: Introduction: Anti-hunger programs have proven to be effective tools for reducing the prevalence of child malnutrition. There are just a few researches of results about patients beneficiaries of the national anti-hunger program.

Objective: To evaluate the effect of anti-hunger program "PANI" in anthrometric and biochemical indicators in children of 4 months to 5 years old, at risk of malnutrition and malnourished attending the regional hospital of Concepcion when entering the program versus six months of intervention.

Methods: Material and method: Quasi - experimental design. Showing: 195 children under the age of five beneficiaries attending clinics at the regional hospital of Concepcion. Variables studied: Weight, height, sex, origin, maternal age, maternal education, practice of exclusive breast feeding, parasites, presence of fluent and clear water and basic sanitation. Score z weight/age, z weight/size and z height/age (WHO Standards). Biochemical indicators of Hb, VCM and ferritin. Parametric and non parametric measures were used. It was considered p<0,05.

Results: 51,8% were male. The average of age were 22,9 months (4 - 59 m). 61,2% were under five years old, teen mothers 12,8% , with less than six years of study 18,5%, prevalence of exclusive breast feeding 10,3%. The prevalence of malnutrition on admission was 17,9% . The severe malnutrition was 4,6% , at risk of malnutrition are 66,2%, with acute malnutrition are 10,8% with chronically malnutrition 28,7%. It was observed a significant decrease in prevalence with malnutrition after six month of treatment, of 15,6% vs 4,4% (p<0,01), prevalence at risk of malnutrition had decreased from 72,6% to 27,6% after six month of treatment. At the admission anemia was recorded 64%) Hb 10,5 g/dL±1,27DE, VCM 74,2 ± 9,03, Ferritin 30,5 ug/L ± 23,58. At the sixth month of treatment was an improvement without anemia 37% vs 55,6% . Finally regarding adherence to regular monitoring (6 visits) 42, 6% irregular (≤5) 44, 6%, neglect 12,8%.

Conclusions: In Concepcion is found a statistically significant decrease of the parameters, anthropometric and biochemical at the sixth month of treatment of the anti-hunger program.

Keywords: nutritional program, children, malnutrition, anemia

NUTRITION AND HEALTH CLAIMS ON A SELECTED SAMPLE OF FOOD PACKAGES IN ARGENTINA

[1]Tiscornia, María Victoria; [2]Castronuovo, Luciana; [3]Allemandi, Lorena Andrea; [4]Gutkowski, Patricia; [5]Nessier, Celeste; [6]Gijena, Julieta.

[1]Bsc. Nutritionist. Fundación InterAmericana del Corazón Argentina. Argentina.; [2]PhD. Sociology. Fundación InterAmericana del Corazón Argentina. Argentina.; [3]BSc. Public Health. Fundación InterAmericana del Corazón Argentina. Argentina.; [4]BSc. Communication Science. Fundación InterAmericana del Corazón Argentina. Argentina.; [5]MSc. Nutritionist. Universidad Católica de Santa Fe. Argentina; [6]BSc. Nutritionist. Universidad Católica de Santa Fe. Argentina.

Background and objectives: Nutrition and health claims have been documented to influence consumers perceptions of products and their purchase decisions. We assessed the use of nutrition and health claims according to the nutritional quality of products.

Methods: Data for breakfast cereals, cookies and milk desserts was collected at a major supermarket chain in Argentina in June 2016. Pictures were taken on the front, sides and back of all products, including Nutrition Information Panel (NIP) and ingredient list. We translated and adapted the internationally standardised International Network for Food and Obesity/Non-Communicable Diseases Research, Monitoring and Action Support (INFORMAS) protocol. Pictures and nutrient data from the NIP were entered into a food database designed and tested for this study. For the analysis of nutritional quality we used the PAHO and the WHO Europe nutrient profiles (NP) models. Statistical analysis were conducted using R Statistical software.

Results: Claims were analyzed for 301 food packages: 42 breakfast cereals, 209 cookies and 50 milk desserts. Of the total, 40% (n=119) had nutrient claims, most claims (73%-n=87) appeared on the front of package. Health claims featured on 9% (n=26) of packages and, of those, 27% (n=7) appeared on the front. For each category, nutrient claims appeared on 71% (n=30) of breakfast cereals, 50% (n=25) of milk desserts and 31% (n=64) of cookies and health claims appeared in 55% (n=23) of breakfast cereals, 2% (n=1) of milk desserts, and 1% (n=2) of cookies. From the total number of products that exceed the WHO Europe NP model thresholds (n=273), 36% (n=99) had nutrition claims and 4% (n=10) had health claims (p<0.0005). From the total number of products that had excess in at least one critical nutrient (n=262) according to the PAHO NP model, 37% (n=97) had nutrition claims and 3.8% (n=10) had health claims (p<0.0005).

Conclusions: Many products that exceeded the thresholds of the selected Nutrient Profile Models had at least one nutrition or health claim. This suggests that, to prevent misleading consumers perceptions of nutritional quality of foods, the regulation of nutrient claims should be revised, so that only products with appropriate nutrient profiles are allowed to display them.

VITAMIN D DEFICIENCY, SOCIO-ECONOMIC STATUS AND DIETARY HABITS OF SCHOOL AGE CHILDREN IN RURAL OF MOROCCO

[1]Benjeddou, Kaoutar; [2]El Hamdouchi, Asmaa; [2]Rabi, Baha; [1]Saeid, Naima; [2]Raji, Fatiha; [3]Barkat, Amina; [2]El Kari, Khalid; [3]Aguenaou, Hassan.

[1]PhD. Joint Research Unit in Nutrition and Food. Ibn Tofaïl University. National Center for Energy Science And Nuclear Techniques. (African Regional Cooperative Agreement for Research/International Atomic Energy Agency). Rabat. Kénitra. Morocco; [2]Dr. Joint Research Unit in Nutrition and Food. Ibn Tofaïl University. National Center for Energy Science And Nuclear Techniques. (African Regional Cooperative Agreement for Research/International Atomic Energy Agency). Rabat. Kénitra. Morocco; [3]Prof. Joint Research Unit in Nutrition and Food. Ibn Tofaïl University. National Center for Energy Science And Nuclear Techniques. (African Regional Cooperative Agreement for Research/International Atomic Energy Agency). Rabat. Kénitra. Morocco.

Background and objectives: Micronutrients deficiencies can affect the growth and development of children. In Morocco many clinical studies showed that vitamin D deficiency is a public health problem. Very few foods naturally contain vitamin D and foods that are fortified with vitamin D can't satisfy human vitamin D requirement.The aim of this study is to determine vitamin D, socio-economic status and dietary habits of schoolchildren in a rural region of Morocco.

Methods: In an observational study, 191 school children aged 7-9 years selected from 3 primary schools. Weight, height, age and sex were recorded. Fasting blood samples were taken to assess vitamin D as serum [25(OH) D] concentration and questionnaires were used to determine socio-economic status and food frequency.

Results: Vitamin D deficiency was prevalent in schoolchildren; 65.8% of subjects had a 25 OHD <75 nmol/l and a median equal to 73.1nmol/l (Q1=65.9nmol/l and Q3=89.6nmol/l). The majority of families were illiterate. Dietary habits of deficient children showed that 21.6% consumed eggs, 3.4% fish, 5.2 %yogurt and 0.9% cheese at least once per day.

Conclusions: This study showed that among the school children in Morocco, the prevalence of vitamin D deficiency is very high and their diet is very poor in foods rich in vitamin D and thus can't satisfy children's growing needs.

Morocco; [3]PhD.Unité Mixte de Recherche Nutrition et Alimentation. CNESTEN- Université Ibn Tofail URAC39 Regional Designated Center of Nutrition Associated with AFRA/IAEA. Rabat. Morocco; [4]PhD. Reseacher.Unité Mixte de Recherche Nutrition et Alimentation. CNESTEN- Université Ibn Tofail URAC39 Regional Designated Center of Nutrition Associated with AFRA/IAEA. Rabat. Morocco; [5]PhD. Nutrition Reseacher. Unité Mixte de Recherche Nutrition et Alimentation. CNESTEN- Université Ibn Tofail URAC39 Regional Designated Center of Nutrition Associated with AFRA/IAEA. Rabat. Morocco.

Background and objectives: The school is an important setting for physical activity. Identifying determinants of sedentary behaviour and in particular those that are modifiable is a necessary step to develop effective interventions targeted at reducing sedentary time. This study is the first one of its kind in Morocco using objective method to assess sedentary time among children. The aim of this study was to synthesize the current evidence base on the determinants of sedentary behaviour specifically in school children.

Methods: 100 children aged between 8-14 years old (mean age =11.28±1.35years, 50% of boys) were recruited from different public schools. Moderate to Vigorous Physical Activity (MVPA) and sedentary time were measured by accelerometers GT3X+. Obesity was defined by the WHO reference body mass index (BMI)-for-age. School environment was assessed by adapted questionnaire

Results: 21% of children were overweight. Boys accumulated more minutes of MVPA compared with girls.56% of boys vs 16% of girls meet the recommendation of at least 60 minutes/day (p<0.0001). Children spent an average of 477.68 ±127.15 min/day in sedentary time. The most frequently available outdoor facilities for children across schools were soccer fields and playgrounds for other games. However, those areas are poorly equipped and most of them are built from cement. All schools programmed only 60 min per week of physical education. Also in the neighborhood surrounding the school, there aren't free/low cost facilities (recreation centers, clubs), there is a lack of outdoor playgrounds, cycle facilities, inaccessible sidewalks around schools caused by street vendors.

Conclusions: This study demonstrated that there is a gender difference in time spent in MVPA .Girls were less active compared with boys, and also that physical school environment factors can

influence children's physical activity levels and sedentary behavior, for example, school neighborhood and design, transport system and also reduced time of physical education per day. Our findings suggest that there is a need to design school environmental changes to promote physical activity in schoolchildren.

Keywords: School environment, children, sedentary, triaxial accelerometer, physical activity.

CHILDHOOD UNDERNUTRITION AND ITS DETERMINANTS AMONG UNDER-FIVE CHILDREN IN NIGERIA

[1]Uzokwe, Chinwe; [2]Landman, Jacqueline; [2]Nestel, Penelope.

[1]MSc. Public Health Nutritionist. Department of Human Nutrition and Dietetics. Michael Okpara University of Agriculture Umudike. Nigeria.; [2]PhD. Nutritionist. Faculty of Medicine. University of Southampton. United Kingdom.

Background and objectives: Child undernutrition continues to be a public health problem in Nigeria. Because few studies indicate the determinants of malnutrition among under-5s re-analysis of nationally representative data could help inform programme planning to meet the national target to reduce stunting and wasting by 20% and 10%, respectively by 2018. This study aimed to find determinants of stunting and wasting among 0-59 months old children in Nigeria.

Methods: A secondary data analysis of the 2011 Nigeria Multiple Indicator Cluster Survey (MICS) including all 25,192 children aged 0-59 months old surveyed. The prevalence of stunting was defined as height-for-age $\leq$-2SD and wasting as weight-for-height $\leq$-2SD of the WHO Growth Reference Standards . The UNICEF conceptual framework of malnutrition was used to build the logistic regression models, following chi-square tests on the MICS measures of the immediate, underlying or basic causes of undernutrition.

Results: The study confirmed that 35.8% and 10.2% of the children were stunted and wasted, respectively. Girls (12%, 15%), children who were no longer being breastfed (20%, 47%), absence of recent episodes of fever (12%, 21%), increase in maternal age (22-35%, 4-30%) and in duration of maternal education (14-36%, 13-18%) and households with higher wealth index (2-63%, 4-27%) were all at reduced risks of stunting and wasting. However, non-Christian children (47-48%, 18-49%) and children residing in the Northern Nigeria (55-64%, 11-39%) had increased risks of stunting and wasting. Children with no birth certificate had increased (23-28%), absence of diarrhoea episodes (15%) and household animals (19%) were associated with a reduced risk of stunting. Households with fewer toddlers ($\leq$2 under-5s) and $\geq$36 months-old were associated with a reduced risk of wasting.

Conclusions: Interventions to reduce child undernutrition should target children $\geq$36 months-old. They should also include strengthening of the Maternal and Child health system and health workers, improving the educational level of women especially in the Northern Nigeria and financial empowerment of women. Every State of the Federation should also develop a costed plan of action on nutrition to tackle the problem in their states.

Keywords: Stunting, wasting, determinants, children, developing countries

POSITION OF THE LATIN AMERICAN SOCIETY FOR NUTRITION ON CONFLICT OF INTEREST

[1]Garcia Chavez, Claudia Gabriela; [2]Sánchez-Bazán, Karina; [3]Barquera, Simon.

[1]MSc. Nutricionist. Center for Nutrition and Health Research. National Institute of Public Health. México.; [2]MPA. Center for Nutrition and Health Research. National Institute of Public Health. México.; [3]PhD. Center for Nutrition and Health Research. National Institute of Public Health. México.

Background and objectives: In November 2015, a group of researchers and nutrition professionals who are members of the SLAN [Latin America Society for Nutrition], sent the current Chair of the SLAN a request to take urgent action on conflict of interest in this society. This due to a critical concern for cases of inappropriate industry influences in the development of academic nutrition events. These measures should allow the research agenda and priority issues to be generated in discussions free of commercial influence. In order to clarify SLAN's relations with industry, the COI-SLAN committee has prepared Guidelines for Prevention and Management of Conflict of Interest [LPGCDI-SLAN].

Methods: Through the collaboration of some SLAN members representing a number of countries, such as Chile, Mexico, Guatemala and the United States, a consensus was reached to determine the guidelines through which the SLAN could be governed, with some Experts on the subject, established the guidelines for the management of conflict of interest of the SLAN (LGCDI-SLAN).

Results: The relationship of the food industry with professional groups are common and have become notorious and problematic in population health and nutrition. The SLAN, recognizes that health professionals and the organizations with which they collaborate have relationships with actors that could represent interest that conflict with the SLAN principles.

Conclusions: The LPGCDI-SLAN provide guidelines for identifying and proceeding with the CDIs that are presented around the Society. Being the first document on its kind, it will serve as a basis for strengthening this critical area for the health sciences.

Beijing Friendship Hospital. Capital Medical University. Beijing. China.; [5]PhD. Epidemiologist.School of Health and Society .University of Wollongong. NSW. Australia; [6]PhD. Epidemiologist. Associate Professor.School of Health and Society. University of Wollongong. NSW. Australia; [7]PhD. Epidemiologist. Behavioral Scientist. Department of Applied Health Science. Indiana Unversity. Bloomington. USA.; [8]PhD. Epidemiologist. Professor. Associate Dean. School of Public Health. Peking Union Medical College. Beijing. China.; [9]PhD. Professor. Dean. School of Public Health. Peking Union Medical College. Beijing. China.; [10]PhD. Epidemiologist. Professor. Director. National Institute of Environmental Health. China CDC. Beijing. China.

Background and objectives: In China, childhood obesity is becoming a significant public health problem. Family with high SES may increase purchasing power of obesogenic goods or control over of children's time which may amplify the children's risk for obesity. We investigated whether parent's educational attainment affect the eating behaviour, physical activity and sedentary activity for weekday and weekend among children.

Methods: A national school-based survey was conducted in China. A total of 11,439 fourth to six grade school children, 11,439 of their fathers or mothers were sampled using a multistage cluster random sampling method. Height and weight was measured for children and self-reported height and weight was collected for parents. Questionnaire collected information on eating behavior, physical activity and sedentary activity for weekday and weekend. Logistic regression models were used to describe the association between educational attainment of parents and children's weight status, eating behavior, physical activity and sedentary activity for weekday and weekend.

Results: Approximately 20% of fourth to six grade school children in urban areas and 12.6% in rural areas were overweight and obese, and 8.5% in urban areas and 4.7% in rural areas were obese. Children whose parents had higher SES were more likely to be overweight or obese, regardless of the weight status of parents (P<0.05). More than one parent having a high school level or above was positively related to healthy eating behaviours among children and negatively related to high-calorie eating behaviours (P<0.05), but associations with consuming western fast food once a day were positive in rural areas (P<0.05), and association with sedentary activity on weekend, i.e., homework, indoor extracurricular activities were positive both in urban and rural areas.

Conclusions: Results highlight the relevance of investigating eating behaviours, physical activity, and sedentary activity for weekday and weekend. Compared with environmental factor, knowledge and eating behaviours appear only minor effects on the rising of childhood obesity in China. In addition to continued focus on school –based intervention, target parent support for weekend physical activity and sedentary activity may be health promotion priorities. Effective intervention should take academic performance into account.

Keywords: childhood obesity, eating behaviour, physical activity. sedentary activity. Parental control.

CHARACTERIZATION OF THE CONSUMPTION OF LIQUID BEVERAGES IN INHABITANTS OF MEDELLIN, COLOMBIA

[1]Deossa Restrepo, Gloria Cecilia; [2]Deossa Restrepo, Gloria Cecilia; [3]Restrepo, Luis Fernando; [4]Rodríguez, Holmes.

[1]Nutritionist dietitian. Specialist and master in food science and human nutrition. Professor. School of nutrition and dietetics. University of Antioquia. Medellin. Colombia.; [2]Nutritionist dietitian. Specialist and master in food science and human nutrition. Professor. School of nutrition and dietetics. University of Antioquia. Medellin. Colombia.; [3]Statistician. Specialist in statistic and Biomathematics. Associate professor. Research group GISER. Faculty of agricultural sciences. University of Antioquia. Medellin. Colombia; [4]Agricultural engineer. PhD. Assistant Professor Faculty of Agricultural Sciences. University of Antioquia. Group GISER. Colombia.

Background and objectives: Background: To evaluate the consumption of liquid and the amount of them consumed per day, is important for health professionals, to design policies that relate to a better well-being of the community in this aspect, in order to prevent diseases that can be derived of inadequate intake of liquids. Objective: To compare between both sexes, the taste for the consumption of different types of drinks and the quantity consumed per day. The study was conducted in inhabitants of Medellin Colombia in over 18 years of age

Methods: We used multivariate analysis of variance (MANOVA) with canonical orthogonal type contrast, multiple correspondence analysis with indexed hierarchical classification, one-dimensional and two-dimensional frequency analysis.

Results: A significant difference was detected between sexes in the taste to consume aromatic drinks, and dietary soda (p<0.05), No difference was detected (p>0.05) in the amount of fluid consumed per day by sex.

Conclusions: The main conclusion is that more than 80% of those surveyed like to consume water frequently and claim to

Keywords: Water, consumption of liquid beverages

EVALUATION OF THE INTENTION OF CONSUMPTION OF FRUITS, AND VEGETABLES OF THE EMPLOYEES OF AN EVENTS SPACE IN THE CITY OF SÃO PAULO - BRASIL

[1]Toscano Ferreira, Rosana; [1]Korukian Freiberg, Clara; [2]Rocha, Amanda Araújo de Assis.

[1]MSc. Nutritionist. Nutrition of Department. São Camilo University Center. São Paulo. Brazil.; [2]Nutritionist. Nutrition of Department. São Camilo University Center. São Paulo. Brazil.

Background and objectives: Fruits and vegetables are essential components of a healthy diet. They have low energetic density, high fiber content, antioxidant components, besides being sources of micronutrients. The World Health Organization advocates consumption of at least 400 g / day. Studies indicate that fruit and vegetable consumption (FLV) is below recommended levels and is among the top ten factors in determining the global burden of disease in the last decade. The main objetive of this study was to evaluate the intention of FLV consumption of employees of a space of events.

Methods: This is a cross-sectional, non-directional, quantitative, descriptive and analytical study. We collected quantities of servings served by the employees, in four days of October / 2014 characterizing the consumption intention. It was stipulated as adequate consumption when the total amount of FLV / day was greater than or equal to 120 g. An average of sixty clients was evaluated, totaling an analysis of 240 meals.

Results: In the menu we observed the incidence of two types of salads daily, besides the presence of fruit in 75% of the days. The presence of tubers (mandioquinha and potato ball) was observed as salads in 50% of the days. 20.4% of the meals did not have any type of salad and the prevalence occurred in the male gender. In 41.8% of the meals people used only one of the salads. In relation to the intention of consumption of the two types of salads was observed 38.3%. Meals that had a salad and fruit, or two salads and fruit were around 14% each. In 4.4% of the meals no type of salad was chosen, only fruit. In 54.6% the fruit was not chosen. Meals without salad and without fruit totaled 12.2%. The quantities of FLV considering the presence or absence of tubers showed that the percentage of adequate consumption decreased from 44.6% to 34.2%. Thus, the proportion of underweight increased from 55.4% to 65.8%.

Conclusions: According to the literature, FLV consumption was low. The female gender had greater consumption than the male. The presentation of the meals, when attractive, can generate increase of the consumption.

Keywords: FLV consumption. Eating habits. Food behavior. Collective feeding.

COMPARISON OF THE AVAILABLE INFORMATION FROM BASIC FOOD BASKET (BFB) IN LATIN AMERICAN COUNTRIES

[1]Graciano, Beatriz Andrea; [2]Monroy Valle, Michele.

[1]Nutritionist. Nutrition School. University of Buenos Aires. Argentina.; [2]Nutritionist. Masters in Public Health. Instituto de Investigaciones Químicas y Biológicas. Universidad de San Carlos de Guatemala. Guatemala.

Background and objectives: Basic Food Basket (BFB) is used in Latin American countries as official poverty measure methodology, indicating the minimum income a household should have to purchase at least the calories and macronutrients they need to live. Is calculated using household consumption aggregate collected by income and expenses national surveys. The BFB gives information about the most commonly purchased foods by the country population, daily amount bought in grams by a family of average members, energy, price in country currency, unit of measurement in grams and cost per day. The objective was to compare BFB characteristics in Latin American Countries.

Methods: Searched BFB for 19 countries reported previously by UN Economic Commission for Latin America and the Caribbean (CEPAL) that use this methodology. Information was collected online from official sources as National Statistics Institutes or similar responsible for BFB monthly price publication in the following countries: Guatemala, El Salvador, Honduras, Nicaragua, Belice, Costa Rica, Dominican Republic, Panama, Mexico, Ecuador, Colombia, Venezuela, Brazil, Peru, Bolivia, Paraguay, Argentina, Chile, Uruguay. Characteristics were compared: Year of creation, Number of BFB (urban, rural or by country regions); for the urban or country capital, we collected information of amount of foods, number of food groups, Nutritional Value (number of calories and % of Protein), out of household purchase included in the foods.

Results: There are countries where BFB methodology is not available and some don´t report monthly prices anymore (Venezuela, since 2014) whilst others have between 2 and 6 official BFB. El Salvador and Ecuador have the oldest BFB from 1982. There are differences in energy (from 2000 Cal in Chile to 2750 Cal in Argentina); food groups (between 5 in Nicaragua to 19 in Uruguay), amount of foods (between 22 in El Salvador and 121 in Mexico). Methodology description is heterogenic, the reference population stratum is not clear in most of the documents.

Conclusions: Poverty is a main concern in Latin America, and BFB is as an indirect indicator of Sustainable Development Goals. Region must make efforts to update the BFB and make information available to calculate the cost of diet.

Keywords: Basic Food Basket. Poverty. Latin America.

DEFINING AN ANTHROPOMETRIC AND PHYSICAL ACTIVITY PROFILE FOR VENEZUELAN POPULATION: PRELIMINARY RESULTS FROM THE LATIN AMERICAN STUDY OF NUTRITION AND HEALTH (ELANS)

[1]Herrera-Cuenca, Marianella; [2]Méndez-pérez, Betty; [3]Martín-Rojo, Joana; [4]Landaeta-Jimenez, Maritza; [5]Castro-Morales, Vanessa.

[1]MD, ScD. Center for Development Studies. (CENDES) Central University of Venezuela. Fundación Bengoa para la Alimentación. Venezuela; [2]ScD. Antropologist. Bio Antropology Unit. Central University of Venezuela. Venezuela; [3]ScM Statistitian. Inmunology Institute. Central University of Venezuela. Venezuela; [4]ScM MD. Bengoa Foundation for Food and Nutrition. Venezuela; [5]ScB. Antropologist. Bio Antropology Unit. Central University of Venezuela. Venezuela.

Background and objectives: Nutrition status is important for the wellbeing of the population and physical activity (PA) is an important component of a healthy lifestyle. Evidence about the benefits have been well documented. The aim of this study is to identify an anthropometric and physical activity profile for Venezuelan population, as part of the Latin American Study of Nutrition and Health (ELANS).

Methods: A randomized representative sample of 1131 subjects ages between 15 -65, underwent through anthropometric evaluation: weight, height and an adapted version of long IPAQ was applied. Descriptive statistics, contingency tables to compare BMI, Vigorous activities and MET categorization were performed. Chi sq test was also performed to identify differences between genders.

Results: 33.4% of the population was overweight and 28.3% was obese. There were no significant differences on BMI values among different socioeconomic status. The bus is the most relevant public transport used by Venezuelans (67%) and 40.2% report using cars and motorcycle. According to SES it is important to highlight the use of individually owned vehicles among low SES (38.1%) and of those 12.5% are motorcycles. Sedentary behaviors reported that 92.4% of the sample perform seated activities of which the most important were: watching TV (92.1%), talking to friends (80.5%), use the telephone (74.8%) and reading (47.2%) being the most important watching TV on most days of the week. Regarding the perception of security of the surroundings, 75.4% reported insecurity in the neighborhood. Comparison between categorizations BMI and vigorous activity shows a Chi square significant values (p= 0.001 in men and p=0.029 in women) and comparison table show a trend for normal BMI on those individuals who perform vigorous PA, a higher BMI is observed on those who do not. Comparison between BMI and MET categorization shows differences among men but not in women, showing a trend for men with higher BMI to report moderate or low MET categories while, men with normal BMI show a higher MET values.

Conclusions: This study shows the need for implementation of public policies that promote physical activity for Venezuelan population.

Keywords: Venezuela, Physical activity, Anthropometry, Health Profile

THE MODELLED EFFECT OF BIOFORTIFIED CROPS ON NUTRIENT ADEQUACY OF CHILDREN AND WOMEN IN BANGLADESH AND GUATEMALA

[1]Talsma, Elise Francina; [2]Borgonjen-van den Berg, Karin; [2]Peletier, Julie; [2]Leyva, Perla; [2]Brouwer, Ingeborg.

[1]PhD. Scientist Human Nutrition. HarvestPlus. International Institute for Tropical Agriculture (CIAT). Cali. Colombia; [2]Division of Human Nutrition. Wageningen University. the Netherlands.

Background and objectives: Guatemala and Bangladesh are countries were micronutrient deficiencies are high and biofortified crops with higher concentration of micronutrients are currently being introduced to reduce these deficiencies. With this study we aimed to assess the effect of the replacement of currently consumed crops with biofortified crops on nutrient adequacy by formulating food based dietary guidelines for women and children in Bangladesh and Guatemala.

Methods: We used two existing data sets with 24 hour recall data from Bangladesh and Guatemala. Target groups were; infants 6-8 months, infants 9-11 months, infants 12-23 months and lactating women for Guatemala; children 24-35 months, children 36-48 months and their mothers for Bangladesh. Optifood, a linear programming tool, was used to model and compare the food based dietary recommendations with and without the replacement of the biofortified crops in reaching nutrient adequacy (> 70% of recommended nutrient intake) for 13 nutrients.

Results: When adding biofortified crops to the diet, reaching nutrient adequacy was not reached for children 6 – 23 months in neither Bangladesh nor Guatemala. For children 24-48 months in Bangladesh, only nutrient adequacy for vitamin A was reached with biofortification, although vitamin A was not a problem nutrient for older children in Bangladesh or in any age group in Guatemala. For children 36-48 months in Bangladesh as well as their caretakers, biofortification ensured adequacy for zinc.

Conclusions: Biofortification is able to ensure nutrient adequacy for vitamin A and zinc in children older than 24 months as well as for zinc in adult women. For children under 24 months of age the intake of crops that could be biofortified is insufficient to result in better nutrient adequacy when biofortified crops are consumed. An increased intake of biofortified crops or other food-based-interventions are needed to ensure nutrient adequacy.

Keywords: Linear programming, Nutrient adequacy, Biofortification, Guatemala, Bangladesh

CHARACTERIZATION OF SODIUM KNOWLEDGE AND ITS USE IN FOOD IN HABITANTS OF MEDELLIN COLOMBIA CITY

[1]*Velasquez, John Edinson;* [1]*Velasquez, John Edinson;* [2]*Deossa Restrepo, Gloria Cecilia;* [3]*Restrepo, Luis Fernando.*

[1]Nutritionist dietitian. School of nutrition and dietetics. University of Antioquia. Medellin. Colombia.; [2]Nutritionist dietitian. Specialist and master in food science and human nutrition. Professor. School of nutrition and dietetics. University of Antioquia. Medellin. Colombia.; [3]Statistician. Specialist in statistic and Biomathematics. Associate professor. Research group GISER. Faculty of agricultural sciences. University of Antioquia. Medellin. Colombia.

Background and objectives: The knowledge of sodium, its uses and implications for health, are of interest to health entities, in order to design information campaigns about the suitable use of this mineral, which lead to a healthy life style to preserve health and prevent appearance of non-communicable chronic diseases. Objective: to evaluate and to compare then knowledge and use of sodium in daily food, in adults of both sexes in Medellin Colombia.

Methods: The size of the sample was constituted by 322 persons randomly selected in the city of Medellin Colombia, whose ages ranged between 18 and 50 years of age. We used multivariate analysis of variance (MANOVA) with canonical orthogonal type contrast, multiple correspondence analysis with indexed hierarchical classification, Z method comparison tests, frequency analysis.

Results: Significant difference was detected between the knowledge of the sexes, related to the risks that brings to the health the excess in the consumption of sodium, in the knowledge of dietary salt and hypertension, noting that is the female sex which demonstrated to possess a greater knowledge

Conclusions: The main conclusion is that the people surveyed know what sodium is and know the recommendation for its use, however, they add salt to the preparations before testing them, and they also consume food sources of sodium as concentrated broths, sausages and packet soups.

Keywords: Hypertension, cardiovascular risk, salt, sodium.

CONSUMER AWARENESS AND PERCEPTION OF SWEETENERS INFLUENCES FOOD AND BEVERAGE DECISIONS

[1]*Samuel, Priscilla;* [2]*Okonneh, Ashi.*

[1]PhD. Global Stevia Institute. Oak Brook. IL. USA.; [2]BA. Research Insights. Marketing and Innovation. PureCircle Ltd. Oak Brook. IL. USA.

Background and objectives: Non-nutritive sweeteners are gaining substantial interest among consumers. Heightened interest for healthier lifestyles and continued concerns with rising obesity in adults and children, have food manufacturers actively looking for ways to reduce sugar and calories. To determine consumer perception of sweeteners and factors that motivate food choice, online surveys were conducted across several countries.

Methods: Data for Mexico (January 2017) and India (March 2016) are provided. Surveys were designed to be nationally representative and included a male/female split of 505/495 in Mexico and 520/480 in India. Most responses were on a scale of "very much agree" to "very much disagree."

Results: Results show that participants in Mexico and India reported high levels of concern around sugar intake with 74% and 84% very/somewhat concerned, respectively. Awareness was higher in Mexico versus India with 76% vs. 35% of participants responding "yes" when asked if aware of stevia. For those aware of stevia, 78% and 83% indicated a very/somewhat positive overall impression, in Mexico and India, respectively. When asked if they agreed or disagreed with whether sweeteners (i.e., stevia, sugar, sucralose, & aspartame) were "good for a healthy lifestyle", "natural" or "great tasting", stevia ranked highest on all three. In Mexico, 75% either completely/somewhat agreed that stevia is "good for a healthy lifestyle" versus 46% who agreed the same for sugar, 45% for sucralose, and 38% for aspartame. In India, 88% completely/somewhat agreed that stevia is "good for a healthy lifestyle" versus 47% for sugar, 51% for sucralose, and 40% for aspartame. Among parents with children at home, 85% versus 80% of parents in Mexico and India, respectively, indicated that were very/somewhat concerned about the level of sugar in foods/beverages they give their children. When asked, how likely these parents would be to purchase foods/beverages with stevia for their children, over 60% of parents in both Mexico and India indicated that they would either definitely/probably purchase foods or beverages with stevia.

Conclusions: As individuals and families pursue healthy lifestyles, sweeteners like stevia can play a pivotal role.

Keywords: consumers, stevia, awareness, sugar, children

FORTIFICATION OF THE WHEAT FLOUR IN MOROCCO: CHANGE OF THE ELEMENTARY IRON BY THE NAFEEDTA

[1]Aguenaou, Hassan; [2]Rahmani, Mohammed; [3]El Ammari, Laila; [4]Sahaba, Mahjoub; [5]Lhoussaine, Saad; [6]Izem, Abdellatif; [7]Labzizi, Saloua; [8]El Hajjab, Amina.

[1]PhD. Nutritionist. Joint Research Unit in Nutrition and Food, URAC 39 (Ibn Tofaïl University-CNESTEN) Regional Designated Center of Nutrition (AFRA/IAEA). Morocco; [2]PhD. Institut Agronomique Hassan II. Rabat. Morocco; [3]PhD. nutritionist. Ministry of Health. Morocco; [4]PhD. Institut de Formation de l'Industrie Meunière. Morocco; [5]PhD. Laboratoire Officiel d'Analyse et de Recherche Chimique. Morocco; [6]PhD. Fédération nationale de la minoterie. Morocco; [7]PhD. Ministry of Health. Morocco; [8]PhD. Office National de Sécurité Sanitaire des produits Alimentaires. Morocco.

Background and objectives: In Morocco, Iron Deficiency Anaemia is 32% among children that are less than 5 years old with 58% of them having ferritin levels less than 12 µg/l. This anaemia is 33% among women in childbearing age, 37% among pregnant women, and 18% among men. The consumption of the wheat flour in Morocco is 365 g / p / d of flour. To fight against this iron deficiency, the wheat flour was fortified with 45mg iron / kg of flour (in the form of electrolytic elementary iron). Unfortunately ten years after this fortification, the iron status of the Moroccan population did not improve. So in Morocco we realized a feasibility study of the fortification of the flour by another iron type, the NaFeEDTA which seems more bioavailability and insensible in chelators, such as the tannins of the tea.

Methods: We have fortified wheat flour with 80 ppm NaFeEDTA. We carried out the feasibility study of fortification under Moroccan culinary conditions. We supplied the premix containing 80 ppm of NaFeEDTA and 1 ppm of vitamin B9 to 30 industrial mills to determine the range of analyzes in order to put in place the legislation for quality control. We analyzed 60 samples (30 samples with fortified flour and 30 samples with non-fortified flour).

Results: The addition of NaFeEDTA and folic acid to the flour did not alter the technological quality of the flour. The organoleptic qualities of the flour were not altered. The range of analysis varies between 22 mg / kg and 49 mg / kg (mg iron / kg flour)

Conclusions: This study of bioavailability showed the possibility of the change of elemental iron by the NaFeEDTA without altering the technological quality and the organoleptic quality of the flour. A bioavailability study of NaFeEDTA under Moroccan culinary conditions is under way in partnership with the IAEA.

Keywords: Fortification, wheat flour, Morocco, elementary iron, NaFeEDTA

EFFECTS OF A FEEDING AND NUTRITION PROGRAM IN SCHOOL CHILDREN IN MEXICO CITY

[1]Cuevas Nasu, Lucía; [2]Shamah-Levy, Teresa; [1]Gómez Acosta, Luz María; [3]Méndez Gómez-Humarán, Ignacio; [4]Hernández Ávila, Mauricio.

[1]MSc. Nutritionist. Center for Nutrition and Health Research. National Institute of Public Health. Mexico.; [2]PhD. Researcher. Center for Nutrition and Health Research. National Institute of Public Health. Mexico.; [3]MSc. Statistician. Mathematics Research Center. Aguascalientes Unit. Mexico.; [4]PhD. National Institute of Public Health. Mexico.

Background and objectives: In Mexico obesity is the most frequent problem among children and adolescent populations, the increasing in overweight and obesity (OW+Ob) prevalence has been a main concern mostly in individuals from 5 to 11 years old. Data from National Health and Nutrition survey (ENSANUT-201) shown a National prevalence of 34.9% and a slightly greater (35.2%) in Mexico City.

Objective: To assess education and nutrition components of SaludArte program in participant schools during 2013-2015.

Methods: A three cohort comparative study was used consisting on 1283 school children from 144 schools. Two panels were defined: complete and continuous time. Information about food intake, feeding behaviors, food preservation and hygiene, physical activity (PI) and anthropometry was obtained. A differences in differences method for effect estimates was applied, logistic-multinomial and logistic regression models were also used.

Results: Effects attributable to the program were as follows: better personal hygiene (p=0.045), better nutrition knowledge's (p=0.003), physical activity (p=0.002 2013-2014; p=0.032 2015) and fiber Intake (p=0.064). Disagreeing with the expected, sugar intake was significant, (p=0.012 continuous time and; p=0.037 complete time).

Conclusions: Findings shown better hygiene practices among the program beneficiaries, this is related with positive effects over the health because decreases infections risk and thereby morbidity costs associated with infections. SaludArte had positive effects over some components, however it is necessary to consider the learned lessons in order to institutionalize the program and give it permanence.

AVAILABILITY OF PORK AND BEEF IN SOUTH AMERICAN COUNTRIES THROUGH THE PERIOD OF TIME FROM 1961 TO 2010

[1]Arboleda, Luz Marina; [2]Restrepo, Luis Fernando.

[1]Nutritionist dietitian. PhD in social Sciences Coordinator of the Socio-anthropology on Food Research Group School of Nutrition and Dietetics. University of Antioquia. Colombia; [2]Statistician. Specialist in statistic and Biomathematics. Associate professor. Research group GISER. Faculty of agricultural sciences. University of Antioquia. Medellin Colombia.

Background and objectives: The knowledge related with the bovine and swine production is of vital interest by part of governmental and private bodies to plan the alimentary supply referred to this products, to design strategies that let the elaboration of plans of action to prospect better a country in this place.

Objective: make a comparative analysis related with the supply of beef and pork, and the quantity of energy, protein, and fat per person for each day that they give in countries in South America in the period of fifty years (1961-2010).

Methods: The General linear model was used, employing the multivariate analysis of variance (MANOVA) technique, with a canonical contrast of orthogonal type, analysis of principal components, explorative and descriptive analysis of unidimensional style, taking into account the base of information coming from the FAO.

Results: Argentina shows a highly important difference in the availability of beef for its population with respect to the rest of South America (p<0.0001). Paraguay is the country with the highest availability of pork for its population. The country with the lowest participation of sources of beef and pork is Peru.

Conclusions: there is a great divergence between dome countries of South America in the quantity of the supplies of meat from the bovine and the swine, which impacts in the availability of energy resources, protein, and fat for the population.

Keywords: beef, pork, availability, consumption, South America.

ASSOCIATION OF MODIFIABLE CARDIOVASCULAR RISK FACTORS WITH METABOLIC SYNDROME (MS) IN ADOLESCENTS

[1]Souza, Paula; [2]Correia, Marcelo; [3]Lorenzo, Andrea; [4]Moreira, Annie Seixas Bello.

[1]Nutritionist. Post Graduation on Nutrition, Health and Food Sciences. Universidade do Estado do Rio de Janeiro. Brazil; [2]MSc. Statistical. Biostatistcs core. Instituto Nacional de Cardiologia. Brazil; [3]PhD. Cardiologist. Education and Research Coordination. Instituto Nacional de Cardiologia. Brazil; [4]PhD. Nutritionist. Education and Research. Instituto Nacional de Cardiologia. Professor. Universidade do Estado do Rio de Janeiro. Brazil.

Background and objectives: The prevalence of overweight and obesity has increased in alarming proportions worldwide, affecting even the youngest age groups and bringing with it the early appearance of several clinical complications due to metabolic disorders. The aim of this study is to assess the presence of modifiable cardiovascular risk factors (MCRF) in adolescents with and without metabolic syndrome.

Methods: Multicenter, cross-sectional study using data from the ERICA study (BMC Public Health (2015)15:94). The sample consists of 7,404 adolescents, aged between 12 and 17 years, enrolled in public or private schools of 4 Brazilian municipalities, whose weight of the stratification represents 900,120 adolescents (Cad. Saúde Pública, Rio de Janeiro, 31(5):1-10). Adolescents were classified as metabolically healthy (MH) and metabolically unhealthy (MU) according to the established metabolic syndrome (MS) criteria and an analysis was made on the presence of MCRF in this population. Parametric and non-parametric tests were performed with the studied variables. The analyses were performed using Stata software version 13 and R version 3.3.1.

Results: The mean age found was 14.4 years, 50% were female, 69.6% studied in public schools and 2.2% presented MS. Among the MCRF evaluated, 47.5% were sedentary, 26% had altered LDL-c, in 43% of cases CRP was altered, 4.3% had abnormal hemoglobin A1c and 11% presented altered HOMA-IR. According to the MS classification, 33.6% of the MH normal weight presented more than one risk factor, 100% of the MU normal weight presented between two and three risk factors, 61.7% of the MH obese presented more than one risk factor and 81.5% of the MU obese presented more than one risk factor.

Conclusions: The present study draws attention to the number of adolescents who presented up to five MCRF associated or not with the MS criteria. The dimension and impact of health problems related to obesity and the presence of cardiovascular risk factors in this age group are of great magnitude, and it is urgent to adopt public health measures to prevent obesity and promote a healthy lifestyle.

Keywords: Adolescent, metabolic syndrome, risk factors.

COMPREHENSIVE INTAKE ASSESSMENT OF TRANS FATTY ACIDS AMONG THE PORTUGUESE POPULATION – RESULTS FROM THE NATIONAL FOOD, NUTRITION AND PHYSICAL ACTIVITY SURVEY 2015-2016

[1]Torres, Duarte; [2]Lobato, Liliane; [3]Severo, Milton; [4]Macedo-Correia, Daniela; [5]Oliveira, Andreia; [6]Casal, Susana; [5]Lopes, Carla.

[1]PhD. Faculty of Nutrition and Food Sciences. University of Porto. Portugal; [2]MSc. Nutritionist. Faculty of Nutrition and Food Sciences of the University of Porto. Portugal.; [3]PhD. Data Scientist. EPIUnit - Institute of Public Health of University of Porto. Portugal.; [4]BSc. Data Scientist. EPIUnit - Institute of Public Health of University of Porto. Portugal.; [5]PhD. EPIUnit - Institute of Public Health of University of Porto. Portugal.; [6]PhD. Requimte-LAQV and EPIUnit - Institute of Public Health of University of Porto. Portugal.

Background and objectives: WHO/FAO recommends that intake of trans fatty acids (TFA) should be restricted to less than 1% of total daily energy intake. Limited information is available on the actual TFA intake.

The present work aims to describe TFA usual intake, and to identify the main sociodemographic factors associated, among the Portuguese population; to estimate the contribution of different food categories to TFA intake.

Methods: Distribution of TFA intake was assessed combining individual food consumption with food TFA concentration datasets. Individual food consumption data was obtained from a national representative sample of 5819 individuals (www.ian-af.up.pt). Food diaries or 24h recalls (if > 10 yrs) were face-to-face applied twice. All reported food items were described using the FoodEx2 system. The content of TFA in foods was extracted from the Portuguese Food Composition Table (PFCT). When applicable, TFA levels presented in the PFCT were substituted by current levels, recently reevaluated and published.

The usual TFA intake was estimated using Statistical program for age-adjusted Dietary assessment (SPADE). A weighted generalized linear model was used to measure the effect of the several exposures on TFA intake.

Results: Median TFA intake among the Portuguese population was 0,43% of energy intake (0.9 g/day). Intake of TFA exceeding 1% of energy intake was estimated to occur in 8, 14, 4 and 7% of the observations in children, adolescents, adults and elderly, respectively. Foods containing TFA produced during manufacturing (fats and oils, pastry and snack products, etc) contributes with 42% to the total TFA intake.

TFA intake (g/day) among young adults (18-40 yrs), middle adults (41-64 yrs) and the elderly (65-84 yrs) was significantly lower [β=-0.49, 95%CI=(-0.80, -0.18), β=-0.64, 95%CI=(-0.98,-0.30) and β=-0.67, 95%CI=(-1.02,-0.32), respectively]; those more educated [β=0.40, 95%CI=(0.24,0.55)] and living in Lisbon [β=0.24, 95%CI=(0.05,0.44)] or Madeira Island [β=0.28, 95%CI=(0.11,0.45)] had significantly higher TFA intake.

Conclusions: TFA intake among the general Portuguese population can be considered low. A relevant proportion of adolescents are consuming more than 1% of energy from TFA. However, it should be noted that ruminant derived products are the main contributors to TFA intake. Younger age, higher education and residence in Lisbon or Madeira regions were positively associated with TFA intake.

This Survey has received funding from the EEA Grants Program, Public Health Initiatives (PT06 - 000088SI3).

DIETARY AND ENVIRONMENTAL TOXIC EXPOSURE IN AN AGRICULTURAL CORE POPULATION OF THE PROVINCE OF CÓRDOBA, ARGENTINA

[1]Montedoro, Franco; [2]Butinof, Mariana; [3]Aballay, Laura; [3]Pou, Sonia Alejandra; [4]Eandi, Mariana; [5]Fernandez, Ricardo; [6]Díaz, María del Pilar.

[1]Bachelor in Science. Chair of General and Nutritional Epidemiology. School of Nutrition. Faculty of Medical Sciences. National University of Cordoba. Argentina.; [2]Ph.D. of Medicine and Surgery. School of Nutrition. Faculty of Medical Sciences, National University of Cordoba. Argentina; [3]Ph.D. of Health Sciences. School of Nutrition. Faculty of Medical Sciences. National University of Cordoba. Argentina; [4]Bachelor in Science. School of Nutrition. Faculty of Medical Sciences. National University of Cordoba. Argentina; [5]Md. Faculty of Medicine. Catholic University of Cordoba. Argentina; [6]Ph.D. in Statistics Applied to Biological Sciences. School of Nutrition. Faculty of Medical Sciences. National University of Cordoba. Argentina.

Background and objectives: Argentina have the major world crop production per capita. To achieve these results, the following production model is applied: genetically modified seeds, direct seeding and intensive use of pesticides. Environmental exposures are multiple and complex; diet and toxic, such as pesticides, participate in the modulation of the occurrence of chronic diseases with high impact in Public Health, being a healthy diet, a protective factor against its the occurrence. Aims: To identify the dietary patterns and exposure to pesticides in a local population of the agricultural core zone of the Pampa Húmeda Argentina

Methods: A population-based study was conducted in a random sample of subjects older than 18 years of age, in Monte Buey, Córdoba Province, Argentina, throughout 2015 to 2016 (n=416). A standardized questionnaire was administered, investigating environmental, sociodemographic and lifestyle characteristics. Potential sources of exposure to agricultural pesticides were identified and geo-referenced: deposits of agricultural machinery, pesticides and silos, proximity of housing to cultivated fields, among others. A validated food frequency questionnaire was used to investigate the usual qualitative and quantitative food consumption. Descriptive statis-

tics and Factorial Analysis of Principal Components were identified for the identification of food patterns using Stata13 software.

Results: Of the total number of subjects studied, 50.4% were women, mean age (SD) was 46.6 (14.7) years. About 60% completed secondary or higher education; 49% had an average socio-economic level and 21% high level. Four dietary patterns, known as "Prudent" (AB vegetables, fruits, oils), "Meat" (red fat meats), "Glucose" (refined grains and sugars) and "Beverages" (alcohol and teas) were identified. Also, 32%; 48 per cent and 37 per cent of households were within 500 m of cultivated fields sprayed with pesticides, agricultural machinery and pesticide and other agricultural inputs, respectively.

Conclusions: There was evidence of a positive change in food selection towards a healthier, more prudent pattern, as a measure of self-care, by the exposed population. However, it is necessary to work on public policies that aim at sustainable production modes by reducing the level of exposure described, accompanying the acquisition of healthy habits.

Keywords: food patterns - pesticides - environmental exposure - agricultural core.

SUSTAINABLE DIETS IN SMALL ISLAND DEVELOPING STATES OF THE WESTERN PACIFIC: A REVIEW

[1]Burlingame, Barbara; [2]Eme, Paul; [3]Foliaki, Sunia; [4]Kim, Nick; [5]Douwes, Jeroen.

[1]PhD. Professor. College of Health. Massey University. New Zealand; [2]PhD scholar. College of Health. Massey University. New Zealand; [3]MD. Research Fellow. Centre for Public Health Research. Massey University. New Zealand; [4]PhD. Senior Lecturer. School of Public Health. Massey University. New Zealand; [5]PhD. Director. Centre for Public Health Research. Massey University. New Zealand.

Background and objectives: The ecosystems of Pacific Island countries, e.g., atoll islands of Melanesia and Polynesia, are rich in terrestrial and marine biodiversity that would likely support sustainable diets. Yet many of these Small Island Developing States (SIDS) are experiencing extensive loss of biodiversity and degradation of natural resources, and the nearly-11 million inhabitants have some of the highest rates in the world of obesity and associated chronic diseases. They are particularly precarious in their vulnerabilities to various manifestations of climate change and other anthropogenic and natural phenomena affecting agriculture, fisheries, food trade. The question to be answered is this: is it possible to have 'sustainable diets' in these Pacific Island States?

Methods: National, regional and UN-compiled data sets from the sectors/disciplines of nutrition, health, agriculture and the environment will be interrogated, along with indicators developed to characterise sustainable diets in selected ecosystems of Pacific Island countries. Tonga, Fiji, Kiribati and Tokelau Islands are used as the test environments.

Results: Diets are laden with high fat/high sugar imported convenience foods with the consequences of high rates of obesity, diabetes, heart disease, and shortened life expectancy. At the same time, highly nutritious traditional foods are neglected and underutilised. Some solutions to the problems are beyond the direct control of SIDS (e.g., rising sea levels), but many, including modifications to practices and policies have yielded, and could further yield, immediate benefits, e.g., conservation of local food biodiversity through sustainable use, benefiting the environment and improving nutrition.

Conclusions: Multi-sectoral policies and actions informed by the Sustainable Development Goals (especially Goal 2 and its targets), Aichi Targets, UN Decade of Action on Nutrition, and regional commitments, are needed. Although the recommendations from this review are based on four Pacific SIDS, there is potential relevance to at least 22 Pacific Island countries and territories, other SIDS around the world, and to low-lying coastal areas in non-island countries that share similar ecosystems and food/nutrition-related vulnerabilities.

Keywords: sustainable diets, ecosystem, nutrition, obesity, biodiversity

NUTRITIONAL STATUS AND FOOD PATTERNS OF PRESCHOOL AGE CHILDREN OF PANAMANIAN INDIGENOUS COMMUNITIES: A CROSS-SECTIONAL STUDY

[1]Auón, Aneth; [1]Álvarez, María Fernanda; [2]Rios, Israel; [2]Valdés, Victoria.

[1]Nutritionist. Nutrition and Dietetic Department. Medicine School. University of Panama. Panama City. Panama; [2]MSc. Nutritionist. Nutrition and Dietetic Department. Medicine School. University of Panama. Panama City. Panama.

Background and objectives: The current nutritional situation among indigenous people from Ngabe Bugle group is affected by increased under nutrition and overweight rates among children under five years. The objective of this study was to determine the nutritional status and food patterns in children under five years of an indigenous group in Panama, the Ngabe Bugle group.

Methods: This is a cross-sectional follow-up study of 110 children under five years whom are beneficiaries of "Chi Nugue Kwin – healthy and happy children" Project implemented by Nutre Hogar, a national NGO working with indigenous people. We ran descriptive analysis including socio-demographics, anthropometric and 24 h recall assessments from January to March 2016.

Results: The mean±SD of HAZ and BAZ were -2.31±0.96 and 1.44±1.42, respectively, and 55% were girls. The prevalence of moderate Stunting (<-2 SD HAZ) was 46% and 19% presented

severe (<-3 SD). According with BAZ, 19% presented overweight (>2 SD BAZ) and 8% was classified as obese (>3 SD BAZ). The reported food patterns was predominantly composed by starch (grains, cereals, and sugar). Low consumption of high value animal protein was observed. As well as a scarce consumption of fruit or vegetables.

Conclusions: Children under five in this analysis are affected by double burden of malnutrition and presented low food diversity based in starch and simple sugar. Comprehensive and multi sectorial nutritional interventions are needed to improve the nutritional situation among children under five years in Panamanian indigenous areas.

Keywords: Stunting, Malnutrition, Overweight, Obesity, Indigenous people.

PATHWAYS TO ACHIEVING DIETARY VITAMIN A ADEQUACY AMONG YOUNG CHILDREN: AN APPLICATION OF AN ECONOMIC OPTIMIZATION MODEL IN CAMEROON

[1]Vosti, Stephen; [2]Engle-Stone, Reina; [3]Kagin, Justin; [4]Luo, Hanqi; [5]Tarini, Ann; [6]Brown, Ken.

[1]PhD. Department of Agricultural and Resource Economics. University of California. Davis. USA.; [2]PhD. Department of Nutrition. University of California. Davis. USA.; [3]Kagin's Consulting. Vacaville. California. USA.; [4]PhD Candidate. Department of Nutrition. University of California. Davis. USA.; [5]MSc. Ann Tarini International Public Health Consulting. Montreal. Quebec. Canada.; [6]MD. Bill & Melinda Gates Foundation. Seattle. Washington. USA.

Background and objectives: National efforts to reduce vitamin A deficiency (VAD) among children need to be more efficient and fiscally sustainable, but vulnerable children must be protected during programmatic transitions. GAVA has proposed a framework that provides guidance for transitions, but data and tools are needed to inform program choices.

Methods: The Micronutrient Intervention Modeling (MINIMOD) tool is used to explore transitional pathways for VA programs. We predict dietary VA adequacy using national dietary data and lives saved using LiST. An economic optimization model links benefits and costs, and identifies alternative 10-year pathways for enhancing efficiency while protecting vulnerable children. We modeled, year-by-year, one possible pathway: a) lagged improvements in an existing VA oil fortification program, b) lagged development of a VA-fortified bouillon cube program, and c) maintaining VA supplementation via Child Health Days (CHD) when/where the prevalence of inadequate VA intake is >10%.

Results: Program costs and impacts vary across Cameroon's macro-regions (South, North, and Cities). In the South, where inadequate VA intake was lowest, after 4 years, the combined oil and cube programs achieve inadequate intake < 10%; cost after year 4 is $336k/year. During the 3-year transition period, VAS protects children at risk of VA-related mortality; total cost of program investments and CHD is ~$1.5m per year and 1913 child deaths are averted. If two biomarker surveys confirm resolution of VAD, as proposed by the framework, CHD are discontinued in the South in year 7, yielding ~$1.3m per year savings. The scenario is similar for the Cities macro-region. However, in the North, where VAD is more severe, combined oil and cube fortification programs do not reduce VA dietary inadequacy below 10%; other VA programs are needed or CHD need to be maintained indefinitely.

Conclusions: Depending on the nature and extent of VA deficiencies, well-planned and well-managed food fortification programs have the potential meet VA dietary intake requirements of young children. Vulnerable children need to be protected until investments in fortification programs mature. In some areas, currently available fortification programs will not meet VA dietary intake needs; new programs need to be developed.

Keywords: VA deficiency. VA fortification. VA supplementation. MINIMOD. Cameroon

TOXIC FOOD ENVIRONMENT INSIDE AND AROUND PUBLIC PARKS IN MEXICO CITY

[1]Medina, Catalina; [2]Hernández, Annel; [3]Tolentino Mayo, María Lizbeth; [4]Rincon-Gallardo, Sofía; [3]Nieto, Claudia; [5]Barquera, Simon.

[1]MSc. Center of Nutrition and Health. National Institute of Public Health. Mexico; [2]BSc. Center of Nutrition and Health. Mexican National Institute of Public Health. Mexico; [3]MSc. Center of Nutrition and Health. Mexican National Institute of Public Health. Mexico; [4]MSc. Virginia Tech. USA; [5]PhD. Center of Nutrition and Health. Mexican National Institute of Public Health. Mexico.

Background and objectives: According to the Mexican National Institute of Statistic and Geography (INEGI), more than 60% of people attend public parks. Urbanists state that offering food in public spaces increases the participation. However, energy-dense food availability and advertising is linked with obesity. The aim of the study is to characterize the toxic food environment inside and around public parks of Mexico City.

Methods: Trained interviewers performed the evaluation of the inside and around food supply and advertising of 33 parks in Mexico City. Data collection was made using a Mexican context questionnaire. Food availability was defined as those foods sold inside and around the parks. Around was defined as the circumference of the parks. Parks were mapped using three different databases including local (Roji Guide), Google and INEGI maps and were classified according to their dimensions into three typologies: 1) metropolitan (>0.01 km2), 2) local (0.003 a 0.01 km2), and 3) district (0.0004-0.003 km2).

Results: Information of 5.9% metropolitan, 36.4% lineal and 12.1% district parks of Mexico City was collected. Overall, 39.4% of the food kiosks were located inside the parks, whereas 78.8% were around. The most prevalent food inside corresponds to sweet snacks

(19.7%), followed by chips (18.2%); while around parks were found traditional Mexican fast food (fried tortilla with meat/chicken/pork/beans) in restaurants (16.9%) and street vendors (16.1%). In total, 3% of the parks have food advertising inside and 15.7% around.

Conclusions: While parks are the most popular public spaces to perform physical activity in Mexico City, our results show that most of the available food inside and around the parks is energy-dense food. In addition, 3% of the parks have food advertising inside. Regulatory guidelines are needed to promote healthy environments, because the beneficial contribution on health of these spaces could be attenuated by the high availability and advertising of energy-dense foods.

Keywords: Parks, energy-dense food, food environment

NEW CHILEAN LABELLING LAW AND SCHOOL SNACKS: CHILDREN PERCEPTION

[1]*Quintiliano Scarpelli Dourado, Daiana;* [2]*Capdevila, Daniella;* [2]*Gajardo, Valentina;* [2]*Melivilu, Paula;* [3]*Cortés, Andrea.*

[1]PhD. University of Development (UDD). Chile; [2]Student. Nutritionist. University of Development (UDD). Chile; [3]MsC. Nutritionist. University of Development (UDD). Chile.

Background and objectives: In Chile with the aim of reducing prevalence of child obesity and create healthy environments the Law 20,606 was created, by the Ministry of Health (MINSAL). It was implemented its first stage in June, 2016 and labels the package of foods/products with "High in" black signs when they exceed the limits of critical nutrients (sugar, sodium, saturated fats and calories).

The objective of the study was to verify the impact of the new labeling on the perception and nutritional quality of the snacks consumption during the school day of adolescents from a subsidized school in Santiago, Chile.

Methods: A crossover study with qualitative approach was done. The nutritional status was evaluated and clasified according to Z-score reference (WHO, 2007). The children filled a weekly snack form specifying the eaten snack. These snacks were clasified according to the presence of the "black signs" according to the nutritional limits of the law. An interview was performed to know what they think about the black signs and if the presence of them impacted on their decision to eat/drink the product. A descriptive analysis was done and the Kruskal-Wallis test was applied considering the significance level of 5%. The Stata 13 software was used. Perception answers were transcribed and analyzed by the iterative method.

Results: We evaluated 48 adolescents (12-14y) of both sexes, being 60,4% females; 58,5% were overweight. 530 snacks were consumed in this period, being only 7,5% without black signs and 35,3% with 3 or 4 black signs. No significant difference in the snacks quality and nutritional status were observed. Perception evidences showed that the adolescents (89,7%) have the knowledge about the problem of obesity in Chile and why some foods/products are receiving the black signs. 75% mencionated that the foods

without signs are healthier, but the presence of the black signs only affected the decision of consumption and aquisition of 8,3%.

Conclusions: The presence of black signs did not impact in the adolescent snack selection. but it is important to mention that they recognized that it is easiest to understand the nutritional information with the "black signs".

Keywords: Nutritional Status, snacks nutritional quality, Chilean law 20,606.

FOOD AND NUTRITION EDUCATION AS CORE ELEMENT OF SCHOOL FOOD AND NUTRITION PROGRAMMES IN LATIN AMERICA AND THE CARIBBEAN

[1]*Rios-Castillo, Israel;* [2]*Salamanca, Anabell;* [3]*Kazi, Nabeeha;* [4]*Henderson, Savanna;* [5]*Hernandez-Garbanzo, Yenory;* [6]*Rivas, RoseMarie;* [7]*Rojas, Jorge.*

[1]MSc. Nutritionist. Regional Nutrition Officer for Latin America and the Caribbean. Food and Agriculture Organization. Sub Regional Office for Mesoamerica. Panama City. Panama; [2]Humanitas Global - Humanitas Global Development. San Salvador. El Salvador; [3]President & CEO. Humanitas Global - Humanitas Global Development. Washington. USA; [4]Humanitas Global - Humanitas Global Development. Washington. USA; [5]Phd. Nutritionist. Nutrition Officer. Food and Agriculture Organization of the United Nations. Headquarter. Rome. Italy; [6]Nutritionist. Food and Agriculture Organization of the United Nations. San Salvador. El Salvador; [7]Humanitas Global - Humanitas Global Development. La Paz. Bolivia.

Background and objectives: Food and Nutrition Education (FNE) is defined as any combination of educational strategies implemented at different levels, whose objectives are to assist individuals in achieving sustainable improvements in their feeding behavior and practices. It is believed that the School Food and Nutrition Programmes (SFNPs) should include FNE in their interventions to create a long-range impact, and not only provide food assistance. The objective of this study was to identify and review successful practices and programmes that may be expanded/replicated in other countries in Latin America and the Caribbean (LAC).

Methods: During the first phase of this study, a desk audit per LAC country was performed to understand experiences at SFNP and FNE levels. An in-depth review was implemented during the second phase to better assess and understand the experiences of countries with active FNE, which may serve as an example for other countries in the LAC region. The countries reviewed included: Brazil, Costa Rica, El Salvador, Mexico, Peru, the Dominican Republic, and Trinidad and Tobago.

Results: Overall, findings from this study support robust insights from FNE programs that call for more effective and responsive policies, programs and funding streams to strengthen school-based efforts. Development of a policy framework is need-

ed to sustain FNE and national malnutrition and hunger plans and strategies. Aspects of FNE such as feeding and hygiene are included in school curricula, but FNE as a core educational subject is not present in most countries in the region. FNE is most effective when promoted and integrated throughout the school environment. This includes the regulation of school kiosks to offer nutritious and local food, adequate physical activities, and presence of pedagogical school gardens.

Conclusions: An effective FNE policy requires that a communication agenda, an implementation methodology, and technical support be provided to central as well as local governments. Its adoption and activation also require that an item be allocated for it in the public budget.

ANALYSIS OF NUTRITION INFORMATION IN PACKAGING OF SWEET AND SALTED BISCUITS AVAILABLE IN MEXICO CITY

[1]Ocampo, Heilen; [2]Castillo, Alejandra; [3]Tolentino Mayo, María Lizbeth.

[1]Nutritionist. Health and Nutrition Research Center. National Institute of Public Health. Mexico.; [2]Nutritionist. Health and Nutrition Research Center. National Institute of Public Health. Mexico; [3]MSc. Nutritionist. Health and Nutrition Research Center. National Institute of Public Health. Mexico.

Background and objectives: Nowadays, large quantities of food and beverages are made with modifications in its composition, so it is necessary to establish nutritional specifications that must be subject to these products. 'Nutrition claim' means any claim which states, suggests or implies that a food has particular beneficial nutritional properties. Analize of nutrition information in packaging of sweet and salted biscuits, of nutrition claims available in Mexico City According to the official Mexican standard 086-SSA1-1994 (NOM-086).

Methods: There were photographed 977 biscuits packaging available in 51 supermarkets in Mexico City, on December 1st 2015 to March 31st 2016. Biscuits are classified in two groups: sweet biscuits (N=883), and, salted (N=98). It was used as an inclusion criteria all those packages of biscuits that showed at least one nutrition claim on the front face of the product. To find out if it meet the nutritional specifications of the NOM-086 were analyzed nutrition claims per serving/100g and using as parameters the classification of the following denominations: fat free (<5g per serving), sugar free (<0.5g per serving) and energy free (<5 calories per serving). A descriptive analysis was made out using the SPSS v. 23.

Results: Of the 977 Biscuits, only 37.9% had nutrition claim; of which 17.9% of the packaging presented 2 nutrition claims and 4.5% had 12 nutrition claims. In comparison sweets biscuits had more nutrition claims than salted (86.5% and 13.5%, respectively).

The nutrition claims identified were: "fat free" 39.2%, "sugar free" 31.9% and "energy free" 7.3%. Only 12.3% met the parameters according to their nutrient content to submit nutrition claims. Of the products who carried a nutrition claim and that do not meet the nutritional parameters, to contain higher values to the permitted was 98% "fat free", 84% "sugar free" and 99.7% "energy free".

Conclusions: There is a need to update and monitor the implementation of the regulation for the use of nutrition claims presented in industrialized cookies, as it may be a determined factor in the choice of food. This would contribute to the various strategies implemented to reduce the high prevalence of overweight and obesity in Mexico.

PREVALENCE OF INADEQUATE MICRONUTRIENT INTAKE AMONG URBAN COSTA RICAN POPULATION: RESULTS FROM THE LATIN AMERICAN STUDY OF NUTRITION AND HEALTH (ELANS)

[1]Gómez Salas, Georgina; [2]Ramírez, Andrea; [3]Sheik, Amed; [4]Chinnock, Anne; [5]Nogueira Previdelli, Agatha.

[1]MSc. Nutritionist. Department of Biochemistry. School of Medicine. University of Costa Rica. Costa Rica; [2]Bch. Nutritionist. Department of Biochemistry. School of Medicine. University of Costa Rica. Costa Rica; [3]Bch. Nutritionist. Department of Bichemistry. School of Medicine. University of Costa Rica. Costa Rica; [4]PhD. Nutritionist. School of Nutrition. University of Costa Rica. Costa Rica; [5]PhD. Nutritionist. Dacultade de Ciencias Biologicas e da Saude. University of Sao Judas Tadeu. Brazil.

Background and objectives: Invisible, but still very common in developing countries, micronutrient deficiencies can lead to serious health consequences. Hypovitaminosis can reduce the ability to combat diseases, diminish cell and organ function and affect the development of children and wellbeing of adults and elderly. The study aimed to estimate the prevalence of inadequate micronutrient intake in an urban Costa Rican population and to identify individuals at risk of nutritional deficiency.

Methods: ELANS is a multicenter cross-sectional study including a representative sample of urban population from eight LA countries (Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela). In Costa Rica, 798 participants (15-65 years old) provided two 24-h dietary recalls. Nutritional data was entered into the Nutrition Data System for Research (NDS-R) software, after a harmonization process between local foods and NDS-R database, and adjusting for mandatory micronutrient fortification of sugar, rice, wheat flour and corn flour and milk. The rates of prevalence of inadequate micronutrient intake were estimated according to gender and age group, using the EAR (Estimated Average Requirement) method as cut off points.

Results: High prevalence (>95%) of inadequate intake of vitamin D, E and Calcium was observed in both genders. The prevalence of inadequate intake of vitamin A, riboflavin and niacin

were 39.8%, 24.6% and 16.5%, respectively. Lower prevalence was found for for iron (3.3%), thiamin (7.8%), cobalamin (10.2%) and folate (13.9%). For all analysis, vitamins and minerals inadequacy was higher for women than men, with exception of riboflavin and vitamin A. For niacin, cobalamin, calcium and thiamin the prevalence of inadequate intake was greater in older groups (p<0.005).

Conclusions: Vitamin and mineral intake among urban Costa Rican population were lower than recommended, with a tendency of a greater inadequacy rate in older groups. Healthy eating that facilitate meeting the EAR from a variety of foods most be encourage to improve this situation.

Keywords: Vitamins. Minerals. Costa Rica. Inadequate intake

FREE SUGARS AND EXCESS WEIGHT IN CHILDREN AND ADOLESCENTS FROM LATIN AMERICA: A SYSTEMATIC REVIEW

[1]Ortiz Calderón, Sarah Lucia; [1]Arroyave Zuleta, Luisa Fernanda; [2]González-Zapata, Laura Inés.

[1]BSc. Nutritionist. School of Nutrition and Dietetics. University of Antioquia. Colombia; [2]PhD. Nutritionist. School of Nutrition and Dietetics. University of Antioquia. Medellín. Colombia.

Background and objectives: Free sugars (FS) contribute to increasing the energy density of the diet and may promote a positive energy balance, its high intake has been associated with excess weight (EW). Our aim was to identify the association between FS consumption and EW in children and adolescents from Latin America.

Methods: We conducted a systematic review of research articles published between 2005 and 2016. We searched VHL, Pubmed and Embase databases since August 26 until September 30 of 2016. The primary variables were children and adolescents, Latin America countries, consumption of FS (Soda, Fruit drinks, Sugar-sweetened beverages, Sweets, Sugary foods), weight gain, overweight and obesity. There was no restriction according to type of study. Articles written in English, Spanish and Portuguese were included. Data Extraction: The Selection of studies, data collection and quality assessment were performed independently by two trained reviewers.

Results: Fourteen of one hundred and seventy-five articles were eligible for systematic review, A single article could have associated more than one variable. Distribution according to type of study: Descriptives: four, Cross sectional: eight, Prospective: one, Cases and controls: one. Nine of the included articles were made in Brazilian population. The measurement of the association between soda consumption and anthropometric indicators related to EW was the highest number of positive associations (p< 0,05). For all food categories containing FS, there were 9 positive and 2 negative associations (p <0.05) with EW indicators, in 12 occasions no association was reported.

Conclusions: The articles found present heterogeneous results respect to the association between FS consumption and EW in children and adolescents of the region. The type of research that has been carried out in Latin America does not allow to infer causal associations between these variables.

Keywords: Child, adolescents, body weight, dietary sugar, free sugar.

NUTRITIONAL STATUS AND MONITORING COVERAGE BY THE FOOD AND NUTRITION SURVEILLANCE SYSTEM IN THE STATE OF MATO GROSSO DO SUL, BRAZIL

[1]Ferraz Moreira, Naiara; [2]Carvalho, Viviane Camila; [1]Martins, Rita de Cássia.

[1]PhD. Nutrtionist. Faculty of Health Sciences. Federal University of Grande Dourados (UFGD). Brazil.; [2]Bachelor student. Faculty of Health Sciences. Federal University of Grande Dourados (UFGD). Brazil.

Background and objectives: The Food and Nutrition Surveillance System (SISVAN) aim to characterize the nutritional status and food consumption among all population groups in Brazil. According SISVAN results, decisions could be formulated to develop health promotion policies and programs. This study aimed to evaluate nutritional monitoring by the SISVAN, in the different lifecycles in the State of Mato Grosso do Sul, Brazil, in 2015.

Methods: It is a descriptive study with secondary data from SISVAN. The 79 municipalities of the State were included, divided into 11 micro-regions. Population coverage was estimated based on the number of people enrolled in SISVAN and the population estimated by the Brazilian Institute of Geography and Statistics (IBGE). In order to classify the nutritional status, we adopted the WHO references for the following anthropometric indexes: children and adolescents (sex- and age-specific BMI z-scores), adults and elderly individuals (age-specific BMI).

Results: The percentage of general population coverage was considered low (10.4%) ranging from 5.3% to 20%. According the age groups, the coverage was higher among children (23.3%) and lower among elderly individuals (2.7%). Regarding nutritional status, the prevalence of underweight was 5.1% for children, 3.0% for adolescents, 2.5% for adults and 11.8% for elderly population. Overweight (including obesity) was found to be high for all age groups, mainly for adults and elderly individuals, as follows: children (14.2%), adolescents (9.1%), adults (66%), and elderly (54%).

Conclusions: The prevalence of underweight was high among children and elderly. Obesity were especially high among all age groups, mainly for adults and elderly. Therefore, the population coverage for the SISVAN was considered low. The SISVAN should be effectively implemented in the basic care to develop health promotion programs.

Keywords: Nutritional Surveillance, Nutritional Status, Age groups.

EVALUATION OF INDUSTRIAL FOOD AND BEVERAGES NUTRITION CLAIMS AVAILABLE IN SUPERMARKET IN MEXICO CITY

[1]Castillo, Alejandra; [1]Ocampo, Heilen; [1]Rodríguez, Julio; [2]Tolentino Mayo, María Lizbeth.

[1]Nutritionist. Health and Nutrition Research Center. National Insitutute Public Health. Mexico.; [2]MSc. Nutritionist. Health and Nutrition Research Center. National Insitutute Public Health. Mexico.

Background and objectives: The high prevalence of obesity is the result of changes in the power supply. The consumption of industrialized products is increasing. The information you provide on your packaging is not conducive to the population. Evaluate the compliance of nutrition claims in industrialized foods and beverages in relation to Official Mexican Standard 086-SSA1-1994 (NOM-86), which specifies changes in the nutritional composition of a product.

Methods: In 2015, 659 food and beverage products were photographed in 11 Supermarkets in Mexico City. The evaluated categories were beverages (N = 173), sweet snack (N = 81), salty snack (N = 98), dairy products (N = 211), breakfast cereals (N = 10). Food and beverages were analyzed by the NOM-086, to evaluate the correct use of nutrition claims. The evaluation of the nutrition claims was made with the nutritional specifications of the NOM-086, having as parameter of the following classification: "low sodium" ($\leq$140 mg / lot), "low fat", "energy free", through a descriptive analysis

Results: 42% of the products presented a nutrition claim in the frontal packing. However, 2% of the products met the requirements according to their nutritional content to carry the nutrition claim. However, of the products complying with NOM-086, 46.4% contain the claims: "low in sodium", 37.6% "low in fat", 15.9% "sugar free" and 5.76 % "energy free". In the salty snack group 90.8% of the nutrition claims presented in the products did not comply with the normativity required by the greater quantity of nutrients than those specified in the standard. In products that presented the claim "no sugar" in the sweet snack category 98.8% does not meet the specifications of NOM-086. On the other hand, in the foods and beverages that contain the nutrition claim "energy free" only in the category of drinks 22% complied with the requirement

Conclusions: The results showed the need to evaluate and monitor, through an independent body, the proper use of the nutrition claims, that appear in the front of industrialized foods and beverages. The actions implementation applies to contribute the correct use of NOM-086 to avoid confusing and incorrect information in the food and beverage industry.

Keywords: Label, Nutrition-claim, Low-sodium, Low-fat, Sugar-free

TERRITORIAL INEQUALITIES IN THE AVAILABILITY OF FOOD IN THE MUNICIPALITY OF RIO DE JANEIRO, BRAZIL

[1]Pereira de Castro Junior, Paulo Cesar; [2]Araújo Nobre, Aline; [3]Rugani Ribeiro de Castro, Inês; [4]de Oliveira Cardoso, Letícia.

[1]PhD student. Nutritionist. National School of Public Health. Oswaldo Cruz Foundation. Rio de Janeiro. RJ. Brazil; [2]PhD. Researcher. Scientific Computing Programme. Oswaldo Cruz Foundation. Rio de Janeiro. RJ. Brazil; [3]PhD. Nutritionist. University professor. Institute of Nutrition. Rio de Janeiro State University. Rio de Janeiro. RJ. Brazil; [4]PhD. Nutritionist. Researcher. National School of Public Health. Oswaldo Cruz Foundation. Rio de Janeiro. RJ. Brazil.

Background and objectives: Food environment can be defined as the set of physical, economic, political and socio-cultural environments as well as opportunities and conditions that influence food choices. Understanding the community food environment, characterized by availability and access to food, is important to help understand the food and nutritional security scenario to which populations are exposed. Objective: The study describes the food environment in the city of Rio de Janeiro, identifying the inequalities in food availability.

Methods: The addresses of food markets and establishments that sell food and meals, licensed and registered in the Health Surveillance Information System (VISAN) of the municipality until 2013 were collected and georeferenced. The 21 types of establishments were classified into three groups: G1) those that sold mainly healthy foods (e.g. food markets); G2) those that sold healthy and unhealthy foods (e.g. supermarkets and restaurants); G3) those that sold mainly unhealthy foods (e.g. fast foods). The following indicators, according to the groups, were constructed to evaluate the food environment of the 33 administrative regions (AR) of the municipality: 1) proportion of establishments (group); 2) density of establishments (group). Food environment was characterized by means of the construction of maps with the location of the establishments (groups) and the presentation of maps with the indicators considering the average income per capita of the AR.

Results: There was a higher proportion of G2 establishments (min: 53%, max: 88%, mean: 72%), followed by G3 (min: 1%, max: 30%, mean: 20%) and G1 (min:0%, max: 42%, mean: 8%). We observed inequality of healthy foods availability, since the RA with better income were also those ones that showed the highest density of G1 and G2 establishments.

Conclusions: The low availability of establishments that sold healthy foods suggests the predominance of an obesogenic envi-

ronment in the municipality, especially in poorer areas, pointing out the need for public supply policies that guarantee food and nutritional security of the population.

Keywords: Food environment, inequality, indicators, socio-spatial analysis

CHANGES IN HOUSEHOLD FOOD INSECURITY BETWEEN ENROLLMENT AND EXIT FROM A BLANKET SUPPLEMENTARY FEEDING PROGRAM FOR CHILDREN 6 – 23 MONTHS OLD IN BURKINA FASO

[1]Langlois, Breanne; [2]Nikiema, Laetitia; [1]Cliffer, Ilana; [3]Suri, Devika; [4]Shen, Ye; [5]Webb, Patrick; [5]Rogers, Beatrice.

[1]MPH. Friedman School of Nutrition Science and Policy. Tufts University. USA.; [2]MD, MPH. Department of Public Health. Institut de Recherche en Science de la Santé. Burkina Faso.; [3]MPH, MS. Friedman School of Nutrition Science and Policy. Tufts University. USA.; [4]MSPH. Friedman School of Nutrition Science and Policy. Tufts University. USA.; [5]PhD. Friedman School of Nutrition Science and Policy. Tufts University. USA.

Background and objectives: In a cluster-randomized trial aimed to assess the effectiveness of four supplementary foods in the prevention of child malnutrition, we assess beneficiaries' household food insecurity between program enrollment and exit.

Methods: Children participating in a blanket supplementary feeding program were recruited on a rolling basis between August 2014 and June 2015. This is a preliminary, descriptive analysis of household food insecurity among participating households. Data were collected at baseline and households' exit from the program to capture socioeconomic characteristics including household food insecurity, based on the Household Food Insecurity Access Scale (HFIAS). A categorical variable representing combinations of seasons of program enrollment and exit was created: dry/dry, rainy/dry, dry/rainy, and rainy/rainy. Descriptive statistics of change in HFIAS score (endline – baseline) were calculated and stratified by baseline HFIAS category and season of program enrollment and exit.

Results: A total of 6,092 children were enrolled. Of these, 5,236 completed the program of food supplementation and 5,206 were included in analysis. At baseline and endline, respectively, 43% and 35% of households were food secure, while 15% and 18% were severely food insecure. Mean HFIAS scores were 3.81 ± 4.82, and 4.31 ± 4.95 at baseline and endline, respectively, with an overall increase in food insecurity of 0.51 ± 5.94 units. Disaggregated by season of baseline and endline, mean changes varied: dry/dry 0.36 ± 5.76, n=1066; rainy/rainy 1.89 ± 5.42, n=170; rainy/dry -1.65 ± 6.17, n=890; dry/rainy 1.10 ± 5.82, n=3080. Households that were food secure or mildly food insecure at baseline had an increase in food insecurity at endline, on average, while households that were moderately or severely food insecure at baseline had a decrease in food insecurity at endline, on average.

Conclusions: Overall, food insecurity increased among households enrolled in a supplementary feeding program for young children, but varied according to baseline status and season of program enrollment and exit. More work is needed to understand the dynamics of household food insecurity in the context of a SFP.

Keywords: supplementary feeding program, household food insecurity

NUTRITIONAL STATUS OF THE PEOPLE ASISTED IN THE PRIMARY LEVEL HEALTH SERVICES IN MONTEVIDEO AND INLAND OF URUGUAY

[1]Elichalt, Marta; [2]Gronros, Diana.

[1]MSc. Nutricionist. Nutrition School. University Republic. Uruguay.; [2]Nutricionist. Nutricion School. University Republic. Uruguay.

Background and objectives: To characterize the nutritional status (NS) of the assisted population in primary care services in Montevideo and inland between April and November 2016. To compare the type and magnitude of the nutritional problems between services of Montevideo and it's inland, and between services of Montevideo, according to municipal grouping based on the proportion of poor families (PF).

Methods: The information collected by the students in the last year of the Nutrition Degree was systematized, and they applied a survey with Google forms. The information collected was: sex, age, reason for referral, anthropometric diagnosis and service. The NS in children was assessed by anthropometric indicators and compared with WHO standard on 2006. In adults, the body mass index was used and compared with the WHO reference on 1998. The services were grouped by location considering the municipal division of Montevideo according to the proportion of FP by level of income.

Results: The assisted population was 1982 corresponding to 17 services. Of all, 75% were women and almost half were over 18 years of age. 50% of referral reasons were Non-Communicable Diseases. Over-malnutrition exceeded the value identified in studies at the national level in one-third of services. Deficit malnutrition varied in services between 5% and 20%. In children under 18, the prevalence of malnutrition due to deficit and excess was bigger than in other national studies. There are important differences in malnutrition due to deficit and excess in adults and children among services with a higher proportion of PF.

Conclusions: There are problems of excess and deficit that surpass the national data. The nutritional stage in which the user is captured and the proportion of PF are probably determinants of the type and magnitude of the nutritional problems found in nutritional care.

SUPPLEMENTATION OF HUMAN MILK AND ITS OSMOLALITY

[1]Nascimento Alves Ferreira, Isabella; [2]Valente Mendes Soares, Fernanda; [3]Carioca da Costa, Ana Carolina; [4]Reis Novak, Franz; [5]Lopes Moreira, Maria Elisabeth.

[1]Ms. Biomedical Scientist. Fernandes Figueira Institute (FIOCRUZ). Rio de Janeiro. Brazil; [2]PhD. Nutritionist. Fernandes Figueira Institute. Brazil; [3]PhD. Statistic. Fernandes Figueira Institute. Brazil; [4]PhD. Pharmaceutical. Fernandes Figueira Institute. Brazil; [5]PhD. Doctor. Fernandes Figueira Institute. Brazil.

Background and objectives: Human milk is the ideal food for newborns. However, due to the increased nutritional need for preterm infants, human milk is often insufficient as an exclusive source of nutrition to meet its nutritional needs. As a result, it is often necessary to add fortifiers and/or vitamins in the milk offered to them. These products, however, do not only increase nutrients, but also osmolality, which can lead to health problems such as necrotizing enterocolitis.

Considering the need to understand the effects of physical and chemical factors on human milk, this study aims to analyze the variations of the osmolality in human milk samples, according to their nutritional and vitamin supplementation, and also to different preparation times and temperatures.

Methods: Prospective, quantitative and experimental study. Samples of human milk, supplemented with FM85®, Enfamil HMF® and vitamins protovit plus®, viter c® and mineral fersil®, collected at the Human Milk Bank of Fernandes Figueira Institute (FIOCRUZ), after the signing of a free and informed consent form by donors. The samples were analyzed in triplicate at the following moments: in up to 5 minutes; after 20 and 40 minutes; every hour until the completion of 8 hours; after 12 and 24 hours, at room temperature and also under refrigeration at 6 °C. The results of the osmolality determinations were obtained automatically using a digital Osmometer (Advanced Instruments A+, model 3320) calibrated according to the recommendations of the manufacturer.

Results: The samples with the FM85® fortifier and with the vitamin protovit plus® were the ones that presented the highest osmolalities, surpassing the value recommended by the American Academy of Pediatrics (AAP), in the different periods of time and temperature. Samples with higher concentrations of vitamins and fortifiers presented proportionally higher values of osmolality.

Conclusions: Increased osmolality was observed with respect to time and temperature. Some samples of human milk did not meet the safety specifications recommended by AAP. It was evidenced the need to elaborate protocols for the supplementation of human milk, in order to maintain control of its osmolality when added with additives and fortifiers, ensuring that it remains at levels that can be tolerated by the newborns.

EMERGING ENVIRONMENTAL FACTORS IN CHILD STUNTING GLOBALLY

Ly, Stephanie.

PhD student. Community Health Sciences. UCLA Fielding School of Public Health. Los Angeles. California. USA.

Background and objectives: Linear growth stunting in children is considered a form of chronic malnutrition. However, nutritional interventions have modest effects on height. The World Health Organization (WHO) estimated that 171 million, or 23.8% of the world's children are stunted. Emerging research has implicated environmental exposures leading to poor intestinal health, which reduces nutrient absorption and growth hormone production. The condition is known as environmental enteric dysfunction (EED) and is onset by constant exposure to fecal pathogens with a possible link to mycotoxins created by mold species. A systematic review was conducted on EED and mycotoxins on stunting to understand current knowledge and novel areas for research expansion.

Methods: Specific search terms were used to conduct a systematic review in WHO Library and PubMed public databases. Next, duplicates were removed and remaining full-text articles were screened for eligibility. The criteria for article inclusion included: primary research, publication between 2011-2016, translatability to humans, and focus on the main topics of research interest.

Results: A total of 302 articles were found after the initial search, 191 articles remained after duplicates, and 23 articles met eligibility criteria. Among the final articles included in the review, 12 focused on EED and 11 on mycotoxins in stunting. EED etiology was confirmed in constant exposure to fecal pathogens in diverse underserved populations. EED interventions used micronutrient supplements, autoimmune treatments, and behavioral trials. None of the interventions significantly alleviated EED or stunting. Among mycotoxin-focused articles, studies found that aflatoxin affected linear growth and mycotoxin prevalence was established in new populations. Mycotoxin interventions tested absorbents for food and replaced contaminated maize in households with both studies showing promising results. Pathways linking mycotoxin exposure to EED was also articulated in recent articles.

Conclusions: Primary research conducted in the last five years have yielded modest impacts on stunting resolution but have expanded knowledge. Novel pathways between EED and mycotoxins have been implicated in linear growth and highlight the unmet need for continued etiologic and interventional research. A majority of studies was conducted in low- and middle-income country settings, which highlights the lack of access to adequate sanitation infrastructure and implications on stunting.

Keywords: review, stunting, environment, enteropathy, mycotoxins

BODY IMAGE PERCEPTION AND ITS RELATIONSHIP WITH SCHOLASTIC ACHIEVEMENT CHILEAN ADOLESCENTS

[1]Villagrán Silva, Francisca Marión; [2]Orellana Zapata, Yasna; [3]Almagià Flores, Atilio; [4]Ivanovic Marincovich, Daniza.

[1]MSc. Professor of Biology and Master in Nutrition and Food. Institute of Nutrition and Food Technology (INTA). University of Chile. Santiago. Chile; [2]PhD. Statistics. Institute of Nutrition and Food Technology (INTA). University of Chile. Santiago. Chile.; [3]Mrs. Biology. Institute of Biology. Laboratory of Physical Anthropology and Human Anatomy. Catholic University of Valparaiso. Valparaiso. Chile.; [4]MSc. Science in Nutrition. Institute of Nutrition and Food Technology (INTA). University of Chile. Santiago. Chile.

Background and objectives: During the last decades, an increase in sedentary lifestyle, poor dietary practices, overweight and obesity in adolescents, resulting in changes both in body image and perception which can affect scholastic achievement (SA). The aim of this study was to evaluate the relationship between scholastic achievement in the University Selection Test (PSU) of Language (PSUL) and Mathematics (PSUM) with the Body Image Perception (BIP) in Chilean adolescents.

Methods: A representative and proportional sample of 33 educational establishments was randomly selected, in the Metropolitan Region, Chile. During 2013, 418 school-age children of the 4st grade of high school, of both sexes, 43.1% were males (n = 180) and 57% females (n = 238) participated. The subjects'consent was obtained according to Declaration of Helsinki to undergo anthropometric measurements of weight and height to calculate BMI. BIP was assessed by Stunkard (1990) method which was validated for adolescents (Cortés et al., 2009), showing 9 male and female body silhouettes, ranging from very thin to more robust each silhouette has assigned its corresponding BMI from 17 kg/m2 to 33kg/m2: Underweight (silhouette 1), Normal (silhouettes 2-5), overweight (silhouettes 6-7) and obesity grade 1 and grade 2 (silhouettes 8-9). The calculated difference between BMI actual and perceived, obtaining three categories: Overestimation (they look fatter than they are), Adjusted Perception and Underestimation (they look thinner than they are). The socioeconomic strata (SES), using the Graffar modified method. SA was measured using the 2013 PSU both PSUL and PSUM, provided by the Department of Education of the Ministry of Education. Statistical analysis of the data was performed using the STATA 13 software.

Results: 25.8% of men tended to overestimate their perceived BIP, and 39.6% of women underestimated (p <0.0001). There was evidence of significant differences in PSUM in women (p <0.05) and in the low-SES adolescents (p <0.05) who underestimated their perceived BIP . They obtained the lowest PSUM scores in both groups.

Conclusions: The self-report survey is a good indicator BIP approach the nutritional status of adolescents and a new factor that could be influencing SA. Grants FONDECYT 1100431 and 1150524.

PERCEPTIONS OF PRICE AND STORE AVAILABILITY OF FRUIT AND VEGETABLE AND THEIR ASSOCIATIONS WITH FRUIT AND VEGETABLE INTAKE AMONG ADULTS IN FOUR SOUTH AMERICAN CITIES

[1]Elorriaga, Natalia; [2]Gutierrez, Laura; [3]Chaparro, Raúl Martín; [3]Melendi, Santiago; [4]Poggio, Rosana; [5]Ponzo, Jacqueline; [6]Lanas, Fernando; [7]Mores, Nora; [8]Rubinstein, Adolfo; [9]Irazola, Vilma.

[1]MSc. BSc. Nutritionist. South American Center of Excellence in Cardiovascular Health. Institute for Clinical Effectiveness and Health Policy. Escuela de Nutrición. Universidad de Buenos Aires. Argentina.; [2]BSc. South American Center of Excellence in Cardiovascular Health. Institute for Clinical Effectiveness and Health Policy. Argentina.; [3]MD. South American Center of Excellence in Cardiovascular Health. Institute for Clinical Effectiveness and Health Policy. Argentina.; [4]Rosana Poggio. MD. MSc. PhD. South American Center of Excellence in Cardiovascular Health. Institute for Clinical Effectiveness and Health Policy. CONICET. Argentina.; [5]MD. MSc. Universidad de la República. Uruguay.; [6]MD. MSc. Universidad de La Frontera. Chile.; [7]MD. Secretaría de Salud. Municipalidad de Marcos Paz. Pcia Buenos Aires. Argentina.; [8]MD. MSc. PhD. South American Center of Excellence in Cardiovascular Health. Institute for Clinical Effectiveness and Health Policy. CONICET. Argentina.; [9]MD. MSc. South American Center of Excellence in Cardiovascular Health. Institute for Clinical Effectiveness and Health Policy. CONICET. Argentina.

Background and objectives: Sufficient intake of fruits and vegetable(FV) has been associated with a reduced risk of chronic diseases and body weight management. South American(SA) diet is characterized by low intakes of FV. There is growing evidence, from developed countries, that consumer nutrition environment is an important determinant of dietary behavior. We investigated the perceptions about FVs availability and price in local food stores and their associations with FV's intake among adults in the following cities: Bariloche, Marcos Paz (Argentina), Temuco (Chile) and Canelones (Uruguay).

Methods: We examined data of 5009 men and women, aged 40-80y, participating in the CESCAS (Centro de Excelencia en Salud Cardiovascular del Cono Sur) I Study, a population-based prospective cohort. Perception about the store consumer nutrition environment was measured using the Perceived Nutrition Environment Measurement Survey(NEMS-P) and FV intake with a Food Frequency Questionnaire. Linear and logistic multivariate regression analyses were conducted to assess associations between the perceived environment and FV consumption (mean intake and frequency of ≥5 servings/d) adjusting for sex, age, city, education and perceived food insecurity.

Results: Average FV intake was 2.5 servings/d; only 7.5% reached ≥5 servings/d. Fifty-two per cent of participants strongly agreed that in their neighborhood "it is easy to buy FV", "the fresh produce is of high quality", and "there is a large selection of fresh FV". However, 71% reported that FV were expensive or very

expensive. Adjusting for covariates, those with better perceptions about FV store availability reported a slight difference in FV intakes (difference: + 0.28 servings/d, 95%CI: 0.19;0.36) and more frequently reached ≥5 servings/d (OR:1.40, 95%CI: 1.17;1.76). Price's perceptions were not associated with FV consumption.

Conclusions: Half of the participants had positive perceptions about FV availability, quality and large selection in local food stores, and that was independently associated with higher FV consumption. Most of the adults had a negative perception about price of these foods, however, that perception wasn't significantly associated with FV intakes. This information contributes to the knowledge of nutrition consumer environments in SA and their relation with diet behaviors. Comparisons with in-store audit measurements will help to further develop interventions to promote healthy diets in the region.

COMPLIANCE OF FOOD AND BEVERAGE MESSAGES WITH THE NUTRITIONAL CRITERIA OF THE ADVERTISING REGULATION IN OPEN TELEVISION IN MEXICO

[1]Tolentino Mayo, María Lizbeth; [2]Hernández, Elizabeth; [3]Bahena, Liliana; [4]Théodore, Florence; [5]Velasco, Anabel; [4]Rivera, Juan; [4]Barquera, Simon.

[1]Instituto Nacional de Salud Pública; [2]MSc. Nutriotinist. Instituto Nacional de Salud Publica. Mexico; [3]MEd. Nutritionist. Instituto Nacional de Salud Publica. Mexico; [4]PhD. Instituto Nacional de Salud Publica. Mexico; [5]MSc. Nutritionist. Instituto Nacional de Salud Publica. Mexico.

Background and objectives: It has been well documented that overweight and obesity are multifactorial diseases. Food and beverage (F&B) advertisements, particularly directed to children are one of such factors that influence food preferences, and consumption. In July 2014, the Government Guidelines of advertising of F&B to children on TV and movie theatres were implemented in Mexico. The Guidelines established nutritional criteria, restriction of time schedules and program genres (excluding soap operas, sports, news and programs directed to audiences above 12 years of age), where products with low nutritional value were restricted to be advertised towards children younger than 12 years of age.

The aim of this study was to observe the pattern of F&B advertisements within children's peak viewing time, time restriction schedule, and different program genres before and after the Guidelines were implemented.

Methods: From January 2013 to February 2015, programs were recorded from the four major Mexican television networks nationwide. A total of 20 recordings per channel were taken prior and after the Guidelines were implemented. Overall 2,533 hours

were recorded and coded. All F&B products were categorized either as core or non-core, according to their nutrient content

Results: From all of the identified advertisements (n=91,913) 18.1% were of F&B. During the restricted hours, after the implementation of the regulation, a reduction in the amount of F&B advertisements from 45.9 to 41.3% was shown; furthermore, there was a reduction in non-core F&B advertisements from 77.9 to 73.3%, nevertheless, this reduction did not happened in all the categories of F&B. For example: the group that increased the number of advertisements during the regulated hours was savory snacks (foods added salt or fat); their prevalence was 5.7% before guidelines and 8.3% after guidelines. Other groups that increased the percentage of advertisements was sweet breads, cakes, muffins, high fat savory biscuits, pies, pastries, and rice pudding, from 7.2% to 10.6% after the regulation

Conclusions: According to the obtained data, it is observed that the general population, especially children and adolescents in particular are exposed to a great quantity and variety of non healthy food and beverages advertisements, and their message is reinforced several times during TV hours

Keywords: obesity, advertisement, regulation, children, non-healhty-food

EFFECT OF EXCESSIVE GESTATIONAL WEIGHT GAIN DURING PREGNANCY ON DAUGHTER'S BREAST DENSITY AT THE END OF PUBERTY ONSET

[1]López Fernández, Ana; [2]Pereira, Ana; [2]Corvalan, Camila; [2]Garmendia, María Luisa; [2]Uauy, Ricardo.

[1]Nutritionist. Institute of Nutrition and Food Technology. University of Chile. Santiago. Chile.; [2]MD. PhD. Institute of Nutrition and Food Technology. University of Chile. Santiago. Chile.

Background and objectives: Breast density (BD), is one of the most important risk factors for breast cancer (BC). The relationship between maternal gestational weight gain (GWG) and BD in their daughters have not been explored.

The Institute of Medicine (IOM) 2009 established recommendations for GWG according to pre gestational body mass index (BMI). Thus our aim is to assess the association between excessive GWG according to IOM recommendations and daughter's breast composition (% of fibroglandular volume (%FGV) and absolute fibroglandular volume (AFGV) at the end of puberty onset (Tanner B4).

Methods: We included 341 girls from an ongoing cohort of 400 low-income Chilean girls born in 2002-2003 and their mothers. Maternal GWG was self-reported by questionnaire (year 2007) and in 2010 we performed digital mammography for measuring BD. In daughters, we collected data on anthropometry (weight and height) and breast composition by DXA at Tanner B4. %FGV and AFGV is derived considering a two-compartment model of adi-

pose and fibro-glandular tissue using a software developed at the University of California San Francisco; test-retest precision was 2.8%. Crude and adjusted (BMI z-score at B4, age at menarche, maternal schooling and maternal breast density) Odds Ratio (OR) and 95%CI were estimated to assess the relation between excessive GWG according to IOM 2009 and 80th percentile of %FGV and AFGV.

Results: Mean GWG was 13.7 kg (SD=7.0). A larger proportion of women with excess weight before pregnancy exceeded the recommended GWG compared to women with normal pre-gestational weight (58.8% vs 31.8% respectively). We did not observe an association between excessive GWG and %FGV; however, women who had excessive GWG their daughters had higher levels of AFGV (OR adjusted: 2.10; 95% CI 1.18 - 3.77) at B4.

Conclusions: Daughters of women who had excessive GWG according to IOM had higher AFGV. This could be explained by metabolic and hormonal exposure in utero, which could be modifiable at early life reducing BC risk in adulthood. Funding: WCRF 2010/245.

FOOD ENVIRONMENT CHARACTERIZATION OF A PUBLIC UNIVERSITY IN RIO DE JANEIRO

[1]*Dias, Juliana Furtado; [2]Batista, Carolina de Araujo; [3]Pereira, Alessandra Pereira; [4]de Aquino, Luana Azevedo; [4]Santos, Claudia Roberta Bocca; [4]Leão, Leila Sicupira Carneiro de Souza; [5]Franco, Amanda da Silva.*

[1]PhD. Professor. Departamento of Aplicated Nutrition. Nutrition School. Rio de Janeiro Federal State University. Brazil; [2]Graduation Student. Nutrition School. Rio de Janeiro Federal State University. Brazil; [3]Professor. UNIRIO. Rio de Janeiro. Brazil.; [4]PhD. Professor. Departament of Nutrition and Public Health. Nutrition School. Rio de Janeiro Federal State University. Brazil; [5]PhD. Professor. Veiga de Almeida University. Rio de Janeiro. Brazil.

Background and objectives: The characterization of the food environment helps to identify factors that can influence food behavior and is considered a promising strategy to promote healthy eating habits. Thus, this study has objective was to describe the food environment of the campuses of a public university in Rio de Janeiro, Brazil.

Methods: The data collection took place was performed during the second semester of 2016 in establishments located on university campuses, totaling 1 snack bar and 4 establishments of the mixed type. The instrument used for the data collection was proposed and validated by Franco (2016) for analysis of the universal food environment. There was preview approval by the Ethics Committee and with consent of all the responsible for the establishments in the analyzed university.

Results: The nutritional information wasn't found at the analyzed establishments. Only the fruit in natura was marketed at all establishment, raw and cooked vegetables and veggies was offered

by 80% and 60%, respectively, and 75% offered leguminous; a 100% of snack bars offered pastry and sandwiches. The products with the highest averages of different types were candy or chewing gum (8±7.1), soft drinks (9±3.7), chocolates and chocolates bar (8 ± 7.1), crackers (8 ± 12.3) and cookies (7±9.1). Sandwiches, snacks and other products with low nutritional value, had lower average price fruit or fruit salads; and sweetened drinks (like soda and natural guarana) also presented average price less than natural fruit juice.

Conclusions: The university's food environment hinders access to healthy feeding, presenting several barriers on college campuses.

Keywords: Food environment. University. Beverages. Foods. Price.

PROGRAM TO IMPROVE FRUIT AVAILABILITY IN A WORKPLACE AND ITS EFFECT ON THE PERCEPTION OF CONSUMPTION BY EMPLOYEES

[1]*Carmona Garcés, Isabel Cristina; [2]Diaz-Garcia, Juliana; [2]Correa-Madrid, María Camila.*

[1]Nutritionists. MSc en Educación. Profesora Escuela de Nutrición y Dietética. Universidad de Antioquia. Grupo de Investigación Interdisciplinaria en Educación para la Salud y Educación Nutricional. GIIESEN. Nutricionista Grupo Éxito. Colombia.; [2]Nutritionist. Grupo Éxito. Colombia.

Background and objectives: Grupo Éxito, is the biggest private employer in Colombia, with an amount of 42.000 employees, contemplates in its Nutrition Policy the promotion of a healthy work place, which aims contribute to the integral health of its employees through programs of health promotion and disease prevention. One of the actions implemented within this strategy is the program that delivery fruit in the office, began in 2015. The aim of this paper was analyze a change perception in the consumption of fruits in the employees who were impact by the program in its first year.

Methods: Cross-sectional study. A total 2,399 employees were qualified to answer the survey during two weeks on the company's virtual platform. The survey includes next variables: daily fruit consumption, portions of fruit consumed per day, origin of the fruit consumed, change perception of the amount of fruit consumed since the beginning of the program. A descriptive analysis was performed using X2 tests to establish the relationship between the variables of interest. α = 0.05. SPSS software v.23.

Results: 282 employees answered the survey, 11.8% of the qualified employees. 78.7% reported consuming fruit daily, of these 30.9% consume one serving daily, 33.0% two portions, 17.7% three portions and 17.0% four or more servings per day. The consumption of fruit comes mostly from the program offered by the company, followed by the home and finally from other sources such as retail. About the increase in fruit consumption, 64% of surveyed mentioned that their consumption increased with the program. A significant relationship was found between the increase of fruit consumption and the implementation of the program (p = 0.0087).

Conclusions: The companies can implement small actions such as facilitating access and availability of fruits in the workplace, promoting an adequate diet and providing environmental support for the achievement of healthy eating habits.

Keywords: Fruit, Workplace, Health, Strategies, Health Promotion.

PREVALENCE OF EXCLUSIVE BREASTFEEDING IIN CHILDREN ACCOMPANIED BY SISVAN-WEB IN THE MUNICIPALITY OF DOURADOS-MS BETWEEN YEARS OF 2008 TO 2015

[1]Alonso Balthazar, Emilia; [2]Spoladore Rego, Ariane.

[1]PhD. Nutritionist. Federal University of Grande Dourados - Faculty of health science - Course Nutrition. Brazil; [2]Nutritionist. Brazil.

Background and objectives: Not breastfeeding (BF) in the first years of life has been raising infant morbidity/mortality rates. Therefore, official governmental must monitor this practice.

SISVAN – WEB (NUTRITIONAL SURVEILLANCE SYSTEM- WEB) was created in 2008 in Brazil in order to facilitate the health follow-ups registrations of Unified Health System's users, attended at basic health Unit. This system allows public acess to reports that contains the Diagnosis of the users' health.

This study's objective was to evaluate the prevalence of Exclusive Breastfeeding (EBF) at Dourados – MS (Brazil) by the SISVAN-WEB, among children aged 0 to 6 months between the years of 2008 and 2015.

Methods: It was analyzed public reports of food consumption from 2008 to 2015. In these reports it was evaluated the distribution of EBF children during the health care attendance and the distribution of EBF children according to the BF duration. Data from the Basic Care Information System (SIAB) were also analyzed to assess the total number of children under six months of age registered at basic health Unit.

Results: Analyzing the results it was possible to verified that the year 2010 was the period with the most prevalence of EBF (98,78% of 492 children), and the lowest prevalence was in 2008 (43,48% of 23 children). The prevalence of BF in Dourados's city have indicators considered good by the World Health Organization (WHO), with the exception of 2008. The SISVAN-WEB, in this period, was able to analyze on average 39% of the children registered by the basic health units. The data also showed that the majority of children were being breastfeed by a period of one month (8%).

Conclusions: Although the numbers show that the city of Dourados-MS has good levels in EBF according to WHO indicators, the results were hampered, due to the lack of Of SISVAN_

WEB data. Oftentimes the workers from units health, doesn't fill the data base due the lack of kwnoledge of its importance. In Brazil there is a need in promoting BF, since many mothers stop breastfeeding due to dificulties and the need for better understandment about breast milk importance.

Keywords: breastfeeding; SISVAN-WEB; basic health units

USE AND PERCEPTION OF THE NUTRITION LABELING OF PACKAGED FOODS AND BEVERAGES IN MEXICO

[1]Tolentino Mayo, María Lizbeth; [2]Rincon-Gallardo, Sofía; [3]Bahena, Liliana; [4]Rios, Victor; [5]Rivera, Juan; [6]Barquera, Simon.

[1]MSc. Instituto Nacional de Salud Publica. Mexico; [2]MSc. Nutriotinist. Instituto Nacional de Salud Publica. Mexico; [3]MEd. Nutrionist. Instituto Nacional de Salud Publica. Mexico; [4]MSc. Universidad Autonoma Metropolitana. Mexico; [5]PhD. Instittuto Nacional de Salud Publica. Mexico; [6]PhD. Instituto Nacional de Salud Publica. Mexico.

Background and objectives: Nutrition labeling has been recognized as a tool that influences food choices towards healthier; furthermore, it promotes reformulation of processed foods. The aim of this study was to document the use and perception of the information of different nutrition labels (Guideline Daily Amounts GDA, nutrition information table, list of ingredients, logos and claims) displayed in packaged foods and beverages of Mexico.

Methods: Data was taken from a national representative survey. The semi-structured labeling questionnaire was previously piloted and validated with population from different socio-economic status, age groups, and regions of the country. The questionnaire consisted of 16 items. The first two questions were related to the knowledge about the daily calorie consumption of a normal healthy adult in a single day. The other questions were related to the knowledge, reading, use, comprehension and perception of the displayed information in the packaged food and beverages, when choosing a food product at the sale point. Answers were reported in a Likert scale.

Results: The survey collected data from 8,667 persons older than 20 years. From which, 52.3% were women, 26.7% were from the group of 20 to 29 years, and 16.9% of 60 years and older. From the total or participants 89.7% knows how to read.

At the national level, 76.3% (IC95%, 73.5,78.8) of the population did not know or did not respond how many calories they are supposed to consume, and 7.2% (IC95%, 6.1,8.6) responded that less than 500 calories.

At the national level, from the total of the population that knows how to read 40.6% (IC95% 38,43.3) reported reading the nutrition labeling of packaged foods and beverages. The percentage of the population that read the nutrition information displayed in the back of the package of processed foods is higher than the percentage of people that disclaimed reading the front of the package labeling (71.6% vs 55.9%) (p<0.05).

Conclusions: It is important to identify and apply a version of the front of the package labeling that is more susceptible of been understood and used by a larger sector of the population. This version must be implemented as a public health strategy.

University of Bordeaux. F-33000 Bordeaux. France.; [8]MSc. PhD. UMR 204. Nutripass. Institut de Recherche pour le Développement. IRD. UM. Supagro (IRD). Montpellier. France.

Background and objectives: A pilot cash transfer (CT) program was implemented in the two regions of Togo concentrating the worst nutritional outcomes. The intervention, which aimed at improving child's nutrition and health, combined Behavior Change Communication activities (BCCA) with a monthly cash transfer given to women during the "1,000 days period". A process evaluation was performed to understand beneficiaries' perception and utilization of the program.

Methods: Qualitative data, encompassing semi-structured interviews (n=60), focus groups (n=15) and non-participant observations of CT's payments and BCCA (n=40) were collected 8 months after the program's start on a purposive sampling of beneficiaries. Quantitative data were also collected on cash utilization from 400 beneficiaries, after 2 years of intervention. All data were collected in local dialects by experienced surveyors. Qualitative data were fully translated, transcribed and analyzed by thematic content using Nvivo®. Descriptive statistics were produced using R-3.3.3®.

Results: Beneficiaries were globally satisfied with the intervention. They particularly appreciated BBCA-CT's synergy that enabled them to acquire knowledge and apply it in practice. They mainly spent CT to meet their child needs: 91% of women declared using CT to buy them food and 68% to cover their health expenditures.This conformist utilization, in line with the program objectives, resulted from a strong social pressure. Despite this tight control, money was not always exclusively used by women nor devoted to children. Nearly 20% of beneficiaries regularly shared half of their CT, mainly with their spouse. Moreover, 30% of women who usually received money from their husband no longer benefited from it since they have entered the program. Another potential adverse effect of CTs lies in birth encouragement: 36% of women thought that CT may promote births, of which 70% said that CT personally encouraged them to have a child. Some women considered pregnancy as a way to continue receiving the CT. More farsighted women anticipated their program's exit by sparing some of their CTs or by initiating income-generating activities (40%).

Conclusions: Using mixed-methods enriched our understanding of beneficiaries' appropriation of the intervention, a crucial aspect that will help decoding program's "black box" and explaining its impact.

DIGITAL MESSAGING INTERVENTION TO PROMOTE APPROPRIATE FEEDING PRACTICE

[1]Hossain, Elora; [2]Kazi Mohammed, Mahmood; [3]Jahan, Nauruj; [4]Afsana, Kaosar.

[1]BDS. MPH. Senio Sector Specialist. Health Nutrition and Population Programme. BRAC. Bangladesh; [2]MBBS. MPH. Senior Medical Officer. Health Nutrition and Population Programme. BRAC. Bangladesh; [3]MBBS. MPH. Senior Manager. Health Nutrition and Population Programme. BRAC. Bangladesh; [4]MBBS. MD. MPH. PhD. Director. Health Nutrition and Population Programme. BRAC. Bangladesh.

Background and objectives: In Bangladesh preparing, serving and feeding children with bare hands is a common practice. Complementary feeding may not promote optimum childhood growth if consuming contaminated foods result in repeated bouts of illness. Proper health education is the only way to raise awareness among the community. So using video content for education is revolutionary approach to disseminate care education and emergency management to the underprivileged community through mobile phones for improving knowledge and practice. BRAC's mHealth programme is a comprehensive community based health care focusing on urban reproductive, maternal, neonatal, child and adolescent health. The purpose of the abstract is to demonstrate the achievement of digital nutritional interventions of the programme of 2016.

Methods: Video messages were implemented in four urban areas of Dhaka by community health workers through smart phones to educate and demonstrate about feeding and hygiene practice to mother of children under 5 years of age. Data were collected by Community Health worker's through observational checklist.

Results: Data from year 2015 shows that 68% of the parents are washing hand for preparing food and feeding. In 2016 about 90% were washing hand for preparing food and feeding, which reveals that using video content for education is more sustainable approach for health education. Data also shows that the incident of diarrhea reduced 35% in 2016.

Conclusions: Awareness and health education can make a big difference in behaviour and health practice of parent during food preparation and feeding. Enteric diseases are often caused by poor hygiene and can contribute to stunting. As the conventional awareness building mechanism cannot influence the parent's behaviour to the expected level, this video method of health education conceptualize an idea of awareness building and emergency management robustly influence their health practicing behaviour. A better understanding of the context of handwashing at these key times could help to develop effective interventions to improve hand hygiene practices thus the nutritional status of children under 5years of age.

Keywords: Complementary feeding, hand washing, health education, digital health messages, mHealth

FUNCTIONAL CAPACITY IN HEALTHY FREE LIVING ELDERLY WOMEN CÓRDOBA CITY, IN ACCORDANCE WITH THE AGE

Asaduroglu, Ana Virginia.

PhD. Nutritionist. Cátedra de Nutrición y Alimentación Humana. Escuela de Nutrición. Universidad Nacional de Córdoba. Argentina.

Background and objectives: Older adults are a vulnerable population group. Given the current conceptions regarding life quality within this group, keeping independence and autonomy at an advanced age is relevant.

Objective: to analyze the relations between functional capacity -physical and cognitive- by age in healthy free living elderly women from Córdoba city.

Methods: 178 healthy free living women ≥60 years old were included, which were evaluated by physical and cognitive functional tests. Functional capacity= physical+cognitive. Categories: independent (I), Partially dependent (PD), Dependent (D). Age (years): 60-69; 70-79; ≥80. Instruments: instrumental activities of daily living -IADLs- (points): with and without functional limitations (8 and 0-7 respectively). Folstein Minimental Examination –MME-(points): with and without cognitive decline (<24 and ≥24 respectively).

Results: Most women were functionally independent (78.09%). Cognitive decline doubled in relation to functional limitations as a cause of partial dependence.

Partial dependence was increased in relation to the age gaps. It was doubled in groups between 70-79 years and to four times more frequently in the ≥80 year's gap, regarding to 60-69 years.

Comparing the categories of functional capacity in each age range, the proportion of partial independence/dependence showed a ratio of almost 2 to 1 (51.41 vs 25%) among young women relation that resulted from 1 to 3 between the 80s and older (7.04 vs 22.22%). The distribution of functional capacity in each age group showed that functional independence decreased as the age was increased from 89.02% to 55.56%. The opposite was observed among partially dependent women, whose frequency doubled and quadrupled to younger people in groups of 70-79 and ≥80 years respectively. The age was associated with functional capacity (p=0.0029)

Two-thirds of partially dependent women had no physical limitations considering the IADLs, and 74.99% presented cognitive impairment.

Conclusions: Functional independence decreased as age increased. The contrary happened between the elderly partially dependent. Age and functional capacity were significantly associated.

Keywords: elderly women, physical function, cognitive function, functional capacity.

DIFFERENCE IN INDIVIDUAL DIURNAL WEIGHT FLUCTUATION IN COLLEGE ATHLETES

[1]*Cho, Chuhwa;* [2]*Nakazawa, Ayumi;* [2]*Kisara, Kumiko;* [3]*Koizumi, Kayo;* [4]*Yao, Norikazu.*

[1]Japan Women's College of Physical Education Graduate School. Japan; [2]M.S. Japan Woman's College Of Physical Education. Japan; [3]Ph.D. Japan Woman's College Of Physical Education. Japan; [4]M.S.Tokai University.Japan.

Background and objectives: The aim of this study was to the college athletes who usually training, it is to clarify diurnal weight fluctuation.

Methods: Twelve female rhythmic gymnasts (19.5±0.5years) and two male rugby player(20.5±0.7years) participated in this study. Body composition was measured InBody230 and 720. Body weight was measured at early morning fasting and then measured at seven times by 16 o'clock at 90 minute intervals using UC-321. After 16 o'clock, measurements were taken after the end of training, After that, before and after dinner and the next day when waking up. It was carried out 11 times in total. The amount of physical activity was measured with a 3-dimensional accelerometer Active style Pro HJA-750C , attached to the waist until the end of measurement. Water was provided and food was taken free, on the day of measurement, and each intake was measured. The change in the day of the weight was based on the first time and calculated a rate of change. In addition, difference between dietary intake and two measurements was obtained and systematic error was confirmed by Bland-Altman analysis.

Results: There was a significant positive correlation between each meal amount and body weight(P <0.05). However, there was

---

no significant relationship in weight loss between meals. A significant negative correlation was observed in weight loss during fasting in the early morning 12 hours after dinner.

Conclusions: In college athletes who usually training, It was suggested that weight gain is more difficult for weight loss at rest.

Keywords: college athletes, diurnal weight fluctuation, rhythmic gymnasts, rugby player, weight loss

AVAILABILITY OF FRUITS AND VEGETABLES IN THE FOOD ENVIRONMENT OF A PUBLIC UNIVERSITY

[1]Franco, Amanda da Silva; [2]Castro, Inês; [3]Bortolot, Beatriz; [4]Perez, Patricia.

[1]PHD. Professor at Veiga de Almeida University. Nutricionist at Duque de Caxias. RJ. Brazil; [2]PHd. Professor. UERJ. Brazil; [3]Student of Nutrition. UERJ. Brazil; [4]PhD. Professor at UERJ. Brazil.

Background and objectives: The university food environment stands out as strategic for the health promotion, since the foods offered can influences the eating habits of the students exposed there. Objective: To analyze the supply of fruits and vegetables in the university food environment of a Brazilian public university.

Methods: Sectional study, conducted in December 2016, in all establishments that produce meals at the university. A checklist was used to assess the availability and quality of fruits and vegetables. To analyze the supply of fruits and vegetables (FV), were considered the ten fruits and ten best vegetables most purchased by the family in the southeast region, according to the "Pesquisa de Orçamento Familiar (POF- 2008-2009). The absolute and relative frequency of establishments selling fruits and vegetables were calculed.

Results: Eight establishments were studied, of which 50% offered fruit (n-4) and 100% (n-8) offered at least one type of vegetable. Of the establishments that offered fruit, 25% offered 1-2 varieties, 50% of 2-3 varieties and 25% more than 3 varieties of fruits. Pineapple, banana, papaya and melon were offered in 50% of establishments. As for vegetables, it was observed that 12.5% offered 1-5 varieties, 37.5% of 5-10 varieties and 50% more than 10 varieties of vegetables. Beet and tomato were offered in 100% of establishments. Regarding the quality of the studied FV, it was observed that all fruits presented good quality. For vegetables, in two establishments (25%) three varieties with poor quality were found.

Conclusions: Most establishments had a wide availability of vegetables and fruits, which had good quality and were therefore facilitators for healthy eating.

DIETARY INTAKE OF PRESCHOOL CHILDREN IN UTTAR PRADESH INDIA

[1]Swaminathan, Sumathi; [2]Thomas, Tinku; [3]Neufeld, Lynnette M.; [4]Larson, Leila; [5]Kurpad, Anura.

[1]PhD. Associate Professor Nutrition. St. John's Research Institute. Koramangala. Bangalore. India; [2]PhD. Department of Biostatistics. St John's Medical College. India; [3]PhD. Global Alliance for Improved Nutrition. Switzerland; [4]MPH. Nutrition and Health Sciences. Emory University. USA; [5]MD. PhD. Department of Physiology. St John's Research Medical College. India.

Background and objectives: Limited data on individual dietary intakes of children up to the age of 60 months is available in India. In a statewide survey of children in Uttar Pradesh, India, dietary intakes of children and its association with nutritional status, defined as stunting, underweight and wasting, were examined.

Methods: We conducted a state representative survey between October and December 2016 to examine nutritional deficiencies, anthropometry, and dietary intake of rural and urban preschool children. A single 24-hour recall was collected from mothers of 564 urban and 674 rural children aged 6 to 59 months of age; duplicate recalls were collected in 100 children. Children were classified as stunted, underweight and wasted based on 2006 WHO child growth standards. Associations between energy-adjusted macronutrient intake and nutritional status of children 6-23 months and 24-59 months were examined in urban and rural settings using logistic regression

Results: Preliminary analyses indicated that median daily energy intake was 524 (95% CI: 452, 597) kcals and 770 (714, 827) kcals in children <2 years and ≥2 years, respectively. The mean percent energy intake from fat and protein were 28% and 12%, respectively in both age groups, and was not different between and urban and rural settings. All macronutrient intakes were comparable between urban and rural settings in both age groups. Prevalence of stunting was higher in rural (50%, 95% CI:47% to 55%) compared to urban children (43%, 95% CI: 39% to 48%). Prevalence of underweight and wasting were comparable in both settings (32% in rural and 7% in urban settings). Macronutrient intake was not associated with stunting and underweight across settings and age groups.

Conclusions: Macronutrient intakes were comparable between rural and urban settings. Co-existence of multiple indicators of undernutrition were observed in urban area.

Keywords: dietary intake, preschool children, stunting, malnutrition

Laboratory of neuroscience and behavior. Cayetano Heredia Peruvian University. Peru; [4]Mrs. Nutrition student. Faculty of science and philosophy. Cayetano Heredia Peruvian University. Peru.; [5]Dra. Pharmaceutical chemist. Dean of Faculty of Science of Health. University "San Ignacio de Loyola". Perú.; [6]MSc. Biologist. Director of Deparment of Nutrition. University "San Ignacio de Loyola". Perú.; [7]BSc. Psychologist. Laboratory of neuroscience and behavior. Cayetano Heredia Peruvian University. Peru.; [8]PhD. Biologist. Laboratory of neuroscience and behavior. Cayetano Heredia Peruvian University. Peru.

Background and objectives: Alterations in normal sleep and wake rhythms directly influence the deterioration of health status and increase the risk of development of noncommunicable chronic diseases and associated comorbidities. The main objective was to determine the prevalence of factors associated with cardiometabolic risk according to the chronotype in children aged 6 to 12 years.

Methods: In this observational, descriptive, cross-sectional study, to determine the chronotype the Munich Chronotype Questionnaire (MCQ) was applied in an interview with 76 children, also anthropometric measurement (weight, height and abdominal perimeter) were measured. For the statistical analysis, the normality of the variables was checked. The variables were described as mean +/- standard deviation (ordinal variable) and n (%) (categorical variable). To determine the differences between groups, a factorial ANOVA was performed between the chronotype categories according to middle sleep time, according to the authors' criteria based on similar studies, (Q1, Q2, Q3, Q4 and Q5) and the cardiovascular risk level (low, high and very high risk).

Results: The prevalence of overweight according to body mass index for age of 13% in men and 20% in women. The prevalence of cardiometabolic risk, according to abdominal perimeter for age, were low risk, high risk and very high risk of 50, 20 and 30% in men and 50, 30 and 19% in women, respectively. No statistically significant differences were found in the prevalence of risk between groups according to MCQ variables, such as bedtime, sleep duration and chronotype; However, dividing the group into quintiles yielded a trend toward significance for the difference between groups. After, in the post hoc analysis no differences were found between the analyzed groups.

Conclusions: The phenotypic characteristics of the sample under study, as well as the related indexes, such as cardiovascular risk, do not show a relationship with the data derived from the MCQ. A large dispersion on data was found, which made it difficult to analyze and interpret the results. New lines of research, which may have a larger sample size, are necessary to elucidate the existing potential relationship between the aspects derived from the Munich chronotype and the nutritional status of a child population.

Keywords: Cardiometabolic risk, chronotype, child overweight.

INVISIBILITY AND VULNERABILITY OF THE CELIAC PATIENT IN THE CONTEXT OF THE FOOD OUT OF HOME

[1]da Silva Gomes Ribeiro, Cilene; [2]Eckert de Campos, Ana Lucia; [3]Auler, Flavia.

[1]PhD in History. Collaborating Professor of the Postgraduate Program in Bioethics of the Pontifical Catholic University of Paraná. Brazil.; [2]Specialist in Teaching for Professional Education. Professor of the Course of Gastronomy of the Positivo Technological Center. Master of the Postgraduate Program in Bioethics. Brazil.; [3]PhD in Health Science. Professor and Coordinator Undergraduate Program in Nutrition of the Pontifical Catholic University of Paraná. Brazil.

Background and objectives: Celiac disease is a chronic enteropathy characterized by total or partial atrophy of intestinal villi and permanent intolerance to gluten, whose prevalence is 1% of the world population. Considered a public health problem, celiac disease is triggered in genetically predisposed individuals by consuming gluten-containing cereals and the treatment consists in the permanent withdrawal of gluten from the diet. Gluten is the protein fraction found in cereals like wheat, oats, barley and malt. The consumption of gluten by celiac disease causes changes in the intestinal mucosa and consequently malabsorption of nutrients, which can lead the individual to serious complications such as osteoporosis and malignant diseases of the intestinal tract. The lack of knowledge about the disease on the part of society and the family, became the celiac in a constant situation of vulnerability.

The objective of this research was to identify the social impacts of the gluten-free diet on eating out of celiac people living in a southern Brazilian city.

Methods: Interviews were conducted with 20 celiac patients from the Celiac Association of Parana, through qualitative research.

Results: In the context of food outside the home, these individuals are often excluded, making themselves invisible to society because of the limited supply of establishments that prepare totally gluten-free foods. To know the difficulties of these people is to provide them with inclusion and visibility, as well as guaranteeing health and the right to an adequate diet, already recognized by the Universal Declaration of Human Rights and the Universal Declaration of Bioethics and Human Rights.

Conclusions: Reporting the invisibility and vulnerability situations these celiac sufferers are exposed to by seeking gluten-free

food in the context of eating out is critical if the right to adequate food is to be fulfilled.

Keywords: celiac disease, feeding, human rights, food.

FOOD INSECURITY AT HOME DECREASES DIETARY DIVERSITY IN MEXICAN ADULTS

(1)Mundo Rosas, Veronica; (2)Gallardo Medina, Delmy del Carmen; (3)Quezada Sánchez, Amado David; (4)Shamah-Levy, Teresa.

(1)National Institute of Public Health. Mexico; (2)School of Public Health of Mexico. Mexico; (3)Information Center for Public Health Decisions. National Institute of Public Health. Mexico.; (4)2 Nutrition and Health Research Center. National Institute of Public Health. Mexico.

Background and objectives: The lack of income to purchase food has the consequence that adults decrease the number, quantity and quality of food they consume and, in extreme cases, stop eating for a whole day. These changes affect the quality of life and health of the population.

The aim of this work is to describe the dietary diversity (DD) of Mexican adults aged 20 to 59 years according to the severity of household food insecurity (HFI).

Methods: The study included 2297 women and men 20-59 years based on data from the Mexican National Health and Nutrition Survey (ENSANUT 2012). A diet diversity index was constructed from a seven-day food frequency questionnaire. The index included nine food groups. HFI was measured with the Latin American and Caribbean Food Security Scale (ELCSA). According to the number of positive responses, households were classified into four categories: food security (FS), mild food insecurity (MFI), moderate food insecurity (MFI) and severe food insecurity (SFI).

The number of foods and food groups consumed by adults according to level of food insecurity was calculated. The proportion of adults consuming each food group according to each level of HFI was obtained. Differences between categories of food insecurity were calculated using linear and logistic regression models adjusted for sociodemographic variables.

Results: FS adults consume a greater diversity (5.6 groups) and number of foods (20) per day compared to adults in SFI (Diversity=4.8 groups and 16.2 foods). A lower proportion of adults in SFI consume meat and fish as well as milk and dairy products.

Conclusions: HFI in the country affects the quality of the diet of a significant fraction of the population. It is necessary to support the existing strategies in public policy to improve the quality of life of the Mexican population.

Keywords: Food security, dietary diversity, nutrition survey, adults

LONGITUDINAL NUTRITION ANALYSIS WITH NUTRIMETRY IN YUCATAN'S ELEMENTARY SCHOOL CHILDREN 2014-2016

(1)Selem Solis, Jorge Enrique; (2)Alcocer-Gamboa, Alberto; (3)Hattori-Hara, Mónica.

(1)MPH. Medical Doctor. Tenabo's Health Center. Campeche Ministry of Health. México.; (2)M.Sc. Medical Doctor. PIAOY Program. Ministry of Education of the Government of the State of Yucatan. México.; (3)Ph.D. in Psychology. PIAOY Program. Ministry of Education of the Government of the State of Yucatan. México.

Background and objectives: Mexico is the first place in overweight and obesity in childhood, and Yucatan is among the first three places in the country, and also has one of the shortest height averages. Under this condition, Yucatán Government has implemented an Integral Program for Childhood Obesity Attention (PIAOIY) since 2010 which first step consists in assess some nutritional indicators at school, year by year to screening risk groups, and channeling them to appropriate health services. The objective of this study is present a longitudinal analysis of the program with Nutrimetry, combining BMI and height.

Methods: Yucatan's elementary school students measured for three consecutive years (2014-2016) were analyzed with Nutrimetry: according to WHO z-scores values were assigned, for height/age: $z \leq -2 = 1$, $z \geq 2 = 5$, or 3 to the rest, and for BMI/age: $z \leq -1 = 0$, $1 \leq z < 2 = 6$, $z \geq 2 = 12$ or 3 to the rest, values were crossed and 12 codes (1-3-5, 4-6-8, 7-9-11, 13-15-17) that combine underweight, normal-weight, overweight and obesity with short, normal and high heigh were obtained. Prevalences and changes over time were analyzed.

Results: Data of 6,011 students with a start age of 8.79 years (S.D.=1.33) were analyzed.

From the first to the third year, prevalence of low-height codes (1, 4, 7 and 13) decreased (mean=1.61); all high-height ones (5, 8, 11 and 17) increased (mean=0.11), and normal-height with overweight(9) and obesity(15) increased (mean=2.30), whereas those with normal-weight(6) and low-weight(3) first increased (mean=1.29) and then decreased (mean=1.73).

According to Nutrimetry first year classification, mean z-scores (BMI/Height) were compared with repeated measures ANOVA, in all codes except those with high-height p-value ≤ 0.05.

On the rest codes: z-height tend to increase yearly, but in underweight group, this was not significant every year. Z-BMI in underweight (1 and 3), and normal-weight (4 and 6) codes tend to increase, but it doesn't in overweight (7 and 9) and obesity (13 and 15) groups.

Conclusions: Prevalence of short-height is decreasing, but in underweight children, it is more complicated to fight against this condition.

Although in the overweight and obesity groups, z-BMI do not increase, the prevalence of these groups is still increasing, indicating that the approach should not only be interventional, but also preventive.

144/2302

ULTRA-PROCESSED FOODS AND ADDED SUGARS IN CHILEAN DIET (2010)

[1]Cediel, Gustavo; [2]Reyes, Marcela; [1]Louzada, Maria Laura da Costa; [3]Martinez, Euridice; [4]Monteiro, Carlos; [2]Corvalan, Camila; [2]Uauy, Ricardo.

[1]Post-doctoral fellow. Department of Nutrition. University of São Paulo. Brazil; [2]Professor. Institute of Nutrition and Food Technology. University of Chile. Chile; [3]Doctoral fellow. Department of Nutrition. University of São Paulo. Brazil; [4]Professor. Department of Nutrition. University of São Paulo. Brazil.

Background and objectives: A rapid simultaneous increase in sales of ultra-processed foods and obesity prevalence has been observed in Chile in the last decade. This study evaluated the consumption of ultra-processed foods in Chile and its association with the intake of added sugars in the diet, one important driver of obesity.

Methods: A probabilistic sample of 4920 individuals (>2y) from a cross-sectional dietary study carried out in Chile in 2010 was included. Food consumption was measured through 24-hour recalls and classified into food groups according to the extent and purpose of food processing (NOVA classification). Gaussian regression analyses were used to estimate the association between energy contribution of ultra-processed foods and the energy intake of added sugars (as proportions of total energy intake). Poisson regression models were used to analyze the proportion of individuals consuming more than 5 and 10% of total energy from added sugars (World Health Organization, WHO, cutoffs) across quintiles of the energy share of ultra-processed foods.

Results: In the Chilean diet, ultra-processed foods represented 28.6±0.5% of total energy intake and 56.5±0.9% of added sugars intake. The mean percent of energy from added sugars was 13.5% and increased from 7.9±0.3% to 20±0.5% across quintiles of the dietary share of ultra-processed foods. After adjusting for several potential sociodemographic confounders, a 5 percentage points increase in the dietary share of ultra-processed foods determined a 1 percentage point increase in the dietary content of added sugars. Individuals in the highest quintile were 2.7 (95%IC: 2.3-3.2) times more likely to exceed the 10% upper limit for added sugars recommended by the WHO compared with those in the lowest quintile, after adjusting for sociodemographic variables. This association was stronger among individuals between 2-19y (3.9 (95%IC: 2.7-5.9)).

Conclusions: Ultra-processed foods are important contributors to the excessive added sugars content of the Chilean diet. Actions aimed at decreasing the consumption of ultra-processed foods emerge as useful tools for achieving WHO dietary recommendations on added sugars, especially among children and adolescents. Funding: FAPESP nº2016/13522-3

NUTRITIONAL STATUS OF CHILDREN UNDER 5 YEARS IN TWO VULNERABLE TERRITORIES IN CALI – COLOMBIA

[1]Villamarín Betancourt, Eder Antonio; [2]Velasco, Carlos; [3]Jimenez, Abelardo; [4]Hernandez Carrillo, Mauricio; [3]Jiménez Urrego, Ángela María; [5]Luna, Monica; [6]Mendoza, Luis Alfonso; [5]Gulloso Pedroza, Leonel; [7]Lince Rivera, Catalina; [3]Cubides Munevar, Angela M.

[1]Doctor. GISAP (public health research group). Universidad Santiago de Cali – Universidad del Valle. Colombia.; [2]Doctor and Magister. GISAP (public health research group). Universidad del Valle. Colombia; [3]Magister. GISAP (public health research group). Universidad Santiago de Cali – Universidad San Martín – Universidad del Valle. Colombia.; [4]Magister. GISAP (public health research group). Universidad San Martín – Universidad del Valle. Colombia.; [5]Magister. GISAP (public health research group). Universidad Santiago de Cali. Colombia.; [6]Doctor. GISAP (public health research group). Fundación Ciencias de la Salud. Colombia; [7]Doctor. GISAP (public health research group). Universidad Santiago de Cali – Universidad Javeriana Bogotá. Colombia.

Background and objectives: Introduction: child nutrition is fundamental for physical, cognitive, emotional and social development. The relevance of nutritional status lies on the fact that it is a direct reflection of a country´s progress and inequalities. Objectives: definition of the nutritional status of children under 5 years in two vulnerable territories in Cali – Colombia.

Methods: prevalence study using cluster randomized sampling. Univariates analysis was performed taking into account de variable nature and distribution. For the qualitative variables frequencies, central tendency and dispersion were estimated. ANTRO software of the WHO was used for child growth standards. The variables used were BMI/age, length/age and weight/length.

Results: for the variable BMI/age; 12% of the patients were obese, 18% overweight, 8% underweight and 11% in underweight risk. In gender terms boys were predominantly overweight and girls underweight with statistical significance. For the variable length/age; 23% presented short size and 27% were in risk. Boys were more affected but girls were more at risk. For the variable weight/length; 11.9% were obese, 15.7% overweight, 12.6% low weight for length and 7.8% very low weight for length. Excess was more frequent in boys and low weight in girls.

Conclusion: in two vulnerable territories in Cali – Colombia one out of two children presents an inadequacy in nutritional status,

this implies that is mandatory to create interventions for children under 5 years that prevent adverse consequences in the future.

Keywords: nutrition, status, prevalence, children, Colombia.

FACTORS ASSOCIATED WITH MATERNAL PROFILE AND NEWBORNS WITH GASTROSCHISIS TREATED AT A REFERENCE CENTER IN THE CITY OF RIO DE JANEIRO

[1]*Amaral, Yasmin;* [2]*Marano, Daniele;* [3]*Costa, Ana Carolina;* [4]*Moreira, Maria Elisabeth.*

[1]Msc. Nutritionist. Instituto Fernandes Figueira/ Fiocruz. Brazil; [2]Dr. Nutritionist. Instituto Fernandes Figueira/ Fiocruz. Brazil; [3]Dr. Statistic. Instituto Fernandes Figueira/ Fiocruz. Brazil; [4]Dr. Neonatologist. Instituto Fernandes Figueira/ Fiocruz. Brazil.

Background and objectives: The increasing number of new cases of gastroschisis associated with lower mortality rate causes the increased prevalence of this disease, resulting in a significant increase of the costs of this malformation to the health systems.

Despite the high incidence of this malformation in Brazil, there is a shortage of national studies published in the literature. Therefore, this study aimed to trace the maternal profile and newborns with gastroschisis and the main associated risk factors.

Methods: Cross-sectional analysis of data collected in the period from January 2012 to July 2013, of all children with gastroschisis operated at the National Institute of Women's Health Child and Adolescent Fernandes Figueira (IFF). Maternal, obstetric and neonatal variables were evaluated.

Results: We found a higher prevalence of adolescent mothers (61.7%), brown (55.9%), single (76.3%) and gilts (81.7%). 73.3% of children were born by cesarean section, and the early majority (61.7%) and low birth weight (66.7%). The surgery steps for gastroschisis correction was the most frequent. The average length of stay was 43 days, 23 days to zero diet and 30 days for total parenteral nutrition. The survival rate was 91.7% and the most prevalent high diet was the exclusive breastfeeding (64.8%)

Conclusions: The results of this study show increased frequency of gastroschisis among infants born to young women, single, brown, gilts and eutrophic. It was also noted that the average length of stay as well as the zero diet differed in relation to other international studies. This can partly elucidated due to technological and socio-economic differences between Brazil and developed countries.

Keywords: Gastroschisis; Epidemiology; Child Health.

Background and objectives: Introduction: few studies analyze the relationship between affection and inadequate alimentary habits, these are remarkably high in low income families where violence and chaotic surroundings are common and are predisposing factors for nutritional – affective repercussions of the minor. Objectives: explore the conditions that favors the affective bond in infants between 0-12 months of age that consult to Mario Correa Rengifo Hospital in Cali city.

Methods: mixed study, exploratory. A semi-structured interview was used, family Apgar and Massie- Campbell Scale for observation of mother – baby bonding indicator.

Results: 60% of the population of the study was considered as "Estrato 1" (classification system of Colombia depending on family incomes, 1 is the lowest and 6 is the highest). 33% of the families sleep in the same room with the baby. 85.71% of the mothers breastfeed the babies exclusively until the sixth month. 26.98% of the babies that don´t breastfeed presents medical complications like malnutrition, intestinal infection and diarrea. 76.19% of the mothers spend most of their time with the baby.

Conclusions: There was a relationship between breastfeeding and mother sensibility and bonding. Positive relation between mother and child are important. The mother represents de whole for the baby, not only in the feeding aspect but also love and well-

being. It is important to continue the investigation for promoting breastfeeding in Cali - Colombia.

Keywords: Nutrition, bonding, affection, children, Cali

FOOD SECURITY'S PERCEPTION OF VULNERABLE FAMILIES IN THE SAN CAYETANO AND SURROUNDINGS NEIGHBORHOOD DURING 2017

[1]Bordón Riveros, Claudia; [2]Benítez, Leyla; [2]Cantero, Eliana; [3]Castillo, Ivana; [2]Elizeche, Lourdes; [2]Zayas, Ximena; [2]Miranda, Katherine; [2]Galeano, Brenda; [2]Vidal, Tamara; [2]Martínez, Orfidio.

[1]Nutritionist. Paraguay; [2]Estudiante. Universidad Catolica Nuestra Senora del Asuncion. Catedra de Evaluación Nutricional en Comunidades. Paraguay; [3]Nutricionista. Universidad Católica Nuestra Senora del Asuncion. Docente Catedra de Evaluacion Nutricional en Comunidades. Paraguay.

Background and objectives: Food security in families would have a positive impact on the quality of food and on proper nutrition of its members. It is related to better growth and development of children. Also, it may impact on the work capacity.

The aim of the study was evaluate the perception of food security in vulnerable families of San Cayetano and surroundings neighborhood during January - 2017.

Methods: A cross sectional study carried out on the head of the household of vulnerable families in the neighborhood of San Cayetano and surrounding areas during January 2017. The ELCSA validated questionnaire was used to measure the perception of food security.

Results: We evaluated 47 families, of which 35 families had at least one member younger than 18 years.

The median number of member of the families was 5.5 person (minimum 1 - maximum 10). The median of number of children younger than 5 years was 1.5 (maximum 4 - minimum 0). The heads of household were predominantly female (n = 39).

Only 10% (n = 5) of the families had the perception that they had food security. Of those who presented food insecurity, the highest percentage corresponded to those with mild food insecurity (45%, n = 21).

Conclusions: The majority of families evaluated presented some level of food insecurity. This situation is relevant because of the characteristics of their vulnerability situation that may worsts in the case of inundation.

Keywords: food security, vulnerability, ELCSA

ASSOCIATION BETWEEN ALTITUDE AND MALNUTRITION IN PERUVIAN CHILDREN UNDER FIVE YEARS

[1]Pajuelo Ramírez, Jaime; [2]Miranda Cuadros, Marianella; [3]Bernui, Ivonne.

[1]MSc. Medical Doctor. Instituto de Investigaciones Clínicas. Universidad Nacional Mayor de San Marcos. Perú; [2]MSc. Nutritionist. Centro Nacional de Alimentación y Nutrición. Instituto Nacional de Salud. Perú; [3]MSc. Biologist. Centro de Investigación de Bioquímica y Nutrición. Universidad Nacional Mayor de San Marcos. Perú.

Background and objectives: One-third of Peru's population lives above 2000 meters above sea level. There is evidence that children in these communities have a higher prevalence of growth retardation than other Peruvian children. Besides, it is a worry that obesity of these children might be increased, for these reasons the objective was to determine the influence of residence altitude on stunting and obesity in Peruvian children under five years of age.

Methods: Secondary analysis of the National Monitoring of Nutrition Indicators (2007-2010). The children (n = 3835) were weighed and carved. Stunting was defined as the Z Size / Age score less than -2SD, and the Obesity with Z score / Weight greater than 2 SD from the WHO growth reference. The cutoff point for altitude was 2500 meters above sea level. The poverty intervening variable had two categories: "poor" those with one or more Unsatisfied Basic Needs (NBI) and "non-poor" those who did not have any NBIs.

Results: In the first level of altitude (<2500 meters above sea level), the stunting was more prevalent in children older than 24m (13.3%) and in the poor (20.5%), while obesity was highest in children younger than 24m. (11.1%) and non-poor (8.5%). In the second level (≥ 2500 meters above sea level), stunting predominated in children older than 24m. (32.5%) and in the poor (35.8%). As for obesity, it was higher in children under 24m. (5.8%) and in the poor (4.5%). For stunting living in cities that are below 2500 meters above sea level, being less than 24 months and being considered not poor represented a protective factor. While for obesity living in cities below 2500 meters above sea level meant having 3 times more Risk of being obese, in the same way, having less than 24 months represented 2 times more risk of being obese.

Conclusions: The stunting is mainly located in the populations of higher altitude, in the majors of 24 months and in the considered as poor, whereas the obesity in the populations of lower altitude, in the children of less than 24 months and in the non-poor group.

Keywords: altitude, stunting, obesity, malnutrition

PERCEPTIONS OF MOTHERS ABOUT SCHOOL BREAKFAST PROGRAM AT AN EDUCATIONAL INSTITUTION IN LIMA, PERU

(1)*Apaza Quispe, Mercedes Lucia;* (2)*Delgado Pérez, Doris.*

(1)Nutritionist. Universidad Nacional Mayor de San Marcos. Peru; (2)PhD. Nutritionist. Centro de Investigación en Bioquímica y Nutrición. Universidad Nacional Mayor de San Marcos. Peru.

Background and objectives: Feeding during the school years is critical for the child and the breakfast is an important part of a good diet is breakfast; School Food Program from Peru provides school breakfasts, but we do not know if parents consider this type of breakfast to be optimal. The present study aimed to investigate mother´s perceptions, concerns, and attitudes about school breakfast program in an educational institution in Lima, Peru.

Methods: Qualitative research approach and grounded theory method. Four focus groups and seven in-depth interviews with a total 31 volunteer mothers of 6-8-year-old children. Mothers were asked their views about the school breakfast program, the attitudes about the food that the program offers their children. Conversations were tape-recorded and transcribed for thematic analysis.

Results: The mothers perceived that eating school breakfast improves health, academic performance and eating habits of children, also acknowledged the financial support to the family and the support offered to the mother; on the other hand, they perceived that at often times, children have breakfast both at their houses and at school, which, combined with junk food, could cause diseases. They also reported that the school breakfast had an inadequate variety, while their perceptions of safety, nutritional value and acceptability were varied. Regarding attitudes, mothers showed favorable attitudes to the consumption of school breakfast. However, some mothers showed favored the consumption of breakfast at home.

Conclusions: Mothers perceived both pros and cons of school breakfast, as well as positive and negative views regarding its quality.

Keywords: School, breakfast, perceptions, attitudes, children

REGULAR MONITORING OF BABY FRIENDLY HOSPITALS STRENGTHEN THE IYCF PRACTICE IN BANGLADESH

(1)*Roy, Swapan Kumar;* (2)*Jahan, Khurshid;* (3)*Salam, Suraya Bintay;* (3)*Chaklader, Hasina;* (4)*Ara, Ferdous;* (5)*Laboni, Fatema;* (6)*Khatoon, Soofia.*

(1)MBBS, MSc, Dip in Biotech, PhD, FRCP. Senior Scientist. Chairperson. Board of Trustees. Bangladesh Breastfeeding Foundation. Chairperson. Nutrition Foundation of Bangladesh. Bangladesh; (2)MSc. Director. Bangladesh Breastfeeding Foundation (BBF). Bangladesh.; (3)MSc. Program Manager. Bangladesh Breastfeeding Foundation (BBF). Bangladesh.; (4)MSc. MPhill. Senior Program Officer. Bangladesh Breastfeeding Foundation (BBF). Bangladesh.; (5)MSc. Research Officer. Bangladesh Breastfeeding Foundation (BBF). Bangladesh.; (6)MBBS, FCPS, Fellowship in Neonatology, MHPEd. General Secretary. Board of Trustees. Bangladesh Breastfeeding Foundation (BBF). Bangladesh.

Background and objectives: Revitalization of Baby Friendly Hospital Initiative (BFHI) program has been started since 2012 and continued till 2016 throughout the country and certified 592 health facilities (HFs) in Bangladesh. To uphold the government investment and initiative, continuous monitoring is ongoing for bringing sustainability of Infant and Young Child Feeding (IYCF) practices in Bangladesh.

The main objective of BFHI monitoring is to strengthen the Baby Friendly Hospital (BFH) practices.

Methods: The revitalized BFHs (60 District hospitals, 414 Upazilla Health Complex (UHC), 64 Maternal and Child Welfare Center (MCWC) and 56 tertiary hospitals) are being continuously monitored through direct observation method following a structured monitoring tool by the 15 trained divisional officer in eight divisions of Bangladesh. Necessary information and technical support were also provided to the BFHs to strengthen BFHI committee, LMC/ breastfeeding Corner and practice of 10 steps of BFHI.

Results: From September 2016 to February 2017, a total of 97% (576) Baby Friendly Hospitals of eight divisions were monitored. According to the monitoring report, 75% (432) HFs are practicing the 10 steps of BFHI. Active BFHI Committee was found in 42% (241) HFs. Though the LMC was established in all HFs but 30% (178) of them were observed as functional. Compliance of Breast Milk Substitute (BMS) Act was increased and reduced violation. BMS products and leaflets were found only in 3% (17) HFs though representative of the BMS Company was not found in these HFs during Monitoring.

Conclusions: All Baby Friendly Hospitals are not following the indicators in all extents, therefore a strong and continuous monitoring system need to strengthen the BFHI practices as well as the IYCF movement in Bangladesh.

NUTRITIONAL STATUS AND NUTRITIONAL KNOWLEDGE ABOUT INFANT AND MATERNAL NUTRITION AMONG PREGNANT AND MOTHERS IN QUICHE, GUATEMALA

[1]Nozue, Miho; [2]Chihara, Shoko; [3]Léon, Juana; [3]Mazariegos, Roberto; [4]Juárez, Alejandra; [5]Martínez, Glenda; [6]Hishida, Yuko.

[1]PhD. Nutritionist. Tokoha University. Japan; [2]Nutritionist. Jiyu Gakuen. Japan; [3]BSc. Nutritionist. Dirección de Área de Salud El Quiché. Ministerio de Salud Pública y Asistencia Social. Guatemala; [4]BSc. Nutritionist. Dirección de Área de Salud Ixil. Ministerio de Salud Pública y Asistencia Social. Guatemala; [5]MD. PhD. Independent consultant. Guatemala; [6]MPH. IC Net Limited. Japan.

Background and objectives: Guatemala is one of the countries of high rate of maternal mortality and under 5 mortality in Latin America. However specific reason which supposed to relate malnutrition in Guatemala is further consideration.

The aim of this study is to clarify nutritional status and nutritional knowledge among pregnant and to examine nutritional knowledge and attitudes for infants among mothers. Further, to detect methodology to improve nutritional status and nutritional knowledge among pregnant and mothers.

Methods: Two non-consecutive days for 24-hour dietary recall and self-reported height and weight were obtained from pregnant. Knowledge, Attitudes and Practices (KAP) survey for nutrition were conducted from both pregnant and mothers. All survey were conducted between August and September, 2016.

Results: Underweight 2nd trimester pregnant was 13.4% and 3rd trimester pregnant was 12.6%. Illiterate pregnant was 48.0%. Only 8.0% of 2nd trimester pregnant and 3.6% of 3rd trimester pregnant consumed energy more than estimate energy requirements.

Infant who exclusively breastfed were 73.7%. Mothers did not feel difficult to breastfeed her baby exclusively for six months (94.6%).

Conclusions: Present study clarified malnutrition of pregnant and very limited nutritional knowledge among pregnant and mothers.

It is needed to consider high rate of illiteracy to develop materials about nutritional education to improve nutritional status of pregnant, mothers and infant in the next period of proyect.

OPINION OF SENIOR UNDERGRADUATE STUDENTS OF A NUTRITION PROGRAM ON THE CONTRIBUTION OF SUPERVISED INTERNSHIP IN THE DEVELOPMENT OF PROFESSIONAL SKILLS AND COMPETENCES

[1]Garcia Peloggia de Castro, Adriana; [2]Fraga Guimarães, Andrea.

[1]PhD. Nutritionist. Curso de Nutrição. Centro Universitário São Camilo. Brazil; [2]MSc. Nutritionist. Curso de Nutrição. Centro Universitário São Camilo. Brazil.

Background and objectives: The National Curricular Guidelines (Brazil) establish that supervised internships in undergraduate nutrition programs should be developed in three basic areas: collective feeding, public health and clinical nutrition. Additionally, professional training must provide them with knowledge to develop the following general skills and competences: health care; decision-making; communication; leadership; administration and management and permanent education. Hence, our aim was to determine the opinion of senior undergraduate students in a nutrition program of a private educational institution of the city of São Paulo on the contribution of the supervised internship in the development of skills and competences required by the National Curricular Guidelines.

Methods: Students graduating in 2016 were asked about the contribution of each area of supervised internship in the skills and competences development. The five-point Likert scale was adopted with the items: totally agree, partially agree, indifferent, partially disagree and totally disagree. The responses were analyzed by means of the average ranking (AR), ranging from 1 to 5, and the closer to 5, the higher the level of agreement. AR below 1.5 constitutes level of "total disagreement", AR between 1.5 to 2.5 is "partial disagreement", AR 2.5 to 3.5 is "indifference", AR 3.5 to 4.5 is "partial agreement "and AR greater than 4.5 is "total agreement". The research was approved by the institution's Ethics Committee.

Results: The study had 102 participants. In the collective feeding area, 58 answered totally agree and 32 partially agree, with AR 4.37 (partial agreement). In the clinical nutrition area, 77 answered totally agree and 22 partially agree, with AR 4.70 (total agreement). In the public health area, 67 answered totally agree and 27 partially agree, and AR 4.53, also represented total agreement level.

Conclusions: The supervised internship allows the students to experience a professional practice. Although it seems to positively influence the development of the professional identity on students in all three basic areas, the levels of agreement were higher in the clinical nutrition and public health.

Keywords: Nutricionist. Internships. Professional practice.

PREVALENCE OF INSULIN RESISTANCE AND RISK OF METABOLIC SYNDROME AMONG YOUNG ADOLESCENTS IN KUALA LUMPUR

[1]Wee, Bee Suan; [2]Awang Mahmud, Bulgiba; [3]Noor, Mohd Ismail; [4]Liu, Ailing; [5]Deurenberg, Paul; [6]Poh, Beekoon.

[1]Bsc. MSc. PhD. Nutritional Sciences Programme. School of Healthcare Sciences. Faculty of Health Sciences. Universiti Kebangsaan Malaysia. Kuala Lumpur. Malaysia; [2]MBBS. MPH. MApp. Stat. PhD. Julius Centre University of Malaya. Faculty of Medicine. University of Malaya. Kuala Lumpur. Malaysia; [3]BSc. Msc. PhD. School of Hospitality. Tourism and Culinary Arts. Taylor's University. Subang Jaya. Malaysia; [4]MD.PhD. National Institute of Nutrition and Food Safety. Chinese Center for Disease Control and Prevention. Beijing. China; [5]PhD. Nutrition Consultant. The Philippines.; [6]BSc. PhD. Nutritional Sciences Programme. School of Healthcare Sciences. Faculty of Health Sciences. Universiti Kebangsaan Malaysia. Kuala Lumpur. Malaysia.

Background and objectives: Insulin resistance, one of the consequences of central obesity, has been proposed to be the metabolic mediator of metabolic dysfunction, such as hyperlipidemia, hypertension, and impaired glucose, which may progress to cardiovascular diseases and type II diabetes. As metabolic alteration is one of the factors that seem to affect obese children and adolescents, therefore, this study aimed to evaluate the prevalence of insulin resistance and the effects of dysregulated glucose homeostasis with metabolic component among children.

Methods: Subjects comprised 207 boys and 201 girls aged 9-14 years old in Kuala Lumpur. Anthropometric measurements included weight, height, waist circumferences (WC), skinfold at 5 sites namely biceps, triceps, subscapular, iliac crest and medial calf; body composition was assessed with bioelectrical impedance technique. WHO 2007 BMI-for-age growth reference was used to group subjects into overweight/obese (O/O) and non-overweight/obese groups (non-O/O). Blood pressure (BP) was taken, fasting blood glucose (FBG), triglycerides (TG), high-density lipoprotein (HDL-C), low-density lipoprotein (LDL-C), total cholesterol (TC) and insulin were determined in overnight fasting blood sample. The International Diabetes Federation 2007 criteria for children were used to identify metabolic syndrome (MS) risk while homeostasis model assessment method was used to calculate insulin sensitivity (IR).

Results: Girls was found to have significantly higher TC (P<0.05), higher skinfold: biceps (p<0.001), triceps (p<0.001), subscapular (p<0.001), iliac crest (p<0.001) and medial calf (p<0.001) compared to boys. MS was found in 2.5% among the adolescents, with 7.9% among O/O subjects. Prevalence of insulin resistance was 14.5%, with 39.7% among O/O subjects. Adolescents with larger WC [OR:19.3 (95%CI: 9.7, 38.5)], high FBG [OR: 8.0 (95%CI: 2.2, 29.2)] and high TG [OR: 4.6 (95%CI: 1.2, 17.2) were found to have higher risk of developing IR compared to adolescents who did not have poor biochemical profiles.

Conclusions: We conclude that Insulin resistance was strongly related to metabolic risk and may be used as an indicator to assess children's risk for MS. Appropriate intervention programs should be planned to increase awareness and to promote healthy lifestyles in order to prevent central obesity among children and thus lower metabolic syndrome risk.

Keywords: children, insulin resistance, metabolic syndrome

NUTRITIONAL STATUS AT BIRTH IS ASSOCIATED WITH BMI IN YOUNG ADULTS. TWO COHORTS STUDY IN CHILE

[1]Vasquez, Ximena; [2]Bustos, Patricia; [3]Ramirez, Marcela; [4]Zumelzu, Elinor; [5]Amigo, Hugo.

[1]Msc. Nutrition. Pediatrician. Department of Nutrition. University of Chile. Chile; [2]PhD. Pediatrician. Department of Nutrition. University of Chile. Chile; [3]Student Msc. Physician. José Joaquín Aguirre Hospital. University of Chile. Chile; [4]Msc. Pediatrician. University of Chile; [5]PhD. Public health. Department of Nutrition. University of Chile. Chile.

Background and objectives: Studies in developed countries have shown that nutritional status at birth was related with early symptoms of chronic disease however, controversy remains whether the Body Mass Index (BMI) in adulthood is also dependent on the nutritional status at birth. As we are following two bidirectional cohorts born 15 years apart –a period of hasty economic growth–in Chile, we aim at evaluating if a differential association between nutritional status at birth and adult BMI would be observed in those cohorts.

Methods: Cohort 1 (n=999), born in 1974-78 was evaluated in 2001-02; Cohort 2 (n=746 as yet), born in 1988-92 is being evaluated in 2014-17. Weight and length were collected from birth records so that birth and BMI at birth are surrogates of nutritional status at birth; weight and height in adult life are being assessed concurrently as they grow old. Analyses used multivariate linear regression adjusting by sex and stratifying by cohort as an effect modifier.

Results: Mean birth weight (±SD) was 12.95 (±1.39) in Cohort 1 and 13.52 (±2.89) in Cohort 2, while BMI at 24-28 were 25.8 (±4.46) and 27.4(±5.6) respectively, all differences significant (p <0.001). Multivariate liner regression reveals that for 1 unit increases of newborn's BMI adult's BMI rise by 0.196 whereas as birth weight increased by 1 kg adulthood BMI rose 1.35 (95% CI 0.88 to 1.83) in adulthood. Cohort effect does not modify the observed effect as shown through stratified analysis.

Conclusions: These data show a direct–rather than Barker's inverse– relationship between birth weight or BMI at birth and BMI in adult life. I seems that both BMI and weight at birth are good predictors of overweight in young adults thus, being useful early alert for children growth surveillance.

Keywords: Birth weight, Adult Nutritional Status, cohort study

FACTS AND MISBELIEVES - REPRESENTATIVE NUTRITIONAL KNOWLEDGE STUDY IN HUNGARY

Antal, Emese Antal.

Msc. Dietitian. Sociologist. TET Platform Association. Budapest. Hungary.

Background and objectives: Recent years the communication of healthy lifestyle has changed a lot. The spread of free access of internet for many people gave opportunity to get information about health even from unverifiable sources, where there is no health care professional control.

Our goal was with this study to collect data among the Hungarian adults regarding their nutritional knowledge, believes, and misbelieves, food safety, labelling, healthy lifestyle and other habits.

Methods: A representative study with a questionnaire for 1,019 participants in Hungary (CAPI=569 and CAWI=450). The sample was representative for Hungarian population in terms of age (15-69), sex, region and settlement type. The study was carried out between June and July in 2016.

Results: Three quarter of the respondents feels informed about healthy diet (62%).

Barriers to a healthier lifestyle are: money (66%), willpower (39%), healthier products (36%). Half of the respondents are unaware of the recommended daily energy intake (48%) and also their own actual intake (57%). 42% finds that certain food types are unhealthy by their nature.

Unhealthy food is characterized by artificial ingredients (47%) and lack of freshness (28%). About half of the consumers claim reading the labels (61%) (but mostly when buying a new product), and considering the indicated nutritional information. For them, the most important info are ingredients (51%) and the expiry date (41%). Nutritional facts are less frequently mentioned (39%).

Conclusions: Proper nutrition and physical activity are fundamental to achieve or maintain good health. However, the average consumer is often reluctant to give up on good (familiar) taste, alcohol and convenience. Low physical activity level is general. Moreover, many of them are not able (or willing to) spend more money on food. The lifestyle-related diseases mean serious medical, public health and economic problems, and they require higher public awareness and political support.

Keywords: facts, misbelieves, attitute, nutritional habits

DETERMINATION OF THE THRESHOLD OF PERCEPTION OF SWEET TASTE IN MOROCCO

[1]Benkirane, Hasnae; [2]Taboz, Youness; [3]Benajiba, Nada; [4]Khadmaoui, Abderrazzak; [5]Bouziani, Amina; [5]Guennoun, Yasmine; [5]Bajit, Habiba; [6]Bentahila, Nawal; [7]Barkat, Amina; [2]Aguenaou, Hassan.

[1]PhD. Joint Nutrition and Food Research Unit. URAC 39. University Ibn Tofaïl. National Center of Energy, Sciences and Nuclear Techniques. Morocco; [2]PhD. Joint Nutrition and Food Research Unit. URAC 39. University Ibn Tofaïl. National Center of Energy. Sciences and Nuclear Techniques. Morocco; [3]PhD. Clinical Nutrition Program. Department of Health Sciences. College of Health and Rehabilitation Sciences. Princess NourahBintAbdulrahman University. Riyadh. KSA.; [4]PhD. Laboratory of Engineering and Biometrics. Faculty of Science. Kenitra. Morocco; [5]PhD Student. Joint Nutrition and Food Research Unit. URAC 39. University Ibn Tofaïl. National Center of Energy. Sciences and Nuclear Techniques. Morocco; [6]Doctor. Research Group on Infant Feeding and Nutrition (GANIM). Morocco; [7]PhD. Health and Nutrition Research Team of the Mother Child Couple. Faculty of Medicine and Pharmacy of Rabat. Mohammed V University of Rabat. Morocco.

Background and objectives: According to its new guidelines, the World Health Organization recommends reducing the intake of free sugars to less than 10% of the total energy intake in adults and children. Following these recommandation, Morocco has recently developed a plan of sugar reduction in order to reinforce prevention of non-communicable diseases which is a major problem at the national level. The present study is a masterpiece of this national strategy since its objective is to determine the threshold of perception of sugar taste in the Moroccan population.

Methods: The study involved 199 people who tested 9 solutions containing different concentrations of sucrose: 0; 0.111; 0.333; 1; 3; 9; 27; 81; 243 mmol/l. The panelists evaluated the samples per session using the blind Alternative Forced Choice method. The test is repeated twice when consumers perceive the sweet taste for confirmation of the threshold of perception. Informations on age, sex, height, weight and Body Mass Idex was collected and transcribed on SPSS software for statistical processing.

Results: The results showed that 40.20% of the testers had a threshold of perception of the sweet taste at 27 mmol/l (9.24g/l) of sucrose. Only 25.62% and 15.07% of the testers have a threshold of perception of sweetness respectively at 9 mmol/l (3.08g/l) and 3 mmol/l (1.03g/l). A proportion corresponding to 7.53% of the testers perceived the sweet taste only from the solutions containing 81 mmol/l (83.17g/l) of sucrose. The khi2 test shows a significant correlation between the perception of the sweet taste and the age of testers (p value = 0,050) and the perception of the sweet taste and the BMI (p value = 0,021). The sexe has no significant effect on the threshold of perception of the sweet taste (p value = 0.610).

Conclusions: The results obtained explain the pronounced taste of Moroccan children and adults for sweet. who takes 2.7 times more sugar compared to a Caucasian for which the thresh-

old of perception of sweet taste is 10 mmol/l. The national plan for the reduction of sugar consumption will take this into account in order to gradually reduce the sugar content in processed foods.

Keywords: Threshold of perception. Sweet taste. Morocco.

Department of Biosciences. Faculty of Chemistry Science. Cuenca University. Ecuador.; [8]PhD. Medic. Department of Biosciences. Faculty of Chemistry Science. Cuenca University. Ecuador.

Background and objectives: Consumption of convenient ready-prepared foods and eating out-of-home has raised in low-and-middle income countries. Eating out-of-home has been associated with unhealthy dietary patterns rich in processed and ultra-processed foods. The aim of this study is to compare the dietary quality and foods processing levels between Substantial out-of-home (SOH) and Non-substantial out-of-home (NSOH) eaters.

Methods: A cross-sectional study was performed among 779 adolescents from an urban and a rural area in Ecuador (2008-2009). Two non-consecutive 24-hour recalls were used to estimate dietary intake; eating out-of home was defined when food items were prepared in any place different than: the student home and relative's or friends home. Participants were classified as SOH eaters if they obtained more than 25% of their daily energy intake out-of-home; meanwhile, those who obtained ≤25% of daily energy intake out-of-home were identified as NSOH. Food processing levels were categorized using the NOVA Brazilian classification into non-processed, culinary ingredients, processed and ultra-processed foods. Two sample t-test was used to compare mean daily energy intake, energy density and macronutrient energy %, as well as energy % intake by food processing levels between SOH and NSOH eaters.

Results: Overall, 71.89% of participants were classified as SOH eaters. Total energy intake (1927 kcal vs. 1825 kcal; p = 0.01), energy density (1.82 kcal/g vs. 1.62 kcal/g; p = 0.00) and total fat %

(24.7% vs. 22.1%; p = 0.00) intakes were higher among SOH eaters compared with NSOH eaters. In addition, SOH eaters obtained less energy from non-processed food (48.4% vs. 60.7%; P<0.001) but more energy from processed (4.5% vs. 2.2%; P<0.001) and ultra-processed (34.7% vs. 22.5%; P<0.001) foods when compared with NSOH eaters.

Conclusions: A great percentage of our population were SOH eaters and their dietary quality was considerably unhealthy. SOH eaters consumed more processed and ultra-processed foods, which are associated with the development of non-communicable diseases. Therefore, out-of-home preparation places should be considered when establishing nutritional policies.

ULTRA-PROCESSED FOODS CONSUMED BY CHILDREN BELOW FIVE YEARS OF AGE IN THE CITY OF RIO DE JANEIRO, BRAZIL

[1]Avelar, Carine; [2]de Moraes, Milena Miranda; [3]Damião, Jorginete de Jesus; [3]de Castro, Inês Rugani Ribeiro.

[1]BSc. Nutritionist. Department of Social Nutrition. State University of Rio de Janeiro. Brazil; [2]PhD. Nutricionist. Posdoctoral fellow. Department of Social Nutrition. State University of Rio de Janeiro. Brazil.; [3]PhD. Associate professor. Department of Social Nutrition. State University of Rio de Janeiro. Brazil.

Background and objectives: The prevalence of obesity and non-communicable chronic diseases has increased rapidly worldwide. Scientific evidence indicates that these outcomes are associated to the inversion of dietary patterns, identified by the substitution of traditional food by ultra-processed and ready-to-eat foods and beverages. Our aim was to characterize ultra-processed foods (UPF) consumed by children below five years of age assisted at the public health care system in the city of Rio de Janeiro, Brazil.

Methods: A descriptive, cross-sectional study was performed in a probabilistic sample of children between six and 59 months assisted in the Unified Health System (n=539). Twenty-four-hour dietary recalls were applied and all mentioned UPF and their respective brands were listed. A market research was conducted aiming the collection of data about UPF's nutritional composition. These products were grouped by similarity (e.g. cookies and crackers, sugary drinks, etc.), and groups were characterized, among others, in relation to: energy, fat and sodium, per 100 g (or 100 ml) and per portion reported by the manufacturers. For this, the mean portions of each group's products were calculated.

Results: A total of 387 UPFs were reported, of which: sugary drinks (97); Cookies and crackers (69), Ice-cream, sweets and candies (58); yogurts and dairy beverages (39); snacks and chips (15), and instant cereals (15). Considering the analysis per 100g and / or per portion, the products that presented the worst nutritional profile in relation to energy (E), lipids (L) and sodium (S) were: E

/ L / S - instant noodles, chips, processed meats and fast food fries; E / L – cookies and crackers, cakes and popcorn; L / S – creamy cheese; E: ready to eat "farofa"; S - margarine, instant seasoning and tomato sauce.

Conclusions: There is a wide range of UPF consumed by the study population. Nutritional profile of these UPF presents characteristics that are harmful to children's health. This evidence supports the revision of the Food Guide for Children under Two Years, conducted by the Brazilian Ministry of Health and currently in progress.

Keywords: Ultra-processed foods; nutritional profile; Macronutrients; Sodium.

ACCEPTABILITY AND FEASIBILITY OF A NUTRITION EDUCATION INTERVENTION TO PROMOTE CONSUMPTION OF PULSE BASED FOOD PRODUCTS IN CHILDCARE CENTRES IN SASKATCHEWAN: A PILOT STUDY

[1]Ramikie, Renee; [2]Haileslassie, Hiwot; [3]Froehlich Chow, Amanda; [4]Shand, Phyllis; [5]Bird, Yelena; [6]Engler- Stringer, Rachel; [7]Vantanprast, Hassanali; [8]RAMDATH, DAN; [7]Henry, Carol.

[1]BSc. College of Pharmacy and Nutrition. University of Saskatchewan. Canada; [2]M.Sc. College of Pharmacy and Nutrition. University of Saskatchewan. Canada.; [3]PhD. College of Kinesiology. University of Saskatchewan. Canada; [4]PhD. College of Agriculture and Bio resources. University of Saskatchewan. Canada; [5]PhD. School of Public Health. University of Saskatchewan. Canada; [6]PhD. College of Community Health and Epidemiology. University of Saskatchewan. Canada; [7]PhD. College of Pharmacy and Nutrition. University of Saskatchewan. Canada; [8]PhD. Guelph Research Development Centre. Agriculture and Agri-Food Canada. Guelph. Canada.

Background and objectives: The consumption of nutritionally beneficial foods during the early years, can lead to healthy eating habits that continue into adulthood. One type of food high in nutritional value are pulse crops. However, despite the nutritional benefits of pulses they are not widely consumed by the young children within the Canada. The study objective was to evaluate the acceptability and feasibility of a pilot pulse based nutrition education curriculum entitled "Pulse Discovery Tool Kit" (PDTK) among 2 to 5 years old children. The kit is designed to promote healthy eating habits and promote pulse consumption within childcare centres.

Methods: The study was conducted in two childcare centres in Saskatchewan, over a 3 –month period. The intervention included weekly lesson plans, a food service guide, pulse recipes and parent's newsletter. Data was captured on feasibility and acceptability of the PDTK through sensory evaluations, lesson plan evaluations, teachers' and cook's interviews and individualized plate waste.

Results: Sensory analysis revealed that majority of the children liked the pulse recipes, 44% liked the green split pea spread initially, which was increased to 56 % during a repeated taste testing session. The lesson plan evaluations and the teachers' interviews indicated that most of the lesson plan activities could be implemented into existing curriculum and had excellent nutrition concepts. Cooks from both centres believed that it was feasible to include recipes from the PDTK into their regular menus and expressed no barriers to cooking and serving pulses within their facilities. Measurements of the individualized plate waste indicated that the pulse recipes had lower amounts of saturated fat, calories and sodium in comparison to regular recipes.

Conclusions: The pilot testing of the PDTK showed that it was both acceptable and feasible to implement this model within childcare centres to improve pulse consumption for children 2-5 years old.

SCALING UP A COMMUNITY-BASED GRAINBANK INTERVENTION FOR IMPROVED INFANT AND YOUNG CHILD FEEDING (IYCF) IN ETHIOPIA

[1]Sako, Binta; [2]Leerlooijer, Joanne N.; [3]Lelisa, Azeb; [4]Hailemariam, Abebe; [5]Brouwer, Ingeborg; [6]Tucker Brown, Amal; [7]Osendarp, Saskia.

[1]PhD. Independant Consultant. Brussels. Belgium; [2]PhD. University of Applied Sciences. Utrecht. The Netherlands; [3]Senior Programme Officer. Micronutrient Initiative. Addis Ababa. Ethiopia; [4]Nutrition Project Officer. UNICEF. Addis Ababa. Ethiopia; [5]PhD. Nutritionist. Division of Human Nutrition. Wageningen University. The Netherlands; [6]MSc. Nutrition Specialist. UNICEF. Addis Ababa. Ethiopia; [7]PhD. Nutritionist. Division of Human Nutrition. Wageningen University. The Netherlands. Micronutrient Initiative. Canada.

Background and objectives: Child malnutrition remains high in Ethiopia and inadequate complementary feeding is a contributing factor. In this context developing partners designed a community-based intervention to provide locally-made quality complementary food for children 6-23 months, using a bartering system, in four Ethiopian regions. After a pilot phase, the intervention was scaled up from 8 to 180 localities in the same regions. We conducted a process evaluation to determine enablers and barriers for the scaling up of this intervention.

Methods: Eight study sites were selected to perform 52 key informant interviews (KII) and 31 focus group discussions (FGD) with purposely selected informants. A total of 52 KIIs and 31 FGDs were performed. For analysis, we used a framework describing six elements of successful scaling up: socio-political context, attributes of the intervention, attributes of the implementers, appropriate delivery strategy, the adopting community, and use of research to inform the scale up process.

Results: A strong political will, the alignment of the intervention with national priorities and the integration with the healthcare

system were instrumental in the scaling up process. The participatory approach in decision making reinforced ownership at community level, and knowledge acquired through program training motivated mothers and women's groups to participate. However, the management of the complex intervention, limited human resources and lack of incentives for female volunteers proved challenging. In the bartering model, the barter rate was accepted but the bartering was hindered by unavailability of cereals, and limited financial and material resources to contribute (like firewood) at community level threatening the sustainability.

Conclusions: Scaling up strategies for nutrition interventions require sufficient time, thorough planning and assessment of the community's capacity to contribute human, financial and material resources.

Keywords: Ethiopia, IYCF, scaling up implementation, community-based, process evaluation.

IMPROVING THE MINIMUM ACCEPTABLE DIET AMONG INFANTS

[1]Ouma, Cyprian; [2]Tanimoune, Mahamadou.

[1]WFP. Kenya; [2]PHN. Nutritionist. WFP. Rwanda.

Background and objectives: In Rwanda, there is a positive correlation between adequate food intake and child stunting. Children under 2 years with adequate infant and young child feeding have about half the prevalence of stunting as those without adequate food. Appropriate complementary feeding of children 6 to 24 months remains extremely low. We assessed the impact of multi sectoral nutrition programme on meeting the child minimum acceptable diet(MAD).

Methods: A cross-sectional survey was conducted to collect data on the targeted population in the two districts between August and September 2016. Two-stage sample stratification by district and wealth category was done and 1679 children were sampled aged 6-23 months. Effects of 1000 days campaign, cooking demonstration, growth monitoring, distribution of nutrition booklets, Micro-Nutrient Powders (MNP), complementary interventions with fortified blended food supplements on MAD to under 2 years children were assessed.

Results: Children enrolled in complementary intervention were able to improve minimum acceptable diet from 2 to 6 times with children 6 to 23 months meeting the MAD ranging between 16.7% for 6-11 months and 21.5% for 12-17 months with an overall rate of 19.2%, higher than baseline rate (12.1%). In households that received MNP, the 27.5 % of the children attained MAD with those who consumed MNP prior to survey increasing to 31.7%. In complementary feeding using fortified blended food supplements in poor households, 37.6% of children that consumed CSB++ the day before the survey met the MAD compared to 7.8% of those who did not consume reaching the minimum acceptable diet. 30.6% of Households that received these booklet met the minimum acceptable diet.

Conclusions: Children receiving high quality diet are less likely to be stunted and inclusion of one UN interventions in future nutrition programs improves the children Minimum Acceptable Diet.

Keywords: micro nutrient powders, minimum acceptable diet,stunting

Immunologist. Faculty of Medicine. Azuay University. Cuenca. Ecuador.; [4]MD, MSc. Ghent University. Ghent. Belgium; [5]BSc. Department of Biosciences. Cuenca University. Cuenca. Ecuador.; [6]Nutritionist. MSc. Department of Biosciences. Cuenca University. Cuenca. Ecuador.; [7]Eng. Department of Biosciences. Cuenca University. Cuenca. Ecuador.; [8]MD, PhD. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Cuenca. Ecuador.

Background and objectives: Food allergy (FA) affects millions of people around the world and is an important risk factor for fatal anaphylaxis in adolescents and young adults. In developing countries little is known about FA. Therefore, the objectives of this study are to determine the prevalence of FA as well as to identify the most common food allergens among Ecuadorian adolescents.

Methods: The study involved 1379 school-going adolescents from Cuenca (n= 917) and Santa Isabel (n= 462) cantons. Parents and adolescents filled-out a self-reported questionnaire to assess sociodemographic characteristics and history of food-associated allergic symptoms either self-perceived or identified by physician. IgE mediated food sensitization was measured by skin prick test (SPT) using food commercial allergens. Positive SPT was defined when the wheal size was ≥ 3 mm that negative control. Self-perceived FA was defined when the participants reported perceived food-associated symptoms and had a positive SPT; meanwhile, physician diagnosed FA was defined with a positive SPT and a concomitant food-associated symptoms identified by a physician. Prevalence rates of FA are reported in percentages with confidence intervals (CI). Differences in FA by gender were estimated using Chi-Square tests.

Results: Self-perceived FA was prevalent among 1.02% (95% CI 0.49-1.54) of the participants. Physician diagnosed FA was prevalent in 0.44% (95% CI 0.04-0.68) of the adolescents. The

most frequent food allergens were shrimp (0.73%; CI 0.28-1.18), followed by milk (0.2%; CI 0.07-0.35), walnut (0.2%; CI 0.07-0.35), peanut (0.2%; CI 0.07-0.35), soybean (0.07%; CI 0.07-0.21), meat (0.07%; CI 0.07-0.21), fish (0.07%; CI 0.07-0.21) and tomato (0.07%; CI 0.07-0.21). The reported prevalence were not different according with the participants' gender.

Conclusions: FA was prevalent among Ecuadorian adolescents. More important food allergens identified in this population (shrimp, milk, walnut, peanut) are similar than those reported in developed countries. Monitoring adolescents with self-perceived FA is crucial to identify and prevent fatal anaphylaxis.

Keywords: adolescent, Ecuadorian, food allergen, skin prick test.

DEVELOPMENT AND EVALUATION OF THE RELIABILITY OF AN INSTRUMENT FOR ASSESSING THE UNIVERSITY FOOD ENVIRONMENT

[1]Franco, Amanda da Silva; [2]Rugani Ribeiro de Castro, Inês; [3]Canella, Daniela; [4]Pereira, Alessandra Pereira; [5]Santos, Claudia Roberta Bocca dos; [5]Rodrigues, Lúcia; [6]Barbosa, Roseane Moreira Sampaio; [7]Tavares, Letícia Ferreira.

[1]PhD. Nutricionist. Municipality of Duque de Caxias. Brazil; [2]PhD. Associate professor. Department of Social Nutrition. State University of Rio de Janeiro. Brazil.; [3]PhD. Associate professor. University of the State of Rio de Janeiro. Brazil; [4]Professor. UNIRIO. Rio de Janeiro. Brazil.; [5]PhD. Associate professor. Federal University of the State of Rio de Janeiro. Brazil; [6]PhD. Associate professor. Fluminense Federal University. Brazil; [7]PhD. Associate professor. Federal University of Rio de Janeiro. Brazil.

Background and objectives: The organizational food environment, including the university, has been recognized as strategic for health promotion, since the foods offered there influence the eating habits of the individuals who attend these spaces. There are few studies on the evaluation of the performance of instruments used to assess university food environment. In developing countries, up to this moment there were no studies. This study proposes an instrument to assess the university food environment and evaluates its reliability in public universities in Brazil.

Methods: A checklist was prepared for the assessment of the university food environment, containing the following blocks: characterization of establishments, observation of the environment, availability, price, nutritional information and advertisements of healthy and unhealthy food markers. A convenience sample (n=64) of establishments with different characteristics distributed on seven campuses of three different public universities located in the state of Rio de Janeiro was studied. Data were collected from November 2015 to February 2016 by trained fieldworkers. The reliability of the instrument was examined by inter-observer and test-retest tests. For categorical and counting variables, instrument stability was estimated by calculating percent agreement (PA), kappa and prevalence- and interviewer bias-adjusted kappa

(ka). For continuous variables intra-class correlation coefficients (ICC) were calculated. The values of PA, k, ka and ICC were classified according to the criteria of Landis & Koch (1977).

Results: 73.5% and 65% of the 204 items evaluated presented a substantial or near perfect agreement, respectively, for the inter-observer test and the test-retest. Considering the ka, both the inter-observer test and the test-retest showed that 93% of the items presented substantial or near-perfect agreement. Of the 176 items also assessed by means of PA, 100% showed substantial or near-perfect agreement for the inter-observer test and the test-retest.

Conclusions: The instrument presented excellent performance in the context in which it was applied.

Keywords: food environment, instrument, reliability, university

UNIVERSITY FOOD ENVIRONMENT: CHANGE IN TIME IN A BRAZILIAN UNIVERSITY

[1]Franco, Amanda da Silva; [2]Perez, Patricia; [3]Rugani Ribeiro de Castro, Inês; [4]Farias, Silvia; [5]Oliveira, Ana Lúcia de; [5]Ferreira, Amanda Peixoto; [5]Santos, Cleide Braz dos; [5]Rocha, Karla da Silva; [5]Cruz, Kelly Veloso da.

[1]PhD. Nutricionist. Municipality of Duque de Caxias. Brazil; [2]PhD. Associate professor. University of the State of Rio de Janeiro. Brazil; [3]PhD. Associate professor. Department of Social Nutrition. State University of Rio de Janeiro. Brazil.; [4]MSc. Nutricionist. University of the State of Rio de Janeiro. Brazil; [5]Undergraduate student. University of the State of Rio de Janeiro. Brazil.

Background and objectives: The food environment is characterized by the availability of food and drink to individuals. The organizational food environment, including the university, has been recognized as strategic for health promotion. Studies suggest that the University food environment (UFE) represents a barrier to healthy eating practices. We did not identify studies that evaluate changes in UFE over time. This study evaluated the availability of healthy food (HFM) and unhealthy food (UFM) markers over time in a public university in the State of Rio de Janeiro.

Methods: Data collection took place in 2011, 2012 and 2016, through a census of food retailers. A checklist (pscicometrically tested for reliability and content validity) was used to evaluate the availability of HFM (fruit juice, fruits, vegetables, meals per kilo or meals per plate) and UFM (sugary beverages, salads, sandwiches, savory snacks and candies). Analyses were performed comparing the relative frequencies of the studied variables observed in each year.

Results: 15, 17 and 25 establishments were evaluated, respectively, at each time point. The availability of HFM has been reduced over the years: juices: 66.7, 58.8 and 44.4%, vegetables: approximately 47% in the first two years and 32% in the last one, fruits: 40%, 47.1% and 24%, meals per kilo or meals per plate: 26.7%, 23.5% e 20%. As for the UFM, there was stability in the availability of sugary beverages (100% in all years) and sandwiches (~ 80%) and reduction in the availability of savory snacks (93.3%,

82.4 and 72% respectively) and candies (93.3%, 88.2 and 84.0%, respectively).

Conclusions: The food environment is dynamic. There was a worsening in the availability of HEM and stability of some UEM at the university studied, representing a barrier to the promotion of adequate and healthy food, since favorable environments are important factors for healthy eating practices. Analyzing the same food environment over time, the present study reveals how much it can change and points out the need to develop interventions that improve this environment focusing on promoting adequate and healthy food and ensuring food and nutritional security.

Keywords: food environment, university, time trend

PLAYGROUND SIZE AND LEVELS OF PHYSICAL ACTIVITY IN FIRST GRADE CHILDREN OF BUENOS AIRES. DATA FROM MINISALTEN STUDY

[1]Indart Rougier, Paula; [2]De Gregorio, Maria Jose; [1]Zonis, Luciana Noemi; [1]Favieri, Andrea Lorena; [3]Rausch Herscovici, Cecile; [4]Kovalskys, Irina.

[1]BSc. Nutritionist. Nutrition and Health Area. ILSI Argentina (International Life Sciences Institute). Buenos Aires. Argentina.; [2]BSc. Sociologist. Department of Anthropological Sciences. University of Buenos Aires. Buenos Aires. Argentina.; [3]PhD. Nutrition and Health Area. ILSI Argentina (International Life Sciences Institute). Buenos Aires. Argentina.; [4]MD. Nutrition and Health Area. ILSI Argentina (International Life Sciences Institute). Buenos Aires. Argentina.

Background and objectives: Schools with more space to play have greater potential to increase children´s physical activity levels. The study aim was to examine if the playground size influences the levels of physical activity (PA) in a sample of first grade children of Buenos Aires.

Methods: This data correspond to the baseline assessment (June to November 2015) of MiniSALTEN Study (obesity prevention program targeting first grade children at public primary schools). All children of first grade attending to the 12 public primary schools from the city of Buenos Aires participating in MiniSALTEN were invited to participate. The levels of PA were measured using ActiGraph wGT3X-BT accelerometers for 7 consecutive days (24 hours). Accelerometers outcomes were: time in light, moderate and vigorous PA (minutes/day) determined by Evenson et al.'s cut points. Time in moderate to vigorous PA (MVPA) (minutes/day) was also determined. Accelerometer data were analyzed using the ActiLife 6.11.8 software. For classifying the playground size and school characteristics a scale was used and they were classified in small (S), medium (M) and large (L). Descriptive statistical analyzes of the variables measured for the total were made. Data were processed using IBM SPSS Statistic 18.

Results: Sample: 185 children (mean age = 6.7 years, 94 girls and 91 boys) wore accelerometers, 26 children were at S playgrounds , 105 at M and 54 at L. Children spent 7.4 more minutes/

day in MVPA in a larger space compare to a small one (S: 63.2, M: 63.8 and L: 70.6 minutes/day, p = 0.158) as well as more time in vigorous PA (17.9, 16.6 and 20.1 minutes/day respectively, p = 0.100). Also light PA and moderate PA increases progressively according the size of the space (light PA: 333.4, 355.1 and 363.3 minutes/day respectively, p = 0.034; moderate PA: 45.3, 47.2 and 50.5 minutes/day respectively, p = 0.237).

Conclusions: In this study a trend is observed, children are more active in large playgrounds compared to medium and small playgrounds. No significant data were found probably due to the small sample, would be interesting to be tested in a larger sample.

Keywords: Playground size, Schools, Physical activity, Accelerometers, Children.

Conflict of Interest Disclosure: The source of funding for the research is the Coca-Cola Foundation. The authors declare that they have no competing interests. The funding source had no role in study design, data collection and analysis, decision to publish, or preparation of manuscripts.

EFFECTIVENESS OF A PROGRAM INTERVENTION WITH REDUCED-IRON MNPS ON MORBIDITY, IRON STATUS AND CHILD GROWTH IN YOUNG CHILDREN IN ETHIOPIA

[1]Samuel, Aregash; [2]Osendarp, Saskia; [3]Adish, Abdul Aziz; [4]Zarifopoulou, Aikaterina; [5]Kebebe, Amha; [2]Brouwer, Ingeborg.

[1]Msc. Nutritionist. Division of Human Nutrition. Wageningen University. The Netherlands. Ethiopian Public Health Institute. Ethiopia.; [2]PhD. Nutritionist. Division of Human Nutrition. Wageningen University. The Netherlands.; [3]Micronutrient Initiative. Addis Ababa. Ethiopia; [4]Division of Human Nutrition. Wageningen University. The Netherlands.; [5]Ethiopian Public Health Institute. Addis Ababa. Ethiopia.

Background and objectives: WHO recommends a daily micronutrient powder supplementation for all young children in populations with a prevalence of childhood anaemia. We assessed the effectiveness of an integrated program with low dose iron (6 mg) MNPs on morbidity, growth and iron status of children 6-23 months of age in Ethiopia.

Methods: In a quasi-experimental design, 2356 infants 6-11 months of age, from program and matched-controlled clusters were followed longitudinally for 8 months. All children in program clusters received 15 sachets/month of lower iron dose (6 mg/serving) MNPs (15 nutrients formulation), in addition to a supply of locally produced complementary food. Iron status (Hemoglobin, serum Ferritin, sTfR) was assessed at base- and endline in a subsample. Morbidity from infectious diseases ((bloody) diarrhoea, upper and lower respiratory infections, fever and hospitalizations) were assessed every two weeks by recall. Anthropometry and information on infant feeding practices were collected every quarter.

Results: Changes in Hemoglobin concentrations during intervention differed significantly (p = 0.054) in intervention (+0.25; SD 1.50 g/dL) compared to non-intervention (-0.08; SD 1.13 g/dL). An increase in height (+11.6; SD 2.9 cm and +10.7; SD 3.3 cm, p<0.000) and decrease in height-for-age z-scores (-0.96; SD 1.20 and -1.18: SD 1.30, p<0.000) were significantly different between intervention and non-intervention groups. The prevalence of anaemia increased (29%) in non-intervention children and reduced (24%) in intervention children. Stunting increased in both groups, but the increase in stunting was lower in the intervention children (from 12.2% to 22.1%) compared to the non-intervention children (from 17.8% to 42.2%). The longitudinal prevalence of diarrhea was 3.65 % in the intervention group and 1.83% in the control group (p=0.000). The longitudinal prevalence of flu was also higher in the MNP group (5.75%) than in the control group (2.78%, p=0.000).

Conclusions: Providing low-dose iron MNPs every alternate day to 6-23 month old children for 8 months in the context of a program on local production of complementary foods, improved Hemoglobin concentrations and linear growth outcomes. However, MNPs also resulted in increased morbidity from infectious disease in the intervention compared to the non-intervention areas.

Keywords: low-dose iron MNPs ; morbidity; iron; young children; Ethiopia

EVALUATION OF THE PRIMARY OBESOGENIC MICROENVIRONMENT IN CHILDREN OF THE CITY DE CORRIENTES

Gorban de Lapertosa, Silvia; Chiapello, Jorge; Sotelo, Nancy; Delsin, Bernabé; Arias Tichij, Valeria.

Facultad de Medicina. UNNE. Argentina.

Background and objectives: Argentina is facing an epidemic of overweight / obesity, particularly in children of school age. To evaluate the frequency and preference of obesogenic foods, as well as, to rate the frequency and type of habitual physical activity and that which is performed during school hours.

Methods: In the course of 2014, by means of systematic random sampling, primary school students were selected with an age ranging from 6 to 14 years of age through a survey among tutors with demographic data. The survey included frequency and consumption of sodas, fast foods, fried foods and processed meat products. The survey inquired about food consumption outside home and its characteristics as well as the frequency of physical activity.

Results: We evaluated 1442 students; 45.63% (658) were female. Consumption of soft drinks was assessed in 449 surveys answered for this item, with 14.57% consuming soft drinks with a frequency of 3 or more times a day. From the total evaluated, 3.58% consumed fast foods, 26.14% fried foods, and 5.55% processed meat products. Of the total number of students, 333 (22.88%) answered for food preferences outside home, 23.14%

preferred hamburgers, 12.40% pizzas, 12.12% cookies, 7.16%, and a varied remaining percentages of low frequency. Physical activity of one hour a day is practiced between 3 to 4 days a week by 49.70% of the students. A 37.97% practice physical activity 2 days a week at school . These data present a relation between the different nutritional states including overweight-obesity (p = 0.02).

Conclusions: High consumption of differents obesogenic food groups is observed, as well as, a high percentage of sedentarism ; teachers and parents discussed strategies to overcome these habits, promoting healthy eating and increase physical activity in order to prevent this age group from engulfing the epidemic of non-communicable chronic diseases in the future.

Keywords: Obesogenic; Physical activity; School Feeding; Obesity; Overweight.

NEEDS OF NUTRITIONAL LABELING IN PROCESSED FOODS OF COSTA RICA

(1)Montero Campos, Marielos de los Ángeles; (2)Heredia-Blonval, Katrina; (3)Vega Solano, Jaritza; (4)Benavides-Aguilar, Karla Francela; (5)Blanco-Metzler, Adriana.

(1)MSc.FoodTechnologist. Unit of Health and Nutrition/INCIENSA. Costa Rica.; (2)Lic. Nutritionist. Independent Researcher. Costa Rica.; (3)Lic. Nutritionist. Hiredby Project # 108167 of the International Development Research Centre. Costa Rica.; (4)Lic. Food Technologist. Hiredby Project # 108167 of the International Development Research Centre. Costa Rica.; (5)MSc. Food and Nutrition Scientist. Unit of Health and Nutrition. Costa Rican Institute of Research and Teaching in Nutrition and Health (INCIENSA). Costa Rica.

Background and objectives: Although in Costa Rica there has existed regulation on nutrition labeling since 1992, currently, according to the Technical Regulation of Central America (RTCA 67.01.60:10), the declaration of nutrients is not mandatory. In addition, there is no optimal government surveillance system. This has caused some inconsistency in the presentation of information to consumers, and possibly causing confusion in them.

To describe the main needs of the legislation on nutritional labeling in processed foods in Costa Rica.

Methods: Quantitative, consists of the analysis of the declaration of nutritional labeling of 5259 processed foods in the year 2013 and 7570 in the year 2015. For the collection and analysis of data was used the smartphone application "Data Collector" and the methodology developed By the George Institute for Global Health of Australia.

Results: The deficiencies found in nutritional labeling in both years were similar. These deficiencies are: A) 36% (2013) - 32% (2015) of products with nutritional labeling did not reported sodium; B) lack of report of portion sizes, C) inadequate contrast, size and type of writing, which make the information illegible; D) lack of nutritional labeling despite the presence of nutritional de-

scriptors; E) incorrect use of units of measurement; F) incorrect translation of labels, among others.

Conclusions: In order to encourage a conscious selection of foods in the consumers and also to avoid confusions, it is necessary to establish as mandatory nutritional labeling of processed foods in Costa Rica and in Central America, through the update of RTCA 67.01.60: 10.

Keywords: Salt, sodium, nutritional labeling, food regulation, Costa Rica.

NATIONAL ACTION PLAN TO REDUCE SALT, SUGAR AND FAT CONSUMPTION 2017-2021

[1]Aguenaou, Hassan; [2]Alla, Amal; [3]Barkat, Amina; [2]Derouiche, Abdelfettah; [3]El Berri, Hicham; [2]Taboz, Youness; [2]Benkirane, Hasnae.

[1]PhD. Nutritionist. Joint Research Unit in Nutrition and Food, URAC 39 (Ibn Tofaïl University-CNESTEN) Regional Designated Center of Nutrition (AFRA/IAEA). Morocco.; [2]PhD; [3]Md. PhD.

Background and objectives: The amount of salt, sugar and / or fat (saturated and trans) consumed in Morocco is at least 50% higher than what is recommended by the World Health Organization (WHO). However, too much salt, sugar and / or fat (saturated and trans) is harmful for the health. This is why the Ministry of Health of Morocco is committed to reduce the consumption of salt, sugar and / or fat (saturated and trans). The target by 2021, is to gradually reduce salt consumption to 6 g / p / d, sugar to 60 g / p / d, reduce consumption of saturated fat and banish trans fatty acids.

Methods: Three studies were carried out, one on salt, another on sugar and the last on fat. Two reports were prepared, one on the status of the nutritional situation in Morocco, another on the action plan for the reduction of salt, sugar and fat consumption. The working methodology of this plan was based on the holding of several workshops and meetings with the different actors concerned directly or indirectly by the reduce of the consumption of salt and fat (saturated and trans).

Results: This plan aims to reduce gradually, in collaboration with the food industry, the salt, sugar and fat (saturated and trans) content in processed products. At the same time, the population should be sensitized and responsible. This action plan includes 5 strategic axes, 10 actions, 24 measures and 46 activities.

Conclusions: In the longer term, consumption of salt, sugar and fat in Morocco must meet the WHO recommendations of 5 g/p/d of salt and 50 g/p/d of sugar, eliminate all trans fats produced industrially and Significantly reduce the saturated fat content of the diet

Keywords: National action plan, salt, sugar, fat (satured and trans)

SOCIALIZATION DURING MEALS AND ITS ASSOCIATION WITH UNIVERSITY STUDENTS' NUTRITIONAL STATUS

[1]Azevedo de Aquino, Luana; [2]Vieira Liberato, Juliana; [2]Alcântra, Solange Pires Leite de; [2]Gobetti, Clara Affonso; [3]Sena, Ana Beatriz Franco; [4]Assis, Bruno dos Santos de.

[1]PhD. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.; [2]BSc. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.; [3]PhD. Graduate Program in Collective Health. Fluminense Federal University. Brazil.; [4]MSc. Graduate Program in Collective Health. Fluminense Federal University. Brazil.

Background and objectives: Eating behaviour is an important factor influencing students' weight. Therefore, the purpose of this study was to evaluate the context of socialization during meals and its association with the nutritional status of university students.

Methods: Cross-sectional analysis of data derived from the baseline of the "Longitudinal Study of Nutrition and Health in University Students (NUTSAU)", conducted in second-semester students of Rio de Janeiro Federal University – Macaé Campus. The instrument used for data collection was a structured self-completion questionnaire. The anthropometric evaluation consisted of body mass and height measurements, and thus body mass index was calculated. Meal pattern was estimated based on six response options. Statistical analysis was performed using the SPSS program, version 19.0. The project was approved by the Research Ethics Committee of UFRJ-Macaé Campus.

Results: The sample consisted of 147 university students. Regarding the realization of the main meals, it was observed that among those who ate breakfast socializing with family (21.2%) and friends (16.8%), the minority was overweight (27.6% and 17.4% %, respectively) (p = 0.43). A similar behavior was observed for those who had lunch socializing with friends (68.6%) with the minority identified as overweight (23.4%) (p = 0.16). Additionally, the habit of having dinner socializing with family members (34.4%) and friends (18.0%) was related to a lower frequency of overweight (27.3% and 30.4%, respectively) (p = 0.50).

Conclusions: We did not observe statistically significant associations between socialization during meals and nutritional status. However, our data indicate a clinical relevance of this habit as a protective factor against overweight.

Keywords: Dietary patterns. Nutritional status. University.

EATING PLACES AND ITS ASSOCIATION WITH UNIVERSITY STUDENTS' OVERWEIGHT

[1]Azevedo de Aquino, Luana; [2]Gobetti, Clara Affonso; [2]Alcântra, Solange Pires Leite de; [2]Vieira Liberato, Juliana; [3]Sena, Ana Beatriz Franco; [4]Assis, Bruno dos Santos de.

[1]PhD. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.; [2]BSc. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.; [3]PhD. Graduate Program in Collective Health. Fluminense Federal University. Brazil.; [4]MSc. Graduate Program in Collective Health. Fluminense Federal University. Brazil.

Background and objectives: College or university is a critical period regarding unhealthy changes in eating behaviours in students. Therefore, the purpose of this study was to evaluate the context of eating places and its association with the nutritional status of university students.

Methods: Cross-sectional analysis of data derived from the baseline of the "Longitudinal Study of Nutrition and Health in University Students (NUTSAU)", conducted in second-semester students of Rio de Janeiro Federal University – Macaé Campus. The instrument used for data collection was a structured self-completion questionnaire. The anthropometric evaluation consisted of body mass and height measurements, and thus body mass index was calculated. Meal pattern was estimated based on six response options. Statistical analysis was performed using the SPSS program, version 19.0. The project was approved by the Research Ethics Committee of UFRJ-Macaé Campus.

Results: The sample consisted of 147 university students. Regarding the consumption of the main meals, it was observed that among those who ate breakfast at home (85.5%) a minority was overweight (24.6%) (p = 0.43). A similar behavior was observed for those who had lunch at home, who prepared their own packed-lunches and who bought packed-lunches (34.8%, 37.0% and 8.7%, respectively) with the minority identified as overweight (20,8%, 31,4% e 41,7%, respectively). Among those who generally ate fast-food the majority was classified as overweight (66.7%) (p=0.04). Having dinner at home was also related to a lower frequency of overweight (23.9%) (p=0.41)

Conclusions: It was observed that the patterns of having lunch at home, taking home-made packed-lunches and of buying packed-lunches may be protective habits against overweight in university students.

Keywords: Dietary patterns. Nutritional status. University.

IMPACT OF OBESITY ON THE WORKING CONDITIONS OF TEACHERS AND EMPLOYEES OF THE BRAZILIAN STATE SCHOOL NETWORK

[1]Silva, Elza Cristina; [2]Almeida Roediger, Manuela de; [3]Monteiro Goulart, Rita Maria; [4]Sanches, Ana Maria; [5]Matsura Shirassu, Mirian; [6]Waisberg, Jaques; [7]do Nascimento da Silva, Maria de Lourdes.

[1]Nutritionist. Master's Degree Program in Health Sciences by the Institute of Medical Assistance to the State Public Servant - HSPE / IAMSPE- SP. Brazil; [2]Posdoctoral student. Nutritionist. Program of Nutrition in Public Health. School of Public Health. University of São Paulo. Brazil.; [3]PhD. Nutritionist. Public Health from the Faculty of Public Health, University of São Paulo. Brazil; [4]Medical doctor at the Hospital of the Public Servant at PREVENIR - IAMSPE. Brazil; [5]Medical Center of the Promotion and Protection of Health of the Institute of Medical Assistance to the State Public Servant. Brazil; [6]Doctor. Professor and Coordinator of the Stricto Sensu Post-Graduation Program in Health Sciences of the Institute of Medical Assistance to the State Public Servant (IAMSPE). Brazil; [7]PhD. Nutritionist. Program of Nutrition in Public Health. School of Public Health. University of São Paulo. Brazil.

Background and objectives: The prevalence of obesity has increased in state school teachers. Studies show that the healthier the workers are in the work environment, the greater and more consistent the company's prospects for success. This study verified the prevalence of obesity and its association with working conditions of teachers and employees of state schools in São Paulo.

Methods: A retrospective cross-sectional study using data of civil servants of the state schools in the city of São Paulo, composed by adults and elderly people of both sexes (n = 23,273). The study variables were: obesity measured by body mass index (BMI; kg/m2) considering obese when BMI ≥ 30 kg/m2; and working conditions (factors at work that affect feeding habits, working hours and annual health leave in the last 12 months) measured by specific questionnaire. Multiple logistic regression was used to verify the association between variables using the Stata / SE 13.0 program.

Results: Of the 23,273 individuals analyzed, 83.5% are female, 63.2% of the 19- to 49-year-old age group. The prevalence of obesity was 29.0%, higher in women (83.5%) and in the age group of 50 years and over (57.0%). It was found that working conditions that affect feeding habits (RP = 1.55), a workload of 30 hours and more (RP = 1.98), and annual health leave (RP = 1.26) were associated obesity in teachers and employees of the state school network.

Conclusions: The obesity was associated with working conditions in teachers and employees of the state school network. These results show the importance of developing political policies, which are able of stabilizing and finally, reverse the epidemiological situation presented.

Keywords: Obesity, working conditions, teachers, employees.

NEXUS OF WATER, SANITATION, HYGIENE, GENDER, AND NUTRITION: A CONCEPTUAL FRAMEWORK OF THE PATHWAYS OF INFLUENCE

[1]Caruso, Bethany; [2]Sinharoy, Sheela; [3]Trinies, Victoria; [4]Freeman, Matthew.

[1]PhD. Post Doctoral Fellow. Department of Environmental Health. Rollins School of Public Health. Emory University. USA.; [2]MPH. PhD Candidate. Nutrition and Health Sciences Program. Emory University. USA.; [3]MPH. Public Health Program Associate. Rollins School of Public Health. Emory University. USA.; [4]PhD. Assistant Professor. Department of Environmental Health. Rollins School of Public Health. Emory University. USA.

Background and objectives: Globally, 2.5 billion people lack access to improved sanitation and 663 million people lack access to improved water for drinking. Of these, a disproportionate number are women and girls. We examined the adverse effects of gender-differentiated restricted access to water, sanitation, and hygiene facilities on women and girls' health and nutrition, and associated causal pathways.

Methods: We synthesized multidisciplinary literature on how gender-differential access to water, sanitation, and personal hygiene (WASH) impacts reproductive, maternal and child health and nutrition. We critically reviewed the evidence and developed a framework to articulate the direct and indirect pathways through which a lack of access to WASH resources and behaviors may affect the health and nutrition of women, adolescent girls, and young children.

Results: Underlying gendered norms and practices around WASH, as well as sex-based biological differences, result in differential impact on women and girls' health and nutrition through a number of causal pathways. These include women and girls' roles as WASH duty-bearers, which can require significant time commitment and caloric expenditure; gender-based constraints on freedom of movement, which pose barriers to necessary WASH resources and behaviors; and the sex-specific need for WASH resources and hygienic facilities for childbirth and menstrual hygiene management. These factors can increase women and girls' vulnerability to undernutrition, anemia, infectious disease, and adverse birth outcomes through multiple pathways. A lack of access to WASH resources and behaviors also increases women's time poverty and risk of depression, which can influence care practices, infant and young child feeding behaviors, and the nutritional status of children. Our review concludes with recommendations for policy, advocacy, and future research.

Conclusions: Women and girls bear a disproportionate burden of responsibilities and health and nutrition impacts related to WASH. Integrated programming that addresses the WASH needs of women and girls is necessary to achieve further gains in health and nutrition. Our framework provides a conceptual basis for future interdisciplinary research into the biological and behavioral pathways by which WASH may affect nutrition and growth.

Keywords: WASH, gender, anemia, undernutrition, women's nutrition

IMPROVING ACCESS TO FRESH FRUIT AND VEGETABLES AMONG LOW INCOME FAMILIES IN THE USA: THE NEAT TRIAL

[1]Segura-Pérez, Sofia; [2]Damio, Grace; [3]Perez-Escamilla, Rafael.

[1]M.S.,R.D. Hispanic Health Council. US; [2]M.S. Nutritionist. Hispanic Health Council. USA; [3]PhD. Professor of Epidemiology and Public Health. Yale School of Public Health. USA.

Background and objectives: Eating a variety of fruit and vegetables has been shown to reduce the risk of chronic diseases. Thus, The Nutrition Education, Access and Texting (NEAT) trial sought to assess the impact of distribution of incentive coupons along with a texting-based marketing campaign promoting usage of a Mobile Market (MM), on increasing access, purchase, and intake of fruit and vegetables among SNAP-Ed participants.

Methods: NEAT was a randomized trial with low-income participants with children under 5 years old. Participants had unlimited texting plans and were willing to receive daily texting for a 4-week period. They completed a ½ hour baseline survey collecting demographic, and fruit and vegetables data. Participants were then assigned to the experimental group (n=100) receiving four $5 coupons for use at the MM during the next 6 weeks plus a month of daily text messages informing them about MM stop locations, tips on preparing/eating more fruit and vegetables, and reminders to use their coupons or the control group (n=93) that only received text messages about free family community events. Participants from both groups completed a 6-week follow-up phone interview.

Results: Both groups had similar baseline characteristics, mean age of 32±8.81 years, 79% were Hispanic, mostly female (96%), and receiving SNAP benefits (80%) (N=193). At follow-up (n=169) intervention group participants spent significantly more on fruits than those in the control group ($42 vs. $30, p=0.027), and were also more likely to buying their produce at the MM (46% vs. 23%, p=0.002). There was a also a significant increase in fruit intake in the intervention group only (p=0.001). Participants accessing the MM were very satisfied with the produce sold as well as the customer service.

Conclusions: NEAT was successfully implemented and led to higher use of MM, and increased spending and intake of fruits.

Keywords: food access, food security, fruit and vegetables, mobile market

QUALITY OF LIFE AMONG ECUATORIAN ADOLESCENTS WITH FOOD ALLERGY DETERMINED BY SKIN TEST REACTIVITY AND SERUM IGE LEVELS

[1]Morillo Argudo, Diana Alexandra; [2]Calle Chalco, Ximena Elena; [2]Sacoto Macías, Rosa Angélica; [3]Andrade Tenesaca, Dolores Susana; [4]Rodas Espinoza, Claudia Rosana; [5]Córdova Jimbo, Diana Paola; [6]Zúñiga Carpio, Gabriela Alexandra; [7]García García, Ana Angélica; [8]Ochoa Avilés, Angelica.

[1]MD. Department of Biosciences. Cuenca University. Cuenca. Ecuador.; [2]BSc. Cuenca University. Cuenca. Ecuador.; [3]Eng. MD, PhD. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Cuenca. Ecuador.; [4]MD, Immunologist. Faculty of Medicine. Azuay University. Cuenca. Ecuador.; [5]BSc. Department of Biosciences. Cuenca University. Cuenca. Ecuador.; [6]Nutritionist. MSc. Department of Biosciences. Cuenca University. Cuenca. Ecuador.; [7]Eng. Department of Biosciences. Cuenca University. Cuenca. Ecuador.; [8]MD, PhD. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Cuenca. Ecuador.

Background and objectives: Food allergy (FA) can affect the quality of life of people. FA determined by skin test reactivity and serum IgE levels increase the precision of the diagnosis. Therefore, the objectives of this study are to determine the prevalence of food allergy (determined by skin prick reactivity and serum immunoglobulin E (IgE) levels) and its affectation on quality of life among Ecuadorian adolescents.

Methods: A cross-sectional study was conducted among 462 Ecuadorian adolescents from Santa Isabel between July 2014 and February 2016. Skin prick test (SPT) was applied in adolescents to identified allergic sensitization (wheal size > 3 mm that negative control) using 20 commercial food allergens. Adolescents with allergic sensitization were examined by a Immunologist to identify: i) history of food-associated allergic symptoms, ii) positive IgE specific serum using ImmunoCAP technique and iii) affectation in the quality of life applying a questionnaire. Positive IgE to a specific food was defined with serum levels ≥ 0.35 IU. FA was identified when the participants reported history of food-associated allergic symptoms and had a positive SPT or positive IgE specific levels. Affectation of quality of life evaluated three items: dietary restrictions, emotional impact and risk from accidental exposure.

Results: FA by SPT was prevalent among 4.33% of the adolescents. FA by SPT and serum IgE levels was prevalent in 1.73% of the participants. Shrimp and peanuts were the main allergens. FA by SPT and serum IgE levels affects the quality of life of adolescents an average of 0.05 / 6, SD ± 0.94.

Conclusions: FA is prevalent in adolescents from Santa Isabel. The use of specific IgE in combination with SPT increased the diagnostic accuracy. Adolescents with FA did not present significant affectation in their quality of life, contrarily to other studies that observe notable affectation. This opposite result can be explained by the lack of knowledge about their condition.

Keywords: adolescent, Ecuadorian, food allergen, IgE, quality of life.

ACCEPTABILITY OF MULTI-MICRONUTRIENT POWDERS (MNP) IN YOUNG CHILDREN: FACTORS AFFECTING CAREGIVERS´ DECISIONS - BY FAMILY, HEALTH PERSONNEL AND COMMUNITY ACTORS IN THREE REGIONS OF PERU

[1]Creed-Kanashiro, Hilary; [2]Bartolini, Rosario; [2]Goya, Cecilia; [3]Jimenez, Michelle.

[1]MPhil. Nutritionist. Instituto de Investigación Nutricional. Lima. Peru; [2]BA. Anthropologist. Instituto de Investigación Nutricional. Lima. Peru; [3]MSc. Nutritionist. Instituto de Investigación Nutricional. Lima. Peru.

Background and objectives: Prevalence of anemia remains high in infants and young children in Peru. This study explored the experiences and practices, of families, health personnel and other community actors from government-funded social programs regarding MNP supplementation in children 6 to 36 months, leading to an understanding of the issues related to their acceptability and consumption by families and young children.

Methods: The qualitative study took place in three regions of Peru: Piura, Ucayali, Huancavelica, served by two Government-funded social programs (Day care centres and Family accompanying program of the Ministry of Development and Social Inclusion, MIDIS). Data was collected using semi-structured in-depth interviews, focus groups, exit interviews from primary health care services, and semi-participative observations during counseling sessions in health services, mealtimes at child care centers and in households, as well as during household visits carried out by the social programs. Data was transcribed, coded and analyzed to identify sub-themes and their relationship to the consumption and acceptability of MNPs.

Results: Caregivers give MNPs until they encounter a negative occurrence (diarrhea, illness) or lack of acceptability from the child. Health personnel and community actors are committed to the delivery of MNP with high perceptions of their value but there were weaknesses in training and counseling, which translated into inappropriate preparation practices and inadequate support networks when caregivers experience difficulties. Quality of monitoring data collected could be improved and further used to feedback into processes and practices.

Conclusions: Qualitative data provides a rich context to the processes surrounding supplementation with MNPs in these 3 regions to improve programs. Improved training, counseling and better support systems could enhance acceptability and consumption of MNP by caregivers.

Keywords: Multimicronutrients; acceptability; infants and young children; social programs; support networks

REASONS ALLEGED BY PUERPERAL WOMEN TO SEEK CARE IN A HUMAN MILK BANK OF A UNIVERSITY HOSPITAL

[1]Thais Resende Teixeira, Karla; [2]Accioly, Elizabeth; [3]de Oliveira Lopes, Fernanda; [4]Azevedo dos Santos, Talita; [1]de Souza Gouveia Moreira, Laís.

[1]Nutritionist of Antonio Pedro University Hospital / Fluminense Federal University. Niterói/ RJ. Brazil.; [2]Dra. Nutricionist. Federal University of Rio de Janeiro. Department of nutrition and dietetics. Rio de Janeiro / RJ. Brazil.; [3]MSc. Nutritionist. Antonio Pedro University Hospital / Fluminense Federal University. Niterói/ RJ. Brazil; [4]Nutritionist. Federal University of the State of Rio de Janeiro. Rio de Janeiro / RJ. Brazil.

Background and objectives: There are many reasons that make breastfeeding difficult. Within this context, it becomes relevant to know the reasons that lead women to seek help in human milk banks (BLH). The objective of the study was to describe the main reasons of women seeking care at the Human Milk Bank of a University Hospital in the city of Niterói, Rio de Janeiro state, also describing the characteristics of these women and their babies.

Methods: This is a retrospective study, based on data from service forms, in the year 2015. The data were extracted from the institution's BLH service forms, applied to women who sought care in that sector, in the year 2015.

To assess the profile of the women were collected socio-demographic, gestational, lifestyle, type of Childbirth, history of current breastfeeding, use of artificial nipples, breast exams, the reason for the demand for the milk bank and the main complaint of these women and the conduct adopted by the Multiprofessional team of the human milk bank.

Data were also collected from the newborn. For the evaluation of weight and gestational age at birth, the cutoff points of the Brazilian Society of Pediatrics and the World Health Organization were used.

Results: The majority of the study participants corresponded to adults, residents of the city of Niterói. Difficulty in breast-feeding was the motive most alleged by women who sought BLH, followed by breastfeeding pain. The majority started prenatal care in the first trimester (78.4%), but it was observed a low frequency of guidelines on breastfeeding during that period. The most prevalent type of delivery was the surgical one (81.1%), 38.5% offered artificial formulas for their babies, and of these 72% reported difficulties in relation to breastfeeding.

Conclusions: The main reasons that motivated the search for BLH were related to difficulties with breastfeeding, which could be avoided or at least minimized, with guidelines to support and promote breastfeeding even during prenatal care and in the Which emphasizes the role of the multiprofessional health team in the attention to women in the pregnancy-puerperal cycle.

EVIDENCE-BASED INTEGRATION OF NUTRITION INTO MULTI-SECTOR BRAC PROGRAMS IN BANGLADESH

[1]Jalal, Chowdhury Jalal; [2]Habicht, Jean-Pierre; [3]Lee, James; [3]Bhuiyan, Muhammad Mahbub; [2]Pelto, Gretel.

[1]Micronutrient Initiative. Ottawa. Canada; [2]PhD. Professor Emeritus. Cornell University. USA; [3]Independent Consultant.

Background and objectives: Integrated multisector nutrition-specific and nutrition-sensitive interventions are a recognized and widely endorsed strategy to ensure sustainable improvements in the nutrition of women, adolescents and children. Despite broad agreement about the nature of barriers to effective integration in recent literature, there remains insufficient evidence of the actions which can eliminate those barriers. The Micronutrient Initiative has been conducting a research to identify these barriers particularly related to adolescent nutrition and inform designing integration of actionable nutrition packages through multisector programs of BRAC - an NGO known for its largest national-level programs in the world. The purpose of this research was to generate evidence on how to integrate nutrition into multiple-sector programs and preliminarily recommended evidence-based integration of actionable nutrition packages through multiple-sector programs

Methods: We conducted a review of nutrition gaps in Bangladesh; prepared Program Impact Pathways (PIP) to understand how BRAC programs operate; and explored nutrition activities carried out by other agencies. A step-wise focused ethnographic studies (FES) was used to understand the barriers and opportunities relevant to adolescent nutrition at individual-, household-, and community-levels. FES also informed existing gaps in delivery of services. The steps in FES provided opportunities for gradually strengthening the research protocols and pinpoint critical gaps that needed to be filled by different programs. Plotting of FES results on the PIPs identified components of different programs through which BCI and other nutrition services may be provided.

Results: Preliminary analysis suggested non-existence of any interventions BRAC or other agencies dedicated specifically to improving adolescent nutrition. Behaviour Change Intervention (BCI) material should be tailored to include different strategies for in- and out-of-school adolescents. Provision of weekly Iron and folic acid (WIFA) supplementation will need to be ensured. BRAC's Village Theatres, Adolescent Clubs, contacts by health volunteers, Nutri-garden, etc. are potential candidates to deliver nutrition services but have been so far neglected.

Conclusions: Preliminary results show opportunities to deliver nutrition interventions through multiple nutrition and non-nutrition sectors and to maximize the demand for services. The research is still in progress and the October IUNS presentation will further include how the evidence-generated interventions will have been operationalized into BRAC programs.

Keywords: Nutrition integration, multi-sectoral, adolescents

COMPARISON OF "OUT OF HOUSEHOLD PURCHASED FOODS" (OHF) IN LATIN AMERICAN COUNTRIES BASIC FOOD BASKETS (BFB)

[1]Monroy Valle, Michele; [2]Graciano, Beatriz Andrea.

[1]Nutritionist, Masters in Epidemiology. Instituto de Investigaciones Químicas y Biológicas, Universidad de San Carlos de Guatemala; [2]Nutritionist. Escuela de Nutrición. Universidad de Buenos Aires. Buenos Aires. Argentina.

Background and objectives: Basic Food Basket (BFB), used in Latin American countries as official poverty measure methodology, gives information about the most commonly purchased foods by the country population. Eating out for leisure is a habit among the 4th and 5th income quintile, but a need for most population during the working week. The expenditure that household allocates to purchase foods outside the household is necessary and more than half urban households had reported to purchase breakfast and/or lunch five to six days a week. The objective was to compare the inclusion and characteristics of OHF in Latin American Countries BFB.

Methods: We check in the official list of foods from 19 countries urban BFB, those that identify OHFs (breakfasts, lunches or dinners) as part of the structure of the average minimum diet. It was excluded from the analysis that the OHF were in the consumer´s price index, because it is not used to measure poverty directly as the BFB. Information was collected online from official sources as National Statistics Institutes or similar responsible for BFB monthly price publication in the following countries: Guatemala, El Salvador, Honduras, Nicaragua, Belize, Brazil, Costa Rica, Dominican Republic, Panama, Mexico, Ecuador, Colombia, Venezuela, Peru, Bolivia, Paraguay, Argentina, Chile, Uruguay.

Results: here are countries where BFB composition is not available. Only 6 include out of household purchase: Ecuador, Bolivia, Uruguay, Chile, Mexico and Paraguay. Ecuador, Bolivia, Paraguay have a food group named "Foods and Beverages consumed out of household" which includes various foods and complete meals such as lunches or dinners. Uruguay measure is more complex with Meals outside the household, prepared meals, expenses in restaurants, bars and hotels. Chile and Mexico reports individually lunch menu of other plates. For all countries, OHF represented more than 15% of household expenses.

Conclusions: Countries must make efforts to update the BFB and include out of household purchase to calculate the real cost of actual diets. Nutritionist must do research on OHF composition, nutrition value and the distribution into the family.

Keywords: Basic Food Basket, out of household purchased foods, Latin America

EFFECT ON ONE UN PROGRAMME ON NUTRITION SECURITY IN RUTSIRO AND NYAMAGABE DISTRICTS

[1]Ouma, Cyprian; [2]Tanimoune, Mahamadou.

[1]BSC Nutritionist. WFP. Kenya; [2]PHN. Nutritionist. WFP. Rwanda.

Background and objectives: Food consumption score(FCS)is a measure of dietary diversity, food frequency and the relative nutritional importance of the food consumed. With evaluation of Food and Nutrition security status of households as a major One UN project objective, we aimed to study the effect of the various components of the One UN interventions on Food Consumption Score.

Methods: A cross-sectional survey was conducted to collect data on the targeted population in the two districts between August and September 2016. Sampled children were 3700. Two stage sample stratification by district and wealth category was done. Final sample size was 3700 children aged 6-59 months.

Results: Households with children enrolled in the Micro nutrient programme had a slightly higher percentage (39%) of children with acceptable food consumption score as compared to those not enrolled (36%). Households with children that consumed MNP before the survey were more food secure than those not enrolled and those enrolled and did not consume the MNP the day before the survey. Children who consumed CSB++ the day before the survey had slightly better consumption score as compared to those who did not consume CSB++ (39.7% vs. 37.6%).

Conclusions: The improvement of Food security situation after the One UN Project intervention highlights the need for incorporating such interventions in future nutrition programs.

ASSESSMENT OF PLASMA CONCENTRATION OF VITAMIN A, VITAMIN B12 AND IRON AMONG TUBERCULOSIS PATIENTS WITH AND WITHOUT HIV INFECTION: A COHORT STUDY

[1]Gebremicael, Gebremedhin; [2]Alemayehu, Mihret; [3]Sileshi, Meron; [3]Gebrezgeaxier, Atsebeha; [3]Ashenafi, Nigat; [3]Tefera, Hulumtaye; [4]Weldie, Mistre; [5]Kassa, Desta.

[1]MSc. Infectious Diseases. Ethiopian Public Health Institute. Ethiopia; [2]MSc. Department of Medical Laboratory Sciences of Addis Ababa University. Ethiopia; [3]MSc. Ethiopian Public Health Institute (EPHI). Ethiopia; [4]PhD. Department of Medical Laboratory Sciences of Addis Ababa University. Ethiopia; [5]PhD. Immunologist. Ethiopian Public Health Institute (EPHI). Ethiopia.

Background and objectives: The impact of micronutrients concentration in the body on TB development diseases progression and TB treatment outcome on micronutrients concentration level in the body is not fully understood. In this study, we determined the level of Plasma Vitamin A, Vitamin B12 and Iron in TB patients with and without HIV Infection before and after TB treatment,

Methods: A total of 262 study participants which composed of 144 active TB patients [57 HIV co-infected (HIV+TB+) and 87 HIV negative (HIV-TB+)], 71 HIV+ and Tuberculin Skin test negative (HIV+TST-), 22 HIV-TST+, and 25 controls (HIV-TST-) were recruited. Vitamin A concentration was measured using high performance liquid chromatography (HPLC), whereas Iron and vitamin B12 concentrations were measured using cobas® 6000 analyzer at baseline and after six months of anti-TB treatment (ATT)

Results: HIV-TB+ patients had low plasma concentrations of vitamin A ($0.07\mu mol/L$) and Iron ($0.25\mu g/dl$) and high level of concentration of vitamin B12 ($626pg/ml$) compared to HIV-TST+ ($0.15\mu mol/L$, $0.86\mu g/dl$ and $354.5pg/ml$ respectively) and to HIV-TST- ($0.15\mu mol/L$, $0.90\mu g/dl$ and $360.4pg/ml$ respectively). Similarly, the concentration of Iron was significantly lower in HIV+TST- patients ($0.58\mu g/dl$) compared to HIV-TST+ and HIV-TST- study participants. After ATT, HIV-TB+ patients had high concentrations of vitamin A ($0.15\mu mol/L$) and Iron ($0.85\mu g/dl$) and low level of concentration of vitamin B12 ($388.6pg/ml$) compared to the baseline concentration levels ($p<0.05$); but not significantly different compared to that of HIV-TST+ concentration and HIV-TST-.

Conclusions: The low concentrations of vitamin A and Iron, and high concentration of vitamin B12 in HIV-TB+ patients which can be due to the preceding deficiencies that enhanced susceptibility to TB diseases, suggests the need of micronutrient supplementation for TB patients . In addition, the changes in plasma vitamin A, vitamin B12 and Iron following anti-TB treatment indicates the value of these parameters used to monitor TB treatment responses.

Background and objectives: Failure to return to pre-pregancy weight after childbirth may contribute to obesity. There is evidence that high protein and low carborhydrate intake in the general population helps to maintain boby weight. However, there is limitted evidence of the effect of high protien intake among postpartum women. To evaluate the effect of high protein intake and nutritional advice on body weight loss during first six months of postpartum.

Methods: Randomized controlled trial with ninety four overweight or obese postpartum womennfrom two public maternity ward situated in Rio de Janeiro state, Brazil. Postpartum women were randomized to intervention (IG) and control group (CG). The IG received protein foods sardine supplementation (130 g / one can per week) to increase dietary protein content combined with instructions to restrict the consumption of carbohydrates. The control group (CG) received nutritional advice to follow that national nutrion guideline with standart quantities of carbohydrate, protein and fat. To guarantee the trial adherence CG received 2 kg of pasta per month. Linear mixed-effects model was applied to test the effect of high protein intake on body weight loss during postpartum. Then, the interaction between IG (high protein intake) and intake of macronutrients (CH and Fat) were also investigated.

Results: The CG gained more weight over time (ß=0.824; SE=0.393; p= 0.037) than women in the IG (ß=0.013; SE=0.402; p= 0.975). Intake of (g/kg) of protein (ß=-0.88; p<0.001), lipids (ß=-1.76; p<0.001) and carbohydrate (ß= -0.39; p<0.001) over time were idenpendently associated with weight loss. There was a significant interaction between IG and lipdid intake (g/kg) (ß=-13.9; p= 0.012)

Conclusions: High protein intake and dietetic advice were associated with the maintenance of body weight during postpartum period.

COEXISTENCE OF OVERWEIGHT, OBESITY AND UNDERWEIGHT AMONG PEOPLE LIVING WITH HIV: A FINDING FROM RWANDA 2015 NATIONAL NUTRITION AND FOOD SECURITY VULNERABILITY ASSESSMENT

[(1)]Ouma, Cyprian; [(2)]Tanimoune, Mahamadou.

Affiliation: [(1)]BSC Nutritionist. WFP. Kenya; [(2)]PHN. Nutritionist. WFP. Rwanda.

Background and objectives: HIV sensitive programming such as safety nets requires strong targeting process in order assist most affected PLHIV. To design appropriate intervention, WFP and Rwandan Biomedical Centre /HIV, STIs and OBBI Division conducted a national survey on the nutrition status, food security status, and vulnerability among PLHIV.

Methods: Two-stage cluster sampling, with cluster defined as district and the primary sampling unit (PSU) was the Hhealth facility (HF). The probability-proportional-to-size (PPS) sampling was applied with pre-stratification by program (Pre-ART and ART). A total of 2,386 PLHIV have been surveyed all category combined in 60 HFs selected countrywide, two by district.

Results: High overweight prevalence among adult PLHIV 17.5 % (BMI≥ 25.00) compared to underweight 13.7 % (BMI <20.00). The majority (79.5 %) was classified as pre-obese (BMI 25.00-29.99) and 20.5 % as obese (BMI ≥ 30.00). Of the 13.7 % underweight prevalence, 68.3 % were classified as mild (BMI between17-18.99), 18.7 % as moderate (BMI 16-16.99) and 13 % as severe (BMI <16). Clients with a higher viral load (greater than or equal to 1000 copies/ml) were found to be overweight/obese (23.1 %) compared to the category of clients with lower viral load category (<400 copies/ml) (18 %).The prevalence of overweight was also higher among women (22.1 %) than men (10.3 %) and in Kigali city (30.1 %). The highest prevalence of overweight/obesity was among clients who had at least completed secondary school (47.3 %), monthly salaried employees (39 %), those earning a monthly income above 50.000 RWF (37.6 %).

Conclusions: Overweight and obesity coexist with undernutrition among PLHIV in Rwanda. Overweight affects more women, urban, highly educated, client with higher viral load and the better off wealth category. However these findings hide critical vulnerability among lower socioeconomic category where undernutrition, food insecurity and poor copying strategy is high. Additional investigation is required to clearly understand the double burden of malnutrition among PLHIV for better targeting.

PREVALENCE OF CARDIOVASCULAR RISK IN ADOLESCENTS REGISTERED IN PUBLIC EDUCATIONAL INSTITUTIONS OF THE CITY OF ASUNCIÓN

[(1)]Alfonzo Maciel, Lilian Fabiola; [(2)]Alfonzo Maciel, Lilian Fabiola; [(3)]Serafini, Maria.

[(1)]Nutritionist. Nutrition Research Coordinator. Faculty of Health Sciences. Universidad Autonoma de Asuncion. Paraguay; [(2)]Nutritionist. Nutrition Research Coordination. Universidad Autonoma de Asuncion; [(3)]Nutritionist. Nutrition Career Direction. Universidad Autonoma de Asuncion. Paraguay.

Background and objectives: Obesity in the adolescent age presents great challenges for health and nutrition services, because if it is not corrected in time, it will be the gateway for the early onset of chronic noncommunicable diseases. Objective: To determine the prevalence of cardiovascular risk factors in adolescents enrolled for the 2016 school year in educational institutions in the city of Asunción

Methods: The study was observational, descriptive, transversal with analytical component. Sociodemographic, clinical, anthropometric and lifestyle variables were evaluated

Results: A total of 250 students were selected from 5 schools, 55% female, the mean age of the total was 13.6 ± 1.7 years, most of them belong to the third cycle of Basic School Education. All of them had a family history, the most frequent being hypertension, diabetes and obesity. The mean body weight was 51.9 ± 9.5 kg, BMI 20.7 ± 3.9 kg / m2, systolic blood pressure (SBP) 99.6 ± 8.7 mmHg, and diastolic blood pressure (DBP) 65.7 ± 5.7 mmHg. 65% presented adequate weight, 23% malnutrition by excess and the rest risk of malnutrition. 5% had high waist circumference and 2% had high blood pressure. 92% affirm to carry out sports, the women, walk and the men play soccer. One student reported smoking, she does it every day. 3% consume alcoholic beverages on certain occasions. The major risk factor for cardiovascular disease was excess malnutrition. There was no significant relationship between increased waist circumference, BMI and mean blood pressure.

Conclusions: The main risks for cardiovascular disease found in the sample were overweight and obesity

Keywords: Adolescents, Cardiovascular Risk, Nutritional Status, Blood Pressure

INFLUENCES OF MATERNAL METABOLIC STATUS ON ADAPTIVE BEHAVIOR AND SOCIAL-EMOTIONAL DEVELOPMENT IN THEIR OFFSPRING AT 6 AND 18 MONTHS OF LIFE

[1]Nieto Ruiz, Ana; [2]Torres-Espínola, Francisco José; [3]Arias, Miriam; [4]Rueda, Ricardo; [5]Campoy, Cristina.

[1]cPhD. Psychologist. EURISTIKOS Excellence Centre for Paediatric Research. University of Granada. Spain.; [2]PhD. Psychologist. EURISTIKOS Excellence Centre for Paediatric Research. University of Granada. Spain.; [3]Nutritionist. EURISTIKOS Excellence Centre for Paediatric Research. University of Granada. Spain.; [4]PhD. MD. R&D Department. Abbott Nutrition. Granada. Spain.; [5]PhD. MD. Prof. EURISTIKOS Excellence Centre for Paediatric Research. University of Granada. Spain.

Background and objectives: Maternal metabolic status before and during pregnancy exerts an important influence on neurodevelopment and behavior in the offspring. Maternal characteristics may be a significant predictor of behavioral problems in childhood and mental health problems during adulthood. The aim of the present study was to analyse the effect of maternal obesity or gestational diabetes (GD) conditions on adaptive behavior and social-emotional development in their offspring at 6 and 18 months of life.

Methods: From a total of 331 pregnant women participating in the PREOBE study, 215 pregnant women and their offspring were evaluated. The mothers were divided into 4 groups according to their pre-gestational body mass index or the development of GD: overweight (n:44), obese (n:32), GD (n:58), and healthy normal weight (n:81). Adaptive behavior and social-emotional development was assessed using the Adaptive Behavior Assessment System-Second Edition (ABAS-II) and Bayley's III Social-Emotional scale. Differences in scores were analysed by ANOVA, MANCOVA and Chi-Square Test, using SPSS version 22.0.

Results: At 6 months of life, those children born to obese mothers showed lower scores in social-emotional (p=0.005) and self-direction (p=0.035) skills, compared to those born to normal weight-healthy mothers. At 18 months of age, children born to overweight/obese mothers presented lower scores in self-direction (p=0.028), leisure (p=0.037) and self-care (p=0.024) than those born to normal weight-healthy mothers. However, in adjusted analysis by maternal age and cultural level, these results disappeared. Additionally, children born to normal weight-healthy and GD mothers showed higher scores in conceptual skills (communication, functional pre-academics and self direction) (p=0.001) than children born to obese/overweight mothers.

Conclusions: Obesity or Overweight during pregnancy are associated to poorer child's social-emotional and adaptive behavior development at 6 and 18 months of life. Problems in early life to adapt to the natural and social demands of environment can be predictors of learning disorders or attention deficits. These results couldn help to understand the underlying aetiology of cognitive and behaviors problems in preschool children.

CHALLENGES AROUND HEALTHY EATING OF MOTHERS OF PRESCHOOL CHILDREN IN LIMA-PERU

[1]Delgado Pérez, Doris; [2]Liria Domínguez, María Reyna.

[1]PhD. Nutritionist. Centro de Investigación en Bioquímica y Nutrición. Universidad Nacional Mayor de San Marcos. Peru; [2]PhD. Nutritionist. Instituto Investigación Nutricional. Peru.

Background and objectives: One of the major health problems in children is overweight and obesity. At the age of preschool, children are still being looked after by an adult. In low-income families, the biological mother is the one who takes this role, which is why it is important to analyze the mother's perceptions of healthy eating, her aspirations, and challenges. The present study aimed to comprehend the challenges faced by low-income mothers when feeding their children in a district of Lima.

Methods: Using qualitative methods, we conducted 4 focus groups and 11 in-depth interviews in Spanish with a total of 30 volunteer mothers of preschool-aged children from low-income households in Virgen de la Candelaria, district of Villa Maria del Triunfo, Lima, Peru. The method was grounded theory. We analyzed verbatim transcripts using an inductive method of open coding, and themes were established by consensus among authors, the information was summarized creating a thematic framework.

Results: Children to reach a good nutritional status. The mother's mean age was of 30 years old; 87% were from different departments of Peru; 56% had a high school education or less, and all of them lived with 20 soles a day. The following themes regarding perceptions, aspirations, and challenges emerged: the ways of preparing food for preschool children showed a positive attitude towards the preparation methods and addressed the child's behavior at mealtime. The themes that emerged on the aspirations of the mothers were in relation to health and eating well. The challenges were to get to fulfill their aspirations were one of the major concerns faced was how to get them.

Conclusions: This finding increased our understanding of the perceptions, aspirations, and challenges faced by the mothers of preschoolers, and can help to inform more cultural aspects for effective nutrition interventions.

Keywords: Preschool, perceptions, aspirations, challenges, feeding.

Background and objectives: Food and nutrition literacy may be the underlying factor that protects nutritional quality during transitions. This study evaluates the association between Food and Nutrition Literacy (FNLIT) and dietary intake of elementary school children in Iran.

Methods: This cross-sectional study was undertaken on 803 students (419 boys and 384 girls) aged 10–12 years from 44 elementary schools in Tehran city, Iran. Demographic characteristics, socio-economic status, as well as three 24-hour dietary recalls (two week-days and one weekend) were collected through interviewing the students and their mothers and/or other caregivers. Food and nutrition literacy was measured by a locally designed and validated questionnaire consisted of 46 items in 7 subscales. Food group consumption was compared with recommendations. Dietary diversity score (DDS) was calculated as part of the pyramid serving database that was categorized into 23 broad food groups.

Results: Adjusted binary regression logistic showed that students with low food and nutrition knowledge were less likely to meet recommended portion of vegetable (OR=2.83, 95% CI=1.12-7.17) and meat (OR=2.37, 95% CI=1.01-5.55) groups. Those with low functional food nutrition literacy were less likely to meet recommended daily intake of fruits (OR=2.42, 95% CI=1.38-4.25). Mean diet diversity score (DDS) was significantly higher in children with high functional food and nutrition literacy and food label literacy (p=0.001 and p=0.04 respectively).

Conclusions: The findings suggest that improving food and nutrition literacy in children can serve as an appropriate mean to facilitate healthy dietary patterns of children.

Keywords: Food and nutrition literacy, elementary school children, dietary Intake, Iran

PREDICTORS OF POOR NUTRITIONAL STATUS AMONG CHILDREN AGED 6–24 MONTHS IN AGRICULTURAL REGIONS OF MALI

[1]Makamto Sobgui, Caroline; [2]Makamto Sobgui, Caroline; [3]Kamedjie Fezeu, Leopold; [4]Diawara, Fatou; [5]Diarra, Honafing; [5]Afari-Sefa, Victor.

[1]Public Health Nutrition Specialist. World Vegetable Centre. Bamako. Mali; [2]World Vegetable Center. West and Central Africa. PO Box 320. Bamako. Mali; [3]Université Paris 13 UFR de Sante médecine et biologie humaine. 74 rue marcel Cachin 93000 Bobigny. France; [4]Agence National de Sécurité Alimentaire. Bamako. Mali.; [5]World Vegetable Center. West and Central Africa. PO Box 320. Bamako. Mali.

Background and objectives: Inadequate nutrition during the first two years of life has tremendous consequences on the health and growth of children. Understanding the magnitude and determinants of nutritional status can help to avert this problem. This study aimed to assess the prevalence and potential causes of undernutrition in children aged 6 - 24 months in poor rural regions of Mali.

Methods: A community based cross-sectional study was conducted in villages in Sikasso and Mopti regions from January to March 2016. A structured questionnaire was used to collect data and characteristics of 959 boys, 856 girls, and their mothers, living in 1764 households. Anthropometric measurements such as weight, height, and mid upper arm circumference (MUAC) were performed using standardized methods. Bivariate and multivariate logistic regression analyses were conducted to identify factors associated with nutritional status of the children.

Results: The prevalence of underweight, stunting and wasting was 23.9%, 28.4% and 13.9% respectively. MUAC also indicated that 16.5% of children were undernourished. Chronic malnutrition was significantly associated with the presence of diarrhea in the past two weeks (p<0.001), higher child age (p<0.001), male sex (p<0.001), households with lowest household amenity score (p<0.002) or fewest dietary diversity score (p<001). Likewise, acute malnutrition was associated with preterm birth (p<0.03), lower child age (0.001), high number of siblings (p<0.03) and living in a household with higher months of inadequate food provisioning (p<0.03). These factors should be considered for any intervention aiming to reduce undernutrition among children in this age group living in Sikasso and Mopti in Mali.

Conclusions: Future efforts should be directed at examining how families in very poor and food-insecure areas can be empowered to feed their children a more diverse diet. These interventions must increase the availability and sustainability of household food provisioning as well as take into account potential illnesses.

Keywords: Stunting, Wasting, underweight, children, Mali

Background and objectives: Food consumption is the primary route of exposure to pesticide residues in general population. Due to its strict regulation, organic farming may contribute to reduce dietary exposure to pesticides but findings based on observational data are scant. In a nested case-control study from the NutriNet-Santé study, we aimed to compare urinary pesticide residues between "organic" and "conventional" consumers.

Methods: Based on self-reported organic food consumption assessed through a food frequency questionnaire, 150 low and 150 high organic food consumers were selected with <10% or >50% of organic food in the diet respectively (expressed as the propor-

tion of organic food in the whole diet in g/d). Participants were matched using the propensity score method including sociodemographic, food intakes and health characteristics.

Urinary pesticide residues and metabolites (organophosphorus, pyrethroid and azole compounds) were assessed. The molar sum of diethyl (total DEPs), dimethyl (total DMPs) and total dialkylphosphates (total DAPs) were computed. Differences in distributions across groups were tested using Wilcoxon signed-rank test for matched data. Median concentrations (MD), expressed in µg/g creatinine, were provided.

Results: Mean age was 58.5y and 70% of participants were women. Significantly lower (p <0.05) urinary levels of DETP (MD: 0.196 versus 0.297), DMTP (MD: 0.620 versus 1.382), total DAPs (0.12 versus 0.16) and free 3-PBA (0.017 versus 0.021) were observed among organic consumers compared to conventional consumers.

Conclusions: Our findings suggest that dietary pesticide exposure in adults may be lowered by switching from conventional foods to organic foods. This is particularly of high interest among consumers of conventional fruits and vegetables, as their exposition may be the highest.

NUTRITIONAL STATUS AT BIRTH AND BLOOD PRESSURE IN CHILEAN YOUNG ADULTS: TWO COHORTS, 15 YEARS APART

[1]*Bustos, Patricia;* [2]*Amigo, Hugo;* [3]*Vasquez, Ximena.*

[1]MD. Nutrition Department. Faculty of Medicine. University of Chile. Chile; [2]PhD. Nutrition Department. Faculty of Medicine. University of Chile. Chile; [3]MSc.MD. Nutrition Department. Faculty of Medicine. University of Chile. Chile.

Background and objectives: Hypertension is one of the main determinants of cardiovascular disease, so is important to identify risk factors of this condition. Birth weight (BW) has been mentioned as one of these factors especially in developed countries. The objective of this study was to assess the association between BW and blood pressure in a follow up of two cohorts in young adults from Valparaiso Region of Chile.

Methods: Two retrospective random samples born between 1974-1978 (cohort 1, n=999) and between 1988-1992 (cohort 2, n= 741), were assessed in 2000-2002 and 2014-2016, a t 24-28 years. BW was obtained from newborn records while blood pres-

sure was ascertained concurrently. Multiple linear regressions were built, adjusted by sex and BMI.

Results: In the cohort 1 the mean of BW was 3.17 Kg (±504), BMI was 25.8 (± 4.45), Systolic blood pressure (SBP) was 114.6 (±13.5) and DBP: 72.4 (±8.79). In cohort 2, BW was 3.33 (±488), BMI: 27.4 (±5.6), SBP 119.7 (±14.1) and DBP 72.5 (±9.8). There were significant differences in these means (cohort 2 versus 1) except in DBP.

In the cohort 1, for each Kg of BW increase, SBP decrease in 2.42 (95% CI=-3.74 to -1.10, p< 0.0001). In cohort 2, this figure was β -0.22 (95%=-2.18 to 1.72 p=0.82). For each Kg of BW increase, DBP decrease in -1.29 (95% CI= -2.26 to -0.33, p< 0.009) in the cohort 1 and β -0.49 (95% CI= -1.95 to 0.95, p=0.51) in cohort 2. These results are similar using BMI at birth instead of BW.

Conclusions: In the first cohort, born in the 1970's , an inverse association between BW and SBP and DBP were found. Fifteen years later, when low birth weight was lower and obesity is public health problem, we couldn't verify these associations. The possible explanation for these results are that better conditions at birth may reflect that there are no major fetal injury that have repercussions in adult life and that the risk of chronic diseases are determined later in life.

EVALUATION OF THE INTENTION OF CONSUMPTION OF FRUITS, AND VEGETABLES OF THE EMPLOYEES OF AN EVENT SPACE IN THE CITY OF SÃO PAULO

[1]Toscano Ferreira, Rosana; [1]Korukian Freiberg, Clara; [2]Araujo de Assis Rocha, Amanda.

[1]MSc. Nutritionist. Nutrition of Department. São Camilo University Center. São Paulo. Brazil.; [2]Nutritionist. Nutrition of Department. São Camilo University Center. São Paulo. Brazil.

Background and objectives: Fruits and vegetables are essential components of a healthy diet. They have low energetic density, high fiber content, antioxidant components, besides being sources of micronutrients. The World Health Organization advocates consumption of at least 400 g / day. Studies indicate that fruit and vegetable consumption (FLV) is below recommended levels and is among the top ten factors in determining the global burden of disease in the last decade. The main objetive of this study was to evaluate the intention of FLV consumption of employees of a space of events.

Methods: This is a cross-sectional, non-directional, quantitative, descriptive and analytical study. We collected quantities of servings served by the employees, in four days of October / 2014 characterizing the consumption intention. It was stipulated as adequate consumption when the total amount of FLV / day was great-

er than or equal to 120 g. An average of sixty clients was evaluated, totaling an analysis of 240 meals.

Results: In the menu we observed the incidence of two types of salads daily, besides the presence of fruit in 75% of the days. The presence of tubers (mandioquinha and potato ball) was observed as salads in 50% of the days. 20.4% of the meals did not have any type of salad and the prevalence occurred in the male gender. In 41.8% of the meals people used only one of the salads. In relation to the intention of consumption of the two types of salads was observed 38.3%. Meals that had a salad and fruit, or two salads and fruit were around 14% each. In 4.4% of the meals no type of salad was chosen, only fruit. In 54.6% the fruit was not chosen. Meals without salad and without fruit totaled 12.2%. The quantities of FLV considering the presence or absence of tubers showed that the percentage of adequate consumption decreased from 44.6% to 34.2%. Thus, the proportion of underweight increased from 55.4% to 65.8%.

Conclusions: According to the literature, FLV consumption was low. The female gender had greater consumption than the male. The presentation of the meals, when attractive, can generate increase of the consumption.

Keywords: FLV consumption. Eating habits. Food behavior. Collective feeding.

INFLUENCE OF INCOME ON THE HOUSEHOLD AVAILABILITY OF FRUITS AND VEGETABLES IN BRAZIL

[1]Vieira Cunha Lima, Severina Carla; [2]de Oliveira Silva, David Franciole; [2]Araújo da Silva, Ana Paula; [3]Lima Torres, Neidjany Patricia; [2]de Lima Motta, Virginia Williane; [2]Bastos Pimentel, Jessica; [4]Oliveira Souza, Thatyane; [4]de Sales Souza, Angélica Luiza; [5]Maurício de Sena Evangelista, Karine Cavalcanti; [5]de Oliveira Lyra, Clélia.

[1]PhD Nutritionist. Professor. Nutrition Department. Federal University of Rio Grande Norte; [2]BSc. Post-Graduation Program of Nutrition. Federal University of Rio Grande do Norte. Natal. Brazil.; [3]BSc. Post-Graduation Program of Health Science. Federal University of Rio Grande do Norte. Natal. Brazil.; [4]BSc. Nutritionist. Natal. Brazil; [5]PhD. Professor. Nutrition Department. Federal University of Rio Grande do Norte. Natal. Brazil.

Background and objectives: The household availability of food is influenced by several factors, such as eating habits, beliefs and income. Investigating the influence of income on the purchase of fruits and vegetables can contribute to the identification of the household availability of these foods according to income classes and provide subsidies for a better targeting of public policies aimed at encouraging the purchase and consumption of fruits and vegetables. The objective of this study is to evaluate the association between household monetary availability (HMA) per capita of fruits and vegetables (FV) and the classes of monthly family income (MFI) in Brazil, in the years of 1987, 1995, 2002 and 2008.

Methods: Were used the microdata from Household Budget Survey (HBS) carried out in the years 1987-1988, 1995-1996, 2002-2003 and 2008-2009, conducted by the Brazilian Institute of Geography and Statistics. The data of the HMA per capita of each food were obtained through the Collective Acquisition Booklet (POF), registered daily, during the period of seven consecutive days. The MFI was evaluated using the Work and Individual Income Questionnaire and classified in MFI classes, according to the minimum wage amount.

Results: The annual HMA per capita of FV, considering all income classes, in the years 1987, 1995, 2002 and 2008 was 93.5, 74.8, 56.8 and 61.4 Kg, respectively. When the income classes are analyzed separately, an increase in annual HMA per capita of FV was verified in all classes of income analyzed, so that from the lowest (<2 minimum wages) to the highest (> 30 minimum wages) the difference was greater than 100 kg in 1987 (50,2 Kg [137,6 g/day] x 162,4 Kg [444,9 g/day] and 2008 (37.7 kg [103.3 g/day] X 146.1 kg [400.3 g / day]).

Conclusions: Income can influence the household availability of FV in Brazil, so that families with higher purchasing power acquire approximately three times more than those with lower purchasing power.

Keywords: Household availability, Income, Fruits, Vegetables, Brazil.

GLOBAL NUTRITION IN THE MDG ERA (1990-2015): A SHRINKING HUNGRY, AND EXPANDING FAT WORLD (REVISED 144/298)

[1]Berry, Elliot; [2]Peng, Wen.

[1]MD. FRCP. Braun School of Public Health. Hebrew University-Hadassah. Jerusalem. Israel.; [2]MD. MPH. School of Medicine. Qinghai University. China. Research Center. The Amity Foundation. China.

Background and objectives: Following its publication in 2008, the global nutritional index (GNI) has been updated for the Millennium Development Goal (MDG) years (1990-2015), to show world trends in malnutrition, as it alone penalizes a country for over-nutrition.

Methods: We have re-calculated the GNI according to the methodology of the human development index, using geometric means, based on three indicators of nutritional status: macronutrient deficiency (DALY rates due to protein-energy malnutrition (PEM)), micronutrient deficiency (MID, DALY rates due to iron, vitamin A and iodine deficiency) and excess (prevalence of female obesity). The GNI (range 0-1) was calculated for 186 countries classified into seven groups according to the World Bank and WHO.

Results: The collective world GNI increased progressively from 0.433 for 1990 to 0.473 for 2015. Although high-income countries (n=52) remained the leading country group, their GNI worsened significantly from 0.657 (0.551-0.723) to 0.611 (0.536-0.675) (P<0.001). African low- and middle-income countries (LMIC)

(n=45) improved significantly from 0.301 (0.258-0.378) to 0.392 (0.372-0.417), (P<0.001) yet remained the lowest ranking group. South-East Asian LMIC (n=11) also improved significantly from 0.456 (0.408-0.522) to 0.564 (0.515-0.598), (P<0.001). The GNI for American LMIC (n=26) and European LMIC (n=20) increased from 1990-2005, but then dropped over the next ten years (both P<0.05). American LMIC, 0.459 (0.419-0.479) to 0.469 (0.444-0.490) to 0.457 (0.432-0.485); European LMIC, 0.571 (0.517-0.602) to 0.582 (0.526-0.606) to 0.575 (0.523-0.608) – values for 1990, 2005 and 2015, respectively, – showing no overall improvement. Eastern Mediterranean LMIC (n=16) 0.484 (0.414-0.525) to 0.483 (0.386-0.498) and Western Pacific LMIC (n=16) 0.433 (0.356-0.538) to 0.494 (0.262-0.604) remained stable across the MDG timespan (P>0.500). In nearly all 7 country groups, there was a decrease in PEM and MID (in high-income countries only PEM decreased), together with increased obesity. The different GNI trends among country groups were caused by the dynamic changes in these two opposing factors—decreased deficits and increased excess.

Conclusions: From 1990 to 2015, under-nutrition decreased, whereas over-nutrition increased steadily to become a major cause of malnutrition worldwide. The next Sustainable Development Goals should include alongside zero hunger – reduce obesity.

Keywords: global nutrition index, obesity, protein-energy malnutrition, micronutrient deficiency, Millennium Development Goal time trend (1990-2015)

CHANGES IN COMPLEMENTARY FEEDING PRACTICES RESULTING FROM A COMMUNITY-BASED BEHAVIOR CHANGE COMMUNICATION PROGRAM IN VIETNAM: A REPEATED CROSS-SECTIONAL STUDY

[1]Takanashi, Kumiko; [2]Phi, Quyen; [3]Dao To, Quyen; [4]Nguyen, Lan; [5]Le Danh, Tuyen.

[1]Registered Dietitian. PhD. International Life Sciences Institute Japan Center for Health Promotion. Japan.; [2]MSc. Scientific Research Management Section. National Institute of Nutrition. Vietnam.; [3]Pharmacist. MSc. International Life Sciences Institute Japan Center for Health Promotion. Japan.; [4]MD. PhD. Scientific Research Management Section. National Institute of Nutrition. Vietnam.; [5]MD, PhD. National Institute of Nutrition. Vietnam.

Background and objectives: Nutritionally balanced and safe complementary food greatly contributes to children's growth in the first two years of life. Community-based behavior change communication (BCC) programs are an effective strategy to improve complementary feeding practices, but little is known about the effects of BCC programs on entire communities. This study aimed to examine the changes of mothers' complementary feeding practices and hand hygiene practices before and after the implementation of a community-based BCC program.

Methods: This is a repeated cross-sectional study which involved 329 mother and child (6-23 months) - pairs in the 2015

July survey and 375 pairs in the 2016 September survey. The study took place in 10 communes across two provinces in Vietnam. The measurements were based on Infant and Young Child Feeding (IYCF) indicators, handwashing with soap at critical times, five keys to safer food, and exposure to BCC program. The changes between two surveys were examined using bivariate analysis.

Results: Most of the socio-demographic characteristics of the participants were similar between the two surveys except income level (higher income category: 36.0% vs 48.5%, P=0.001) and the mean age of children (13.1 months vs 14.6 months, P<0.001). The prevalence of stunting among children decreased from 20.1% in 2015 to 5.3% in 2016 (P<0.001). The percentage of children meeting minimum dietary diversity increased from 66.3% in 2015 to 86.3% in 2016 (P<0.001) and the percentage of children meeting minimum acceptable diet increased from 49.5% in 2015 to 70.0% in 2016 (P<0.001), but no significant changes were observed in the percentages of children meeting minimum meal frequency. The percentage of mothers who washed their hand with soap after using the toilet also increased from 44.4% in 2015 to 77.6% in 2016 (P<0.001). More participants were exposed to the BCC program in 2016 (98.7%) than in 2015 (77.9%, p<0.001).

Conclusions: This study demonstrates that a BCC program targeting entire communities may positively affect the percentages of children who meet minimum dietary diversity and minimum acceptable diet as well as the percentage of mothers practicing appropriate hand hygiene.

Keywords: Stunting, Complementary feeding, IYCF indicators, Behavior change communication, Vietnam

HOW CRITICAL WATER SECURITY IS TO ENSURE AN OPTIMAL NUTRITION AND GROWTH AMONG CHILDREN: RESULTS OF A CROSS-SECTIONAL STUDY CONDUCTED IN THE WEST REGION OF CAMEROON

[1] *Dharod, Jigna;* [2] *Nounkeu, Carole Debora.*

[1]University of North Carolina-Greensboro. USA; [2]MS Student. Department of Nutrition. University of North Carolina-Greensboro. USA.

Background and objectives: Food security or consistent access to adequate and nutritious food is a significant and direct predictor of growth and development among children. However, very little is known about the role water security plays in predicting food security through its third and ultimate pillar of food utilization. The three main objectives of the study were to: 1) assess the prevalence and severity of water security; 2) examine the relationship between water and food security; 3) estimate the association between water security and growth among children through food utilization pathway, among the rural households in the West region of Cameroon

Methods: Based on the sample size estimation, 134 caretakers and children dyads were recruited in Bafou-- a village in the Menoua division- Cameroon (December 2016 – April 2017).

Female caretakers were selected for the interview, if they were: non-pregnant; > 18 years old; main meal preparer of the household; and, primary caretaker of children in the household. The participants were interviewed in French, English, or the local dialect (Yemba) to collect information on socio-demographics, food, water security and other water access and storage related practices. At the end of interview, one of the children in the household between 2 and 5 years was selected as an index child for anthropometric measurements of height and weight.

Results: Preliminary results indicate that the water insecurity is high in the study area due to poor quality and limited physical access to water. High water insecurity is associated with: a long distance of walking for water acquisition, paying money to get water, and rationing water use to last its storage for several days. The bivariate analysis indicated that poor water access is associated with limited dietary variety at the household level and underweight among children.

Conclusions: In conclusion, improvement in water security is critical in ensuring sustainable and long-term improvement in food security and optimal development for children.

Keywords: Water insecurity, food insecurity, growth, food utilization

THE RELATION BETWEEN JAMU (TRADITIONAL HERBS) CONSUMPTION AND FOOD RESTRICTION (TABOO) AGAINST HEMOGLOBIN LEVEL OF PRECONCEPTION WOMAN IN BANGGAI REGENCY, CENTRAL SULAWESI PROVINCE

Indonesia.

Background and objectives: Nutritional status during preconception period is an important determinant of pregnancy outcome. Cultural norms, taboo, and beliefs lie within the contextual

factors that could potentially affect nutritional status and health in preconception women

Methods: This study aims to identify relation between Jamu consumption (traditional herbs) and food restriction (taboo) against hemoglobin (Hb) value in preconception women in Banggai Regency in the year 2016-2017. This study used cross sectional design with saturated sampling technique. The population in this study were 53 preconceptional women that meet the inclusion and exclusion criteria to judge the several factors that affect the value of Hb. Bivariate analysis using unpaired t test.

Results: The result show that stated hemoglobin levels average is 12.76 g / dL and the mean value 13.0 g / dL with the lowest hemoglobin value of 7.3 g / dL and hemoglobin highest value 15.9 g / dL. The test results of bivariate showed no significant difference in mean hemoglobin values among women whose consume herbs and women who did not (p = 0.751), there was no significant difference in mean hemoglobin values between groups of women with certain food restriction (taboo) and those who do not have restriction on certain foods (p = 0.231), there are no significant differences in mean hemoglobin values among women who do not consume herbs and those who consume herbs (p = 0753)

Conclusions: It is important to be aware of the pharmacological content of the medication particularly when it is systemically administered. Food taboos influence the amount, frequency and quality of nutrients as contributing factor against hemoglobin level and nutritional status of women before pregnancy. Hence, we need integrated and comprehensive approaches, with interventions to improve the overall health of the preconception women in this specific cultural context.

GROWTH CHANGES FROM INFANCY TO CHILDHOOD AND GLUCOSE TOLERANCE IN LATE ADOLESCENCE: EVIDENCE FROM HONG KONG'S "CHILDREN OF 1997" BIRTH COHORT

[1]Cheng, Tuck Seng; [2]Leung, Gabriel M.; [3]Schooling, C. Mary.

[1]BSc. MPhil student. School of Public Health. Li Ka Shing Faculty of Medicine. The University of Hong Kong. Hong Kong SAR. People's Republic of China.; [2]MD. School of Public Health. Li Ka Shing Faculty of Medicine. The University of Hong Kong. Hong Kong SAR. People's Republic of China.; [3]PhD. School of Public Health. Li Ka Shing Faculty of Medicine. The University of Hong Kong. Hong Kong SAR. People's Republic of China.

Background and objectives: Previous studies on the association of growth with glucose metabolism have yielded inconsistent findings. Also, the role of growth at different phases remain unclear. We investigated the associations of growth changes from infancy to childhood with glucose tolerance in late adolescence.

Methods: Singletons born in Hong Kong from April to May 1997 were recruited into a prospective population-based "Children of 1997" birth cohort (n=3276). Growth changes (weight-for-age z score (WAZ), length/height-for-age z score (LAZ) and body-mass-index-for-age z score (BAZ) based on the WHO growth charts) at different time intervals from infancy to late childhood were estimated using a spline model. Fasting plasma glucose (FPG) and glycated hemoglobin (HbA1C) concentrations at 16 to 18 years old were measured. Impaired glucose tolerance (IGT) was defined as FPG≥5.7 mmol/L or HbA1C≥5.6%. The multivariable linear and logistic regression models were adjusted for maternal characteristics (passive and active smoking status, migrant status, education, age, parity), infant characteristics (breastfeeding status, gestational age, WAZ at birth or LAZ or BAZ at 3 months), family history of diabetes and household income, while the second models were additionally adjusted for previous growth.

Results: Higher LAZ gain from 3 to 36 months (β=0.016mmol/L,95% confidence interval (CI)=0.001,0.030), WAZ gain from 36 to 108 months (β=0.032mmol/L,95% CI=0.019,0.044), LAZ (β=0.028mmol/L,95% CI=0.007,0.048) and BAZ (β=0.024mmol/L,95% CI=0.007,0.041) gains from 132 to 180 months were associated with higher FPG, while higher BAZ gain from 108 to 132 months was associated with lower HbA1C (β=-0.017mmol/L,95% CI=-0.017,0.000) and odds ratio (OR) of IGT (OR=0.68, 95% CI=0.54,0.86). The positive associations of BAZ from 36 to 108 months with FPG (β=0.013mmol/L,95% CI=0.002,0.025), WAZ gain from 36 to 108 months with HbA1C (β=0.009mmol/L,95% CI=0.000,0.019) and WAZ (OR=1.13,95% CI=1.00,1.27) and BAZ (OR=1.14,95% CI=1.03,1.25) gains from 36 to 108 months with IGT and the negative association of LAZ gain from 108 to 132 months with IGT (OR=0.73,95% CI=0.54,0.98) were more evident after additional adjustment for previous growth.

Conclusions: Our study demonstrated that there may be independent associations of growth across life stages with glucose metabolism. Further studies are warranted to improve understandings on the underlying mechanisms at different growth phases.

DIETARY CHANGES NEEDED TO IMPROVE DIET SUSTAINABILITY: ARE THEY SIMILAR ACROSS EUROPE?

[1]Vieux, Florent; [2]Perignon, Marlène; [3]Gazan, Rozenn; [2]Darmon, Nicole.

[1]PhD. MS-Nutrition. France; [2]PhD. Unité Mixte de Recherche 1110 Markets, Organizations, Institutions and Stakeholders Strategies (UMR MOISA). INRA, CIRAD CIHEAM and Montpellier SupAgro. France.; [3]MSc. MS-Nutrition. France.

Background and objectives: It is not known whether the dietary changes needed to achieve nutritional adequacy while reducing diet-related greenhouse gas emissions (GHGE) are similar across Europe when cultural and gender specificities are taken into account.

Methods: Starting from each mean observed diet in five European countries (France, UK, Italy, Finland and Sweden) and for each gender, nutritionally-adequate diets departing the least from observed diet were designed with linear programming by applying stepwise 10% GHGE reductions. Other models directly minimized GHGE.

Results: For most countries and whatever the gender, achieving nutritional adequacy implied substituting sugared and fatty products by fruit, vegetables and starchy foods, but increased GHGE. Within-food-groups substitutions were reinforced when imposing a stepwise GHGE reductions while meeting nutritional adequacy. Changes in consumption of animal-based products occurred but differed according to country and gender, particularly for fish, poultry and non-liquid milk dairy. The maximal GHGE reductions achievable ranged from 62% to 78% but they induced large departures from observed diets (at least 2.8 kg/day) by modifying the quantity of at least 99% of food items.

Conclusions: Setting nutritional goals with no consideration for the environment may increase GHGE. However, diet sustainability can be improved by substituting sugared and fatty food products by fruit, vegetables and starches, which involves country-specific changes in consumption of animal-based products. Standardized surveys and individual diet modeling are promising tools for further exploring ways to achieve sustainable diets in Europe.

Keywords: Sustainability. Diet modelling. Europe. Greenhouse gas emissions. Nutrition.

Federal University of Rio Grande do Norte. Natal. Brazil.; [4]BSc. Registered Dietitian Nutritionist. Public Health Graduate Program. Federal University of Rio Grande do Norte. Natal. Brazil.; [5]BSc. University Center of Rio Grande do Norte. Natal. Brazil.; [6]PhD. Dentist. Professor. Departament of Dentistry. Public Health Graduate Program. Federal University of Rio Grande do Norte. Natal. Brazil.; [7]PhD. Registered Dietitian Nutrition. Professor. Departament of Nutrition. Nutrition Graduate Program. Public Health Graduate Program. Federal University of Rio Grande do Norte. Natal. Brazil.

Background and objectives: The National Health Research (PNS, in Portuguese) conducted in Brazil in 2013, identified that 6. 2% of the adult population (9 million people) had diabetes. Eating habits and life style may be related to this prevalence. Therefore, this study aimed to analyze the spatial correlation between diabetes and food intake in the Brazil adult population in 2013.

Methods: Ecologic study of spatial analysis, using data from the PNS, by the Brazilian Institute of Geography and Statistics, representing the 27 federative units (UF) of Brazil, in 2013. The dependent variable was diabetes prevalence in adults. The independent variables were the regular intake of vegetables, fruits and fruit juice (minimum of 5 servings/day); Soft drinks (> 5 days/week); Sweets (> 5 days/week); Replacement of meals by sandwiches, savory pastries or pizzas (> 5 days/week). Spatial analysis was conducted to verify the univariate and bivariate spatial correlations using the GeoDa software, through which thematic maps were built and the Local Moran's I (LMI) was calculated. This index presents results exclusively for significant spatial statistic correlations.

Results: It was found a significant and positive spatial correlation ($p < 0.05$) between diabetes prevalence and the consumption of sweets (LMI = 0.5878); soft drinks (LMI = 0.2056); vegetables, fruits and fruit juice (LMI = 0.1082); and, replacement of meals (LMI = 0.4561). High/High Clusters were identified between diabetes prevalence and all the independent variables in the Southeast, South and Midwest states. Low/Low Clusters between diabetes and consumption of sweets in states of the North, and for vegetables, fruits and fruit juice in states of the Northeast. These findings suggest spatial coexistence of a higher diabetes prevalence in UF where the adult populations have a higher intake of ultra-processed foods, such as in South Central Brazil.

Conclusions: The results demonstrate that the ingestion of ultra-processed foods and diabetes prevalence are correlated and are different in Brazil's territory. The habitants of different UF have different eating habits that favors diabetes prevalence, possibly related to the development of those places. Health actions and the prevention of this NCD , considering eating habits and nutrition, should be strengthened in Brazil.

Keywords: Spatial analysis; Chronic Disease; Noncommunicable diseases; Food habits; Food consumption.

WHICH DIETARY CHANGES TO MOVE TOWARDS NUTRITIONALLY ADEQUATE DIETS WITHOUT INCREASING THEIR IMPACT ON BIODIVERSITY, WATER AND LAND-USE? THE CASE OF TUNISIA

[(1)]Perignon, Marlène; [(2)]El Ati, Jalila; [(3)]Sinfort, Carole; [(4)]Drogue, Sophie; [(1)]Darmon, Nicole; [(1)]Amiot-Carlin, Marie Josephe; [(5)]Group, MEDINA-Study.

Unité Mixte de Recherche 1110 Markets, Organizations, Institutions and Stakeholders Strategies (UMR MOISA). INRA, CIRAD CIHEAM and Montpellier SupAgro. France.; [(5)]INRA.

Background and objectives: As several Mediterranean countries, Tunisia has experienced an epidemiological and nutritional transition resulting in an increase in overweight, obesity and co-morbidities. In the last decades, food consumption departed from traditional diets towards higher consumption of animal-based and sweet products. Tunisia also faces environmental issues such as water scarcity, soil erosion and biodiversity loss. This growing concern for health issues and climate change has emphasized the need to promote sustainable diets, i.e. nutritionally adequate, affordable, culturally acceptable, and with low environmental impact. The objective was to identify dietary changes needed to move towards nutritionally adequate diets without increasing their environmental impact.

Methods: Nutrient intakes were estimated using dietary data from the nationally representative Tunisian study on food consumption (n=7209, 35-70y), and food composition from a Tunisian database and the Food Processor software. Environmental impact of diets was assessed through 6 indicators - water scarcity, biodiversity, and 4 indicators for land-use (erosion resistance, mechanical filtration, groundwater replenishment, biotic production) – estimated for 161 foods. For each gender, two optimized diets respecting all nutritional recommendations from WHO and with minimized departure from the mean observed diet were designed with linear programming under 2 scenarios to fulfill: i) all nutritional constraints (NUTRI) and ii) all nutritional constraints without exceeding observed levels for the 6 environmental indicators (NUTRIENV).

Results: Calcium, copper, iron (for women), magnesium and potassium intakes were below their recommendations in the mean observed diets, while sodium and fats exceeded them. Under the NUTRI scenario, i.e. reaching nutritional adequacy without controlling for the environmental impacts, the main dietary changes were the increases of vegetables, starchy foods, fish and dairy products, and decreases of fats and sweet products. All the environmental indicators were impaired, except erosion resistance and biotic production. Under the NUTRIENV scenario, i.e. when environmental indicators were limited to their observed levels, changes in dairy and starchy products quantities were lower than in the NUTRI scenario. In addition, fruits increased and meat decreased.

Conclusions: Environmental impacts should be assessed when identifying food consumption changes to reach nutritional adequacy. Dietary changes identified to move towards more sustainable diets in Tunisia will be translated into action proposals.

ANALYSIS OF THE USAGE AND CHARACTERISTICS OF DIETARY SUPPLEMENT CONSUMERS OF URBAN COSTA RICAN POPULATION

[(1)]Guerrero Calderon, Fabiola; [(2)]Pacheco Arteaga, Maria Amalia; [(3)]Gómez Salas, Georgina.

[(1)]Bch. Nutritionist. School of Nutrition. University of Costa Rica. Costa Rica; [(2)]Bch. Nutritionist. School of Nutrition. University of Costa Rica. Costa Rica; [(3)]MSc. Nutritionist. Department of Biochemistry. School of Medicine. University of Costa Rica. Costa Rica.

Background and objectives: Previous studies reveal that dietary supplement (DS) consumption has increased in the Western world in all ages groups and is influenced by gender, age, educational level, socioeconomic status and other factors. In Costa Rica there is no information regarding DS use in the general population. The present study was focused on assessing the prevalence of use and determining the socio-demographic, anthropometric and nutritional characteristics of urban Costa Rican DS consumers, and to explore the reasons for their consumption.

Methods: Data were obtained from Latin American Nutrition and Health Study (ELANS), is a cross-sectional study including a representative sample of urban population from eight LA countries (Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela). In Costa Rica 798 participants were asked about DS use, and six months after the first contact a second questionnaire was applied by telephone to subjects who had previously reported DS use, in order to delve on the characteristics and perceptions involved in DS consumption. Chi-square test was used to compare observed and expected frequencies

Results: Approximately 6% (n=48) of the population surveyed reported the use of DS, mainly in the form of multivitamins. No significant differences for sex, age, socioeconomic status (SES), educational level and body mass index (BMI) were found for DS intake. DS consumers reflected significantly higher intakes of dietary calcium in both sexes, and dietary vitamins C and vitamin E in women, compared to nonusers. Reasons for consumption of DS focused on health benefits, prevention of illness, improved immunity, and energy boost. Although perceived as beneficial for 58% of the cases, the use was discontinued after six months.

Conclusions: The prevalence of DS usage was lower than reported by other studies in the field. A pattern similar to that described in the literature (BMI <25 kg/m2, physically active, healthy lifestyles and favorable socio-demographic backgrounds) was not found in this study.

Keywords: dietary supplements; consumers; perceptions, Costa Rica

SELF-REPORTED ADVERSE EVENTS DURING LONG-TERM VITAMIN D SUPPLEMENTATION: DATA FROM A RANDOMIZED CONTROLLED TRIAL (VITAMIN D ASSESSMENT STUDY)

[1]Malihi, Zarintaj; [2]Lawes, Carlene M.M; [3]Waayer, Debbie; [4]Toop, Les; [5]Khaw, Kay-Tee; [6]Camargo Jr., Carlos A.; [7]Scragg, Robert.

[1]Msc. PhD student. Department of Epidemiology and Biostatistics. School of Population Health. Faculty of Medical and Health Sciences. University of Auckland. New Zealand; [2]MBChB. PhD.School of Population Health.The University of Auckland. Auckland. New Zealand; [3]MEd. School of Population Health.The University of Auckland. Auckland. New Zealand; [4]MBChB. MD.Department of Public Health & General Practice. The University of Otago. Christchurch. New Zealand; [5]MBBChir. MSc.Department of Public Health. University of Cambridge. Cambridge. England; [6]MD.DrPH. Department of Emergency Medicine. Massachusetts General Hospital. Harvard Medical School. Boston. USA; [7]MBBS.PhD. School of Population Health. The University of Auckland. Auckland. New Zealand.

Background and objectives: Many randomized controlled trials (RCTs) are examining the health effects of long-term vitamin D supplementation. To date, there are limited data on long-term adverse events (AEs); recently published RCTs briefly reported on AEs, without undertaking a detailed assessment. Many earlier studies of vitamin D supplementation had small sample sizes and/ or short follow-up periods.The main purpose of this study was to assess self-reported non-serious AEs during long-term monthly 100,000 IU vitamin D3 supplementation in 2558 participants in the vitamin D arm, compared to 2550 participants in the placebo arm.

Methods: We analysed data from the vitamin D assessment study (ViDA) trial's monthly-to-4monthly questionnaire over four years of follow-up to assess the incidence rate of the first reported AE, and first event in each category of the AE, including pain, respiratory illnesses and infection, gastrointestinal problems, tiredness, dizziness, skin-related symptoms and complications related to other health conditions. SAS package 9.4 was used for data analysis.

Results: There was no significant difference between the treatment arms for the first reported AE. 358 (14.0%) participants from vitamin D arm versus 337 (13.2%) participants from the placebo arm said they had AEs after taking the assigned capsule. Including repeated events by the same individuals, there were a total of 1153 AEs (627 and 526 in the vitamin D and placebo arms, respectively). However, only 559 participants (288 in the vitamin D and 271 in the placebo arm) explained the type of event. The incidence rate of any first event in participants of vitamin D arm was 5.1 versus 4.9 in the placebo arm with an attributable risk of 0.23 (P=0.56). Further regression analysis showed that being from minority ethnic groups (Māori, Pacific, South Asian; p<0.0001), a non-drinker or monthly drinker (p=0.011), or being a non- or ex-smoker (0.004) were associated with more AE reporting.

Conclusions: Monthly supplementation of 100,000 IU vitamin D3 did not increase participants' self-reported AEs in the ViDA study.

Keywords: Vitamin D3, supplementation, RCTs, adverse-events

THE IMPORTANCE OF THE EVALUATION OF COMPETENCES OF A COOK OF A FOOD AND NUTRITION UNIT OF A CANCER HOSPITAL

[1]Sandoval, Ana Paula; [2]Cardenas, Thais de Campos; [3]Araujo do Nascimento, Ivanice; [4]Toscano Ferreira, Rosana.

[1]Nutrition'Student. Nutrition of Department. São Camilo University Center. São Paulo. Brazil.; [2]MSc. Nutritionist. Nutrition of Department. Brazilian Cancer Control Institute - IBCC. São Paulo. Brazil.; [3]Nutritionist. Nutrition of Department. Brazilian Cancer Control Institute - IBCC. São Paulo. Brazil.; [4]MSc. Nutritionist. Nutrition of Department. São Camilo University Center. São Paulo. Brazil.

Background and objectives: The hospital is an organization specialized in prevention, recovery and maintenance of the health of the community. Understanding hospital activity as a business and balancing with its mission requires business management. The food service indirectly constructs and maintains the positive or negative image of the hospital, becoming the indicator of the service provided. Given this, food workers are required not only to prepare quality meals, but to develop their cognitive potential and the fundamental role of communication, participation and leadership in order to achieve the proposed objectives, increase productivity, minimize Efforts and costs. It is fundamental that the cook for the exercise of his activities present competences according to the requirements of the position. To evaluate the competences of the cook within a Food and Nutrition Unit of a cancer hospital.

Methods: This is a cross-sectional observational descriptive study with primary data collection. It was performed in March 2017 in a hospital UAN, administered by self-management located in the eastern region of the city of São Paulo. The study was carried out with a collaborator, the cook, who was responsible for the meals of the patients, and the data collection took place during three days from the observation of the daily routine by means of a check list elaborated on the basis of the literature and the internal rules of the hospital Containing 26 competencies required for that position. An unstructured interview was conducted in order to contribute to the data collection.

Results: The cook presented a 70% adequacy, being a responsible and attentive professional with the team and the patients, but was verified 30% of inadequacy, mainly in relation to the leadership, demonstrating difficulty in conducting the team in an efficient and satisfactory way.

Conclusions: The employee does not present all the competencies required for the position, mainly in relation to the leadership in relation to the team, being necessary to implement training program in order to promote the development and potentialization of its leadership spirit, contributing to personal and professional growth And therefore improvement in interpersonal relationships, with positive results for the UAN hospital and for the patients attended.

Keywords: Competencies. UAN Hospitalar. Cook.

AN EXPLORATION OF CHINESE CONSUMERS UNDERSTANDING OF EARLY AGE NUTRITION

[1]Conroy, Denise; [2]Smith, Sandy.

[1]PhD. Marketing. Consumer Behaviourist. University of Auckland Business School. New Zealand; [2]PhD. Marrketing. University of Auckland. New Zealand.

Background and objectives: China is potentially a large export market for New Zealand, particularly for milk products, yet little is understood about the Chinese consumer's understanding of nutrition. Most insight to date has been gained by taking a product focused perspective, but such research has yielded many failures and few successes for New Zealand companies trying to gain traction in the Chinese market. Consequently, this research has a different aim. It focuses on exploring the consumers' understanding, knowledge, attitudes, emotions and cognitive reactions regarding a general category, and the nutritional benefits sought from this category, rather than a specific product. Importantly, the research also includes an exploration of the environment, culture and political scape in which consumer understanding is derived and purchase decisions are made. The category for this project is supplementary infant and toddler foods. By supplementary foods we mean foods which are fed to a child either to support breast milk or instead of breast milk, weaning foods, and foods given to a child in addition to regular, shared family foods.

Methods: 14 in-home interviews were conducted in Shanghai, China. Participants were parents of infants between 2 months and 12 months of age. The interviews were conducted in Mandarin and an instantaneous translator was present to translate. 4 focus groups were also undertaken with mothers of toddlers ranging from 2 years to 5 years. A thematic analysis was undertaken utilising NVivo and a complimentary corpus analysis was also conducted.

Results: Emergent themes revealed a serious lack of basic understanding of nutrition, together with enormous trust in overseas milk powders and weaning food, and a total lack of trust in any Chinese products.

Conclusions: Policy makers in China have significant work to do to engage the trust of citizens and protect their dairy industry.

For NZ exporters insight into trust of foreign brands and the need for simple, clear labeling will be of benefit, together with insight into promotion

Keywords: Chinese consumers, early age nutrition

NORT (Nutrition Obésité et Risque Thrombotique). Aix Marseille Université. INRA. INSERM 13005. Marseille. France; [8]MSc. Environmental scientist. Solagro. Toulouse. France.

Background and objectives: Substantial climate change mitigation will not happen without a drastic reduction of greenhouse gas emissions (GHGEs). This involves important shifts in dietary patterns by a large proportion of the world's population.

The aim of this observational study was to compare and characterize diets with various levels of GHGEs from participants of the French NutriNet-Santé study.

Methods: Food consumption of 34,193 French adults included in the NutriNet-Santé cohort was assessed using an organic food frequency questionnaire. Dietary GHGEs (expressed in kg-CO_2eq/year) of participants were computed, taking into account farming practices (organic or conventional production). Adjusted means of contribution of food groups to the diet (in percentage), percentage of organic food as well as compliance with the nutritional guidelines (reflected by the modified Programme National Nutrition Santé Guidelines Score, mPNNNSGS) were compared between weighted quintiles of GHGEs, using ANCOVA models.

Results: Dietary GHGEs ranged from 677 kgCO2eq/year (Q1) to 2954 kgCO2eq/year (Q5), after adjustment for sex, age and energy intake. Contribution of meat to the diet increased along GHGEs (ranging from 2.6% (Q1) to 11.5% (Q5)) while an inverse trend was observed for fruit and vegetables. Concerning dairy products, the lowest contribution was found in the most climate-friendly diet (Q1).

After adjustment for age and sex, daily energy intake significantly increased along GHGEs (Q1: 1580 kcal/d (95%CI=1569-1592) versus Q5: 2647 kcal/d (95%CI=2633-2662), (p-trend<0.0001)). Percentage of organic food in the diet decreased along with GHGEs (from Q1: 43.4% (95%CI=42.8-44.0) to Q5: 15.4% (95%CI=14.6-16.2)), as well as the adherence to the nutritional recommendations (mPNNSGS ranged from 8.34/13.5 (95%CI=8.30-8.38) in Q1 versus 7.95/13.5 (95%CI=7.90-7.80) in Q5).

Conclusions: Based on observational data, our study provides new arguments concerning the potential of actual healthy and alternative diets, with low environmental impact. Participants with low GHGEs diets have the highest contribution of fruit and vegetables, and the lowest contribution of animal's origin products. Their diets are more organic, provide fewer calories, and their compliance with French guidelines are better.

Our results highlight the importance of promoting holistic changes in dietary patterns to meet future environmental challenges, including the mitigation of global warming.

U1153 INSERM. U1125 INRA. CNAM. Sorbonne Paris Cité. Paris 13 University. France.

Background and objectives: It is known that several modifiable lifestyle indicators, including diet quality, smoking status, alcohol consumption, weight and physical activity are independently associated with depression; however, their combined effects on depression risk is less studied. This study aimed to develop a Healthy Lifestyle Index (HLI) score composed of all of the above indicators and to investigate their association with the risk of incident depressive symptoms in a large French cohort.

Methods: The study sample consisted of 25,837 middle aged participants from the NutriNet-Santé study, initially free of depressive symptoms. The HLI was computed by assigning 1 point for each healthy behavior related to diet quality (measured by the modified French Programme National Nutrition Santé-Guideline

Score), smoking status, alcohol consumption, body mass index and physical activity. Incident cases of depressive symptoms were defined by a Center for Epidemiologic Studies Depression Scale (CES-D) score ≥17 for men and ≥23 for women at least once during the follow-up. Hazard Ratios (HR) and 95% confidence intervals (95% CI) were estimated using Cox proportional hazards models and population attributable risk (PAR) was calculated for each individual lifestyle indicator.

Results: A total of 2,112 first cases of incident depressive symptoms were identified over a mean follow-up of 6 years. In the adjusted models, compared with participants with a low score (0-2 healthy behaviors), participants with high and medium scores (4-5 and 3 healthy behaviors respectively) had a significantly lower risk of incident depressive symptoms (HR=0.75; 95% CI: 0.67-0.83) and (HR=0.84; 95% CI: 0.75-0.94) respectively, P-trend<0.0001. The estimated PAR representing the proportion of depressive symptoms cases in the population that are attributable to non-adherence to specific healthy lifestyle indicators were 8%, 5% and 5% for healthy diet, healthy weight and non-smoking respectively. The PAR was not estimated for physical activity and limited alcohol consumption because the estimated HR for these individual indicators was not statistically significant in multivariable models.

Conclusions: In this study, the combined healthy lifestyle behaviors were associated with a lower risk of incident depressive symptoms, indicating that modifying unhealthy lifestyles is of major interest in a context of prevention of depressive symptoms.

Keywords: Depressive symptoms; Lifestyle indicators; Population attributable risk

IMPACTS OF USING AN INTEGRATED HOME-STEAD FOOD PRODUCTION AND NUTRITION PROGRAM PLATFORM TO PROMOTE UTILIZATION OF MULTIPLE MICRONUTRIENT POWDERS: A CLUSTER-RANDOMIZED CONTROLLED TRIAL

[1]Becquey, Elodie; [2]Olney, Deanna; [3]Golan, Jenna; [4]Praygod, George; [5]Veryser, Stephen; [6]Smith, Erin; [7]Kitilya, Brenda; [4]Kidola, Jeremiah; [2]Ruel, Marie; [1]Rawat, Rahul.

[1]PhD. Poverty, Health and Nutrition Division. International Food Policy Research Institute. Senegal.; [2]PhD. Poverty, Health and Nutrition Division. International Food Policy Research Institute. United States.; [3]MSc, MPH. Poverty, Health and Nutrition Division. International Food Policy Research Institute. United States.; [4]MD, PhD. Clinical Research Programme. National Institute for Medical Research-Mwanza. Tanzania.; [5]MSc. Helen Keller International. Tanzania.; [6]MPH. Helen Keller International. Tanzania.; [7]MPH. Clinical Research Programme. National Institute for Medical Research-Mwanza. Tanzania.

Background and objectives: HKI's enhanced homestead food production (EHFP) model aims at improving maternal and child nutrition through food production, and nutrition, health and hygiene behavior change communication (NHH-BCC). In Tanzania, HKI also used the EHFP platform to promote utilization of multiple micronutrient powders (MNP) for young children.

We assessed the effectiveness of HKI's EHFP platform for increasing MNP knowledge and utilization and reducing anemia compared to a non-EHFP beneficiary group that received MNP at home.

Methods: We used a cluster-randomized, longitudinal design. We randomly allocated 30 wards to EHFP or the comparison group (n=~1,150 children aged 6-12 months at baseline/group), and followed-up after 3, 12, and 18-months. At baseline and 12-months, both groups received a 2-month supply of MNP at home with MNP-relevant BCC. Village-level MNP sensitization was conducted before the 12-month delivery. In addition, the EHFP group received agricultural training and inputs, NHH-BCC and monthly MNP-specific interpersonal counselling (MNP-IPC) between 12- and 18-months. We assessed program exposure and impacts on maternal knowledge of MNP benefits, MNP utilization, and child anemia. We used intent-to-treat, cluster-adjusted OLS regression and linear mixed models to identify differences between time points (p-change<0.05) and study groups (p-group<0.05).

Results: MNP-IPC was higher (by design) in the EHFP compared to the comparison group (64% versus 5%, p-group<0.001); attendance at the MNP community sensitization was also higher (64% versus 29%, p-group<0.001). Between 3- and 18-months, knowledge of MNP benefits increased more in the EHFP group (+16pp versus +6pp, p-group=0.006); however, adequate MNP preparation increased in both groups (+20-21pp/group, p-change<0.001) and daily MNP consumption remained high in both groups (+8-11pp/group, p-change>0.05), with no group-wise differences. Similarly, anemia decreased between baseline and 3-months (-9-10pp/group, p-change<0.001) and between 12- and 18-months (-8pp/group, p-change<0.02) in both groups, with no differential decline between groups.

Conclusions: Promotion of MNP through EHFP increased exposure to MNP sensitization and MNP knowledge, but not utilization or effectiveness. However, given the effectiveness of EHFP in mobilizing communities for MNP sensitization events, community intervention platforms such as these may be a more viable delivery channel for distribution and promotion of MNP and other nutrition-specific interventions than possibly more costly and logistically challenging individual approaches.

COMPARISON OF TWO PREGNANCY NUTRITIONAL EVALUATION STANDARDS IN ADOLESCENT CHILEAN PREGNANT WOMEN

[1]Villalobos Restovic, Andrea; [1]Mardones, Francisco; [2]Rosso, Pedro; [3]Farias, Marcelo; [4]Villarroel, Luis; [5]Bacallao, Jorge; [6]Rojas, Ivan.

[1]MD. MSc. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.; [2]MD. Department of Pediatrics. Pontificia Universidad Católica de Chile. Chile.; [3]MD. PhD. Department of Obstetrics and Gynecology. Pontificia Universidad Católica de Chile. Chile.; [4]PhD. Department of Public Health. Pontificia Universidad Católica de Chile. Chile.; [5]PhD. Universidad de Ciencias Médicas. Cuba.; [6]MD. Head of the Maternity Service at the Santa Maria Clinic of Santiago. Chile.

Background and objectives: There are no curves to assess nutritional status and weight gain during pregnancy for adolescent women. We aimed to compare the diagnostic ability of the so-called Rosso-Mardones (RM) and Atalah et al (AEA) curves to detect newborns at risk in pregnant adolescents.

Methods: A sample of 5554 adolescent pregnant women was selected. The mothers had their deliveries at the Sótero del Río Hospital in Santiago, Chile, between 2001 and 2004. They were nutritionally classified with both evaluation patterns at the beginning of gestation. The distribution of newborns at risk for each maternal nutritional status according to both curves was calculated for the following categories: birth weight < 3000 g, birth weight > 4250 g, and birth length < 50 cm. Sensitivity and specificity values of the RM and AEA charts were calculated to determine newborns at risk in both obese and underweight women.

Results: A higher proportion of obese and underweight women were diagnosed with the RM curve. Proportions of at risk newborns were similar for each maternal nutritional category according to both curves. However, absolute numbers for those live births were much higher in women classified by RM. This led to a greater sensitivity of the RM curve.

Conclusions: The higher RM sensitivity could support its use to improve preventive actions for pregnant women younger than 20 years of age.

Keywords: birth weight and length, body mass index, adolescent pregnancy.

THE EFFECT OF GENDER ON NUTRITION FACTS LABEL USAGE OF CERTAIN FOOD PRODUCTS

[1]Inan-Eroglu, Elif; [2]Dedebayraktar, Damla; [1]Ayaz, Aylin; [1]Buyuktuncer, Zehra.

[1]PhD. Dietitian. Hacettepe University Faculty of Health Sciences, Nutrition and Dietetics Department. Turkey; [2]MSc. Dietitian. Hacettepe University Faculty of Health Sciences, Nutrition and Dietetics Department. Turkey.

Background and objectives: Gender is an important socio-demographic factor that might determine the nutrition facts label usage. This study aimed to describe the prevalence of nutrition facts label use on certain food products by gender.

Methods: The study sample comprised of 647 (67.5%) female and 311 (32.5%) male participants. The mean age of participants was 21.5±1.86 years. In order to determine participants' nutrition facts label usage about certain food products including dairy and dairy products, meat and meat products, egg, legumes, bread, grains, pastry products, cereals, snacks, packed vegetables and fruits, cans and olives, oils, breakfast food products, sauces, salt and spices, beverages, ready to serve foods, instant soups, ready to serve desserts, frozen foods and diet products for special occasions were asked to participants by nutritionists. The responses are measured on a 3-Likert scale ranging from 1 (never) to 3 (always). The questionnaires were analysed with the statistical programme SPSS 22.

Results: While 501 (77.4%) of women participants read the nutrition facts label, 170 (54.7%) of men participants read the nutrition facts label (p<0.05). The frequency of female participants who always read the nutrition facts label of meat and meat products (71.9%), egg (72.5%), bread (70.3%), pastry products (%75.1), cereals (78.0%), snacks (77.1%), canned products and olives (75.2%), oils (73.9%), breakfast food products (75.8%), sauces (73.6%), salts and spices (76.2%), beverages (73.5%), ready to eat foods (73.7%), instant soups (74.0%), ready to eat desserts (75.9%), frozen foods (73.9%) and diet products for special occasions (77.8%) were higher than men participants (p<0.05). In the case of dairy and dairy products, legumes, grains, packed vegetables and fruits, there was no difference related to reading the nutrition facts panel among gender (p>0.05).

Conclusions: Understanding of nutrition facts label might be an important strategy for nutrition education. This study showed that men should be focused to improve their usage of nutrition facts labels by increasing their awareness about food labels.

Keywords: nutrition facts label, gender, certain food groups

IS THERE ANY RELATIONSHIP BETWEEN BODY MASS INDEX AND NUTRITION FACTS LABEL USAGE IN CERTAIN SITUATIONS?

[1]Inan, Elif; [2]Dedebayraktar, Damla; [1]Ayaz, Aylin; [1]Buyuktuncer, Zehra.

[1]PhD. Dietitian. Hacettepe University Faculty of Health Sciences, Nutrition and Dietetics Department. Turkey.; [2]MSc. Dietitian. Hacettepe University Faculty of Health Sciences, Nutrition and Dietetics Department. Turkey.

Background and objectives: Information provided on nutrition facts label could assist consumers to make healthier food choices. It is suggested that some individual factors might be related with nutrition facts label usage and understanding. In this context, this study aimed to examine how nutrition facts label usage change by body mass index (BMI) in certain situations.

Methods: The face-to-face questionnaire was administered to participants (n=958), aged 18 -34 years, in order to compare their nutrition facts label reading in situations such as buying a product for the first time, buying an unknown brand product, comparing the similar products of two different firms, wondering about the nutritional content of the product and being careful about nutrition because of the health problems. The responses are measured on a 3-Likert scale ranging from 1 (never) to 3 (always). Anthropometrical measurements including weight and height of participants were taken by nutritionists. The participants were classified into four groups according to WHO BMI classification. The questionnaires were analysed with the statistical programme SPSS 22.

Results: Mean BMI of participants was 21.98±3.20 kg/m2. It was obtained that the percentage of participants with a normal BMI who always read the nutrition facts label were higher than obese individuals in each situations. Furthermore, participants with a normal BMI read the nutrition fact label more frequently than other BMI groups in that situations: buying an unknown brand product (74.9%), comparing the similar products of two different firms (74.7%), being careful about nutrition because of the health problems (74.6%) (p<0.05). In other situations such as buying a product for the first time and wondering about the nutritional content of the product there was no difference related to reading the nutrition facts panel among BMI groups (p>0.05).

Conclusions: It is crucial to identify the situations that people gives attention to the label of the products. Furthermore, understanding of nutrition fact label in obese individuals should be improved as a part of nutrition education.

Keywords: body mass index, nutrition facts label, certain situations

ACCELERATED SHELF LIFE STUDIES: TESTING MICRONUTRIENT STABILITY OF NEW AND UPGRADED FOOD AID PRODUCTS

[1]Schlossman, Nina; [2]Johnson, Quentin; [3]Wood, Lauren; [4]Coglianese, Nicole; [5]Santoso, Vicky; [6]Koeppel, Leah.

[1]PhD. President. Global Food & Nutrition Inc. Adjunct Assistant Professor. Tufts University. United States of America.; [2]President. Quican Inc. Everton. Canada.; [3]MSc. Program & Research Coordinator. Global Food & Nutrition Inc. Washington, DC. United States of America.; [4]RD. MSc. Program & Research Coordinator. Global Food & Nutrition Inc. Washington, DC. United States of America.; [5]MSc. Program & Research Assistant. Global Food & Nutrition Inc. Washington, DC. United States of America.; [6]MSc. MPH. Program & Research Coordinator. Global Food & Nutrition Inc. Washington, DC. United States of America.

Background and objectives: Accelerated shelf life/stability studies are a critical part of product research and development and are being included as new/upgraded food aid products are introduced. Objective: determine the vitamin and mineral stability and integrity of U.S. products included in the Food Aid Quality Review (FAQR) Phase II food aid effectiveness trials. Tests were carried out on Corn-Soy Whey Blend (CSWB), Super Cereal Plus (SC Plus), Corn Soy Blend Plus (CSBP), and Ready-to-Use Supplementary Food (RUSF).

Methods: Samples were analyzed for vitamin A and mineral (iron, calcium and phosphorus) content, and organoleptic properties (appearance, odor, taste, packaging appearance). Testing followed certified methods of the Association of Official Analytical Chemists (now AOAC International). Products were stored at 40 degrees Centigrade (104 degrees Fahrenheit) and 75 percent relative humidity for 26 weeks to mimic 26 months in real time. Products were sampled/tested seven times.

Results: Vitamin A levels in all fortified blended foods (FBFs) degraded substantially during testing but remained stable in RUSF, a lipid-based product. Mineral levels varied among the FBFs, partially due to inherent micronutrient differences in product ingredients. Organoleptic characteristics: FBFs all developed a slight grainy odor over their shelf lives. Three of the four showed sparse black flecks at various points, likely due to the dark germ color and heat processing of the raw corn. RUSF odor, appearance, texture and packaging remained stable and normal.

Conclusions: Advances in micronutrients and ingredients can impact shelf life duration and organoleptic properties of FBFs through the supply chain. As innovation changes ingredients (e.g., amylase, probiotics, chemical forms), shelf life studies are crucial in verifying the stability and integrity of food aid products. Accelerated shelf life studies are industry standard for new product development and should become standard for all new or upgraded food aid products. Intrinsic micronutrient values of product ingredients, product packaging, and the product food matrix should be considered in determining product specifications, including shelf life.

Further research is needed to: 1) improve vitamin A stability in dry premixes for FBFs, 2) determine the most appropriate delivery

mechanism, 3) develop packaging materials that reduce vitamin degradation.

Keywords: food aid, product, stability, micronutrient, shelf life

ASSESSMENT OF THE FITNESS CENTERS USERS PROFILE ON THE CONSUMPTION OF NUTRITIONAL SUPPLEMENTS IN THE CITY OF ALFENAS, BRAZIL

[1]*Vasconcelos, Debora;* [2]*Aparecida Oliveira da Silva, Amanda;* [2]*Rita Paitax da Silva, Angela;* [3]*Aparecida Almeida Paula, Hudsara.*

[1]PhD student in Biosciences Applied to Health. Nutritionist. Federal University of Alfenas. Brazil.; [2]BSc student in Nutrition. College of Nutrition. Federal University of Alfenas. Brazil.; [3]PhD in Food Science and Technology. Nutritionist. Professor of the College of Nutrition. Federal University of Alfenas. Brazil.

Background and objectives: The fitness center is the place to go for workout. In this context, there is a lack of information and guidance regarding proper nutrition and, thus, the exercise practitioner may erroneously consume dietary supplements, impairing the achievement of their goals, as well as health damage. The objective of this study was to evaluate the profile of the fitness centers users and the use of nutritional supplements, in Alfenas, Minas Gerais.

Methods: A survey of information about the consumption of supplements by the general public was made, focusing on the use and knowledge of nutritional supplements, through a structured script.

Results: We interviewed 152 people with an average age of 24; of these, 71,05% (n= 108) attended or had completed college education. The most practiced physical activity was bodybuilding 85,18% (n= 138), so, 42,1% (n= 64) of the interviewees declared that they did use nutritional supplements. About the profile of supplementary consumers: 57,81% (n= 37) consumed one type of food supplement and were predominantly male 65,63% (n= 42); 56,76% (n= 42) were used without the advice of a specialist and the most cited reason for consumption was to increase muscle mass by 31,25% (n= 30).The most widely consumed supplement was Whey Protein 34,50% (n= 40). The data obtained from this sample point to the desire to achieve muscular hypertrophy.

Conclusions: There wasn't association between the use of nutritional supplements and factors such as sex, age, education level and type of sports practiced, which indicates the need for continuation and development of studies of this nature.

Keywords: Fitness center, gym, sporting performance, food supplements.

BRINGING K-12 NUTRITION EDUCATION INTO THE DIGITAL AGE: RESEARCH AND RESOURCES FROM THE UNITED STATES DEPARTMENT OF AGRICULTURE

Jackson Lewis, Cheryl.

MPA, RD, LDN. National Director. Nutrition, Education, Training, and Technical Assistance Division. Child Nutrition Programs. U.S. Department of Agriculture, Food and Nutrition Service Agency. United States.

Background and objectives: The U.S. Department of Agriculture (USDA), Food and Nutrition Service (FNS) Agency is on the forefront of Federal efforts to develop evidence and technology-based nutrition education for more than 50,000 schools across the U.S. through its Team Nutrition initiative. In 2016, an environmental scan was conducted to evaluate the current state of educational technology and discuss future implications for the development of nutrition education for schools. The digital revolution is characterized by the expansion of internet access, mobile connectivity and the use of digital technology to develop nutrition education materials. Educators should be aware of the ways that technology can be used to deliver effective nutrition education programs that can support lifelong healthy eating and physical activity behaviors.

The environmental scan is designed to collect comprehensive information about the use of technology in U.S. public schools and to identify the technology-based methods effective in increasing children's nutrition knowledge, healthy eating and physical activity. The identification of the educational technology tools and approaches that best support children's healthy behaviors and physical activity provides FNS with a valuable resource for future planning.

Methods: To evaluate educational technology opportunities in schools, an Environmental Scan was conducted that included a literature review, formative research, and input from technology and health educators.

Results: Findings from the formative research confirm that technology is an integral part of students' and teachers' daily classroom experiences. Teachers support the use of technology to provide classroom instruction and students are more engaged when technological enhancements are integrated into curricula. Teachers agreed that using technology increases student engagement, enabling children to become active participants in their learning. Teachers reported using a variety of technologies – including interactive whiteboards, laptop, desktops, tablets, and game-based learning platforms. Digital materials can integrate a variety of instructional strategies to support different learning needs and provides flexibility for educators.

Conclusions: This research will inform the developmental of nutrition educational technology initiatives and assist nutrition and health educators to design and deliver effective technology-based nutrition education.

SUPPORTING CHILD NUTRITION PROGRAMS WHEN SCHOOL IS OUT OF SESSION - USING EVIDENCE-BASED NUTRITION EDUCATION IN THE SUMMER FOOD SERVICE PROGRAM FOR CHILDREN IN THE UNITED STATES OF AMERICA

Jackson Lewis, Cheryl.

MPA, RD, LDN. National Director. Nutrition, Education, Training, and Technical Assistance Division. Child Nutrition Programs. U.S. Department of Agriculture, Food and Nutrition Service Agency. United States.

Background and objectives: When the school year ends, food insecurity becomes more prevalent among 35 million school-aged children and many experience declines in diet quality over the summer. The U.S. Department of Agriculture (USDA), Food and Nutrition Service (FNS) Agency administers the Summer Food Service Program to help alleviate nutrition gaps by offering healthy meals and nutrition education at summer meal sites. In 2016, FNS conducted pilot testing and formative research to inform the development of effective nutrition education aimed at promoting summer meals sites and healthy eating behaviors among children.

This research assesses summer program site operator's perceptions of the usability of nutrition education materials and activities and their impact on children's knowledge and attitudes related to key nutrition messages (fruits and vegetables, sugar-sweetened beverages) and physical activity. Parent perceptions of program participation and nutrition promotional materials were also examined.

Methods: To evaluate nutrition education and promotion materials, pilot research was conducted with summer meal site operators, children who attended program and their parents. Additional formative research was conducted with parents to inform the development of nutrition education materials to promote healthy eating behaviors for families during the summer.

Results: Parents reported that children consumed a greater quantity of lower quality meals and snacks during the summer months when compared to the school year. Parents were receptive to nutrition promotional materials and reported a greater likelihood to engage children in summer meals if other activities, like nutrition education, were offered.

Summer meals site operators responded favorably to the materials' usability and feasibility and noted they filled two needs – educating children about nutrition and making sites more appealing to families. Children demonstrated statistically significant gains in their knowledge of the five food groups. There was also a statistically significant increase in children's self-efficacy for snacking on fruits instead of cake or cookies. Additionally, children reported consumption of soda decreased significantly after attending summer meal programs.

Conclusions: Materials developed to promote summer meals sites and engage children in nutrition education are effective and should include concrete ideas to help families and students achieve nutrition and health goals.

DIETARY SOURCES AND INTAKE OF ADDED SUGAR AMONG COLOMBIAN POPULATION: RESULTS FROM ELANS STUDY

[1]*Cortes, Lilia Yadira;* [2]*Nogueira Previdelli, Agatha;* [3]*Vargas, Luz Nayibe;* [3]*Castillo, Yuri Milena;* [3]*Tobar, Luisa Fernanda;* [4]*Fisberg, Mauro;* [5]*Kovalskys, Irina;* [6]*Gómez Salas, Georgina.*

[1]Nutritionist. PhD. Professor. Departamento de Nutrición y Bioquímica. Pontificia Universidad Javeriana. Bogotá. Colombia; [2]Nutritionist. PhD. Professor. Faculdade de Ciências Biológicas e da Saúde. Universidade São Judas Tadeu São Paulo. Brazil.; [3]Nutritionist. MSc. Professor. Departamento de Nutrición y Bioquímica. Pontificia Universidad Javeriana. Bogotá. Colombia.; [4]MD. Instituto Pensi. Fundação Jose Luiz Egydio Setubal. Hospital Infantil Sabara. São Paulo. Brazil; [5]MD. International Life Science Institute (ILSI). Buenos Aires. Argentina.; [6]Nutritionist. MSc. Professor. Departamento de Bioquímica. Escuela de Medicina. Universidad de Costa Rica. Costa Rica.

Background and objectives: Over the past 30 years, total calorie intake has increased by an average of 150 to 300 calories per day, approximately 50% of this increase comes from added sugar (AS). This study aimed to identify the dietary intake and sources of AS among Colombian population.

Methods: Data was obtained from 1230 Colombians (15-65 years old) participating in Latin American Health and Nutrition Study (ELANS), a multicenter study of urban areas of 8 Latin-American countries (Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela). The intake information was collected using two 24 hours' dietary recall, following the multiple pass methodology and analyzed with the NDS- Software. To identify the intake of AS and the major food items accounting for AS, the weighed-proportions formula developed by Block et al (1985) was used. Median intake and sources of AS were performed by age group, gender and socioeconomic level (SEL).

Results: Median AS was 59.5g/day and 11% of total energy (11.8% females and 11% males). The main source of AS for the whole population was carbonated soft drinks (CSDs) 21.4% and Infusions were the second source (18.5%), the first one was higher in the youngers 32.1% (15-19 y.o.) and 23.6% (20-34 y.o.) and the infusions in the older groups 20.7% (35-49 y.o.) and 26.6% (50-65 y.o.). CSDs were the main source of AS in high and medium SEL (20.4 and 25.7%) and infusions on low SEL (20.6%), due to the high consumption of "panela" (unrefined sugar used to prepare infusions and as sugar substitute, source of low cost energy). Within the total AS intake, sugar sweetened beverages (SSBs) represented 71% and other sources as foods 29%.

Conclusions: Colombians are consuming 1% of AS above the level recommended by the World Health Organization (10%). The main source of AS was SSBs independent of gender, age group and SES, being CSDs and infusions the two mains sources depending on the age group. This results reinforce the high intake of AS as a source of energy and shows the importance of public health programs focusing on strategies to reduce the quantity and frequency AS sources on the diet.

FACTORS AFFECTING HOUSEHOLDS FOOD INSECURITY AND ITS ASSOCIATION WITH UNDERNUTRITION AMONG UNDER 5 CHILDREN IN NORTH EASTERN STATE OF MEGHALAYA

[1]Meshram, Indrapal; [2]B, Naveen kumar; [3]K., Venkaiah; [4]Phrang, Phrang; [5]Kuhnlein, Harriet; [3]T, Longvah.

[1]MD (SPM). National Institute of Nutrition. Hyderabad. India; [2]PhD (Bio-statistics). National Institute of Nutrition. Hyderabad. India; [3]National Institute of Nutrition. ICMR. Tarnaka. Jamai-Osmania PO. Hyderabad. India; [4]Indigenous Partnership for Agrobiodiversity and Food Sovereignty. c/o Bioversity International. Rome. Italy; [5]Centre for Indigenous Peoples' Nutrition and Environment (CINE). McGill University. Montreal. Canada.

Background and objectives: The World Food Summit of 1996 defined food security as existing "when all people at all times have access to sufficient, safe, nutritious food to maintain a healthy and active life". The study was undertaken to assess household's food insecurity and undernutrition among under 5 year children in West Khasi district of Meghalaya, India.

Methods: A community based cross sectional study was undertaken. The FAO Voices of the Hungry (VOH) project has developed an experience-based measure called the Food Insecurity Experience Scale (FIES), which consists of a set of eight questions that focus on reported food-related behaviors associated with difficulties in accessing food during the previous 12 months period. Food insecurity was analysed using Rasch model and RAW score. Prevalence rates was computed using raw scores taking into account of equal weights for each individual in the sample whereas Rasch model takes into account of the sampling weights for each individual in the sample proportional to the original population in the district.

Results: A total of 621 children from 500 households (HHs) were covered. Food insecurity was observed among 80% of HHs using RAW score and 81% by RASCH model, of which 4% had severe food insecurity. Food insecurity was observed to be associated with type of house, sanitary latrine, monthly per capita income, education of father, and occupation of parents.

The prevalence of underweight, stunting and wasting was 30%, 57% and 10% respectively. The prevalence of underweight was significantly higher among children from HHs with food insecurity (34%) as compared to those with food security (24.8%), while stunting & wasting although higher among children with food insecurity (59% & 12% respectively) as compared to secured HHs (52% & 6.6% respectively), but was not significant.

Conclusions: Food insecurity was observed in 80% of HHs and is associated with type of house, income, literacy of father, per capita income and occupation of parents. The prevalence of undernutrition was also higher among children from HHs having food insecurity. Appropriate measure such as employment opportunity, food for work program, strengthening of public distribution system should be taken to meet HHs food security.

COMPARISON OF DIETARY BEHAVIOR AND NUTRITIONAL STATUS BY MILK INTAKE

[1]Kim, Hye Young; [2]Ju, Bo Ra; [3]Lee, Jung-Sug; [4]Hwang, Ji Yun; [5]Chung, Hae Rang; [6]Kwak, Tong-Kyung; [7]Kwon, Sehyug; [7]Kang, Myung-Hee; [8]Choi, Young-Sun.

[1]PhD. Professor. Department of Foods and Nutrition. Yongin University. Republic of Korea; [2]MS. Nutritionist. Center for Children's Food Service Management. Republic of Korea.; [3]PhD. Professor. Kookmin University. Republic of Korea.; [4]PhD. Professor. Sangmyung University. Republic of Korea.; [5]PhD. Chairman. Nutrition for the Future Inc. Republic of Korea.; [6]PhD. Professor. Yonsei University. Republic of Korea.; [7]PhD. Professor. Hannam University. Republic of Korea.; [8]PhD. Professor. Daegu University. Republic of Korea.

Background and objectives: Average milk intake of Korean is very low and it was about a half cup a day (111.4g) in 2013. For Koreans, milk is consumed mainly as a snack, so milk intake may be related to people's dietary behavior.Therefore, the purpose of this study was to compare the dietary behavior and nutritional status according to milk intake of Koreans.

Methods: A total of 1,043 subjects (219 in primary school students, 209 adolescents, 355 adults and 260 elderly) were included in the study. According to milk intake guideline of the Korean DRI, school-aged children are required to drink two cups (400g) of milk per day and adults and elderly are required to drink one cup (200g) per day. The subjects were divided into milk-adequate or milk-deficient groups by the milk guideline of the specific age. 24-hour dietary record and food behaviors of the subjects were compared between the milk-adequate and milk-deficient groups.

Results: Milk-adequate groups had significantly higher intake of essential nutrients, including calcium, phosphorus and vitamin B2 than milk-deficient groups. Milk-adequate groups also had higher intake frequency of fruit and vegetables than milk-deficient

groups. In addition, milk-adequate elderly group had higher intake of whole grain, meat, soybean, egg, fish and nut intakes than milk-deficient elderly group. In case of primary school students, milk-adequate group had higher intakes of processed milk and dairy products, but lower intake of pizza compared to the milk-deficient group. Milk-adequate groups had better dietary behaviors than milk-deficient groups. In detail, milk-adequate primary school students checked nutrition labelling more frequently and milk-adequate school-aged children exercised more frequently than their counterparts. Milk-adequate adults tried to avoid overeating and milk-adequate elderly tried to eat more regularly and had more frequent snacks than their counterparts.

Conclusions: When the milk was consumed at the level recommended by the dietary guidelines, the intake of various food groups showed a better direction, especially in the elderly, and various dietary behaviors were found to be more desirable. More active nutrition education would be needed to consume milk as recommended by the dietary guidelines.

Keywords: milk, dietary guideline, dietary behavior, nutritional status

ADDED SUGAR INTAKE AND SOURCES AMONG URBAN COSTA RICAN POPULATION: RESULTS FROM ELANS STUDY

[1]Gómez Salas, Georgina; [2]Nogueira Previdelli, Agatha; [3]Kovalskys, Irina; [4]Guajardo, Viviana Beatriz; [5]Zalcman Zimberg, Ioná; [6]Fisberg, Mauro.

[1]MSc. Nutritionist. Department of Biochemistry. School of Medicine. University of Costa Rica. Costa Rica; [2]PhD. Professor. Faculdade de Ciencias Biologicas e de Saude. Universidade Sao Judas Tadeu. Sao Paulo. Brazil; [3]MD. Nutrition & Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina; [4]BSc. Nutrition & Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina; [5]PhD. Departamento de Psicobiología. Universidad Federal de Sao Paulo. Brazil; [6]MD. Instituto Pensi. Fundação Jose Luiz Egydio Setubal. Hospital Infantil Sabara. São Paulo. Brazil.

Background and objectives: Added sugar (AS) intake has been associated with the increasing prevalence of obesity. The objective of this study was to estimate added sugar intake and main sources of AS among urban Costa Rican population.

Methods: Data were obtained from the Latin American Health and Nutrition Study (ELANS), a multicenter study developed in urban areas of 8 Latin American countries: Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela. Dietary intake among 798 Costa Rican participants (15-65 y) was assed using two 24-hour recall. Usual AS intake was estimated using the Multiple Source Method. The major food items accounting for AS was assessed using the weighed-proportions formula developed by Block (1985) in which the relative contribution (RC) of a given food item/food group is defined as: RC= [(Total AS grams from a food item x 100)/Total AS grams from all food items]. Median intake, expressed as grams per day (g/d), and sources of AS were performed by age group, gender, socioeconomic level and nutritional status.

Results: Median AS consumption for overall Costa Rican population was 64.6g/d, accounting for 14.7% of total energy intake. Sugar sweetened beverages accounts for 71.3% of total added sugar intake in urban Costa Rican population. The highest intake was reported by male adolescents (75.8g/d) and male of low socioeconomic level (73.4g/d). Infusions (coffee or tea) are the main source of added sugar among urban Costa Ricans, followed by carbonated soft drinks (20.7% and 18.1% respectively). For adolescents and young adults (20-34 y) carbonated soft drinks are the higher contributor of AS intake, while for adults >35 y or older are infusions, followed by sweetened fruit juices. The main AS sources were infusion, natural juice (with sugar) and carbonated soft drinks for both in people with and without excess weight.

Conclusions: Added sugar intake among Costa Rican population is above the World Health Organization recommendation (10%). Infusions represent the main source of AS, followed by carbonated soft drinks and sweetened fruit juices. To decrease sugar intake, it is important to rice awareness about the quantity of sugar added to infusions and to reduce sugar content in manufactured foods.

Keywords: Food source, Added sugar, Costa Rica, multicenter study.

Conflict of Interest Disclosure: The ELANS is supported by a scientific grant from the Coca Cola Company and support from the Instituto Pensi / Hospital Infantil Sabara, International Life Science Institute of Argentina, Universidad de Costa Rica, Pontificia Universidad Católica de Chile, Pontificia Universidad Javeriana, Universidad Central de Venezuela (CENDES- UCV)/ Fundación Bengoa, Universidad San Francisco de Quito, and Instituto de Investigación Nutricional de Peru. Institute of Nutrition of Central America and Panama; [5]M). Biochemist. Nutritional Biochemistry Laboratory. Institute of Nutrition of Central America and Panama. Guatemala; [6]MSc. Nutrition Officer. Guatemala Office. United Nations Children's Fund. Guatemala.; [7]PhD. Health Scientist. Division of Nutrition, Physical Activity and Obesity. U.S. Centers for Disease Control and Prevention. USA; [8]DrPH. Nutrition Branch. Division of Nutrition, Physical Activity and Obesity. U.S. Centers for Disease Control and Prevention. USA; [9]Centers for Disease Control and Prevention. USA.

Background and objectives: Malnutrition is a public health priority in Guatemala. Stunting is 47% among children <5 y, therefore Guatemala is the Latin American country with highest stunting and is 6th in the world. Guatemala faces a double burden of malnutrition showing a rate of overweight/obesity of 52% among non-pregnant women of reproductive age (WRA). In order to measure progress in achieving international targets - the 2025 Global Nutrition Targets and the 2030 SDG´s - and domestic ones, authorities need to monitor changes to support national decisions to implement strategies toward those goals. For that purpose, national and international institutions set out to design and implement a surveillance system that would supply accurate, reliable, representative and timely data.

Methods: The National Malnutrition System, and recently the Epidemiological Surveillance System in Health and Nutrition (SIVESNU), has undergone various phases of development: in 2010, negotiations and preparation; in 2011, prototype development and testing; and from 2013 onwards, institutionalization and technological transfer. In this last phase, the national institutions: Food and Nutrition Security Secretariat and Ministry of Health became involved in system operations and decisions to include the system in the central government annual budgeting and planning processes.

Results: In 2013 and in 2015 nationally representative data were collected in a sample of 2,700 and 2,800 households. Stunting in 3-59 month-olds showed a non-significant decline from 47.5% to 44.9%; overweight and obesity in WRA remained at 52%; and no significant changes were observed in iron deficiency in WRA and children. Data also showed a non-significant decline of exclusive breastfeeding (from 58.4% to 50.5% in 0-5 month-olds) and a significant reduction in coverage of micronutrient powders in

children (from 79.6% to 56.0 %). Micronutrient supplementation (iron and folic acid) during last pregnancy among WRA remained above 80% in both years.

Conclusions: By generating national estimates on nutrition indicators, the SIVESNU demonstrated its feasibility. Sharing results has increased policy makers' awareness that the system can contribute to policy making with reliable evidence, but that there is a need to strengthen their capacity to use data.

BECOMING BREASTFEEDING FRIENDLY IN GHANA: OPPORTUNITIES FOR SCALING-UP EFFECTIVE ACTIONS

[1]*Aryeetey, Richmond;* [2]*Hromi-Fiedler, Amber;* [3]*Perez-Escamilla, Rafael.*

[1]PhD. Senior Lecturer. University of Ghana. School of Public Health. Ghana; [2]Associate Research Scientist. School of Public Health. Yale University. New Haven. United States; [3]Professor. School of Public Health. Yale University. New Haven. United States.

Background and objectives: Over the past two decades, Ghana has achieved significant progress in optimal breastfeeding practice. Currently, 56% of mothers initiate breastfeeding within one hour of delivery and 52% of infants <6 months are exclusively breastfed. However the challenge remains how to further improve optimal breastfeeding practice with limited government funding and declining donor support for breastfeeding programs.

Methods: Between April 2016 and March 2017, a 12-person expert committee representing government, United Nations, academia, and donor agencies within Ghana applied the Becoming Breastfeeding Friendly (BBF) process to assess the enabling environment for scaling-up effective actions for breastfeeding nationally. The BBF process is grounded in the Breastfeeding Gear Model which stipulates that eight 'gears' must work harmoniously to achieve country-level scale-up of breastfeeding. The BBF assesses each gear using specific benchmarks: advocacy (4 benchmarks); political will (3 benchmarks); legislation and policy (10 benchmarks); funding and resources (3 benchmarks); training and program delivery (17 benchmarks); promotion (3 benchmarks); research and evaluation (10 benchmarks); and coordination, goals and monitoring (3 benchmarks). Over a series of 4 meetings across 7 months, the committee used available evidence (document reviews and stakeholder interviews) to score each benchmark, identify gaps, and provide recommendations to improve the breastfeeding national program.

Results: The committee reached consensus on the individual benchmark scores, which ranged from 0 (no progress) to 3 (major progress). Benchmark scores for each gear were aggregated as a

weighted average to estimate the final gear scores, ranging from the gear not being present (0 score) to strong gear strength (3.0). Four gear scores reflected strong gear strength: advocacy (2.25); political will (2.3); legislation and policy (2.3); and coordination, goals and monitoring (2.7). The rest reflected moderate gear strength: funding and resources (1.25); training and program delivery (1.94); promotion (2.0); and research and evaluation (1.3). The overall BBF score was 1.99, indicating moderate scale-up environment for breastfeeding in Ghana.

Conclusions: Consequently, stakeholders prioritized four actions for scale-up: 1) strengthen advocacy by enlisting and empowering breastfeeding champions, 2) strengthen maternity protection, 3) strengthen capacity for delivering services, and 4) expand and sustain breastfeeding awareness initiatives.

A NEW METHOD TO MONITOR THE PERFORMANCE OF COMPANIES IN RELATION TO NUTRITIONAL TARGETS

[1]Bandy, Lauren; [2]Harrington, Richie; [3]Jebb, Susan; [4]Rayner, Michael.

[1]PhD Student. Nuffield Department of Population Health. University of Oxford. England; [2]PhD. Nuffield Department of Population Health. University of Oxford. England; [3]Professor of Diet and Population Health. Nuffield Department of Primary Care Health Sciences. University of Oxford. England; [4]Professor of Population Health. Nuffield Department of Population Health. University of Oxford. England.

Background and objectives: Public health recommendations encourage industry to reformulate its products to reduce sugar, saturated fat and salt and to encourage the development of healthier options, yet there is no systematic method to monitor progress. The aim of this study is to utilise 'big data' on the composition of foods and drinks to monitor the nutritional quality of the food supply and to combine with sales data to examine the

changes by category, brand and company. Here we use soft drinks in the UK in 2015 as an example of the method.

Methods: Nutrition composition data were collected online using a novel tool, 'foodDB', which collects date-stamped nutrition information directly from supermarket websites. A score based on the UK FSA/Ofcom nutrient profile model was ascribed to each product (NP) and for each category; bottled waters, carbonated drinks, dilutables, flavoured waters, juices, ready-to-drink tea and coffees and sports and energy drinks. A NP score >70 is classified as 'healthy'. Sales data for soft drinks were obtained from a commercial source, Euromonitor (n=193), and combined with the composition data to calculate a sales-weighted NP score. NP scores were calculated at a category, brand and company level to create an index, which can be used as an indicator of the overall 'healthiness' of the products.

Results: Results showed the average sales-weighted score (SD) for total soft drinks in the UK was 68.8 (4.8). The category with the highest score was juice (72.7 2.3) and the lowest was sports and energy drinks (67.55.7). The biggest overall contributor to sugar intake was carbonated drinks (43%) followed by juice (27%). Three of the top five scoring companies were retailers, while energy drink companies scored the lowest on the index.

Conclusions: Combining purchase data with nutrition composition data is potentially a valuable approach to track the impact of reformulation and to benchmark companies. This method provides new opportunities to evaluate the impact of food policies, including both legislative and voluntary measures.

Keywords: Reformulation, nutrient composition, monitoring, policy

EFFECT OF A PEER SUPPORT INTERVENTION TO ENCOURAGE ADOPTION AND MAINTENANCE OF A MEDITERRANEAN DIET IN ESTABLISHED COMMUNITY GROUPS: A CLUSTER RANDOMISED TRIAL

[1]O'Neill, Roisin; [1]McGowan, Laura; [1]McEvoy, Claire; [2]Kee, Frank; [2]Patterson, Chris; [2]Cupples, Margaret; [3]McKinley, Michelle; [2]Woodside, Jayne.

[1]Research Fellow. UKCRC Centre of Excellence for Public Health. School of Medicine, Dentistry & Biomedical Sciences. Queen's University Belfast. Northern Ireland.; [2]Professor. UKCRC Centre of Excellence for Public Health. School of Medicine, Dentistry & Biomedical Sciences. Queen's University Belfast. Northern Ireland.; [3]Reader. UKCRC Centre of Excellence for Public Health. School of Medicine, Dentistry & Biomedical Sciences. Queen's University Belfast. Northern Ireland.

Background and objectives: Peer support offers a potential alternative, low cost social support approach to encouraging lifestyle behaviour change. The Trial to Encourage Adoption and Mainte-

nance of a MEditerranean Diet (TEAM-MED) was designed to pilot test a peer support (PS) programme and compare this to a proven intensive Mediterranean Diet (MD) intervention and a minimal MD education intervention for encouraging adoption of the MD in adults at high CVD risk in Northern Ireland (NI).

TEAM-MED PS groups were newly formed, however, research suggests that leveraging existing social networks in established groups can enhance the effectiveness of peer support strategies and further encourage behaviour change. This study is an extension of TEAM-MED aiming to explore the effect of the PS intervention when compared to a minimal education intervention in already established community groups.

Methods: NI based community groups were recruited through established community links and randomised to receive a PS intervention or a minimal education intervention. Trained peer supporters delivered the PS intervention over a 12-month period; this consisted of 11 group-based sessions each lasting 2 hours. The minimal intervention group received written educational literature focusing on the MD.

Mediterranean Diet Score (MDS) was assessed at baseline, 3, 6 and 12 months. The primary outcome was change in habitual MDS at 6 months from baseline (adoption). Change in MDS at 12 months from 6 months (maintenance) is a secondary outcome.

Results: Four community groups recruited: n=2 randomised to the PS intervention and n=2 to the minimal education intervention, with n=8 participants per group. At 6 months, MDS increased by 2.6±2.7 in the PS intervention and 3.3±2.2 in the education group, from baseline; the between group difference was non-significant after adjusting for baseline scores (-0.9 (95%CI -2.9, 1.2)) (p=0.39).

Conclusions: It is possible that the true effect of the peer support intervention may be underestimated due to the comparison with a minimal education intervention. One year follow-up results (June 2017) will allow the evaluation of whether the PS intervention encourages the maintenance of a MD longer term. Findings will inform a future large-scale RCT where the efficacy and cost-effectiveness of the peer support MD intervention will be tested.

Spanish Society of Community Nutrition (SENC). Spain; (3)Nutritionist. Spanish Society of Community Nutrition (SENC). Spain; (4)Nutritionist. SPRIM. Spain; (5)MSc BSc. SPRIM. Spain; (6)MD. PhD. Spanish Society of Community Nutrition (SENC). Department of Food Sciences and Physiology. University of Navarra. CiberOBN. Instituto de Salud Carlos III. Madrid. Spain.

Background and objectives: In this paper we describe the food consumption pattern and adherence to recommendations in a random sample of the Spanish population.

Methods: Data drawn from a cross-sectional study conducted on a representative random sample of the Spanish population > 3 years (n = 6,800). The protocol included socio-demographic data, diet assessment by means of 24 hours-recall (2 days), food frequency questionnaire and questionnaire on food habits and food preferences. Information was collected in household face-to-face interviews and self-administered questionnaire. The protocol was in accordance with the Declaration of Helsinki for human studies of the World Medical Association and was approved by the ethics committee of clinical research of the Basque Country. Fieldwork: May 2014- May 2015, four seasonal waves.

Results: On the average Spanish food pattern, the cereal group (28%), meat and meat products (16%), oils and fats (14%) and milk and dairy products (12%) contribute most to daily energy intake. Some 92,7% of the sample usually consume food in three eating occasions during the day, namely breakfast (16,5% of daily energy intake), main meal (42% of daily energy intake) and evening meal (30% of daily energy intake). In addition, 36,8% reported a mid-morning snack and 40,8% a mid-afternoon snack. Some 98% of men and women usually consume meat or processed meats, poultry 2,1 portions/week and red and processed meats 7,5 portions/week. On average 97% consume fish (2,1 portions/week), eggs (3,1 portions/week) and 95% consume legumes (2,1 portions/week). 99% consume foods from the cereal group (2,4 portions/day), potatoes (2,5 portions /week) as well as milk and dairies (2,7 portions/day). 93% usually consume vegetables (1,7 portions/day) and 96,3% fruit (2,2 portions/day). Consumption of sugary foods and beverages as well as red and processed meats is above recommendations, while that of vegetables and fruit is below recommendation.

Conclusions: Consumption of sugary foods is above recommendations while consumption of fruit and particularly vegetables is below recommended levels.

EFFECT OF DIETARY AND EXERCISE INTERVENTIONS IN SARCOPENIC, PRE-FRAIL AND FRAIL OLDER ADULTS

[1]Hida, Azumi; [2]Anton, Stephen; [3]Mankowski, Robert; [4]Layne, Andrew; [5]Solberg, Laurence; [6]Mainous III, Arch; [3]Buford, Thomas.

[1]RD, PhD. Nutritionist. Department of Nutritional Science. Faculty of Applied Bioscience. Tokyo University of Agriculture. Japan.; [2]Prof. Department of Aging and Geriatric Research. University of Florida. USA; [3]PhD. Department of Aging and Geriatric Research. University of Florida. USA; [4]MSci. Department of Aging and Geriatric Research. University of Florida. USA; [5]MD. Department of Aging and Geriatric Research. University of Florida. USA; [6]PhD. Department of Community Health and Family Medicine. University of Florida. USA.

Background and objectives: Sarcopenia is a debilitating condition that involves loss of muscle mass and function, which affects virtually everyone as they age, and can lead to frailty and ultimately disability. It is well known that diet and exercise training is important to increase muscle mass and strength in young persons, but the effect of these intervention in improving function in sarcopenic and frail older persons is not well understood. The purpose of this review was to summarize the strength of evidence from human clinical trials on the effects of dietary was to identify clinical trials that tested the effects and exercise intervention on changes in muscle mass and strength in sarcopenic and frail older adults.

Methods: We searched PubMed for the years of 1980 to May 2016. Filters were set to allow only "clinical trials," "human" studies, and "English" studies. Our preset inclusion criteria were the following: (1) interventional controlled clinical trials, clinical trials, and randomized controlled trials, with orally administered nutritional supplementation and/or exercise training, (2) sample size of at least 15 participants, (3) intervention period of 12 weeks or longer, (4) inclusion of older adults (age ≥ 60 years) who met criterial for pre-defined criteria for sarcopenia and/or frailty.

Results: We identified 19 clinical trials and there were a few key findings. First, dietary interventions involving protein supplementation improved functional and/or strength outcomes in a few trials, however, these interventions had less consistent effects on walking speed and grip strength. Lifestyle interventions not involving calorie restriction generally did not induce significant changes in body composition.

Conclusions: These results suggest that dietary interventions alone are not enough to improve sarcopenic and frail conditions, but the combination of dietary and exercise intervention was effective in improving some aspects of physical function. There were a limited number of trials in which participants with sarcopenia were specifically targeted, and thus there is an important need for

more research to determine the appropriate types of intervention approaches for the high risk population of sarcopenic and frail older adults.

FACTORS ASSOCIATED TO PHYSICAL ACTIVITY IN PERUVIAN ADOLESCENTS AND ADULTS: RESULTS FROM THE ELANS STUDY

[1]Liria Domínguez, María Reyna; [2]Pareja, Rossina Pareja.

[1]PhD Nutritionist. Instituto de Investigación Nutricional. Peru.; [2]MSc Nutritionist. Instituto de Investigación Nutricional. Peru.

Background and objectives: Physical activity is an important component of lifestyle which determines the state of health and nutrition of an individual and population. In Peru, recent surveys show that overweight and obesity are widespread problems with higher rates in urban areas of large cities. The objective of this study was to determine the factors associated with physical activity in Peruvian population.

Methods: Data were obtained from the Latin American Health and Nutrition Study (ELANS), a multicenter tansversal study conducted in urban areas of 8 Latin American countries: Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela. METS from a modified long-IPAQ were calculated in 1113 Peruvians using the time in minutes, times a week (for at least 10 minutes of the following activities: walking, cycling, moderate and intense physical activity) and, multiplying factors suggested by IPAQ (3.3, 4.0, 4.0 and 8.0, respectively). METS are expressed in METS/min/week. A multiple regression model was used to determine the variables associated with METS at a 95% confidence level.

Results: The results of METS/min/week showed: (i) by sex: men spend more than women (2632 vs 1950 METS/min/week, p <0.000), (ii) by city: Pucallpa showed higher expenditure (3697 METS/min/week, 0=0.001) in contrast with other cities (1248-2680 METS/min/week), except for Iquitos (3102 METS/min/week); in contrast Piura showed lower expenditure (1258 METS/min/week, p <0.000) than the other cities (1858-3697 METS/min/week), except for Chiclayo (1562 METS/min/week, p = 0.423); (iii) labor status: housewives spend less than students (1930 vs 2660 METS/min/week, p = 0.008) and dependent workers (2369 METS/min/week, p = 0.043); and students spend marginally more than independent workers (2159 METS/min/week, p = 0.065) and that the unemployed, retired or living on their incomes (1987 METS/min/week, p = 0.062); (iv) socioeconomic status: low socioeconomic status tend to spend less than high (2125 vs 2511 METS/min/week, p = 0.058, respectively). No differences were found in the variables: age, nutritional status and educational level.

Conclusions: Physical activity was associated with sex, labor activity, socioeconomic level and city. Research on the motivations for physical activity is required in order to propose strategies that increase this in all population groups.

only domestic consumption. Restrictions on storage time as well as the need for careful handling of non-aggregated data needed, in order to avoid identification of specific enterprises or individuals are potential challenges. Data providers may not be able to disclose the full details of the household panelists to the proposed future European RI, unless active consent

Conclusions: Data generate new potentials, potentially leading to new methods of analysing population nutrition behavior. Data owners see benefits sharing data with science in a multi stakeholder operated data platform on certain conditions, including fair exchange mechanisms to avoid clients/competitors potentially benefitting from such data while not sharing own data.

Keywords: Big Nutrition data, EU Richfields, digital consumer behavioral patterns, digitalization, data philanthropy

CAN BUSINESS GENERATED BIG FOOD DATA HELP NUTRITION SCIENCE –   CASE INSIGHTS FROM INTERVIEWS WITH COMMERCIAL BIG DATA OWNERS IN THE RICHFIELD DESIGN STUDY

Mikkelsen, Bent Egberg.

Professor. PhD. Aalborg University. Denmark.

Background and objectives: Rapid digitalization create new digital images of consumer food behavior and new potentials of analyzing population behavior in nutrition science. However, data is created in many different settings, with many different technologies, has many different owners and is often fragmented and in complete. As a result, the utility of the big food data has so far been limited. Aim: investigate to what extent different sources of data on food behavior created by businesses can be shared among stakeholders for the purpose of policymaking and research

Methods: Data was collected through interviews with big 4 food dataproviders in DK/SE covering procurement and domestic consumer purchasing. An exploratory qualitative approach was adopted. Inclusion: informants having insight, in control of relevant data, interest in the project, willing to give an interview and willing to provide data probes for the analysis. The transcripts were coded independently by 2 researchers assigning relevant names to highlight the relevance of text, using QSRNvivo11.

Results: Commercial big data owners see clear potentials in sharing data from different sources for the purpose of societal/scientific enquiry. Large data diversity is viewed as an asset since data is collected to suite different data needs. Potential sharing benefits is valuable since commercial data owners can benefit from scientific cooperation. Data providers see potential benefits in sharing data for data philanthropic reasons as a type of CSR. Interviewees see limitations since data might cover only out of home eating or

ALCOHOL CONSUMPTION AND HYPERTENSION IN YOUNG ADULTS

[1]*Castro Jordán, Bárbara;* [2]*Bustos, Patricia;* [2]*Amigo, Hugo.*

[1]PhD. MD. Department of Nutrition. Faculty of Medicine. University of Chile. Santiago. Chile; [2]MD. Department of Nutrition. Faculty of Medicine. University of Chile. Santiago. Chile.

Background and objectives: It has been pointed out that excessive alcohol consumption is detrimental to health, increasing the risk of various health problems, while it is not yet fully accepted that consumption in low quantity would play a protective role for cardiovascular diseases. The objective of this study was to determine the association between mild to moderate consumption and also high alcohol intake with hypertension (HT) in young adults.

Methods: Cross-sectional study in people born in Limache, Region of Valparaíso, Chile between 1974-78 who were evaluated between 2010-12. Blood pressure was taken and intake of alcohol was assessed by AUDIT questionnaire (and then classified as low risk, risk, harmful or probable dependence) and by a food frequency questionnaire (FFQ), with the following categories: mild, moderate and high consumption.

Results: The prevalence of HT was 13% (95% CI=11.0-15.7), higher in men (19.7 % vs 10.2 % in women). 71% (95% CI =37.8-74.2) of the participants consumed alcohol according to AUDIT. Only 12% had an intake of risk, harmful or probable dependence. 30% (95% CI = 26.7-33.3) consumed alcohol the previous month according to the FFQ, only 10% reported moderate or high intake. The alcohol more frequently consumed was beer and wine, the higher intake was in men. High consumption of alcohol in FFQ was associated with HT, with an OR = 3.271 (95% CI: 1.045-10.240). Mild to moderate alcohol consumption wasn't associated with HT.

Conclusions: Alcohol intake was between 30 and 70% according to the survey used. Consumption was characterized by low quantity and was more frequent in men. This study confirms that high alcohol intake is a risk factor for HT but it was not possible to verify that low or moderate alcohol intake constituted a protective factor. This may be because the protective effect is probably due to a sum of factors, making it difficult to find this association. Educational campaigns aimed at reducing alcohol intake will help to prevent or manage hypertension.

Keywords: Alcohol intake, risk factor, hypertension

ACUTE OR LONG TERM CONSUMPTION OF BEVERAGES CONTAINING LOW CALORIE SWEETENERS DO NOT ALTER APPETITE, ENERGY INTAKE OR MACRONUTRIENT SELECTION IN HEALTHY ADULTS: A NON-INFERIORITY COMPARISON WITH WATER

[1]Fantino, Marc; [2]Fantino, Agnès; [3]Mistretta, Frédéric; [4]Bottigioli, David.

[1]Honorary Professor. Medical Scool of the Burgundy University; [2]CRA. MSc. CreaBio-RA. Centre Hospitalier Montgelas. Givors. France; [3]Statistican. RCTS. Lyon. France; [4]BSc. CreaBio-RA. Centre Hospitalier Montgelas. Givors. France.

Background and objectives: Background: The substitution of intense sweeteners (LCS) for caloric sugars is currently recommended to reduce energy intake and fight obesity. Conversely it is often claimed that the use of LCS would rather increase energy intake (EI) and enhance the appetite for sweetness. In this context, the effects of LCS in beverages have often been compared to sugar but have rarely been tested against water.

Objective: To test the hypothesis that LCS beverages and water, when consumed with meals, do not affect appetite differently in healthy adults before and after habituation to daily intake of LCS beverages.

Methods: The food consumption of 80 female and 86 male LCS-naïve healthy adults was measured on three 2-day measurement sessions performed one week apart (sessions 1, 2, 3) and again after a 4-week habituation to daily consumption of LCS or water at mealtimes. 1) In the early phase of the study, LCS-naïve participants were required to drink either 330 ml water or commercial LCS lemonade with each meal, in a randomized cross-over design. Their ad lib intakes were recorded on two successive days. 2) Participants were then randomly assigned to either the LCS-habituated group (2 x 330 ml/d for 4 wks), or to a control LCS-naïve group (2 x 330 ml/d water for 4 wks). Ad libitum intakes before and after the habituation period were measured in similar conditions. Energy and macronutrient intake, selection and consumption of sweet and savory foods were measured; appetite ratings (VAS) assessed huger, gastric fullness and desire-to-eat. The hypothesis was tested using equivalence/ non-inferiority statistics.

Results: LCS beverage consumption at mealtime did not increase energy/ macronutrient intakes or selection of sweet foods, either in LCS-naïve male and female subjects, or after the 4-week habituation period to daily LCS consumption.

Conclusions: LCS use does not disrupt eating behaviour, and does not affect appetite or energy intake in LCS-naïve or LCS-habituated adults, when compared with water.

Keywords: Human subjects, Low calories sweeteners (LCS), Energy intake, Sugar intake, Sweet/savory food choices

WHAT ARE THE FOODS THAT CONTRIBUTES (TOTAL ENERGY CONSUMPTION) TO THE MEXICAN DIET?

[1]Garcia Chavez, Claudia Gabriela; [2]Rivera Dommarco, Juan Ángel; [3]Monterrubio Flores, Eric; [4]Aburto, Tania; [5]Pedraza, Lilia.

[1]MSc. Nutricionist. Center for Nutrition and Health Research. National Institute of Public Health. México.; [2]PhD. General Director. Center for Nutrition and Health Research. National Institute of Public Health. México.; [3]PhD. Statistician. Center for Nutrition and Health Research. National Institute of Public Health. México.; [4]MCs.Nutricionist. University of North Carolina at Chapel Hill. Gillings School of Global Public Health. USA.; [5]MCs. Nutricionist. University of North Carolina at Chapel Hill. Gillings School of Global Public Health. USA.

Background and objectives: In México and Latin-American the non-communicable diseases (NCDs) has become the principal public health problems. Diet influences on health and contribute to NCDs such cancer, diabetes and cardiovascular diseases. Studies on burden of diseases and risk factors attempt to quantify the magnitude of health losses due to illness, injury and risk factors including dietary risks. Risk factors related to diet include diets low in fruits, vegetables, whole grains, nuts and seeds, fiber, milk; and high in sodium read meat, sweetened beverages, and others. It is important to know what the population is eating; therefore, the objective of this study is to describe the foods that contributes, to the total energy consumption, to the Mexican diet.

Methods: Dietary information was obtained through the 24-hour recall (multi-step method) of 7,983 subjects older than 5 years of the National Health and Nutrition Survey (ENSANUT) 2012. Reported foods were classified according to their nutritional characteristics in 49 food groups. We estimated the mean contribution percentage of the food groups at national level and sociodemographic variables (population group: schoolchildren, adolescents, adults; region: north, center, south; area of residence: rural and urban; and socioeconomic level: high, medium and low). To determine level of significance, a regression was performed adjusting the model by sociodemographic variables, and using Bonferroni method for multiple comparisons.

Results: The main foods that contribute to the total energy intake in the Mexican population for each age group are "Tortilla and corn products" (16.5%, 18.5% and 22% respectively), followed by "Mexican sweet bread" (6.2%, 5.9% and 7% respectively); whole milk (5.9%) in schoolchildren, and "Soda drinks" for adolescents and adults (5.3% and 5% respectively). The food group "Orange and other citrus" was the principal contributor of fruits; nevertheless the contribution is very low along with any kind of vegetables.

Conclusions: Changes in food consumption are necessary to improve diet quality in mexican population. It is necessary to support this with changes in food policy as taxation to help fomentation of healthy environments.

Keywords: Diet, food contribution, energy intake, public health nutrition

A SYSTEMATIC REVIEW OF REVIEWS ON EFFECTIVE HOME, FAMILY AND COMMUNITY BASED INTERVENTIONS FROM LOW- AND MIDDLE-INCOME COUNTRIES TO INFORM THE BREASTFEEDING ACTION PLAN FOR SOUTH AFRICA

[1]Witten, Chantell Beverley; [2]Kruger, Salome; [2]Taljaard, Christine; [3]Kahler, Belinda; [4]Verstraeten, Roosmarijn; [5]Booth, Andrew.

[1]MSc. Dietitian. School of Physiology. Nutrition and Consumer Science. North West University. South Africa; [2]PhD. Dietitian. Center of Excellence for Nutrition. North West University. South Africa; [3]BSc. Nutritionist. Center of Excellence for Nutrition. North West University. South Africa; [4]. Independent researcher PhD. Consultant in public health nutrition. Affiliated as voluntary staff with the Department of Food Safety and Food Quality. Ghent University; [5]PhD. School of Health and Related Research (ScHARR). University of Sheffield. United Kingdom.

Background and objectives: South Africa has one of the lowest breastfeeding rates globally and an exclusive breastfeeding (EBF) rate below 10%. If South Africa is to to reach the World Health Assembly target of 50% EBF rate by 2025 and reap the full benefits of breastfeeding, South Africa would need an evidence-informed action plan. We undertook a systematic review of reviews to i) summarise the evidence on the various community-based interventions for breastfeeding of infants aged 6-24 weeks in low- and middle-income countries (LMICs) and ii) produce an evidence-informed recommendation on the most appropriate interventions for South Africa.

Methods: We searched six electronic databases for peer-reviewed reviews published between 2001 and 2017. To be included, systematic reviews had to: at least have 60% of their primary studies conducted in LMICs, report on community-based interventions compared to routine care, be aimed at pregnant or breastfeeding women and/or their families, and report on exclusive or any breastfeeding rates between 6 and 24 weeks as the primary outcome. Quality of the studies included for data extraction was appraised independently by two author pairs using the AMSTAR

checklist. To assess quality of each study, we used the Cochrane risk of bias tool.

Results: Title and abstract screening of 1037 references resulted in retaining three eligible systematic reviews, from which six primary studies in LMICs emerged. These six primary studies represented data collected from 1996 to 2008. To bridge this data and publication gap, citation searches of the six primary studies were performed which rendered four additional studies. Combined, these ten studies now presented data from 1996 to 2015 and the publication date ranged from 2005 to 2016. The evidence suggests that breastfeeding counselling, despite the wide range in number and frequency of breastfeeding counselling contact sessions, had a positive impact on breastfeeding duration and exclusivity at 24 weeks.

Conclusions: There is a paucity of studies in LMICs. While our review of reviews suggests that breastfeeding counselling has the potential to improve EBF rates, scale-up and rigorous evaluation of community-based interventions to identify the pathways through which these effects can be sustained must be explored.

Keywords: Review of reviews, exclusive breastfeeding, community-based

BLOOD GLUCOSE IN SEDENTARY OLDER ADULTS DURING PROLONGED SITTING TIME VERSUS INTERMITTENT SITTING TIME

[1]Pinheiro Amador dos Santos Pessanha, Fernanda; [2]Maira da Cruz Alves, Natália; [3]de Lopes Pontes, Tatiane; [4]Pfrimer, Karina; [5]Giacomo Fassini, Priscila; [6]Foss Freitas, Maria Cristina; [6]Ferriolli, Eduardo.

[1]MSc. Division of General Internal and Geriatric Medicine. Ribeirão Preto Medical School. University of São Paulo. Ribeirão Preto. Brazil; [2]MSc. Physiotherapist. Division of General Internal and Geriatric Medicine. Ribeirão Preto Medical School. University of São Paulo. Ribeirão Preto. Brazil.; [3]BSc in Nutrition by the Federal University of Amazonas. Brazil.; [4]PhD.Nutritionist. Division of General Internal and Geriatric Medicine. Ribeirão Preto Medical School. University of São Paulo. Ribeirão Preto. Brazil; [5]PhD. Division of General Internal and Geriatric Medicine. Ribeirão Preto Medical School. University of São Paulo. Ribeirão Preto. Brazil.; [6]MD. PhD. MSc. Division of General Internal and Geriatric Medicine. Ribeirão Preto Medical School. University of São Paulo. Ribeirão Preto. Brazil.

Background and objectives: In adults, sedentary behavior is related to cardiovascular risk markers, independent of physical activity (PA) level. Besides this, interruption of prolonged sitting time (PST) has shown positive results, even when performed in low intensity and duration. The aim of this study was to analyse the influence of PST, as well as different forms of PST breaks in relation to the glycaemic curve.

Methods: controlled clinical study in women from the community (≥ 65 years) of the city of Ribeirão Preto/ Brazil. Volun-

teers with BMI ≥ 30 kg/m2, diabetics or in use of glycemic control medication, or who present absolute or relative contraindications to practice PA were excluded. Volunteers performed 4 phases of intervention: (1) PST: seated posture for 5 uninterrupted hours; (2) PA Low Intensity and Short Duration (LiSd): 2 min of PA breaks (50-60% of maximum heart rate - HRmax) every 20 min of PST; (3) Moderate Intensity and Short Duration (MiSd): 2 min of PA breaks (65-75% HRmax) every 20 min of PST; (4) Moderate Intensity and Long Duration (MiLd) in which PST was interrupted every 75 min for 10 min breaks (65-75% HRmax). Breaks were performed by walking in a hallway and monitored by a heart rate monitor. The glycaemic curve (AUC) was analysed by blood samples collected serially (Basal) and after eating a standard mixed meal (30min, 1h, 2h, 3h, 4h and 5h). For data analysis, a linear regression for mixed effects was performed and data were adjusted for age, weight and PA.

Results: 16 women, mean age 69.2 ± 4.1 years, participated in this study. The highest values of glycaemic curve were found in the PST phase (AUC 555.9 ± 75.4 mg/dl) in relation to breaks phases (AUC LiSd: 514.0 ± 55.1, AUC MiSd: 531.7 ± 69.1 and AUC MiLd: 530.0 ± 45.5) (p≤0.05). No differences were observed when the 3 phases of breaks were compared between them (p> 0.05).

Conclusions: PST is related to higher blood glucose levels, while PST breaks, even with light intensity, seems to promote benefits in reducing blood glucose levels.

Keywords: sedentary behaviour, glycemic curve, older adults

144/2761

ASSESSMENT OF FOLATE INSUFFICIENCY IN WOMEN OF REPRODUCTIVE AGE AS THE BASIS OF NTD RISK ASSESSMENT IN LOW- AND MIDDLE-INCOME COUNTRIES: INTERDISCIPLINARY COMMITTEE GUIDANCE

[1]Bailey, Lynn; [2]Martinez, Homero; [3]Weakland, Aliki; [4]De-Regil, Luz Maria.

[1]PhD. Professor and Department Head. Foods and Nutrition Department. University of Georgia. USA.; [2]PhD. Senior Advisor. Micronutrient Forum. Canada.; [3]MPH MSW. Director. Core Engagement LLC. USA.; [4]PhD. Director of Research and Evaluation. Nutrition International. Canada.

Background and objectives: This folate status presentation represents one section of a more comprehensive report from an interdisciplinary technical consultation coordinated by the Micronutrient Forum and supported by the Bill & Melinda Gates Foundation encompassing issues related to prevention of folic acid responsive neural tube defects (NTDs) in low- and middle-income (LMI) populations. The objective is to present a description of how to define folate insufficiency as the basis of characterizing NTD risk by the application of the new WHO guideline in population groups of women of reproductive age (WRA) in LMI countries.

Methods: The evidence basis for the selection of red blood cell (RBC) folate concentration as the key folate status biomark-

er to define folate insufficiency and NTD risk within population groups will be critiqued. The issue of whether serum/plasma folate concentration may also be used to assess NTD risk will also be addressed. The importance of using the most appropriate analytical method to measure RBC folate concentration will be presented with a focus on the microbiological assay (MBA) which is considered the most reliable assay to use to assess RBC folate. The importance of using assay-adjusted cut-offs to define folate insufficiency and NTD risk will be presented. To utilize the WHO guideline to estimate NTD risk globally, the ideal scenario would be to have country-specific population-based RBC folate concentrations determined microbiologically and data harmonized to account for assay differences.

Results: Select examples of studies conducted in Guatemala and Belize will be highlighted to illustrate how the WHO guideline can be appropriately applied to assess NTD risk based on RBC folate concentration in the most vulnerable population groups of WRA.

Conclusions: In conclusion, folate status data will be used as a basis for the design, implementation and evaluation of sustainable folate interventions in vulnerable populations to reduce the prevalence of NTDs globally.

Keywords: Folate status neural tube defects

THE INVESTMENT CASE FOR FOLIC ACID FORTIFICATION TO REDUCE NTD RISK IN LOW- AND MIDDLE-INCOME COUNTRIES

[1]Hoddinott, John; [2]Martinez, Homero; [3]Weakland, Aliki; [4]De-Regil, Luz Maria.

[1]PhD. Babcock Professor of Nutrition and Economics. Department of Nutritional Sciences. Cornell University. USA.; [2]PhD. Senior Advisor. Micronutrient Forum. Canada.; [3]MPH MSW. Director. Core Engagement LLC. USA.; [4]PhD. Director of Research and Evaluation. Nutrition International. Canada.

Background and objectives: Folic acid fortification has proved to be effective in reducing mortality associated with neural tube defects (NTDs). However, when a government has limited resources on which there are many competing claims, it has to decide what intervention may save the most lives. An "investment case" requires information on the benefits of folic acid fortification, the costs associated with implementing fortification and a means of bringing the two together in such a way that it is possible to compare these against alternative interventions.

Methods: Costs associated with folic acid fortification can be grouped in: 1) "upfront" costs associated with the introduction of folic acid fortification; and 2) on-going or recurrent costs. We compare the benefits and costs of folic acid fortification using the cost of averting deaths or the costs of averted DALYs, over a period of 10 years.

Results: Using data from two African countries, we estimate that the cost per death averted by folic acid fortification varies be-

tween $957-319. In comparison, it is estimated that cost per death averted for the rotavirus vaccine is $3,015, and that the scale-up of insecticide treated bed nets and other malaria prevention activities in sub-Saharan Africa between 2000 and 2010 cost $2,770 per death averted. As for DALY, we estimate that the averted DALY per dollar spent on folic acid fortification is $14.90. This is lower than nearly all other forms of fortification and lower than two other widespread interventions aimed at averted infant and child mortality, i.e., insecticide treated bed nets or treatment for severe acute malnutrition.

Conclusions: Even under our most conservative assumption, mandatory folic acid fortification compares favorably against these other widely adopted life saving interventions, and the cost per averted DALY from mandatory folic acid fortification is low compared to other widely adopted life savings interventions.

Keywords: Folate fortification, neural tube defects, investment case

THE ASSESSMENT OF NUTRITIONAL STATUS OF CHILDREN BELOW FIVE YEARS IN HOUSEHOLDS WHICH PARTICIPATED IN FOOD AND LIVELI- HOOD SECURITY (FLS) PROJECT IN RAJSHAHI DIVISION – BANGLADESH

[1]Lukmanji, Zohra; [2]Mubarak, Mahfuza; [3]Das, Luther.

[1]Public Health Nutritionist/Clinical Dietitian. Independent Consultant/Advisor. Tanzania; [2]Assistant Professor. Dept. Of Public Health and Informatics. Jahangirnagar University. Savar. Bangladesh; [3]Director. The Abacus for applied information services. Dhaka. Bangladesh.

Background and objectives: Food and Livelihood Security (FLS) project aimed to improve food security of rural ultra-poor households (HH) in 3 districts of Rajshahi division, Bangladesh through the promotion of improved vegetable production, food preparation, health and nutrition status of 50,000 ultra-poor women headed HHs and 30,000 marginal farmers HHs. The objective of this study was to assess the nutrition status of the under-fives, their mothers/caretakers and women who participated in the project and determine how FLS interventions impacted their nutrition status and diet intake

Methods: No baseline information on the nutrition status of the target population was available, hence the study included non-beneficiary HHs with same socio economic characteristics as controls. Both target and control HH were surveyed simultaneously in the same randomly selected unions in 3 districts. Weights and heights of the under-fives and MUAC of mothers/care takers and women who participated in the project were measured. Information on child feeding and caring practices, morbidity and mortality, household food availability, dietary intake, income generating activities and hygienic practices was also recorded

Results: Wasting was more prevalent among the non-beneficiary children while stunting and underweight were higher among

the beneficiary under-fives. Under-fives in farmers HH were better off nutritionally than women's under-fives. Both morbidity (diarrhoea, cold, fever) and mortality were reported to be higher in non-beneficiary children compared to beneficiaries. Dietary intake evaluated by diet diversity scores (DDS) was higher in both beneficiary under-fives and HHs. Additionally; beneficiary children consumed more vegetable and meat/fish than non-beneficiary under-fives. Results: **Conclusions:** Participation of beneficiary HHs in agriculture and livelihood activities increased by almost 90%. The project was found to be effective for the improvement of dietary and nutritional status of beneficiary groups in Rajshahi. Future food security projects should include more nutrition expertise and nutrition specific/ relevant objective(s) and nutrition status baseline, midterm and end project indicators in the logical framework and with budgetary allocation for situation analysis, skilled personnel, training, survey tools and adequate training materials.

Keywords: Food security interventions, nutritional status, underfives

EVALUATING PRE-PREGNANCY DIETARY DIVER- SITY VS. DIETARY QUALITY SCORES AS PREDIC- TORS OF GESTATIONAL DIABETES AND HYPER- TENSIVE DISORDERS OF PREGNANCY

[1]Gicevic, Selma; [2]Gaskins, Audrey J.; [3]Fung, Teresa T; [4]Rosner, Bernard; [5]Tobias, Deirdre K.; [6]Isanaka, Sheila; [7]C. Willett, Walter.

[1]MSc. Doctoral Candidate. Department of Nutrition. Harvard T.H. Chan School of Public Health. USA.; [2]ScD. Research Associate. Department of Epidemiology. Harvard T.H. Chan School of Public Health. USA.; [3]ScD. Professor. Department of Nutrition. Simmons College. USA.; [4]PhD. Professor. Department of Biostatistics. Harvard T.H. Chan School of Public Health. USA.; [5]ScD. Instructor and Associate Epidemiologist. Harvard Medical School and Brigham and Women's Hospital Division of Preventive Medicine. USA.; [6]SD. Department of Global Health and Population. Harvard T.H. Chan School of Public Health. USA.; [7]MD DrPH. Departments of Nutrition and Epdemiology. Harvard T.H. Chan School of Public Health. USA.

Background and objectives: Dietary diversity scores (DDS) are considered as potential metrics for monitoring the implementation of the Sustainable Development Goals. However, if these scores are to be used as global measures of efforts to improve health outcomes, they must be rigorously tested. This study aims to evaluate the relation of two pre-pregnancy DDS, the Food Groups Index (FGI), and the Minimum Dietary Diversity for Women (MDD-W), and two pre-pregnancy dietary quality scores, the Alternate Healthy Eating Index (AHEI-2010) and the Prime Diet Quality Score (PDQS), with risks of gestational diabetes mellitus (GDM) and hypertensive disorders of pregnancy (HDPs).

Methods: The analysis included 21,334 (GDM) and 19,943 (HDPs) singleton live births reported from 15,232 (GDM) and 14,359 (HDPs) women in the Nurses' Health Study II cohort (1991-

2001), without previous chronic disease or GDM/HDPs. Data collected by a comprehensive food frequency questionnaire were used to derive the four scores. Multivariable log-binomial regression models with generalized estimating equations were used to calculate adjusted relative risks (aRR) and 95% confidence intervals (CIs).

Results: Incident cases of GDM (917) and HDPs (1,427) were reported. While the MDD-W and the FGI were unrelated to risk of GDM or HDPs, the AHEI-2010 and PDQS were related to significantly lower risk of GDM and marginally lower risk of HDP. The aRR's of GDM comparing the highest (Q5) vs. lowest (Q1) quintiles were 0.65 (95%CI:0.50, 0.80; p-trend <0.001) for the AHEI-2010, 0.69 (95%CI:0.56, 0.86; p-trend=0.002) for the PDQS, 0.99 (95%CI:0.80,1.23; p-trend=0.71) for MDD-W and 0.95 (95%CI:0.76,1.18; p-trend=0.76) for FGI. Similarly, the aRR's of HDPs were 0.85 (95%CI: 0.72, 1.01; p-trend=0.07) for AHEI-2010, 0.91 (95%CI:0.76,1.07; p-trend=0.05) for PDQS, 0.91 (95%CI:0.76,1.09, p-trend=0.93) for MDD-W, and 0.96 (95%CI:0.81,1.14; p-trend=0.91) for FGI.

Conclusions: Dietary diversity scores did not predict risk of GDM or HDPs, yet both dietary quality scores were associated with a substantially lower risk of GDM. The food-based Prime Diet Quality Score is a promising candidate for measuring a sustainable and healthy diet on a global scale and warrants further testing. Our research suggests that DDS should not be widely used as measures of dietary quality in their present form.

FOOD ENVIRONMENT CHARACTERIZATION OF A PUBLIC UNIVERSITY IN RIO DE JANEIRO

[1]Dias, Juliana Furtado; [2]Batista, Carolina de Araujo; [3]Pereira, Alessandra Pereira; [4]Leão, Leila Sicupira Carneiro de Souza; [4]de Aquino, Luana Azevedo; [4]Santos, Claudia Roberta Bocca; [5]Franco, Amanda da Silva.

[1]PhD. Professor. Departamento of Aplicated Nutrition. Nutrition School. Rio de Janeiro Federal State University. Brazil; [2]Graduation Student. Departamento of Fundamental Nutrition. Nutrition School. Rio de Janeiro Federal State University. Brazil; [3]Professor. UNIRIO. Rio de Janeiro. Brazil.; [4]PhD. Professor. Departamento of Nutrition and Public health. Nutrition School. Rio de Janeiro Federal State University. Brazil; [5]PhD. Professor. Nutrition Graduation. Veiga de Almeida University. Rio de Janeiro. Brazil.

Background and objectives: Food environment analysis helps to identify factors that can influence food behavior and is considered a promising strategy to promote healthy eating habits. Thus, the objective of this study was to describe the food environment of a public university in Rio de Janeiro, Brazil.

Methods: The data collection was performed during the second semester of 2016 in establishments located inside the university campuses, totalizing 1 snack bar and 4 establishments with mixed service (snack and lunch or dinner). The instrument used for the data collection was proposed and validated by Franco (2016) to analyze the university food environment. The study was approved by the Ethics Committee and with the consent of all establishments involved.

Results: In all establishments analyzed there was no nutritional information for the clients. Considering the disponibility of healthy foods only the fresh fruit was sold at all establishment, raw and cooked vegetables and veggies was offered by 80% and 60%, respectively, and 75% offered leguminous; a 100% of snack bars offered pastry and sandwiches. The products with the highest different types disponibility averages were candy or chewing gum (8±7.1), soft drinks (9±3.7), chocolates and chocolates bar (8 ± 7.1), crackers (8 ± 12.3) and cookies (7±9.1). Sandwiches, snacks and other products with low nutritional value, had lower average price than fruits or fruit salads; and sweetened drinks (like soda and natural guarana) also presented average price lower than fresh fruit juice.

Conclusions: The university's food environment seems to hamper access to healthy feeding during the period students use its environment, presenting several barriers to a healthy eating habits.

EVALUATION OF THE QUALITY OF LIFE OF HYPERTENSES IN AMBULATORIAL TREATMENT

[1]Dias, Marcia Regina Messaggi Gomes; [2]Damin, Samara; [2]Sousa, Viviane de; [3]Kopruszinski, Cíbele Pereira.

[1]PhD Nutricionist. Nutrition Department. Federal University of Paraná. Brazil; [2]Doctor. Evangelical College of Paraná. Brazil; [3]PhD Nutricionist. Nutrition of Department. Federal University of Paraná. Brazil.

Background and objectives: Hypertension is a clinical condition and is considered one of the most important modifiable risk factors for cardiovascular disease. The perception of the disease and its risks, the development of target organ damage, adverse effects of drug therapy and the difficulty faced in changing the lifestyle of this condition are significant determinants of life quality. Objective: To evaluate the life quality and how it is associated with socioeconomic profile.

Methods: Descriptive cross-sectional study of individuals in ambulatory treatment with systemic hypertension. The Minichal questionnaire was used to evaluate the life quality and the questionnaire of the Brazilian Institute of Geography and Statistics (BIGS) to assess the socioeconomic level.

Results: The sample consisted of 51 individuals (59% female). The mean age was 61.10±10.60 years, no statistical difference between the sexes; p=0.25. The mean time of diagnosis of systemic arterial hypertension was 11±8.84 years. The mean systolic blood pressure was 143±21.66 mmHg and the mean diastolic blood pressure was 88±12.44 mmHg. The mean arterial pressure was

106±14.69 mmHg. Of the total sample, 25 (49%) never smoked, 20 (39.2%) were smokers and 6 (11.8%) were still smokers. The mean time of smoking was 4.33 ± 12.84 years and the mean time that ex-smokers quit smoking was 6.95±11.56 years. Only 23 (45%) reported physical activitypracticing on a regular basis, and the average frequency in the week were 1±1.91 times. Regarding the Minichal questionnaire on life quality, the mean scores of the responses on the mental state was 6.8±4.99 (0-27), the average scores on the somatic manifestations were 7.2±4.3 (1-17), and the mean total score, summing up the state of mind with somatic manifestations, were 14±8.48 (3-42). Regarding the socioeconomic profile of the sample, according to the BIGS census questionnaire, 38 (74.5%) were classified as low-income senior, 5 (9.8%) low-income and lower 8 (15.7%) lower middle-income.

Conclusions: Women showed a worse life quality in relation to the somatic manifestations, compared to men. The lower the individual was classified by the BIGS survey, the worse was the life quality. Those who engage in physical activity had a better quality of life.

Keywords: Hypertension, ambulatory treatment, socioeconomic level, quality of life.

A NOVEL PROCESSED FOOD CLASSIFICATION SYSTEM APPLIED TO DISAGGREGATED FOOD CODES IN THE AUSTRALIAN FOOD NUTRIENT DATABASE 2011-13

[1]Machado, Priscila Pereira; [1]Steele, Euridice Martínez; [2]Monteiro, Carlos.

[1]PhD candidate. Nutritionist. School of Public Health. Center for Epidemiological Studies in Health and Nutrition. University of Sao Paulo. Brazil; [2]PhD. School of Public Health. Center for Epidemiological Studies in Health and Nutrition. University of Sao Paulo. Brazil.

Background and objectives: Evidence that the degree of food processing effectively addresses the quality of diets and their impact on all forms of malnutrition has been documented in several countries. Categorizing foods by the level of processing and by disaggregating both composite and single-ingredient food codes provide more accurate consumption data. The objectives of the study are to disaggregate composite food codes used in the Australian food composition database in order to provide a more precise estimate of intake at the individual level and categorize food components according to the level of food processing.

Methods: We identified composite food codes from the Australian Food Nutrient Database (AUSNUT) 2011-13 that were subject to disaggregation. For all those food items judged to be a handmade recipe, food recipes provided by AUSNUT were applied to disaggregate. We classified food items and/or the underlying ingredients into four groups according to NOVA, a new food classification system based on the extent and purpose of industrial food processing. Food item classification was accomplished by taking into account food descriptions in document provided

by AUSNUT, the source of food (e.g. homemade, fast food, takeaway) and the ingredient list of food items sold in Australia. The proportion of NOVA food groups by AUSNUT food group and underlying ingredients were calculated.

Results: A total of 3701 food codes (67% of the total) from the AUSNUT 2011-13 were subject to disaggregation. Less than 1% of the food codes that were supposed to be disaggregated was classified in the food code level. Across the food composition database, the overall proportion of unprocessed and minimally processed foods was 34%, culinary ingredients was 3%, processed foods was 12%, and ultra-processed products was 51%.

Conclusions: By incorporating disaggregated data combined with the application of the classification system based on the degree of food processing into AUSNUT food composition database, variations can be seen in the proportion of some food groups whose consumption used to be underestimated. This strategy will allow researchers to quantify properly the contribution of the food groups in order to assist in assessing the nutritional quality of the dietary intake of population.

Keywords: Food Processing; Classification; Disaggregation; Food composition database

RELATIONSHIP BETWEEN KNOWLEDGE, BELIEFS AND PRACTICES IN BREASTFEEDING OF NURSING MOTHERS AND THE HEALTH TEAM OF THE BARRIO ALTOS DE LA REJA, MORENO, PROVINCE OF BUENOS AIRES. ARGENTINA. 2014

Naumann, Sonia Ana.

MPH. Nutritionist. Research Centre on Food and Nutritional Problems. University of Buenos Aires. Argentina.

Background and objectives: This research consisted in identifying knowledges, beliefs and practices (KBP) in breastfeeding (BF) of mothers and local health team members of the Health Unit Nº 39, Barrio Altos de la Reja, Moreno, Province of Buenos Aires, Argentina and the relations between this KBP during 2014.

Methods: Qualitative approach favored by semi-structured interviews, participant observation, in situ photographs and notes. Convenience sample of 15 nursing mothers borned in the Province of Buenos Aires, BF or not, and 9 members of the local health team. Categories of analysis: knowledge, beliefs and practices.

Results: The majority of the nursing mothers was deprived of BF in the first hour of life. Mothers and health workers known official guidance on exclusive breastfeeding (EBF), but dominated the early introduction of foods/drinks. Both groups doubt about duration of BF and extend it for one year. The main reason for discontinuation of EBF is mothers perception of "my milk is not enough / not fed" . The local health team believes is due to lack

of containment of mothers in their environment. The main difficulty linked to the BF according mothers are complications with their breast care and their main preparations for enhanced BF is to modify their diet to produce more and better quality of milk. Knowledge of both groups about benefits of BF focus on nutritional and immunological properties, others are almost unknown to the mothers. Among the disadvantages of BF, some mothers raise their body image, cause leading to interrupt BF, while the health team imaginary supposed to belong this to upper-class levels. Some mothers expressed "shyness" about BF in public spaces. Some males breastfeed longer than women, while health personal ignored BF in terms of gender. BF training aimed at health team is negligible, circumscribing BF promotion activities to nursing mothers in the consulting room.

Conclusions: Tensions between KBP regarding BF between the two study groups, mainly in relation to the official recommendations of BF, maternal nutrition during lactation, female and BF aesthetics, gender and BF and the need to strength training BF and promotion in community and primary care health.

Keywords: Breastfeeding, health promotion, nutrition, childhood, weaning.

SODIUM CONSUMPTION PATTERNS ACCORDING TO SOCIODEMOGRAPHIC CHARACTERISTICS IN AN ECUADORIAN POPULATION: RESULTS FROM THE LATIN AMERICAN STUDY OF NUTRITION AND HEALTH (ELANS)

[1]Villar, Monica; [2]Cruz, María Cecilia; [3]Eguiguren, Lucia; [4]Yepez Garcia, Martha Cecilia.

[1]MSc. Nutritionist. Colegio Ciencias de la Salud. Salud Publica. Universidad San Francisco de Quito. Ecuador; [2]BSc. Nutritionist. Colegio Ciencias de la Salud. Salud Publica. Universidad San Francisco de Quito. Ecuador; [3]BSc. Colegio Ciencias de la Salud. Salud Publica. Universidad San Francisco de Quito. Ecuador; [4]MSc. Medical Technology. Ciencias de la Salud. Escuela de Medicina. Universidad San Francisco de Quito. Ecuador.

Background and objectives: The World Health Organization (WHO), states that one of the most important risk factors in the emergence of chronic non communicable diseases (NCDs), is the high consumption of sodium and salt in the diet. Due to this, the average of sodium intake in an Ecuadorian population was assessed according to sociodemographic characteristics.

Methods: Sample study compris 800 Ecuadorian participants between 15 and 65 years old, living in the urban area of different cities of the Coast and Sierra. This data was from LANS study (Latin American Study of Nutrition and Health). Two 24-hour recall surveys were performed according to the multi-step methodology on non-consecutive days, so it may be determined the relationship of usual sodium intake and total caloric intake per day. Sodium intake was analyzed according to the different sociodemographic

characteristics (sex, age, region of residence and socioeconomic level) by applying statistical tests T-student, one-way ANOVA and Post Hoc Bonferroni.

Results: The average sodium intake was 4901.9 mg per day in the entire sample. Men consume more sodium than women (5387.4 mg and 4423.7 mg, respectively, p= 0.00). There is no significant difference in average sodium intake between the Coast and Sierra of Ecuador, as well as the socioeconomic level. A positive correlation coefficient of 0.73 was found between the consumption of calories and sodium. The foods that contribute most to the diet are popcorn, bacon, pork rind, olives, cheeses, ham and different types of sausages, although not necessarily the most consumed.

Conclusions: The average sodium intake found exceeds the amount of sodium recommended by the World Health Organization (up to 2300 mg) by 113%. There is a positive correlation coefficient between the caloric and sodium intake. Foods that contribute the most sodium consumption in Ecuadorians´ diet (popcorn, bacon, pork rind) are not necessarily the most frequently consumed.

Keywords: Sodium, chronic non communicable diseases, consumption pattern, sociodemographic.

Conflict of Interest Disclosure: The ELANS is supported by a scientific grant from the Coca Cola Company and support from the Instituto Pensi / Hospital Infantil Sabara, International Life Science Institute of Argentina, Universidad de Costa Rica, Pontificia Universidad Católica de Chile,Pontificia Universidad Javeriana, Universidad Central de Venezuela (CENDES-UCV)/ Fundación Bengoa, Universidad San Francisco de Quito, and Instituto de Investigación Nutricional de Peru. EXECUTING A TECHNICAL CONSULTATION ON FOLATE STATUS IN WOMEN AND NEURAL TUBE DEFECTS RISK-REDUCTION TO PRIORITIZE INVESTMENTS AND ACCELERATE FEASIBLE AND EFFECTIVE INTERVENTIONS

[1]Martinez, Homero; [2]Weakland, Aliki; [3]Brown, Ken; [4]Bailey, Lynn; [5]Botto, Lorenzo; [6]De-Regil, Luz Maria.

(1) MD PhD. Senior Advisor. Micronutrient Forum. Canada.; (2) MPH MSW. Director. Core Engagement LLC. USA.; (3) MD. Senior Program Officer and Initiative Lead. Nutrition Global Development. Bill & Melinda Gates Foundation. USA.; (4) PhD. Professor and Department Head. Foods and Nutrition Department. University of Georgia. USA.; (5) MD. Professor of Pediatrics. University of Utah School of Medicine. USA.; (6) PhD. Director of Research and Evaluation. Nutrition International. Canada.

Background and objectives: Reducing the risk of neural tube defects (NTDs) represents a significant and feasible opportunity to decrease the toll of birth defects globally. A large fraction of NTDs are preventable through relatively simple nutritional interventions, based on improving folate status in the population. Yet, many challenges remain including lack of global data on folate sta-

tus and NTDs, implementing sustainable folic acid interventions at scale, and identifying better low-cost, field friendly methods and innovations to assess folate status, deliver interventions for NTD risk-reduction, and monitor outcomes. The objective is to present the development and execution of a technical consultation utilizing an accelerated and directed integrated process, to define the burden of folate inadequacy in women of reproductive age as a basis of assessing NTD risk, to characterize NTD prevalence, and to recommend feasible intervention approaches in low- and middle-income countries.

Methods: A multi- and inter-disciplinary committee was established to develop a roadmap that considered the magnitude of the problem, identified knowledge gaps in research and practice, identified feasible opportunities to implement and accelerate interventions, and reflected on the challenges of methodological approaches to risk-reduction. The committee was composed of global experts in nutrition, epidemiology, policy translation, public health program implementation, foalte biomarker assessment, economics, and private industry.

Results: An independent, knowledgeable and unbiased committee was formed and a roadmap for action in low- and middle-income countries was developed that includes key scientific and technical contributions to the fields of nutrition and birth defects risk-reduction.

Conclusions: A structured, integrated, multi-disciplinary approach to address long-standing gaps in folate assessment and NTD burden yielded long-considered advances in the fields of nutrition and birth defects risk-reduction. Further, the roadmap developed through the consultation is just one part of the necessary equation to amplify prevention globally, as it is imperative to engage collectively and directly with those working at national and sub national levels. This approach harmonized efforts to realize an untapped and significant opportunity to reduce the risk of NTDs through nutritional interventions.

Keywords: Folate, neural tube defects, development

EFFECTS OF ASTRAGALUS EXTRACT MIXTURE ON BONE GROWTH RATE IN STUNTING-INDUCED ANIMAL MODEL

[1]Kim, Hocheol; [2]Lee, Donghun; [3]Lee, Sung Hyun; [4]Kang, Yunhee.

[1]KMD PhD. Herbal Pharmacologist. Department of Herbal Pharmacology. Kyung Hee University College of Korean Medicine. Seoul. Korea; [2]KMD PhD. Herbal Pharmacologist. Department of Herbal Pharmacology. Kyung Hee University College of Korean Medicine. Seoul. Korea; [3]MSc. Korea Institute of Science and Technology for Eastern Medicine. NeuMed Inc.. Seoul. Korea; [4]PhD. Nutrition consultant. Center for Human Nutrition. Department of International Health. Johns Hopkins Bloomberg School of Public Health. Baltimore. Maryland. USA.

Background and objectives: Globally, more than one fourth of children under 5 years of age were stunted. Three quarters of total stunted children are from sub-Saharan Africa and South Asia,

where aflatoxin exposure is common through contaminated maize and groundnuts. Previous studies have demonstrated a correlation between aflatoxin-exposure and stunting. HT042 is a standardized functional food ingredient approved by Korean FDA with a claim "height growth of children". We evaluated efficacy of HT042 on bone growth rate in dietary aflatoxin-induced stunting animal model.

Methods: Newly weaned animals were given aflatoxin contained diets with or without HT042 supplementation from 21-42 day old. Tibial length, bone mineral content and bone microstructure were measured at baseline and endpoint by micro CT. Serum or hepatic gene and protein expressions of growth hormone signaling were determined using established methodologies.

Results: Aflatoxin-exposed animals exhibited stunted growth, liver pathology and suppression of gene expressions of growth hormone signaling. HT042 supplementation significantly reduced stunted bone growth, bone mineral content compared with a control group. HT042 also attenuated aflatoxin-induced suppression of growth hormone signaling.

Conclusions: HT042 protects normal bone growth and bone formation against the experimental stunting induced by dietary aflatoxin. The effects of HT042 may be attributable to its growth hormone stimulating properties. Based on these findings, it is tempting to speculate that HT042 may be a therapeutic candidate for stunted children with aflatoxin exposure.

Keywords: stunting, children, HT042, Astragalus extract mixture

OPTIMIZATION OF NUTRITIONAL MONITORING OF SCHOOLCHILDREN, JOIN ACTIONS FROM THE MINISTRIES OF EDUCATION AND HEALTH. JUJUY, ARGENTINA

[1]Barsimanto, Graciela Raquel; [2]Aramayo, Hugo; [3]Humacata, Vanesa; [4]Tabera, Celia; [5]Najar, Cristobal; [6]Burgos, Andrea; [7]Cabello, Manuela; [8]Carabajal, Ana Maria; [9]Velasquez, Rita.

[1]MSc. Nutritionist. APS Nutrition. Public Health Ministry. Jujuy. Argentina; [2]Certify Public Account. General Administration Department. Education Ministry. Jujuy. Argentina; [3]BSc. Informatic Sistems. Education Ministry. Jujuy. Argentina; [4]Nutririonist. School food.Education Ministry. Jujuy. Argentina; [5]Physical Education Teacher. Education Ministry. Jujuy. Argentina; [6]Nurse. School Food. Education Ministry. Jujuy. Argentina; [7]Bsc. Medicine. APS Director. Public Health Ministry. Jujuy. Argentina; [8]BSc. Medicine. Public Health Ministry. Jujuy. Argentina.

Background and objectives: Background: In the Province of Jujuy, north of Argentina, the ministries of education and health have taken on the responsibility of developing procedures for nutritional monitoring and follow-up with schoolchildren since 2011 using the WHO Reference 2007, and through conducting a census on paper with manual entry of data. In 2016, they added the anthropometric fields of the software WHO AnthroPlus to the Student Unique File (Legajo Único del Alumno, LUA) of the Student Management Computer System, to use twice yearly in student assessment.

Objective: Use WHO AnthroPlus to describe the nutritional status of schoolchildren. Promote, monitor, and evaluate interventions from an inter sectional approach

Methods: We used the WHO BMI/Age indicators, which provides differentiated standard deviations (SD): risk of being underweight (-1.9 SD, -1 SD), underweight (<-2 SD), Normal (-0,9 SD, 1 SD), overweight (>1 SD, 1,9 SD), obese (>2 SD). Measurements of weight and height are taken by physical education teachers, and these measurements are then loaded into the LUA system in nominalized form. These results are shared with the primary health care system (Atención Primaria de la Salud; APS) to facilitate any necessary interventions.

530 schools and a total of 120,000 children were projected to participate in this monitoring.

Results: In the first census in the year 2016, the monitoring system reached a total of 85473 students. Find that 48.6% of the students had a normal nutritional status, 5,2% presented a risk of being underweight, 1.4% were underweight, 24,3% were overweight and 20,5% were obese.

This allows knowing the prevalence of malnutrition in each region of the province

Conclusions: The incorporation of the WHO AnthroPlus software in the LUA system has allowed for the collection of timely indicators for an integral approach to the school-age population through the primary health care system (APS). It has also proved to be an adequate system for epidemiology nutritional monitoring in schools and in primary health care centers at the different geographic areas of Jujuy.

FOOD CONSUMPTION AND PHYSICAL ACTIVITY IN ADOLESCENT OBESE WOMEN WITH INSULIN RESISTANCE

[1]Bernui, Ivonne; [2]Pajuelo Ramírez, Jaime; [3]Miranda Cuadros, Marianella; [4]Sánchez González, José; [4]Arbañil Huamán, Hugo; [5]Cochachin Henostroza, Omaira; [5]Aquino Ramírez, Anthony; [5]Baca Quiñonez, Jean.

[1]MSc. Biologist. Instituto de Investigación Bioquímica y Nutrición. Universidad Nacional Mayor de San Marcos. Perú; [2]MSc. Medical Doctor. Instituto de Investigaciones Clínicas. Universidad Nacional Mayor de San Marcos. Lima. Perú; [3]MSc. Centro Nacional de Alimentación y Nutrición. Instituto Nacional de Salud. Lima. Perú; [4]Medical Doctor. Servicio de Endocrinología. Hospital Nacional Dos de Mayo. Lima. Perú; [5]Student. School of Nutrition. Universidad Nacional Mayor de San Marcos. Lima. Peru.

Background and objectives: The prevalence of obesity concerns for its close relationship with metabolic disorders and even

more when it occurs in adolescents. The objective was to determine the food consumption and physical activity of a group of obese adolescents with insulin resistance.

Methods: After an anthropometric census to 1,206 high school adolescents, it was detected that 25.1% (n = 303) were obese. With the obese adolescents who agreed to participate (n = 246), insulin resistance (IR) was determined using HOMA-I, with a cutoff value >=3.16, to define IR. We interviewed 59 adolescents with two questionnaires. One was a Food Frequency which included ten food groups: Whole dairy products, Integral cereals, Legumes, Fruits, Vegetables, Added Sugar, Fatty foods, Confectionery, Salt added and Fried foods. For every food group consumed suitably a point was assigned. Two groups were formed "Adequate Consumption" with >= 7 points, and "Inconsistent Consumption" <7 points. Regarding the instrument on physical activity, a validated instrument was used (Godard et al., 2008). According to this questionnaire, "active" participants should have >=5 and "Inactive" less than 5 points.

Results: Seventy nine percent (n=47) presented an "Inadequate Consumption" of food groups. The most prevalent was the Sugar Candy and Soft Drinks with 94.9% (n = 57). Among the foods most consumed in this group were candies / chewing gum, sweet cookies and potato chips with a frequency greater than 3-4 times/week in more than 20% of the respondents. The next group of foods with a high percentage of "Inadequate Consumption" was whole dairy products, 57.6%   (n=34). Fifty five percent (n=33) of the adolescents was in the 'Active' category. Finally, it was found that in the 'Active' group as well as in the 'Inactive' one, more than 70% of the participants had "Inadequate Consumption".

Conclusions: There is a high prevalence of inadequate food consumption, especially from the Sugar Candy and Soft Drinks group. Although more than half of the adolescents were considered as physically "Active" however 70% of them had inadequate food consumption.

Keywords: obesity, adolescents, physical activity,diet

SEDENTARY BEHAVIOR AND ITS ASSOCIATION WITH UNIVERSITY STUDENTS' NUTRITIONAL STATUS

[1]Vieira Liberato, Juliana; [2]De Alcântara, Solange Pires Leite; [2]Gobetti, Clara Affonso; [3]De Alcântara, Bruno Dos Santos; [4]de Aquino, Luana Azevedo.

[1]IC à BSc. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.; [2]BSc. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.; [3]MSc. Graduate Program in Collective Health. Fluminense Federal University. Brazil.; [4]PhD. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.

Background and objectives: Sedentary behavior is an important factor influencing students' weight. Therefore, the purpose

of this study was to evaluate the sedentary behavior and its association with the nutritional status of university students.

Methods: The present study consisted of a cross-sectional cut-out of the baseline of the "Longitudinal Study of Nutrition and Health in University Students (NUTSAU)", with students enrolled in the second period of UFRJ-Campus Macaé. The instrument used for data collection was a structured self-completion questionnaire. The anthropometric evaluation consisted in the measurementof body mass and height, and later the body mass index was estimated. Sedentary behavior was estimated based on responses to sitting time, time spent watching television and time spent using consumer electronics daily. It was considered sedentary behavior more than 6 hours per day sitting (Craig et al, 2003), more than two hours watching television or using electronics (Strasburger et., 2013). Statistical analysis was performed using the SPSS application version 19.0. The project was approved by the Research Ethics committee of UFRJ-Campus Macaé.

Results: The sample consisted of 147 university students, of whom 22.6% of the women and 26.2% of the men were overweight. Regarding the sitting time, in the use of electronics and watching TV, it was observed that 75%, 92.1% and 38.6% of the students, respectively, performed such activities above the recommended time. There was a higher time of excessive use of electronic devices among women (66.4%, p = 0.02), totaling 396.3 ± 322.2 min / week among non-overweight university students compared to 413.3 ± 318.5 min / week in college students with excess weight (p = 0.79).

Conclusions: There was a high prevalence of excessive time in sedentary behavioral activities, with a greater association of the use of electronic devices among the female sex.

SOCIODEMOGRAPHIC AND NUTRITIONAL RISK FACTORS ASSOCIATED WITH MALNUTRITION DUE TO EXCESS AND DEFICIENCY IN CHILDREN AGED 3 TO 9 YEARS IN RURAL COMMUNITIES OF GUATEMALA

[1]López-Donado, Lorena; [2]de Leon, Mercedes; [2]Quiñonez, Esthefany; [2]Ruiz, Carolina; [2]Sabido, Juan Carlos; [2]Suazo, Pavelka; [2]Galicia, Cristian.

[1]MSc Nutritionist. School of Nutrition. Faculty of Medicine and Health Sciences. Mariano Galvez University. Guatemala; [2]BSc physician. Faculty of Medicine. Mariano Galvez University. Guatemala.

Background and objectives: In Guatemala, 49% of children have chronic malnutrition. A state of malnutrition, both in excess and deficiency, is associated with several health problems. Low weight can affect proper growth and development and obesity during childhood is related to chronic diseases in the adult stage. The objective was to identify children with malnutrition as well as their associated risk factors.

Methods: A descriptive cross-sectional study was carried out in six rural communities of Guatemala. The study included 538 children of both genders three to nine years and 1,060 parents. The instrument included sociodemographic, anthropometric (BMI/age), dietary and environmental aspects. The analysis used regression and multivariate models.

Results: 49% of children in the study had some type of malnutrition due to excess or deficiency. In children under five, 8% presented mild undernutrition, 2% moderate undernutrition, 76% normal nutritional status, 9% overweight and 5% obesity. In children 5 to 9 years old, 1% showed underweight, 84% normal nutritional status, 13% overweight and 2% obesity. An increased risk for chronic malnutrition was found in children under 5 (OR 2.35), male (OR 1.40), children of illiterate mothers (OR 1.41), children with extended family (OR 1.93), and children with hemoglobin levels lower than 11 g/dl (OR 2.93). The risk for acute malnutrition and anemia increases with the number of children in the family (OR 1.50 and 20.56 for each additional child respectively). Western children under five, male, of families with two children had a 19.29 times higher risk of acute malnutrition than children from the East. Two percent of the children showed coexistence of malnutrition, stunting along with overweight or obesity. The dietary pattern identified was low in protein and fiber and high in sugars, salt and fat.

Conclusions: The study identified a higher prevalence of malnutrition due to excess than to deficiency in the group of children from rural communities in Guatemala. The study identified risk factors for malnutrition due to deficiency such as being a child under five, male, child of an illiterate mother, be part of an extended family, have two or more siblings, well water use and ground floor.

EATING HABITS OF BREAKFAST AND LUNCH IN MEXICAN CHILDREN

[1]Chávez Palencia, Clío; [2]Arellano Gómez, Laura.

[1]PhD. Nutritionist. Department of Population Health Sciences. University of Guadalajara. Mexico.; [2]PhD. Nutritionist. Department of Health, Psychology and Community. Jesuit University of Guadalajara. Mexico.

Background and objectives: Children's obesity is a global nutritional issue with an increasing prevalence. In 2012, the prevalence of overweight and obesity in Mexico was 34.4% in school-aged children. There is evidence that processed food and sweetened beverages are main contributors to obesity epidemic in children. The objective to this study was to describe eating habits of breakfast and lunch in Mexican children.

Methods: Descriptive observational study. The data were obtained from a current participatory intervention study in 330 school-aged children at six public schools from Acatlán de Juárez, Jalisco, Mexico. These are descriptive baseline results were obtained by an interview about breakfast eating habits and observation of food consumption in lunch. We analyzed food and beverages available at schools and surroundings. Food intake at lunch was observed and analyzed with National Health and Nutrition Survey 2012 database.

Results: More than half of the children did not eat breakfast before school (54.4%). 55% of the children brought lunch from home, the rest bought in school. The main reason because they didn't brought it was because the parents did not have time to prepare lunch. The person who decides what to take with snacks in all the subjects who do it is the mother or the father (62.6%), followed by the same child (30.7%), grandparents (5%) and others %). Of the schoolchildren who carry home snacks in total, only 21.1% carry between 0-3 times a week fruit and 7.8% vegetables. The percentage of children who had an adequate energy intake at lunch was only 5.2%. On average, lunch provided 314.4 kcal (±246.6 SD), 9.7 g (±9.7 SD) of protein, 43.8 g (±35 SD) of carbohydrates ad 11.7 g (±12.7 SD) of lipids. Sugar provided more than recommended daily (20.9 g). The percentages of daily recommendation were 10.3 for calcium, 21.9 for iron, 15 for zinc, 14.6 for vitamin A, 76.7 for vitamin C. Percentage of school children who were higher than the sodium recommendation for lunch was 57.6.

Conclusions: Eating habits of breakfast and lunch in Mexican children found to be inadequate. Advice is required on the sale and preparations of snacks according to the recommendations.

DETERMINANTS OF FOOD CHOICES AND ITS ASSOCIATION WITH UNIVERSITY STUDENTS' NUTRITIONAL STATUS

[1]De Alcântara, Solange Pires Leite; [1] Gobetti, Clara Affonso; [1]Vieira Liberato, Juliana; [2]De Assis, Bruno Dos Santos; [3]de Aquino, Luana Azevedo.

[1]BSc. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.; [2]MSc. Graduate Program in Collective Health. Fluminense Federal University. Brazil.; [3]PhD. Department of Public Health Nutrition. Federal University of Rio de Janeiro State. Brazil.

Background and objectives: Food choices are one of the most important factor influencing students' weight. Therefore, the purpose of this study was to evaluate the context of determinants of food choices and its association with the nutritional status of university students.

Methods: Cross-sectional analysis of data derived from the baseline of the "Longitudinal Study of Nutrition and Health in University Students (NUTSAU)", conducted in second-semester students of Rio de Janeiro Federal University–Macaé Campus. The instrument used for data collection was a structured self-completion questionnaire. The anthropometric evaluation consisted of body mass and height measurements, and thus body mass index was calculated. The determinant choice pattern was estimated based on nine questions with three response options.Statistical analysis was performed using the SPSS program, version 19.0. The project was approved by the Research Ethics Committee of UFRJ-Macaé Campus.

Results: The sample consisted of 62 university students. In relation to BMI, 21% overweight. It was observed that the motivation for food choices in relation to the natural content (n = 50), 60% of the students indicated natural ingredients, of which 73.3% were classified as adequate, 26% indicated that they did not contain artificial ingredients, of these 92.3% classified as adequate and 14% without additives, 57.1% with excess (p = 0.055). Regarding ethics (n = 48), 72.9% of students preferred foods with packaging that did not harm the environment, of which 80% were classified as adequate (p = 0.047). W eight control (n = 50), 50% indicated foods that are low in fat, 84% rated as adequate, 40% assist in weight control, 70% as appropriate, 10% foods with low calories, 60% in excess P = 0.107). Considering the price (n = 53), it was observed that 60.4% indicated a fair price, 22.6% cheap and 17% not expensive (p = 0.294).

Conclusions: The present study showed that the determinants of "natural content" and "ethics" may be a protective factor for overweight in university students.

FACTORS ASSOCIATED WITH ENERGY ADEQUACY IN PERUVIAN ADOLESCENTS AND ADULTS: RESULTS FROM THE ELANS STUDY

[1]Pareja, Rossina Pareja; [2]Liria Domínguez, María Reyna.

[1]MSc. Nutritionist. Instituto de Investigación Nutricional. Peru; [2]PhD Nutritionist. Instituto de Investigacion nutricional. Peru.

Background and objectives: The adequacy of energy intake is associated with nutritional requirements and therefore nutritional status. The aim of this study is to determine the factors associated to energy adequacy in Peruvian adolescents and adults.

Methods: Data were obtained from the Latin American Health and Nutrition Study of Peru (ELANS-Peru), a multicenter study conducted in urban areas of 8 Latin American countries. Two 24 hour dietary recall were conducted in 1113 Peruvians (15 to 65 years old) and processed using the Nutritional Data System for Research (NDS-R) software. Multiple Source Method was applied to estimate the usual intake (kcal). For energy adequacy (EA), basal energy expenditure-BEE was calculated according to age, sex and physical activity level-PAL proposed by Gerrior et al (2006), using the long IPAQ. A multiple regression analysis was conducted to estimate the associated factors at 95% confidence level.

Results: Associated factors with EA were: (i) by age: adolescents had higher percentage of energy adequacy than the 20 to 49 years old population (106% vs 99% p=0.006), (ii) by sex: women showed greater EA than men (104% vs 94%, p<0.000), (iii) by PAL:

as the level of physical activity (PA) decreases, EA increases (active-very active 82%, low active 94%, sedentary: 106%, p<0.000 between each PA category, (iv) by region, the adequacy found was as follow: Lima city and Callao 101%, Coast 97%, Mountain 100% and Forrest 108%, where the Forrest had significantly higher adequacy than the others (p=0.015), (v) by socioeconomic level: an inverse association was found between socioeconomic level and EA (low 103%, middle 100% and high 95%), significant differences were found between low vs high level (p<0.000) and middle vs high (p=0.021), (vi) by BMI: people with higher BMI had lower EA (normal 127%, overweight 107%, obese: 95%, p<0.000).

Conclusions: The inverse association found between BMI and EA could be due to an overestimation of energy requirements and/or underreporting of overweight and obese people.

EA is higher in young boys and girls, in woman, in poor and in sedentary people. Developing strategies to adjust intake to recommendations should take into account the associated variables.

COOKING SKILLS INDEX - BRAZIL: DEVELOPMENT AND RELIABILITY ASSESSMENT

(1)Adriano Martins, Carla; (2)Baraldi, Larissa; (3)Scagliusi, Fernanda; (4)Slater Villar, Betzabeth; (5)Monteiro, Carlos.

(1)PhD candidate. Nutritionist. School of Public Health. Center for Epidemiological Studies in Health and Nutrition. University of Sao Paulo. Brazil; (2)PhD. Nutritionist. Center for Epidemiological Studies in Health and Nutrition (NUPENS). Department of Nutrition, School of Public Health, University of Sao Paulo. Brazil; (3)Professor. Nutritionist. Center for Epidemiological Studies in Health and Nutrition (NUPENS). Department of Nutrition, School of Public Health, University of Sao Paulo. Brazil; (4)Professor. Departament of Nutrition. School of Public Health. Center for Epidemiological Studies in Health and Nutrition. University of Sao Paulo. Brazil; (5)Professor. Center for Epidemiological Studies in Health and Nutrition (NUPENS). Department of Nutrition, School of Public Health, University of Sao Paulo. Brazil.

Background and objectives: Despite the importance of the cooking skills for healthy eating, this subject has hardly been explored scientifically in Brazil. The lack of an instrument for measure those skills and adapted to the Brazilian reality may be one of the reasons for the scarcity of these studies. This work describes the development and the reliability assessment of an index to evaluate cooking skills in Brazil.

Methods: The Cooking Skills Index - Brazil (CSI-Brazil) is a 0-100 index specially designed for this research, which was based on the Brazilian's Dietary Guidelines (2014), and results from the application of ten questions about the confidence regarding cooking skills considered relevant in Brazil. The reliability assessment was conducted with the repeated application (test-retest) of the questions to 51 parents of school-age children residing in São Paulo, SP, Brazil. Internal consistency was assessed by the Cronbach's alpha. Reproducibility was assessed by the quadratic weight kappa (95% CI) and the prevalence and bias adjusted kappa (PABAK).

Results: The participants (n=51) were mostly mothers (92.2%), aged between 30 and 39 years (64.7%), white (67.4%), married (84.3%), employed (80.4%) and with complete secondary education (44%). According to the Cooking Skills Index – Brazil, these participants reached similar average points on test-retest interviews (71.3 points -range 46.7-93.3; 71.8 points - range 50-96.7, respectively). The Cronbach's alpha of the instrument (0.75) indicated good internal consistency. The weighted quadratic kappa for the total of the items indicated moderate instrument reproducibility (0.55), while the PABAK showed almost perfect reproducibility (0.89).

Conclusions: As advantages, the developed instrument is short and simple, has easy, fast and standardized application, and synthesizes skills in a scale from zero to 100, which facilitates their interpretation. In this first evaluation, the CSI-Brazil showed good internal consistency (Cronbach's alpha> 0.70) and acceptable reproducibility (weighted kappa 0.55; adjusted kappa 0.89), recommending its use in studies to evaluate cooking skills in Brazil.

Background and objectives: Aging determines several changes in body composition, and is associated with increased fat

mass and changes in its distribution pattern. All changes in body composition have importance in the functionality of the elderly, as they culminate in a reduction of muscle with the increase of total body fat, making the elderly more susceptible to a limitation of mobility. The purposes of this study were: To compare the intramuscular fat infiltration in frail and non-frail elderly and to verify its association with muscle mass and body mass index.

Methods: Cross-sectional exploratory study. A total of 40 elderly people (10 non-frail men and 10 non-frail women, 10 frail men and 10 frail women) selected at the Geriatrics Outpatient Clinic of the Hospital das Clínicas de Ribeirão Preto. Body weight and height were measured and body mass index (BMI) calculated. Thigh muscle volume (MV) and intramuscular fat infiltration (IMAT) were assessed by nuclear magnetic resonance.

Results: The mean BMI, IMAT and MV of the groups were: non-frail women: 28.8±5.5kg.m-²; 6,84±2,4 % and 150,0±19,2cm3; Frail women: 31.75 ± 5.8 kg.m-²; 11.16±3.5% and 130.8±28.6cm3; Non-frail men: 26.8±5.1 kg.m-²; 5.75±1.77% and 223.7±15.8 cm3; Frail men: 24.3±5.3kg.m-², 7.55±2.3% and 237.2±26.8 cm3. In the frail elderly group IMAT had a moderate positive association with BMI (r=0.57, p<0.05). In the non-frail elderly group, IMAT presented a strong negative association with muscle volume (r= -0.62, p<0.05).

Conclusions: Increase in total body fat, as assessed by the BMI, was associated with increased fat infiltration in muscle, which seems to influence negatively muscle volume.

Keywords: intramuscular fat infiltration, body composition, aging

PROVISION OF LIPID-BASED NUTRIENT SUPPLEMENTS AND INFANT AND YOUNG CHILD FEEDING PRACTICES IN HUÁNUCO, PERU

[1]Matias, Susana; [2]Vargas-Vasquez, Alejandro.

[1]PhD. Epidemiologist. University of California. Davis. USA; [2]MS. Nutritionist. Fundación Acción Contra el Hambre. Perú.

Background and objectives: The use of small-quantity lipid-based nutrient supplement (SQ-LNS), a food-based home fortification product, may be an effective strategy to prevent undernutrition, however there are concerns about the possibility of affecting infant and young children feeding (IYCF) practices.

We aimed to examine the effects of providing SQ-LNS to children from 6 to 12 months on their IYCF practices.

Methods: In a two-arm randomized effectiveness trial conducted in Huánuco (Peru), children were enrolled at 6 months of age (n=422) and received either SQ-LNS or multiple micronutrient powders (MNP) from 6-12 months. Supplements were distributed during their monthly child well-being appointments at Ministry of Health (MOH)-run health centers. Baseline information included infant, maternal and sociodemographic data. In addition of the primary (growth and anemia) and secondary (child development) study outcomes, information on breastfeeding, dietary diversity and meal frequency during the previous 24-h were collected at 12

months of age. The proportions of children meeting the minimum dietary diversity (MDD), minimum meal frequency (MMF) and minimum acceptable diet (MAD) were calculated.

Results: At 12 months, the proportion of children who were breastfed (97.5% in the SQ-LNS vs. 95.0% in the MNP group, p=0.238), received food from a 4 or more food groups (93.6% in the SQ-LNS vs. 94.9% in the MNP group, p=0.590), received solid, semi-solid, or soft foods the minimum number of times or more (86.8% in the SQ-LNS vs. 91.9% in the MNP group, p=0.118), received a MAD (87.0% in the SQ-LNS vs. 91.2% in the MNP group, p=0.149) did not differed by group. When season was taken into account (which differed between groups at baseline), provision of SQ-LNS was associated with higher odds of meeting the MMF (Odds Ratio [OR] =2.7, 95% CI: 1.3-5.9) and MAD (OR=2.7, 95% CI: 1.2-5.8) indicators. Further adjustment for food insecurity, maternal education and child's age did not further change these results.

Conclusions: Provision of SQ-LNS to infants receiving regular preventive care services did not reduce breastfeeding rates, or the proportion of them meting the MDD, MMF or MAD indicators, while it may positively affect meal frequency and acceptable diet in this population.

Keywords: lipid-based nutrient supplements, breastfeeding, dietary diversity, minimum meal frequency, minimum acceptable diet

International Institute of Nutritional Sciences and Applied Food Safety Studies. School of Sport and Wellbeing. University of Central Lancashire. Preston. UK.

Background and objectives: Type 2 diabetes mellitus (T2DM) is one of the leading chronic diseases worldwide. Zinc

plays an important role in glucose metabolism, joining in the synthesis, storage, secretion and action of insulin. A large number of studies have compared serum/plasma levels of zinc in subjects with T2DM vs. nondiabetic subjects, but their results are inconclusive. This systematic review and meta-analysis aimed to compare serum/plasma levels of zinc in type 2 diabetic subjects without complications vs. healthy subjects.

Methods: This study has been registered in Prospero (2015: CRD42015020178). A robust search developed in the EURRECA Network was performed at Embase, Pubmed/Medline, and The Cochrane Library until March 16, 2016. Studies were selected if a) they had an observational design, b) were performed on subjects >18 years, c) had data on the mean and standard deviation of serum/plasma levels of zinc in both type 2 diabetic subjects without complications and nondiabetic subjects. Animal/lab studies, studies with diabetic participants other than T2DM, and study designs other than cross-sectional, case-control and prospective cohort studies were excluded. Potentially relevant articles for the systematic review and meta-analysis were selected for full exploration. Data are expressed as mean differences (MD) with 95% CIs, using the generic inverse-variance random-effects model. Heterogeneity was assessed by the Cochran Q-statistic and quantified by the I2 statistic (significance P<0.100). Publication bias was investigated by visual inspection of funnel plots and quantitatively assessed using Egger's and Begg's tests. All analyzes were performed using STATA 12.

Results: The search strategy initially yielded 12,044 publications, of which 29 were initially selected. Finally, 19 studies were included in the final meta-analysis after excluding poor quality studies according the STROBE checklist. Pooled analysis showed that MD for serum/plasma levels of zinc was -11.82mg/dL (95% CI: -18.86, -4.78). There was no evidence of publication bias (P = 0.723), but heterogeneity was high (I2 = 97.7%, P <0.001).

Conclusions: In this systematic review and meta-analysis we observed lower serum/plasma levels of zinc in subjects with T2DM than in healthy subjects. However, given the high heterogeneity, further studies would be necessary to confirm this result.

Keywords: Zinc, type 2 diabetes mellitus, systematic review and meta-analysis,

READING HABITS OF FOOD LABELS BY PROFESSORS OF A PRIVATE UNIVERSITY IN SÃO PAULO-BRAZIL

[1]*Kato Takano, Deise;* [2]*Baldan Pineda, Paula Henrique;* [3]*Lucca, Alessandra.*

[1]BSc. Nutritionist. Health Sciences Institute. Universidade Paulista. Brazil.; [2]MSc. Biologist. Health Sciences Institute. Universidade Paulista. Brazil.; [3]PhD. Nutritionist. Health Sciences Institute. Universidade Paulista. Brazil.

Background and objectives: Food labels allow for consumers choosing food products according to their characteristics, es-
pecially those one regarding the nutrition facts label (NFL). However, the comprehension of the food labels remains inadequate for most of consumers. In this context, the aim of this study was to report the reading habits of food labels and NFL by professors of a private university in São Paulo-Brazil.

Methods: A descriptive study was performed through a cross-sectional approach. A structured questionnaire with 29 questions was applied addressing socio-demographic features and food labels-related variables, such as, reading habits and reading motivations. The nutritional characteristics most observed in the NFL were identified as well as its possible influence in the purchase intention. A group of 38 professors from a private University in São Paulo-Brazil, from both gender, was randomly interviewed. The exclusion criterion was professors graduated in Nutrition.

Results: The mean age of the interviewed was 43.0 years (±10.9) and the average household income was greater than 10 minimum wages (68.4%). Regarding the food label, the expiration date was the item most observed (27.2%). Most of interviewed (70.6%) reported reading the NFL frequently. The main reason for using NFL was the consumer's concern for a healthy diet (21.2%). The other reasons were the fat, cholesterol and sodium content. The information most and less read were quilocalories content and daily value percentage, respectively. About 92% of the interviewed reported NFL content influence in their purchase intention.

Conclusions: It was observed that most of the interviewed was concerned about NFL content to keep a healthy diet, which influence their purchase intention.

Keywords: food label; nutrition facts label; purchase intention.

READING HABITS OF FOOD LABELS BY STUDENTS OF A PRIVATE UNIVERSITY IN SÃO PAULO-BRAZIL

[1]*Oliveira Sampaio Novaes, Karina;* [2]*Baldan Pineda, Paula Henrique;* [3]*Lucca, Alessandra.*

[1]BSc. Nutritionist. Health Sciences Institute. Universidade Paulista. Brazil.; [2]MSc. Biologist. Health Sciences Institute. Universidade Paulista. Brazil.; [3]PhD. Nutritionist. Health Sciences Institute. Universidade Paulista. Brazil.

Background and objectives: Food labels allow for consumers choosing food products according to their characteristics, especially those one regarding the nutrition facts label (NFL). However, the comprehension of the food labels remains inadequate for most of consumers. In this context, the aim of this study was to report the reading habits of food labels and NFL by students of a private university in São Paulo-Brazil.

Methods: A descriptive study was performed through a cross-sectional approach. A structured questionnaire with 29 questions was applied addressing socio-demographic features and food labels-related variables, such as, reading habits and reading motivations. The nutritional characteristics most observed in the NFL were identified as well as its possible influence in the pur-

chase intention. A group of 53 students from a private University in São Paulo-Brazil, from both gender, was randomly interviewed. The exclusion criterion was students attending in Nutrition graduation course.

Results: The mean age of the interviewed was 21.93 years (±5.72) and the average household income was between 2 and 5 minimum wages (52.8%). Regarding the food label, the expiration date was the item most observed (42.5%). Minority of interviewed (28.3%) reported reading the NFL frequently. The main reason for using NFL was the consumer's concern for a healthy diet (33.8%). The other reason was the non-understanding of the food label (23.6%). The most and less familiar terms were quilocalories (19.2%) and daily value percentage (80%), respectively.

Conclusions: The minority of the interviewed was concerned about NFL content, mainly due to the non-understanding of the specific terms.

Keywords: food label; nutrition facts label; healthy diet.

INTERNET BASED PRECISE INDIVIDUAL DIETARY INTERVENTION STRATEGY, A PILOT SCHEME FOR IODINE

Zhang, Wanqi; Cui, Tingkai.

Department of Nutrition and Food Hygiene. School of Public Health. Tianjin Medical University. Tianjin. China.

Background and objectives: Though the Universal Salt Iodization (USI) eliminated Iodine Deficiency Disorders in China, a number of people still remain iodine deficient or excessive. Single level of table salt iodization does not fit everyone as iodine content in diets and the environment varies dramatically, and dietary habits differ greatly among populations. Precise individual dietary intervention is essential to change this situation. Individual iodine status assessment is the prerequisite for iodine intervention but so far there is no acceptable biomarkers to reflect it. Meanwhile, individual dietary guidance requires food consumption assessment. Food Frequency Questionnaire (FFQ) is a good tool for individual nutrients intake calculation, but respondents need to be guided by professions when filling the paper-based questionnaire, and calculation and interpretation of the results is also nutritional specialists dependent, which precludes large-scale utilization.

Methods: To build up an internet-based iodine status evaluation and intervention system, the following work must be completed. Local optimized iodine-specific food frequency questionnaire (I-FFQ) is revised. Iodine content data of local food and drinking water is determined. An internet-based software is developed. By transforming the paper based I-FFQ into an Internet-based App that calculates precise iodine intake with a food composition database, an accurate, fast, free and convenient self-evaluation tool is made available to the public as a simple individual guidance to choose from multiple levels of iodization salt.

Results: To achieve an optimal iodine intake, a tailored diet guidance is constructed from user's physiological data and diet

trend as the feedback result, along with a table salt option suggestion. By prioritizing food with popularity and iodine concentration using data analyzed from thousands of I-FFQ surveys, we improved App usability.

Conclusions: Revising USI with the combined strategy of our App and multi-level salt iodization, optimal iodine intake can be easily achieved. On the basis of the above plan, other nutrients can be added so that the system will be applicable to all diet nutrients.

Keywords: iodine; internet; USI; individual; intervention

ASSESSMENT OF SODIUM INTAKE IN SAMPLE OF MOROCCAN CHILDREN USING 24 H URINARY EXCRETIONS

[1]Saeid, Naima; [2]Elmzibri, Mohamed; [1]Qandoussi, Latifa; [3]Elberri, Hicham; [1]Raji, Fatiha; [1]Baddou, Issad; [2]Elkari, Khalid; [4]Aguenaou, Hassan.

[1]PhD. Joint Research Unit in Nutrition and Food. URAC 39 (CNESTEN-Ibn Tofaïl University). Regional Designated Center of Nutrition (AFRA/IAEA). Morocco; [2]Dr. Joint Research Unit in Nutrition and Food. URAC 39 (CNESTEN-Ibn Tofaïl University). Regional Designated Center of Nutrition (AFRA/IAEA). Morocco; [3]Dr. Epidemiology & Control Diseases Directorate Ministère de la Santé / Ministry Of Health. Morocco; [4]Pr. Joint Research Unit in Nutrition and Food. URAC 39 (CNESTEN-Ibn Tofaïl University). Regional Designated Center of Nutrition (AFRA/IAEA). Morocco.

Background and objectives: Background: Worldwide, non-communicable diseases (NCDs) are the leading cause of mortality and morbidity accounting globally for 60% of all deaths and 43% of disease burden globally. Nowadays, it is widely accepted that an excessive intake of salt is associated with a broad range of NCDs, such as hypertension and cardiovascular diseases. The World Health Organization (WHO) recommendation outlines the importance of prioritizing sodium intake reduction, as a main approach to reduce blood pressure and to decrease the risk of CVDs and strokes. WHO recommends for adults, the consumption of less than 2 g of sodium / day (5g of salt / day). For children, the reduction of sodium intake prevents and decrease risk of hypertension during childhood. In fact, 33% of Moroccans suffer from hypertension, and 13% are obese. Aims: The present study was planned to assess the status of sodium in a Moroccan children living in Rabat region. This study takes place as part of the national action plan for the fight against non- communicable diseases (NCD) of 2014-2016.

Methods: The study was conducted on 131 children aged 6-18 years. Sodium excretion was measured by 24-h urinary collection by Inductively Coupled Plasma Mass Spectrometry and the creatinine excretion was used to validate completeness of urine collections.

Results: The average of urinary sodium was 2234 ± 824.15 mg/day (equivalent to 5.7g/d of salt). In 94% cases, the sodium intake is higher than the recommended adequate intake, 40% of children have a sodium status exceeds the upper limit, as recommended.

Conclusions: The dietary sodium intake of children was Higher compared to the WHO recommended value. Thus, there's need to elaborate strategies at national levels to reduce salt intake and limit the associated diseases.

Keywords: Salt intake, 24h urine sodium excretion, ICP-AES, children, Rabat.

EVALUATION OF IRON STATUS IN CHINESE POPULATION IN POVERTY RURAL AREAS

[1]*Wang, Lijuan;* [2]*Huang, Jian;* [3]*Li, Hong;* [4]*Shao, Bing;* [2]*Piao, Jianhua;* [5]*Yang, Xiaoguang;* [5]*Huo, Junsheng.*

[1]PhD. Nutritionist. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China; [2]BD. Nutritionist. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China.; [3]BD. Nutritionist. Beijing Center for Disease Control and Prevention. China.; [4]PhD. Nutritionist. Beijing Center for Disease Control and Prevention. China.; [5]PhD. Nutritionist. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China.

Background and objectives: To assess the iron status among populations by age and gender in poverty rural areas in China.

Methods: Sampling of participants was based on a large population sampling frame for 2010-2012 China National Nutrition and Health Survey by stratified multistage cluster sampling method. Serum ferritin (SF), serum soluble transferrin receptor (sTfR) and high sensitive C-reactive protein (hsCRP) were measured by the immunoturbidimetric assay. Body iron (BI) was calculated from sTfR and SF concentrations. Subjects with indication of inflammation (hsCRP>5 mg/L) were excluded from the analyses. A total of 4059 participants including 1983 males and 2076 nonpregnant females($\geq$6 years old)were involved.

Results: The average concentrations of SF, sTfR and BI for the whole population in poverty rural area were 103.1 ng/mL, 3.33 mg/L and 9.18$\pm$4.19 mg/kg, respectively. For males, the corresponding values were 140.0 ng/mL, 3.19 mg/L and 10.42$\pm$3.70 mg/kg, and for females, they were 77.0 ng/mL, 3.46 mg/L and 7.99$\pm$4.28 mg/kg. The difference of SF, sTfR and BI among different age and gender groups were statistically significant. Except 6-11-y subgroup, the lg(SF) was positively correlated with BI and Hb, and the lg(sTfR) was negatively correlated with lg(SF), BI and Hb (p<0.01). Depending on the iron status indicator applied, the prevalence of ID ranged from 1.2% to 7.5% among males and 5.0% to 19.0% among nonpregnant females. Comparison of the prevalence of ID by different iron indicators and cutoffs, the prevalence of defined ID by sTfR was the highest and the lowest by BI. In addition, the prevalence of ID for male is higher than for female, and for 18-44-y female is the highest.

Conclusions: The observed iron status of Chinese populations in poverty rural areas suggested females aged 12-17-y and 18-44-y

suffered ID at high risk. Male were at low risk for ID. It supports the program planning for iron nutrition promotion on females.

GOVERNANCE OF WATER, SANITATION AND HYGIENE (WASH) IN SUB-SAHARAN AFRICA AND ASSOCIATIONS WITH NUTRITIONAL STATUS IN CHILDREN UNDER FIVE YEARS OF AGE: A SYSTEMATIC REVIEW

[1]*Momberg, Douglas;* [2]*Ngandu, Christian;* [3]*May, Julian;* [4]*Norris, Shane;* [5]*Said-Mohamed, Rihlat.*

[1]PhD Fellow. MRC/Wits Developmental Pathways for Health Research Unit. Department of Paediatrics and Child Health. School of Clinical Medicine. Faculty of Health Sciences. Faculty of Health Sciences. University of the Witwatersrand. Johannesburg. South Africa.; [3]Economist. DST-NRF Centre of Excellence in Food Security. University of the Western Cape. Cape Town. South Africa; [4]Epidemiologist. MRC/Wits Developmental Pathways for Health Research Unit. Department of Paediatrics and Child Health. School of Clinical Medicine. Faculty of Health Sciences. University of the Witwatersrand. Johannesburg. South Africa.; [5]Biological Anthropologist. MRC/Wits Developmental Pathways for Health Research Unit. Department of Paediatrics and Child Health. School of Clinical Medicine. Faculty of Health Sciences. University of the Witwatersrand. Johannesburg. South Africa.

Background and objectives: In 2011 global estimates put the number of children in the developing world that were stunted at 165 million. African prevalences have stagnated since 1990 at about 40%, with little improvement expected. Stunting is a major public health concern because of associations with adult health and disease risk later in life. The realisation that physical growth cannot completely be improved by optimized diet and reduced diarrhoea has led to the hypothesis that another underlying cause of stunting is early exposure to poor WASH and recurrent infectious episodes leading to immune impairment across the lifecourse.

Methods: A systematic review is underway to examine the governance of WASH in sub-Saharan settings and associations with nutritional status in children under five years of age. Articles are selected from PubMed Central, Science Direct, and ProQuest Social Science databases published between 1990 and 2017. The PRISMA Statement, evidence-based guidelines that provide a set of items to report in systematic reviews and meta-analyses, is

being utilised while this systematic review will also be registered with PROSPERO.

Results: Initial searches and preliminary results have yielded <50 items per search-string indicating a limited body of knowledge on the nexus between governance, water, sanitation, hygiene, and nutritional status in children in the African context. Of importance are gaps in financing, with SSA countries on average committing a mere 0.52% GDP to WASH expenditure. While actors and stakeholders at various levels in the policy and governance arena advocate for multi- and inter-sectoral approaches, most indicators show disappointing results. Promotion of breastfeeding, food fortification, as well as micronutrient supplementation during pregnancy and infancy, has not been sufficient to shift the prevalence of stunting. Further analysis of the literature is being undertaken.

Conclusions: Undernutrition has a complex set of political, social, and economic causes, none of which are amenable to easy solutions. Important knowledge gaps still remain concerning critical aspects of child malnutrition, including environmental risks in the neonatal and infant periods, in the SSA context.

NUTRITIONAL STATUS OF RURAL SCHOOLCHILDREN IN TACUAREMBÓ/URUGUAY IN RELATION TO DIET CHARACTERISTICS AND ENVIRONMENTAL FACTORS

[1]Etchevarne, José Andrés; [1]Silva, Guillermo; [2]Marquez, Julia; [3]Ongay, Elena; [4]Nari, Maria del Huerto; [5]Marino Donangelo, Carmen.

[1]Licenciado en Nutrición. Escuela de Nutrición. Universidad de la República. Uruguay; [2]Promotora de Salud. Intendencia de Tacuarembó. Uruguay; [3]Licenciada en Nutrición. Escuela de Nutrición. Universidad de la República. Uruguay; [4]PhD en Ética. Escuela de Nutrición. Universidad de la República. Uruguay; [5]PhD en Nutrición. Escuela de Nutrición. Universidad de la República. Uruguay.

Background and objectives: Information on nutrition and health conditions of rural school children in Uruguay is scarce. Our objective was to evaluate the nutritional status of children of a rural school in Tacuarembó/Uruguay during a 6 month period, in relation to characteristics of their diet at home and school and environmental factors known to affect the biological utilization of food.

Methods: This was a descriptive study with two components, one cross-sectional at baseline (November 2015) and a follow up (May 2016). The study population was composed by all children registered at School N°116 of Punta de Carretera, Tacuarembó (n=30; 5-12y; 50% girls). Information on sanitary conditions and on frequency of intake of specifics foods, food preparations and beverages, at home and at school, was obtained by direct ob-

servation and by semi-structured questionnaires directed to the families and the school teachers and assistants. Weight and height were measured by standard procedures and expressed as Z scores of weight for age (WAZ), height for age (HAZ) and BMI for age (BAZ). Associations between anthropometric Z scores and environmental factors were examined by ANOVA. Changes in Z scores over time were analyzed by paired t test.

Results: At baseline, mean anthropometric Z scores were adequate (0.01, -0.117, 0.100, for WAZ, HAZ and BAZ, respectively) irrespective of age and gender, and did not change significantly after 6 months. 10% of children were overweight at both study periods, whereas cases of obesity increased from 6.6% to 10% over time although not significantly. Meals consumed at home included foods rich in carbohydrate and saturated fat, and protein sources, mainly milk, meat and legumes. Meals provided at school appeared to be low in animal protein, iron, zinc, vitamin C, and fiber. The most critical environmental factors identified were the regular use of semi-surging water near dumps and the presence of domestic animals. There were no significant associations between these factors and the nutritional status of the schoolchildren.

Conclusions: Most schoolchildren presented adequate nutritional status, although inadequate dietary characteristics and environmental factors were observed, which should be corrected since they may result in hidden malnutrition.

Keywords: rural schoolchildren, anthropometry, diet, sanitary conditions.

ASSESSMENT OF IODINE AND SODIUM INTAKE IN MOROCCAN CHILDREN BY 24-H URINARY EXCRETION

[1]Saeid, Naima; [2]Elmzibri, Mohamed; [1]Qandoussi, Latifa; [1]Baddou, Issad; [2]Elkari, Khalid; [3]Aguenaou, Hassan.

[1]PhD. Joint Research Unit in Nutrition and Food. URAC 39 (CNESTEN-Ibn Tofaïl University). Regional Designated Center of Nutrition (AFRA/IAEA). Morocco; [2]Dr. Joint Research Unit in Nutrition and Food. URAC 39 (CNESTEN-Ibn Tofaïl University). Regional Designated Center of Nutrition (AFRA/IAEA). Morocco; [3]PhD. Nutritionist. Joint Research Unit in Nutrition and Food. URAC 39 (Ibn Tofaïl University-CNESTEN) Regional Designated Center of Nutrition (AFRA/IAEA). Morocco.

Background and objectives: Iodine deficiency has several adverse effects on human growth and development, categorized collectively as iodine deficiency disorders (IDD). Among school-age children, it's estimated that 29.8% at the world level, had insufficient iodine intake. However iodization of salt is the preferred method of increasing iodine intake in a community, it's legally mandated in many countries. Thus Morocco where the IDD is considered as moderate, adopted the universal salt iodization strategy, in order to prevent and control (IDD). The aim of our study is to determine the consumption intake of supposed fortified salt by iodine, and to evaluate the iodine deficiency in sample of

school children, as a pilot study for the preparation of the future National Survey.

Methods: This transversal study is conducted on 280 children and adolescent aged 6 to 18 years. Anthropometrics data and clinical survey were collected. Urinary sodium and iodine excretion was measured on 24-h urinary collection assessed respectively, by Inductively Coupled Plasma Mass Spectrometry and spectrophotometrically using the Sandell-Kolthoff reaction, the creatinine excretion was used to validate completeness of urine collections

Results: The means were 2.2 ±0.08 g/day (equivalent 5.7±0.2g/day of salt) for daily urinary sodium, and 96 μg/l for iodine excretion. 70% of children presented iodine deficiency, and 50% consume more than recommended sodium intake, among which 62% presents IDD

Conclusions: Most of children consume more than recommended intake of supposed fortified salt by iodine, and children still suffer from iodine deficiency, so the Ministry of Health must consider other's alternatives than salt iodization in his future strategy of IDD reduction.

Keywords: Iodine, sodium, 24-h urinary excretion, children, adolescent, Morocco

marinated egg on each school day for two years. No intervention was provided for 292 students in the control group. Height, weight and dietary intake were measured to assess their nutrition status, and body composition was measured by bioelectrical impedance method. The mixed linear model of repeated measurements was adopted for the comparison of each index.

Results: The lean body mass of boys in the intervention group increased by 0.5 kg, statistically higher than those in the control group after one year intervention (P=0.0007), which became no significant after two years. Boys in the intervention group showed more increase of body fat by 0.2 kg after one year (P=0.0343) and by 0.5 kg after two years (P=0.0013) , compared with those in the control group. Moreover, the difference between groups was significant in boys only in lowest and middle tertiles of body weight for lean body mass, and in highest tertile for body fat. However, no significant effect was observed in girls on body composition indices.

Conclusions: The two-year milk and egg supplementation could promote the increase of lean body mass and body fat in Chinese pre-pubertal boys in poor rural area, but not in girls.

THE EFFECT OF TWO YEARS MILK AND EGG SUPPLEMENTATION ON BODY COMPOSITION OF PRE-PUBERTAL CHILDREN IN CHINESE POOR RURAL AREA

[1]Zhang, Qian; [2]Zhao, Ran; [2]Gan, Qian; [1]Xu, Peipei; [2]Li, Li; [3]Pan, Hui; [2]Li, Shuang; [2]Wang, Tingting; [4]Hu, Xiaoqi.

[1]PhD. Department of Student Nutrition. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China; [2]Master. Department of Student Nutrition. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China; [3]Bc. Department of Student Nutrition. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China; [4]Prof. Department of Student Nutrition. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China.

Background and objectives: Under-nutrition of children remains popular in Chinese poor rural area. It was due in part to their low protein intake and would affect growth and development. So a two-year milk and egg supplementation trial was conducted to evaluate the effect on the growth, especially on body composition of pre-pubertal children in Chinese poor rural area.

Methods: Four primary schools were recruited randomly in a poor rural county of Chinese southwest as the intervention group, and four compared schools with similar background as the control group. A total of 672 students were recruited aged 7 to 11yrs from the Grade 2nd to Grade 4th. About 380 students in the intervention group were supplied with 200 g of School Milk and 50 g of

DIETARY CHANGE AND LIFESTYLE DISEASES AMONG TIBETAN NOMADS : FIELD NUTRITION RESEARCH AT TIBETAN REFUGEE CAMPS IN LADAKH, INDIA

[1]Kimura, Yumi; [2]Norboo, Tsering; [3]Sakamoto, Ryota; [3]Okumiya, Kiyohito.

[1]Graduate School of Human Sciences. Osaka University. Japan; [2]MD. Ladakh Institute of Prevention. India; [3]Ph.D. MD. Center for Southeast Asian Studies. Kyoto University. Japan.

Background and objectives: Highland is one of the most severe places to get enough foods in the world. However, our current study found relatively high prevalence of lifestyle diseases such as obesity, hypertension and diabetes even in such remote highland. Assessing dietary status is important to know one of the backgrounds of these lifestyle-related diseases. This study aims to reveal the nutritional intake of the Tibetan nomads living in Himalayan highland in Ladakh, India, and analyze the relation between nutritional intake and diabetes. It also introduces the lifestyle of Tibetan nomads who settled in town, with a special focus on dietary changes from their nomadic lifestyles to ones in the city.

Methods: Field nutrition research, the field work methodology with a combination of epidemiology, nutrition and anthropology, had carried out in 3 different settings; 1) Leh town (elevation approximately 3200–3600 m ASL), the central city of Ladakh, 2) Domkhar village, located in the mountains valley (3000–3800 m ASL), 3) Changtang plateau, nomadic highland (4200-4900m ASL). Health checkups in Leh have mainly covered ethnic Tibetans living in Tibetan refugee camps around Choglamsar. We car-

---

ried out health checkups of local residents aged 40 or over who voluntary joined the check-up (Leh, n = 304; Domkhar, n = 208, Changtang, n=300) . Diabetic status was diagnosed by 75g oral glucoses tolerance test and total energy intake was estimated using 24h recall method.

Results: The incidence of diabetes and IGT among the study subjects were 33% in Leh, 30% in Domkhar village, and 17% in Changtang plateau. Total energy intake was lower in Changtang plateau and the food variety was poor compared to the Leh town. Through the interview, dietary changes were found especially among the former nomads who currently moved in the town from nomadic lifestyle.

Conclusions: Lifestyle diseases are higher among the subjects living in Leh town than those who living in nomadic area, Changtang plateau. For the former nomads, the lifestyle had changed a lot after they settled in town. It is important for healthcare workers to pay attention to those population as a high risk group of developing lifestyle diseases in the future.

CONSUMPTION OF NUTRIENT DENSE FOODS IN NORTHEAST CITIES OF ARGENTINA, RESISTENCIA AND CORRIENTES

[1]Szymula, Claudio; [2]Rubio, Carlos; [3]Imfeld, Mabel.

[1]Phd. Nutricionist. Argentina; [2]Phd. Faculty of Medicine. National University of the Northeast. Corrientes. Argentina.; [3]Phd. Faculty of Medicine. National University of the Northeast. Corrientes. Argentina.

Background and objectives: Background

From year 2000 we have been monitoring the consumption of food in our region, noting that the intake of foods rich in fats, sugar and starch are the most used. The various dietary guidelines suggest eating nutrient-dense foods and reducing those rich in sugars and fats which does not really happen.

Objectives

To study the weekly frequency the consumption of various nutrient-dense foods in the cities of Resistencia and Corrientes in the northeast of Argentina.

Methods: With the Nutrition students of the Medicine School we surveyed in the year 2016, 5167 persons of the cities of Corrientes and Resistencia. The study population selected by convenience was 18 years or older. A weekly food consumption trend survey was conducted (daily, almost daily, infrequent and never). The total was divided into two groups: daily intake and non daily consumption

Results: We observed that the daily food consumptions in percents were: milk 71.47, various types of meats 81.81, green vegetables 60.47, non green vegetables, 45.62, fruits 61.29, oil 49.89, and the totality of the six groups of foods were 25.43

Conclusions: The daily consumption observed is far away from the recommended. 74,66 % didn't consume nutrient-dense foods on a daily basis, with a risk of poor nutrient intake. This iwas analyzed in context of overweight increase.

The consumption of food with high nutrient content was low. There must be taken public population measurements, especially education.

Keywords: Milk. Meats. Vegetables. Fruits. Oils

KNOWLEDGE OF UNDERGRADUATE NUTRITION STUDENTS ABOUT THE NOVA FOOD CLASSIFICATION

[1]Maiara Lopes Cardozo, Carla; [2]Ramos Langa, Fernanda; [3]Menegassi, Bruna.

[1]Bachelor student. Faculty of Health Sciences. Federal University of Grande Dourados (UFGD). Brazil.; [2]Statistician. Faculty of Health Sciences. Federal University of Grande Dourados (UFGD). Brazil.; [3]MSc. Nutritionist. Faculty of Health Sciences. Federal University of Grande Dourados (UFGD). Brazil.

Background and objectives: The second edition of the Dietary Guidelines for the Brazilian Population, published in 2014, gained prominence in the national and international media because this document deploys a new food classification NOVA, that is based on the processing levels of foods. It is important, however, that NOVA food classification reaches its target audience, starting with undergraduate nutrition students. The aim of this study was to assess the knowledge of students entering and graduating nutrition school concerning the NOVA food classification.

Methods: It was performed a study of quantitative approach, transversal and descriptive carried out in a higher education in a public institution in the state of Mato Grosso do Sul, Brazil. A questionnaire was use with a list of 30 foods divided into four groups: natural or minimally processed foods (I), processed culinary ingredients (C), processed foods (P) and ultra-processed foods (U). The study was composed of 69 participants selected for convenience, and 64% of students entering and 36% graduating nutrition school, of these 96% female and 4% male.

Results: According to the U Mann-Whitney test, the score of correct classification in the overall analysis (C, I, P, U) was significantly higher (p = 0.000) between the group of graduating nutrition school (median = 17) that the group of students entering (median = 14).

Conclusions: Thus, there was the necessity to approach the content of the Guide from the first semester of graduation allowing students greater knowledge and performance on this subject.

Keywords: Students, Food processing, Dietary guidelines.

FREQUENCY OF OBESITY IN CITIES OF THE AR-GENTINE NORTH-EAST, RESISTENCIA AND CORRIENTES

[1]Szymula, Claudio; [2]Rubio, Carlos; [3]Imfeld, Mabel.

[1]Phd. Nutritionist. Argentina; [2]Phd. Faculty of Medicine. National University of the Northeast. Corrientes. Argentina.; [3]Phd. Faculty of Medicine. National University of the Northeast. Corrientes. Argentina.

Background and objectives: Introduction

Since 2.000 we study the frequency of overweight (OW) and obesity (O) in the region, with values between 48 and 55 %. In 2011, we find 70 % of OW and O, in persons of 40 years or older.

Objectives

To study the frequency of overweight and obesity in cities of Resistencia and Corrientes.

Methods: With the Nutrition students of the Medicine School we studied in the year 2017, 5167 persons of Resistencia and Corrientes. The studied population selected by convenience, was 18 years or order. The frequency of OW and O, according to BMI, was established in the whole population, and also by sex,and age

Results: OW O frequency in the total population was 34.71 % and in the group of 40 years or older was 60,95 %. The frecuency of OW O in males was 40. 28 % and in fameles 46.37.

Conclusions: The frecuency of OW O is biggest in the 40 years or older population, than the youngest group

The frecuency of OW O is biggest in females than males

Keywords: Overweight. Obesity. Index Corporal Mass. Sex. Age.

144/2984

EVOLUTION OF FOOD INSECURITY (INSAN) IN HOUSEHOLDS OF MONTEVIDEO DURING 2014-2016

[1]Fajardo, Gabriela; [2]Cauci, Adriana; [3]Muniz, Florencia; [3]Piñeyro, Cecilia; [4]Britz, Monica.

[1]Nutritionist School of Nutrition. University of the Republic. Uruguay; [2]Nutritionist. School of Nutrition. University of the Republic. Uruguay; [3]Nutritionist. School of Nutition. University of the Republic. Uruguay; [4]MSc. Epidemiology. Nutritionist. School of Nutrition. University of the Republic. Uruguay.

Background and objectives: Information regarding the distribution of food insecurity in the population and the location of those most affected can contribute to building political to counteract this phenomenon. Applying the Latin American and Caribbean Food Security Scale (ELCSA) complements the data from other indicators by including dimensions that underlie different issues that are affected against INSAN situations. The aim of the study was analyze in households of Montevideo the evolution of INSAN during 2014-2016.

Methods: Descriptive study, non-probabilistic annual sample of 1,500 households. The households were grouped in three zones: east, center and west according the Ministry of Social Development proposal. The ELCSA, which measures INSAN based on household experience, was applied.

Results: The INSAN situation in households was maintained during this period, 9% -10% INSAN moderate, 4% -3% INSAN severe. In households with children under 18 years old, the prevalence of INSAN moderate increased from 9% to 15% and INSAN severe from 3% to 5%, while the opposite occurred in households without children under 18 years old: INSAN moderate remained in 8% and the INSAN severe decreased (4% to 2%), which reaffirms poverty in childhood in Uruguay. The analysis by zone identified that the prevalence of households with INSAN moderate in the central area decreased (7% to 5%) and with INSAN severe remained at 2%. In households of the east and west of Montevideo, poverty levels range between 3.1 and 11.5%. When the ELCSA was applied it was detected in the eastern zone that INSAN moderate households increased (12% to 15%), the INSAN severe remained (6%). In the west, INSAN moderate and severe households increased by 4% and 1%, respectively; prevalences 3 and 2 times more than those observed in the central zone. The three most commonly cited reasons for INSAN moderate households were "to stop having a healthy diet" or "unvaried diet" "concern that they would run out of food". In INSAN severe households was added "having eaten less than they should".

Conclusions: The quantity and quality of food are presented as underlying dimensions in the INSAN households studied.

Keywords: Food Insecurity, households, ELCSA

PATTERNS OF RISK AND PROTECTIVE BEHAVIORS RELATED TO NON-COMMUNICABLE DISEASES AMONG BRAZILIAN ADOLESCENTS

[1]Ricardo, Camila; [2]Azeredo, Catarina; [3]Levy, Renata.

[1]Master Student. Faculdade de Medicina. Universidade de São Paulo. Brazil; [2]PhD. Faculdade de Medicina. Universidade Federal de Uberlândia. Brazil; [3]Phd. Faculdade de Medicina. Universidade de São Paulo. Brazil.

Background and objectives: A small group of modifiable risk factors accounts for most of the disease burden and mortality due to non-communicable diseases (NCD). These risk behaviors frequently originate in adolescence and remain in adulthood with short-, medium- and long-term consequences. Currently, in addition to determining the prevalence of each of the risk factors, it is important to evaluate how they cluster among the population, since some of these behaviors might interact with each other, producing an even greater risk than the sheer sum of individual risks. We aim to identify patterns of risk and protection behaviors related to chronic diseases among Brazilian adolescents and

to verify their association with socioeconomic and demographic characteristics

Methods: Our data source was the Brazilian National Survey of School Health (Pesquisa Nacional de Saúde do Escolar – PeNSE) 2012, which collected data on adolescent health through a self-administered questionnaire in a representative sample of students enrolled in the 9th grade of elementary education in public and private Brazilian schools. We used data about diet, physical activity, smoking, alcohol consumption, socioeconomic and demographic characteristics. Factor analysis was used to identify patterns of behavior from a list of risk and protective factors for NCD. The association between the identified patterns and students' characteristics was evaluated using linear regression models.

Results: Four patterns of behavior were found: "unhealthy diet", "healthy diet", "physical activity" and "alcohol and cigarette use". In general, the groups that presented the worst profile of adherence to the behavioral patterns found were: girls, older adolescents, and those who did not live with their mother and their father.

Conclusions: Four behavioral patterns were found among Brazilian adolescents. The identification of more vulnerable groups can support strategies for health promotion and prevention of diseases related to the control of NCD even during adolescence.

Keywords: behavioral patterns; c; risk factors; adolescent; non-communicable diseases; epidemiological surveillance.

REACH, EFFECTIVENESS, ADOPTION AND IMPLEMENTATION OF A NATIONAL HEALTHY EATING CAMPAIGN: A PROCESS AND IMPACT EVALUATION USING A MIXED-METHODS APPROACH

[1]*Fernandez, Melissa Anne Fernandez;* [2]*Desroches, Sophie;* [3]*Marquis, Marie;* [1]*Turcotte, Mylene;* [2]*Provencher, Veronique.*

[1]MSc. Nutritionist. Institute of Nutrition and Functional Foods. Laval University. Canada.; [2]PhD. Nutritionist. Institute of Nutrition and Functional Foods. Laval University. Canada.; [3]PhD. Nutritionist. Department of Nutrition. University of Montreal. Canada.

Background and objectives: Evaluation ensures government accountability for spending, provides evidence of the impacts of an intervention and gives decision makers opportunities to improve subsequent initiatives. The Eat Well Campaign (EWC): Food Skills was a year-long national healthy eating initiative that Health Canada (HC) developed and disseminated with cross-sector partners to promote food skills to Canadian parents. The purpose of this study was to evaluate the reach, effectiveness, adoption and implementation of the EWC among Canadian parents and HC's cross-sector partners.

Methods: The reach and effectiveness of the EWC was evaluated among a representative sample of Canadian parents by using a series of web-based questionnaires that captured sociodemographic data, information of EWC exposure and the impacts of the campaign. A qualitative process evaluation was conducted

to describe the adoption and implementation of the EWC among HC's multi-sector partners using thematic analysis of telephone interviews.

Results: Reach was significantly greater among French-speaking parents, those with lower income and less education. The perceived effectiveness appeared to be greater for beliefs and knowledge components than for behaviors. The majority of parents were only exposed to one campaign element and exposed one or fewer times per month. Nevertheless, the perceived effectiveness of the campaign was significantly greater for each additional campaign element and for every additional time the campaign was viewed. The process evaluation revealed that compatibility between organizations and the campaign was a significant facilitator for EWC adoption, and there were relatively few barriers. Barriers were more prominent during implementation than adoption and included time, concerns over campaign strategy and financial resources. Compatibility during adoption was associated with partners' commitment, flexibility and understanding during implementation.

Conclusions: Early collaborative planning is recommended to anticipate and minimize potential barriers such as time and financial resources. Behavior change should be the primary focus of future initiatives. These initiatives should seek to include partners that have high compatibility with the initiative, as this is likely to result in improved implementation and greater engagement of partners.

Keywords: Cross-sector partners, food skills, impact evaluation, parents, process evaluation.

COMPARISON OF NUTRITIONAL QUALITY OF SNACKS FOR CHILDREN AND NOT FOR CHILDREN

[1]*Natero Felipe, María Virginia;* [2]*Fernandez, Estela;* [3]*Saravia, Luisa.*

[1]MSc. Lic. Nutritionist. Departamento de Alimentos. Escuela de Nutrición. Universidad de la Republica. Uruguay; [2]MSc. Lic. Nutricion. Depto. Alimentos. Escuela de Nutrición. Universidad de la República. Uruguay; [3]MSc. Lic. Nutricion. Posgrado. Escuela de Nutrición. Universidad de la República. Uruguay.

Background and objectives: The aim of this study is to compare the nutritional quality of a snack individually packed with marketing techniques packaging for children, with those snacks whose packaging are not intended for children, at a supermarket chain in the city of Montevideo during 2014.

Methods: The universe was composed of the snacks available in the supermarket, that meet the Health Ministry of Uruguay (MSP) directives. The criteria for assessing advertising and promotion on the snacks packaging followed the ones of the INFORMAS project. Snacks were classified according to whether or not the snack packaging was intended to children (PITC) or not (PNITC). The criteria to assess nutritional content of snacks was the MSP one.

Results: The nutritional quality was classified as: do not meet the criteria of MSP, partially met (only for one serving size) or fully met; 13.3% of the snacks partially satisfied and 12.3% fully meet these criteria. Statistical analysis showed that PITC selected by packaging marketing techniques , have no nutritional quality difference with those not intended for children and both groups have the same nutritional quality (p = 0.201). Significant differences were found assessing food groups (cookies, alfajores, milk desserts and yogurt, cereal bars) by nutrient composition.

The PITC alfajores have lower caloric intake, lower fat content, and lower sodium intake.

In the case of cookies, PNITC have a higher caloric intake, total fat, saturated fat, and trans fat ,than PITC.

In the group of dairy yogurts and milk desserts, PNITC have lower intake of sodium, total fats, saturated fats compared to PITC.

Cereal bars intended for children have a greater contribution of calories and total fats than those that are not.

Conclusions: The nutritional quality of snacks aimed to children and those who are not, is the same. In the analysis by food groups there are differences that may be showing a tendency to improve the nutritional quality of food PITC in relation to the PNITC

Keywords: nutritional quality, children, food packaging, childhood obesity

EXPOSURE TO ADVERTISING AND FOOD INTAKE OF SCHOOL-AGE CHILDREN IN ARGENTINE PROVINCES

[1]Virgolini, Mario; [2]Leonardelli, Eduardo; [3]Carrazana, Carla; [4]Fallocca, Veronica; [5]Alfaro, Agustina; [6]Exner, Natalia; [7]Lavayen, Fabiola; [8]Sordini, Natalia; [9]Scarinci, Guillermo.

[1]Anthropologist. Facultad de Ciencias Médicas de la Universidad Nacional de La Plata. Argentina; [2]Psychologist. Universidad Favaloro. Ciudad de Buenos Aires. Argentina; [3]Nutritionist. Universidad Isalud. Ciudad de Buenos Aires. Argentina; [4]Psychologist. Facultad de Ciencias Medicas. Universidad Nacional de La Plata. Argentina.; [5]Social Communicator. Instituto Populorum Progressio. Jujuy. Argentina; [6]Nutritionist. Universidad Católica de La Plata. Argentina; [7]Nutritionist. Universidad Nacional de Córdoba. Argentina; [8]Nutritionist. Universidad FASTA. Mar del Plata. Argentina; [9]Nutritionist. Universidad Nacional de Rosario. Argentina.

Background and objectives: In a context of a worldwide growing concern about the advertising of food for kids it was proposed to study in school kids in Argentina the relationship between exposure to television, the remembrance of advertisements, the meaning, purchase intentions and consumption of ultra-processed products (UP) and non-processed o slightly processed products (NP).

Methods: Observational study in a non-probabilistic sample of 8 to 12 year old school kids and their parents from primary education schools from 6 Argentine districts. Structured questionnaires were applied to kids and parents. Additionally the school environment was observed and the faculty and personnel interviewed.

Results: 1261 school kids and 778 parents from 20 schools were evaluated. 48,4% of the school kids (n=610) watch television at least 30 hours per week. 69,9% remembered UP food advertising spots and 19,8% NP food advertising spots, similar ratios were identified for billboards, internet and promotions. Regarding credibility, 20% of the school kids and 35% of the parents expressed that advertisements either don´t lie or lie just a little.

The number of UP purchase requests from the kids to the parents showed a significant correlation with the amount of hours exposed to television, standing out a rho= 0.19 (p < 000).

An association between higher consumption of some processed foods and UP (solids and beverages) with higher exposure to TV (p=-0,03; p=-0,002), internet (p=-0,004; p=-0,004), billboards (p=-0,019; p=-0,01), and promotions (p=-0,006; p=-0,003) was found.

Conclusions: The frequency of exposure of school kids to advertisement is significantly related with their remembrance and purchase requests to their parents of all kinds of food, especially processed and UP. An association of higher consumption of some processed and ultra-processed foods with TV exposure has been detected. The evidenced influence of UP food advertising on children shows the need to adopt legislation to regulate it.

Keywords: Feeding Behavior, Food Publicity, Child Nutrition

THERE IS LOW-HANGING FRUIT UP THERE: URBAN ACCESSIBILITY OF STREET MARKETS IN SANTIAGO, CHILE

[1]Weisstaub, Sergio Gerardo; [2]Mora, Rodrigo; [3]Greene, Margarita; [4]Herrmann Lunecke, Geraldine; [4]Bosch, Francisco.

[1]MD, Msc. INTA. University of Chile. Chile; [2]PhD. School of Architecture. University Diego Portales. Chile; [3]School of Architecture. Catholic University of Chile. Chile; [4]School of Architecture. University Diego Portales. Chile.

Background and objectives: To analyse how much of the urban grid is covered by street markets in each of the municipalities of Santiago, Chile, considering a 600 m threshold (roughly equivalent to a 10-minute walk).

Methods: All street markets of Santiago were mapped and geo-referenced. Then, an accessibility analysis of street markets within the urban grid was performed, including a socio-economic analysis of households living in the city.

Results: Street markets cover 52% of the city´s urban grid. It is also indicates that this percentage varies depending on people's in-

come, for However, while only 28.6% of the ABC1, the wealthiest group that represents nearly 15% of the population, have a street market within the 600 m radius, nearly 70% of all households belonging to the D and E groups, representing 35% and 20% of inhabitants of Santiago, can access a street market within the same distance.

Conclusions: The paper argues that Chile`s nutritional policies should incorporate street markets as key players in the fight against obesity and sedentary lifestyles. Conclusion: Street markers should be included as part of a national strategy to tackle the obesity problem.

Keywords: street markets, nutritional policies, lifestyles, people's income.

PROFILE OF THE USERS OUTDOOR GYMS IN SANTIAGO DE CHILE

[1]Mora, Rodrigo; [2]Weisstaub, Sergio Gerardo; [3]Greene, Margarita; [4]Herrmann Lunecke, Geraldine; [5]Bosch, Francisco.

[1]Phd.School of Architecture. University Diego Portales. Chile; [2]MD. Msc. INTA. University of Chile. Chile; [3]School of Architecture Pontifical Catholic University of Chile. Chile; [4]School of Architecture. University Diego Portales. Chile; [5]School of Architecture . University Diego Portales. Chile.

Background and objectives: To put together a registry of the location of all existing outdoor gyms (OGs) in Santiago, 2 Chile, and establish a profile of the users of these gyms.

Methods: All OGs in Santiago located in public spaces were identified and geo-referenced, and 4 an accessibility analysis of them was carried out. A total of 1023 users of OGs were surveyed 5 (71% men, average age 31.5 years old, SD =16.6), about the frequency of use of OGs, amount of 6 time spent using them, transportation habits, motivation for usage, and their perceptions 7 regarding their own health, among other questions. In addition, each person's neck circumference 8 was measured.

Results: There are a total of 1981 OGs in the city squares, sidewalks and parks, mostly located in 10poorest areas of the city. Most OG users live less than one kilometer away from an OG.In line with international studies, this research demonstrates that OGs have positive 12collateral effects, as they not only contribute to an increment in the physical activity made by 13their users, but also because they attract people with sedentary lifestyles to make physical 14activity. This, in turn, might contribute to make urban areas more livable and safer, for they bring 15new "eyes to the street" and permit to use under-occupied public space of cities

Conclusions: The proliferation of outdoor gyms should be regarded as an opportunity for public health policies aimed at tackling the obesity problem and increasing the physical activity of 18people.

Keywords: outdoor gyms, public health policies

BODY SHAPE QUESTIONNAIRE: APPLICATION IN BRAZILIAN AND PORTUGUESE WOMEN AND MEN

[1]da Silva, Wanderson Roberto; [2]Marôco, João; [3]Ribeiro Dias, Juliana Chioda; [4]Alvares Duarte Bonini Campos, Juliana.

[1]PhD. Nutritionist. Department of Food and Nutrition. School of Pharmaceutical Sciences of São Paulo State University (UNESP). Brazil.; [2]PhD. Associate Professor. William James Center for Research (WJCR). Instituto Universitário de Ciências Psicológicas, Sociais e da Vida (ISPA). Lisbon.; [3]PhD. Nutritionist. Centro Universitário Unifafibe. Brazil; [4]PhD. Associate Professor. Department of Food and Nutrition. School of Pharmaceutical Sciences of São Paulo State University (UNESP). Brazil.

Background and objectives: Body Shape Questionnaire (BSQ) was developed to assess the women's body shape concerns, which are different from those of men. Some studies have used the BSQ in women and men and the results in male samples show that men do not care about the issues related to body shape concern. The aim of this study was to assess the correlation of the BSQ with other instruments specific for women and men, and to discuss the theoretical approximation of scales.

Methods: A total of 2,484 Brazilian and Portuguese college students completed the BSQ. The Weight Concerns Scale (WCS) and the Male Body Dissatisfaction Scale (MBDS) also were completed by women (n=1,613) and men (n=871), respectively. Individuals' nutritional status was estimated by Body Mass Index (BMI) using the weight and height self-reported. The psychometric properties of all scales were assessed by confirmatory factor analysis. The scales' internal consistence was assessed by Cronbach's alpha coefficient (α). Structural equation modeling was used to assess the correlation of BSQ with WCS and MBDS.

Results: Among students, 64.9% were women and the average age was 21.0 (standard deviation=2.8) years old. 5.5% of the students were classified in underweight (men=2.8%, women=7.0%), 74.5% eutrophic (men=69.9%, women=77.0%), 16.2% overweight (men=21.9%, women=13.1%), and 3.8% in obesity (men=5.4%, women=2.9%). The BSQ and the WCS showed good fit to sample. The MBDS did not show good fit and was refined. Internal consistence was adequate for all scales (α=.73-.97). There was a significant and strong correlation between BSQ and WCS (r=.981, p<.001) and low correlation between BSQ and MBDS (r=.417, p<.001).

Conclusions: The BSQ presented strong correlation with the WCS showing that BSQ's items are more specific to assess the body concerns of female population. (Grant#2014/03093-2; FAPESP).

NUTRITIONAL STATUS OF HIV SEROPOSITIVE VOLUNTEERS IN OYO STATE NIGERIA

[1]Ekele, David Ochedomi; [2]Okekunle, Akinkunmi Paul; [3]Sanusi, Rasaki Ajani.

[1]Senior Technical Officer Monitoring & Evaluation. FHI 360. Nigeria; [2]BSc. MPH. Graduate Student. Department of Nutrition and Food Hygiene. Harbin Medical University. China.; [3]MBBS. MSc. PhD. Reader. Department of Human Nutrition. University of Ibadan. Nigeria.

Background and objectives: Human Immunodeficiency Virus (HIV) infection is a global epidemic with long-term impact on nutrition and life expectancy of HIV-seropositive subjects. Nigeria has the second largest HIV epidemic globally and accounts for 180,000 deaths from HIV-related illness in 2015. Intervention strategies adopted to address the burden of HIV infection are mostly ART provision-based with less attention on the nutritional wellbeing of HIV-seropositive subjects. In this study, we evaluated the nutritional status of HIV-seropositive volunteers in Oyo State, Nigeria.

Methods: 200 HIV seropositive volunteers attending community-based support groups (CSGs) in two cities (Ibadan and Ogbomosho) of Oyo state, Nigeria participated in the study after duly informed consent. Information on socio-demographic status was assessed using interviewer-administered; semi-structured questionnaire, weight and height were evaluated using a standardised weighing scale and stadiometer to the nearest 0.1kg and 0.1cm respectively and body mass index (BMI) was categorised using WHO cut-off points. While 24hour recall of all food and drinks preceding the interview were queried and assessed using the adapted total dietary assessment (TDA) software, descriptive statistics and independent sample t-test was carried out at p<0.05.

Results: Most volunteers (55.0%) were from HIV-CSG in Ibadan, 16% were males, 50% were symptomatic and mean age was 38.1±9.7years. Also, 21% and 3.5% of volunteers were underweight and obese respectively. In addition, significantly lower (t=2.6, p=0.014) mean daily protein intake was observed among females (56.6±31.2g) compared to male volunteers (78.1±44.9g). While, mean BMI of symptomatic volunteers (20.6±3.6kg/m2) was significantly lower (t=4.5, p=0.000) compared with asymptomatic subjects (23.0±4.1 kg/m2), mean daily energy intake was insignificantly different (t=0.3, p=0.801) among symptomatic (2188.4±1114.1kcal) and asymptomatic (2228.3±1120.1kcal) volunteers.

Conclusions: Voluntary participation of HIV seropositive males in CBGs is low, under-nutrition is prevalent among HIV-seropositive subjects. Intervention strategies targeting the management of the HIV infections should be nutritionally inclusive to minimise the impact of the infection.

SERUM ALBUMIN LEVELS AND ALL-CAUSE MORTALITY IN PREVALENT PERITONEAL DIALYSIS PATIENTS

[1]Chen, Jin-Bor; [2]Chuang, Yuan-Chih; [2]Cheng, Ben-Chung; [2]Wu, Chien-Hsing; [3]Chen, Chiao-Jung; [3]Kuo, Li-Chueh; [3]Wang, Pei-Ying; [3]Chao, Mei-Chen; [4]Moi, Sin-Hua; [4]Yang, Cheng-Hong.

[1]M.D. Physician. Division of Nephrology. Department of Internal Medicine. Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine. Kaohsiung; [2]M.D. Physician.Division of Nephrology. Department of Internal Medicine.Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung. Taiwan; [3]BSc. Nurse.Division of Nephrology. Department of Internal Medicine. Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung. Taiwan; [4]PhD. Department of Electronic Engineering, National Kaohsiung University of Applied Sciences, Kaohsiung, Taiwan.

Background and objectives: There are few studies to examine the long-term effect of serum albumin levels on mortality in prevalent peritoneal dialysis (PD) patients. We investigated the association of serum albumin levels with mortality over a 5-year period.

Methods: This study included 302 patients who received maintenance PD in a hospital-facilitated PD center. Five-year medical records (2011–2015) were retrospectively reviewed, and the cut-off level for serum albumin level was set at 3.5 g/dL. To examine the association between serum albumin levels and mortality, we used time-averaged albumin level and serum albumin reach rate to 3.5 g/dL in the first 2 years (2011–2012) as the predictor variables and all-cause mortality in the subsequent 3 years (2013–2015) as outcome variables. Univariate and multivariate Cox proportional hazard regression models were used to examine the hazard function of the all-cause mortality of the study participants.

Results: Although the patients with 75–<100%, 50–<75%, and 1–<50% albumin reach rates exhibited non-significantly increased risk for all-cause mortality, patients with 0% albumin reach rate exhibited significantly increased risk for all-cause mortality (HR 7.59, 95% CI 2.38–24.21) by fully-adjusted analysis. A similar trend for all-cause mortality was demonstrated in patients with time-averaged albumin levels <3.5 g/dL (HR 15.49, 95% CI 1.74–137.72) exhibiting increased risk for all-cause mortality when compared to patients with serum albumin level ≥4.0 g/dL.

Conclusions: This long-term study demonstrated that higher reach rates of serum albumin levels and higher time-averaged serum albumin levels are associated with a lower mortality rate in patients undergoing maintenance PD.

Keywords: albumin, mortality, peritoneal dialysis

EFFECTIVENESS OF A DIETOTHERAPEUTIC IN-TERVENTION ON THE LIPIDS PROFILE AND THE NUTRITIONAL STATUS IN BREAST CANCER WOMEN

[1]Lasserre, Nicole; [2]Lasserre, Nicole.

[1]MSc. Nutritionist. Nutrition and Dietetics Department. School of Health. University Santo Tomas, Los Angeles VIII – Bio Bio Region. Chile; [2]MSc. Nutrition and Dietetics Department. School of Health. University Santo Tomas, Los Angeles VIII – Bio Bio Region. Chile.

Background and objectives: Women with Breast cancer (BC) present metabolic changes during cancer treatment as weight gain and abnormal serum lipids profile, which increase the risk of cancer recurrence and mortality. The aim of this study was to evaluate the effectiveness of a diet therapy intervention on serum lipid profile and nutritional status in BC woman.

Methods: This is a randomized experimental design. Were recruited 11 woman between 35 and 65 years with BC, randomized in intervention group (n=6) or control group (n=5). Subjects in the intervention group received a personalized diet therapy based on semi-vegetarian diet, adjusted to energy requirement. Control group received one session of nutritional counseling. Anthropometric measurements (weight, height, waist circumference, and body fat percentage) were performed, the serum lipid profile (TC, LDL, HDL and TAG) was measured and dietary surveys were applied (24-hour records and modified frequency survey consumption) to assess the diet of the participants. The statistical significance of the data was assessed by student's t test for unpaired data and two-way analysis of variance (ANOVA).

Results: The mean age was 52.1 ± 3.3 years, 54.5% of participants were overweight, 72.7% exceeded the limit of waist circumference and 54.5% excess body fat percentage, 34.6% had high levels of TC, TAG 45.5% and 18.2% LDL. No significant differences were found between pre- and post-intervention groups on nutritional status and lipid profile. The intervention group significantly increased consumption of vegetables (ANOVA 0.031) and fruit (ANOVA 0.043) and decreased consumption of cereals (ANOVA 0.001). A intervention effect was found on the distribution of protein (P%), lipids (L%) and carbohydrates (CHO%).

Conclusions: A diet therapy intervention can improve diet profile in BC women , however more studies are needed to see the effect it can have on the serum lipid profile and nutritional status.

DIETARY SUFFICIENCY IN MINERAL CONTRI-BUTION FROM AFRICAN YAM BEANS (SPHENO-STYLIS STENOCARPA) AND SOYA BEANS (GLY-CIN SP) SP) CONSUMED IN SOUTHERN NIGERIA

[1]Obono Ekpe, Onot; [2]Okon, Emmanuel; [3]Madugba, Echefu.

[1]PhD. Nutrition and Food Science. University of Calabar. Nigeria.; [2]PhD. Pure and Applied Chemistry. University of Calabar. Nigeria.; [3]BSc. Environmental Laboratory. Fugro Nigeria Limited. P.M.B.053. Port Harcourt. Nigeria.

Background and objectives: Our ancestors' foods are lacking in modern diets and human biology has not evolved significantly different (Broadhurst ,1994). Speculations are , plethora of diet related disorders could be linked to human gastrointestinal track evolutionary factors. Despite efficacy of supplements in treating degenerative diseases, minerals are absorbed more efficiently if supplied in foods rather than as supplements (British Nutrition Foundation 2015). Consequently, data driven promotion of minerals contribution from African yam beans, an indigenous crop that was in our ancestor's food, threaten with extinction (Porter, 1992; Amoatey, 2000) can foster nutrition security. The specific challenge is to generate data on African yam beans (AYB) mineral contribution in the dietary vis-a-vis the nutritionally dense soya beans.

Methods: About 3g of each were oven dried at 110O C, reduced to < 2µm diameter by crushing , pulverised because of inhomogeneity of samples and transferred to the sample compartment of an X-Ray Fluorescence (XRF) Spectro Xepos model 03STD Gas serial Spectro-11001700. Then, screened for their elemental composition.

Results: Fifty one (51) elements were quantified in each sample. Twenty five (25) in their free- state and 26 existed as oxides. These oxides, 16 were minerals and others in free state, 7 minerals. Therefore, 23 minerals from AYB. Soya beans had same complement of predominant elements ($\geq$ 100ppm), both contained all known essential minerals. Elements in trace amount($\leq$20ppm) for soya beans were at micro-levels ($\leq$100ppm) in AYB. Silicon, was significantly high in AYB to about (189.4ppm). Corollary, the naturally highly reactive chlorine and barium, detected in their free states. Sodium was not detected.

Conclusions: X-Ray Fluorescence Spectrometry analytical method gave a total profiling of all elements present in samples, thus total mineral composition of AYB as a legumes that can indeed be resource-efficient in mineral contribution to the diet and highly economical food source of minerals.

DIETARY PATTERN AND DIETARY INTAKE AMONG CHINESE ADULTS WITH DIFFERENT SELF-AWARENESS AND MANAGEMENT STATUS OF HYPERTENSION -A CROSS-SECTIONAL STUDY IN SEVEN CITIES OF CHINA

[1]Zhao, Ai; [2]Zheng, Wei; [3]Szeto, Ignatius Man Yau; [4]Wang, Yan; [4]Li, Ting; [5]Zhang, Yumei.

[1]Peking University Health Science Center; [2]PhD.School of Public Health.Peking University Health Science Center. P.R. China.; [3]PhD.Manager.Yili Innovation Center, Inner Mongolia Yili Industrial Group Co., Ltd. Inner Mongolia Dairy Technology Research Institute Co., Ltd. P.R. China.; [4]MSc.Yili Innovation Center, Inner Mongolia Yili Industrial Group Co., Ltd. Inner Mongolia Dairy Technology Research Institute Co., Ltd. P.R. China.; [5]PhD.Professor. School of Public Health.Peking University Health Science Center. P.R. China.

Background and objectives: Hypertension is one of the key risk factors for cardiovascular disease. The prevalence of hypertension in Chinese adult population was reported as high as around 30% and characterized by a low self-awareness rate. This study was conducted 1) to estimate the awareness rate and control rate of hypertension in Chinese adults, and 2) to explore the dietary pattern and intakes in participants with different awareness and management status of hypertension.

Methods: A multi-center study was conducted in seven cities of China. A total of 1704 adults aged 18-80 years were recruited. A three discrete times of 24h dietary records were used to obtain the data of dietary intake. Food Frequency questionnaire was used to obtain intake frequencies of 17 food categories in past one month and analyzed for the food pattern with Principal Component Analysis.

Results: A total of 26.1% of participants were showed an abnormal blood pressure (BP), however, only 12.7% of them had self-awareness. The control rate of hypertension was 40.5%. According to the self –awareness and management status of hypertension, we divided the participants to four groups which were healthy group, ignorant group, bad-controlled group, and well-controlled group. Overall, 87.6% of participants salt intake higher than 6g/d. The ignorant group had a significant higher salt intake(10.1±5.4 g/d), comparing with well-controlled group(8.9±4.1g/d), healthy group (9.4±4.6g/d) and the bad-controlled group(9.6±4.3g/d). For the nutrients intake, the well-controlled group had a lowest sodium intake, the median(25th,75 th) was 3665.4(2643.9,5019.1)mg/d, while sodium intake in bad-controlled group and ignorant group were 4093.8(2697.4,5200.7) mg/d and 4015.6(2892.2,5481.7.7) mg/d respectively. A significant higher intake of energy and carbohydrate were also found in ignorant group. There were no significant associations between dietary pattern's factor loading and self-awareness and management of hypertension. However, pickles had a significant higher intake frequencies in ignorant group (P=0.018).

Conclusions: The self-awareness of hypertension associated with dietary behaviors and might result in a different health outcome. A comprehensive dietary strategy should be conducted in Chinese population. To reduce sodium intake not only the salt intake should be emphasized to the public in China.

PROMOTION OF HEALTHY EATING AND EXERCISES AT A WORKPLACE – TANZANIAN EXPERIENCE

Lukmanji, Zohra.

Public Health Nutritionist/Clinical Dietitian. Independent Consultant/Advisor.

Background and objectives: Overnutrition is a growing problem in countries including Tanzania along with the existing undernutrition problem. The Tanzania Steps Survey in 2012 reported that 26% of adults over 25 were overweight and 8% obese. From 2005 to 2015 over nutrition increased among both rural and urban women aged 15-49(Demographic health survey). Workplaces are proven to be ideal settings for health promotion and disease prevention. A 3 month health promotion program intended to prevent and manage overweight and obesity was initiated at a food aid organization, in collaboration with the management.

Methods: The program, the first of its kind in Tanzania, was targeted at all 60 staff based in the head office in Dar es Salaam. Activities included orientation and advocacy workshops, baseline health assessment (anthropometry, fasting blood sugar, blood pressures measurements, and an interview to determine knowledge, attitude, and practices about weight, fruit and vegetable consumption, diet, and exercise. Individual counselling, education seminars, exercise sessions, and pop up health messages continued for 8 weeks. The menu at the staff canteen was changed. Evaluations, including a structured questionnaire for participants, examined the feasibility and sustainability of the interventions

Results: Of 55 staff assessed at baseline, 60% were obese or overweight; 2/3 hypertensive (diagnosed or undiagnosed). Few women engaged in regular exercise. Almost 60% reported consuming fruits and vegetables 4-7 times per week, and few reported 5 a day. Many had been or were on fad or crash diets. Workload and lack of time appeared to affect food consumption and exercise patterns.

By the end of 3 months, the participants were more conscious of their weight, healthy eating, and regular exercise. But, the impact on their BMIs was insignificant.

Conclusions: Extensive and varied interventions over 3 months sensitized the staff to healthy eating and the benefits of exercise, which they practiced. They understood the health risks of overnutrition, although their BMIs did not change much. A longer term program (atleast 9 months) is necessary.

Department of Clinical Nutrition.The First Affiliated Hospital of Sun Yat-sen University. .R.China.; [6]BS. Department of Clinical Nutrition.The First Affiliated Hospital of Sun Yat-sen University. .R.China.

Background and objectives: Few study with large sample size has assess effects of dietary patterns, susceptibility genes and their interactions on the risk of cardiovascular complications among diabetic patients. This study aimed to examine the effects of dietary patterns, susceptibility genes, and their interactions on the risk of cardiovascular complications with diabetes.

Methods: We used a case-control design and diabetics were recruited in hospital. Cases were diabetics with new onset cardiovascular events including non-lethal myocardial infraction and stroke, and controls were diabetics. 20 polymorphisms within 11 candidate genes were measured. Dietary intake was assessed by a food frequency questionnaire through face-to-face interview. Factor analyses and dietary scoring methods were used to establish dietary patterns and dietary scores. Logistic regression analyses were used to analyze the effects of dietary patterns, polymorphisms, or their interaction on the risk of cardiovascular complications among diabetics.

Results: A total of 1005 participants included in the final analysis (543 cases, 461 controls). No significant results were observed for the distribution of 20 polymorphisms among cases and controls, and no polymorphism was significantly associated with the risk of the study disease. Dietary pattern typified by the consumption of soybeans and fungus (soybean and fungus pattern) and another pattern typified by the consumption of vegetables (vegetables pattern) were associated with a 38% (95%CI: 9%, 58%) and a 54% (95%CI: 32%, 69%) decrease risk of cardiovascular complications respectively. Dietary index of HEI2005 can also decrease risk of 35% (95%CI: 7%, 55%) at maximum. Analyses of interactions showed that, ADOIPOQ gene rs37563 polymorphism and soybean and fungus pattern had an interaction effect (P interaction = 0.007), and the inversely linear trend were among patients with C allele (GC + CC) (P trend = 0.013); MTHFR gene rs1801131 polymorphism and the vegetables pattern had an borderline interaction effect (P interaction = 0.053), and the strong inversely linear trend were found among patients with wild type TT (P trend <0.001).

Conclusions: Diabetics consumed more soybeans, fungus, vegetables, and a balanced diet are recommended to reduce risk of cardiovascular complications, and these effects were more effective among patients with rs37563 C allele and rs1801131 TT genotype.

Keywords: cardiovascular complications with diabetes; dietary patterns; susceptibility genes; interactions

UREMIC TOXINS: IS THERE ANY RELATIONSHIP WITH PERSONAL, CLINICAL, OR NUTRITIONAL FACTORS?

[1]Pansani Maniglia, Fabíola; [2]Casale Aragon, Davi; [3]Sumie Nakao, Lia; [4]Juliana Ribeiro Dolenga, Carla; [5]Cardeal da Costa, José Abrão.

[1]MSc. Nutritionist. Ribeirão Preto Medical School. University of São Paulo. Brazil.; [2]PhD. Statistician. Ribeirão Preto Medical School. University of São Paulo. Brazil.; [3]PhD. Chemist. Biological Sciences. Federal University of Paraná. Brazil.; [4]MSc. Veterinarian. Biological Sciences. Federal University of Paraná. Brazil.; [5]PhD. Nephrologist. Ribeirão Preto Medical School. University of São Paulo. Brazil.

Background and objectives: Chronic renal patients may have high concentrations of uremic toxins, which when bound to protein become difficult to remove on dialysis. Some of these toxins originate from dietary protein and may have harmful effects, especially related to the cardiovascular system. The present study had as objective to evaluate the concentrations of two uremic toxins and to relate their values with personal, clinical and nutritional variables.

Methods: This study was performed with 39 patients older than 18 years on hemodialysis for at least 5 months. Personal and clinical data, such as: age, time of dialysis and biochemical tests (Kt/V, urea, creatinine and albumin) were obtained through interviews and medical records. The food consumption was assessed through a 3-day food diary and the nutritional status was investigated by the 7-point Global Subjective Assessment and the Body Mass Index (BMI). For the measurement of the uremic toxins p-cresyl sulfate (PCS) and indoxyl sulfate (IS) blood samples were collected, which were prepared and dosed by high performance liquid chromatography (HPLC). The data statistical analysis consisted of verifying the mean and standard deviation values and the application of the Spearman Correlation Coefficient. The level of significance was 5% (p <0.05).

Results: The mean and standard deviation of serum IS and PCS concentrations were 147.5 ± 71.6 μM and 279.9 ± 161.1 μM, respectively. There was an association between serum IS and creatinine (r = 0.49, p <0.01), but this was not observed with PCS concentrations. There was no correlation between the serum concentrations of IS and pCs with the values of protein intake, as well as with the other personal, clinical and nutritional variables.

Conclusions: Although admittedly derived from the metabolism of consumed proteins, uremic toxins showed no correlation with dietary intake and nutritional status of patients. It is believed that studies with a larger sample are necessary to investigate the effects of clinical and nutritional status, as well as food consumption in the production and, consequently, the concentrations of these toxins.

Keywords: uremic toxins, hemodialysis, nutritional assessment, chronic kidney disease.

SENSORY PROPERTIES AND GLYCAEMIC EFFECT OF A FORMULATED 'ACHA' BASED BISCUIT IMPROVED WITH RED KIDNEY BEAN AND UNRIPE PLANTAIN

[1]*Eme, Paul;* [2]*Nwambeke, Evaristus;* [3]*Mbah, Obioma.*

[1]PhD student. School of Public Health. Massey University. New Zealand; [2]BSc. Department of Nutrition and Dietetics. University of Nigeria, Nsukka. Nigeria; [3]PhD. Department of Nutrition and Dietetics. University of Nigeria, Nsukka. Nigeria.

Background and objectives: Diabetes mellitus (DM) is on the increase yearly. The increase in younger age group diagnosed with diabetes poses an economic threat over and above more direct disease cost to the public. The study evaluated the sensory properties and glycaemic effect of a formulated 'acha' based biscuit improved with red kidney bean and unripe plantain.

Methods: 'Acha' (Digitaria exilis), unripe plantain (Musa paradisiaca) and red kidney (Phaseolus vulgaris) bean flours were produced and blended in the ratio of 70:10:20 and 70:15:15 to obtain composite flour, 100% 'acha'were also produced. The blends were labelled thus, 100% 'acha' (AB1), 70% 'acha', 10% unripe plantain and 20% red kidney bean (AB2) and 70% 'acha', 15% unripe plantain and 15% red kidney bean (AB3), 100% wheat flour (WB) served as control. These composite flour blends were used with baking ingredients to produce biscuits. The biscuits were fed to normoglycemic adult human beings aged (20-25 years) to determine their effect on post prandial blood glucose. Glycemic control was carried using ACCU –CHEK, glucometer. Statistical Product for Service Solution (SPSS) version 20 was used to analyze for descriptive statistics (the mean, standard deviation) and the analysis of variance (ANOVA) was used to separate the means of the biscuits

Results: All the formulated products had good rating; however, the biscuit produced from 100% wheat (WB) and ratio of 70:15:15% acha, unripe plantain and red kidney bean (AB2) had the best scores. The glycemic indices (GI) were found to be 55.11%, 41.60% and 49.31% for AB1, AB2 and AB3 respectively

Conclusions: The values recorded scored well for low glycemic index which invariably posits that the biscuit would be a good diabetic snack.

QUINOA CONSUMPTION REDUCES SERUM TRIGLYCERIDES IN OVERWEIGHT AND OBESE PEOPLE

[1]*Navarro Perez, Diana Teresa;* [2]*Jois, Mark;* [3]*Shepherd, Sue;* [3]*Radcliffe, Jessica.*

[1]PhD Candidate. Department of Physiology, Anatomy and Microbiology. La Trobe University. Melbourne. Australia; [2]PhD. Department of Physiology Anatomy and Microbiology. La Trobe University. Melbourne. Australia; [3]PhD. Department of Rehabilitation Nutrition and Sport. La Trobe University. Melbourne. Australia.

Background and objectives: Quinoa (Chenopodium quinoa) is a pseudocereal originally cultivated in the Andean region. The popularity of its seeds has increased in recent years due to the claims of health benefits and superfood qualities. Studies to date on health benefits of quinoa have been mostly restricted to animal models, with few human studies providing weak to moderate evidence to support improved lipid profiles. Clinical trials in humans to examine the claims of health benefits of quinoa in overweight and obese are lacking. The aim of this randomized clinical trial was to investigate the effect of quinoa consumption on body composition and serum lipid profile in overweight and obese humans

Methods: A total of 57 subjects with a body mass index of 25 or greater completed the 12-week intervention trial. Participants were randomly allocated to one of three different treatment groups: 0 (control), 25 or 50 g quinoa seeds per day. Measurements made at 0, 6 and 12 weeks ncluded body composition by Dual Energy X-ray Absorptiometry, serum concentration of total cholesterol, LDL, HDL and total triglycerides by enzymatic methods and nutrient intake (3-day food diary). At 0 and 12 weeks physical activity was monitored for 3 days by tri-axial accelerometry (ActiGraph wGT3X).

Results: Body composition, total cholesterol, LDL, HDL, nutrient intake, and activity were not significantly altered by quinoa consumption (P>0.05). Serum triglyceride concentration was reduced significantly in the 50 g quinoa group from 1.36 mmol /L to 0.83 mmol/L at 12 weeks (P<0.05). No significant changes in triglyceride levels were observed in the control and 25 g quinoa groups

Conclusions: Consumption of 50 g / d of quinoa consumption lowers serum triglyceride levels in overweight and obese subjects.

Keywords: Quinoa seeds, randomized controlled clinical trial, dose response, triglycerides

WHOLE MILK INCREASED HDL CHOLESTEROL COMPARED TO SKIMMED MILK WITHOUT ADVERSELY AFFECTING OTHER LIPIDS, GLUCOSE, AND INSULIN IN A 2X3 WEEK CROSSOVER STUDY

[1]Engel, Sara; [2]Tholstrup, Tine.

[1]MSc. PhD-student. Department of Nutrition, Exercise and Sports. Faculty of Science. University of Copenhagen. Denmark.; [2]PhD. Associate Professor. Department of Nutrition, Exercise and Sports. Faculty of Science. University of Copenhagen. Denmark.

Background and objectives: Dietary guidelines have for decades recommended to cut down on high-fat dairy products such as whole milk due to the high content of saturated fat which is known to increase LDL cholesterol concentrations in the blood. However, meta-analyses of prospective cohort studies have found no association between saturated fat or dairy intake and risk of cardiovascular disease (CVD) and even point to an inverse association with type 2 diabetes (T2D). Whole milk and skimmed milk contain almost the same food matrix except from the fat content (3.5 vs 0.1%). Therefore, it was possible to compare high-fat with low-fat milk and study the effect of milk fat on risk of CVD and T2D.

Methods: In a randomized, controlled, 2x3 week crossover intervention study we compared the effect of intake of 0.5 L of whole milk with skimmed milk on blood lipids, glucose, and insulin. Besides drinking milk the 17 men and women consumed their habitual diet.

Results: Subjects were 65 % women with a mean age of 25.7 y and a body mass index (in kg/m2) of 21.8. Whole milk increased HDL cholesterol significantly (P < 0.05) compared to skimmed milk. We found no significant differences between whole milk and skimmed milk in effect on total and LDL cholesterol, TAG, glucose and insulin. There was a tendency (P = 0.06) for total cholesterol to be higher with whole milk compared to skimmed milk.

Conclusions: Intake of 0.5 L/d of whole milk did not adversely affect risk markers of CVD and T2D compared to skimmed milk. Moreover, intake of whole milk increased HDL cholesterol concentration compared to skimmed milk. These findings suggest that it might be reasonable to include whole milk as part of a healthy diet.

Keywords: Dairy, milk, CVD, cholesterol, healthy adults

VITAMIN D DEFICIENCY IS ASSOCIATED WITH HIGH BLOOD PRESSURE IN 24-H AMBULATORY BLOOD PRESSURE MONITORING IN PATIENTS WITH TYPE 2 DIABETES

[1]de Paula, Tatiana; [2]Sperb, Luiza; [3]Moreira, Juliano; [4]de Freitas, Mauren; [5]Miller, Maria Elisa; [6]da Silva, Andressa; [7]Viana, Luciana; [7]Azevedo, Mirela.

[1]PhD. Nutricionist. Federal University of Rio Grande do Sul. Brazil; [2]Medical Student. Federal University of Rio Grande do Sul. Porto Alegre. Brazil; [3]Medical Doctor. Hospital de Clinicas de Porto Alegre. Porto Alegre. Brazil; [4]Registered Dietitian. Hospital de Clinicas de Porto Alegre. Porto Alegre. Brazil; [5]Medical Student. Federal University of Rio Grande do Sul. Porto Alegre. Brazil; [6]Nutritional Science student. Hospital de Clínicas de Porto Alegre. Porto Alegre. Brazil; [7]Medical Doctor. Hospital de Clínicas de Porto Alegre. Porto Alegre. Brazil.

Background and objectives: Plasma vitamin D measurements are negatively correlated with BMI and blood pressure (BP) in general population (1,2). Since most patients with type 2 diabetes (DM2) are obese and hypertensive, it is relevant to identify vitamin D status in this population. The aim of this study was to evaluate factors associated with vitamin D deficiency [25(OH)D<20 ng/ml] in patients with DM2 and hypertension.

Methods: In this cross-sectional study BP was assessed by office measurements (Omron HEM-705CP) and 24h ambulatory blood pressure monitoring (ABPM) - Spacelabs®. Physical activity was evaluated by steps count (pedometer – Yamax Digi-Walker). Clinical, nutritional, and laboratory parameters were evaluated by a standardized protocol. Body composition was determined by DXA-Lunar®. Exclusion criteria were: use of vitamin supplements, serum creatinine >2.0 mg/dl, BMI >40 kg/m , gastrointestinal diseases associated with malabsorption.

Results: A total of 116 patients (age 65±8.9 years; 43% males; BMI 30.3±4.1 kg/m², diabetes duration 12.3±8.3 years; HbA1c 7.6±1.4%) were included. Mean 25(OH)D was 20.1±9.1 ng/ml and 43% of patients were considered as deficients. Office systolic and diastolic BP were 150.7±20.9 and 83.5±11.0 mmHg, respectively. At ABPM, patients with hypovitaminosis D had higher systolic BP in 24h (135.7±10.2 vs 130.2±13.3 mmHg; P=0.016) and during daytime (138.1±11.3 vs 132.8±13.4 mmHg; P=0.026) than sufficient patients. Patients with vitamin D deficiency had also lower steps count [4350.0 (2647.8-6598.0) vs 6390.6 (4706.9-8081.1) steps/day] and urinary calcium [47.0 (32.0-141.2) vs 89.5 (67.7-152.5) mEq/24h) than sufficient patients. Regarding to dietary intake, patients with hypovitaminosis D consumed less milk (35.6 vs 64.4%; p =0.009) and less fish (31.2 vs 68.8%; p<0.001) than non-deficient patients. In multivariate logistic regression, steps count <5600 steps/day (OR=2.9, CI95% 1.1-7.6) and no milk (OR=3.9 IC95% 1.3–11.9) and no fish consumption (OR=3.4 IC95% 1.4–10.8), remained associated to vitamin D deficiency; fat mass was not associated with vitamin D deficiency.

Conclusions: Hypovitaminosis D is highly prevalent in patients with type 2 diabetes and hypertension. In this group of patients, vitamin D deficiency was associated with higher BP levels in 24h and daytime ABPM. In addition, less physical activity, milk and fish intakes were also associated with vitamin D deficiency.

EFFECT OF PRE, CO AND POST LOAD OF DRIED STRIPPED RADISH WITH A RICE ON POSTPRANDIAL GLYCEMIA IN HEALTHY FEMALE SUDENTS

[1]Sueda, Kaori; [2]Asano, Ai; [2]Katoh, Miyuki; [2]Kadowaki, Natsumi; [2]Satoh, Shouko; [2]Hasegawa, Risa; [3]Sakai, Eiko.

[1]PhD. Faculty of Phychological and Physical Science. Aichi Gakuin University Japan.; [2]Nutritionist. Faculty of Phycological and physical Science. Aichi Gakuin University Japan.; [3]PhD. Faculty of Phycological and Physical Science. Aichi Gakuin University. Japan.

Background and objectives: Fibre contribute glycaemic response. The present study aimed to compare the effect of Dried Stripped Radish (DSR) , when consumed before /co /after a rice, on postprandial blood glucose in healthy students.

Methods: Ten subjects were served the total 50g carbohydrate of the white rice alone, or together with 15g DSR. In experiment 1 (control meal), white rice (carbohydrate 50g) was provided. In experiment 2 (test meals), three 15g DSR with white rice (total carbohydrate 50g) were provided. Three studies were conducted, 1)15min before 2) together with, and 3) 15min after a white rice consumption, three 15g DSR were provided to the subjects. This was a randomized, cross over design study where subjects consumed test meals on separate occasion, followed by the measuring blood glucose (fasting (0) , 15, 30, 60 ,45, 60, 90 and 120 min). The area under the curves for glucose (GAUC) were calculated. Comparisons of blood glucose, GAUC among meals were analyzed based on paired t-test.

Results: 1) Compared with the rice only (control), the blood glucose of DSR before 15min was significantly high at 0min ,15min (both P< 0.05) and then it was low 45 min, 60min (both p<0.01). Compared with control, the blood glucose of DSR together with was significantly low 45 min, 60min (both p<0.01).   2) 15g DSR before 15min / together with had significantly lowered the GAUC values, compared to control (p<0.001, P<0.05, respectively). 3) There are no differences in GAUC among 3 DSR diets with different eating order of rice and DSR.

Conclusions: The loading of DSR, 15min before and together with a rice, lowers postprandial blood glucose concentrations, probably by slowing gastric emptying and intestinal absorption .

Keywords: postprandial blood glucose; rice ; dried stripped raddish ; preload

RELATIONSHIP BETWEEN THE AGE OF INTRODUCTION OF THE EGG IN THE DIET AND THE DIAGNOSIS OF IGE MEDIATED EGG ALLERGY

[1]Sotomayo,r Giubi, Viviana, Olivia; [2]Sanabria, Marta.

[1]MD.; [2]MsC. MD.

Background and objectives: Background: The prevalence of food allergy has increased, which represents a public health problem. Although egg allergy itself can be overcome, these children are at increased risk of other atopic diseases. The Dietary Guidelines for long recommended delaying the introduction of potential food allergens to prevent food allergies without real evidence. This study examined this issue with a focus on egg allergy, one of the most common IgE mediated food allergies.

Objectives: To analyze the relationship between age at first egg intake and the onset of IgE mediated egg allergy. To describe the presence of risk factors associated. To describe the profile of the patient with egg allergy.

Methods: Retrospective observational analytical study of cases and controls

Results: 116 patients allergic and no allergic to eggs were found in which no relationship between age at first egg intake (mean: cases 9,2 months, controls 9,8 months, median 9 month) and the onset of IgE mediated egg allergy (EA) was found. EA patients presented with a male predominance with positive personal history of atopy, normal weight and size, the average duration of breastfeeding of 10.5 months, mean introduction of solids to 5.7 months and respiratory symptoms predominantly. Similar characteristics are found in the control group. Age of diagnosis of EA: 41 months. Associated risk factors: Nutritional Status: Cases: Malnutrition 10.3% Risk of malnutrition. 22.4% Overweight 8.6% and Controls Malnutrition11.3%. Risk of Malnutrition 10.3 and Overweight: 11.3%, (p = ns). Ig E total 83% (Cases) and Control 48% (p = 0.0001). Symptoms in cases: Skin 60%, respiratory 70% and digestive 33% (p <0.04). Allergy to cow's milk protein: 72% (p <0.0001). Other food allergies 32%. (P <0.04)

Conclusions: There is no difference in the age of introduction of the egg and the occurrence of IgE mediated egg allergy .This lack of apparent relationship would support the new dietary guidelines where it is recommended not to delay the introduction of egg into the diet. There were found as factors associated with the egg allergy: allergy to other food allergens, digestive symptoms and the presence of elevated total IgE.

Keywords: Egg allergy

EFFECTS OF AVENA NUDA L. ON CHINESE PATIENTS WITH HYPERTENSION ASSOCIATED WITH TYPE 2 DIABETES MELLITUS: SECONDARY ANALYSIS OF A RANDOMIZED CLINICAL TRIAL

[1]Li, Yong; [2]Mao, Ruixue; [2]Xu, Meihong; [2]Wang, Junbo.

[1]Prof. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191,; [2]PhD. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191.

Background and objectives: While China-original naked oat with whole germ (NOG, Avena nuda L.) is an excellent choice of whole grain for its higher soluble dietary fiber (beta-glucan), unsaturated fatty acid and lower slowly digestible starch than common oat (Avena sativa L.), there is limited information about the effect of NOG intake with structured dietary intervention on patients with hypertension associated with type 2 DM.

Methods: In a randomized, single-blinded, 28-day centralized trial in China, a total of 73 participants meeting the WHO/ISH hypertension guidelines (1999) diagnostic criteria were selected from 445 patients meeting the ADA standards of medical care in diabetes (2013) diagnostic criteria between 50 and 60 years of age, randomly assigned into one of the 3 groups: diet group (n=24, systematic diet plans and intensive health education), 50g-NOG group (n=25) and 100g NOG group (n=24). The composition of NOG has been determined. Subsequently NOG was daily boiled into porridge as replacement based on diet group. The relative changes in systolic blood pressure (SBP), diastolic blood pressure (DBP), fasting blood glucose (FBG), 2-hour postprandial blood glucose (PBG) measured respectively on day 0, 28 (SBP, DBP) and day 0, 7, 14, 21, 28 (FBP, PBG) were the primary outcomes. Data was analyzed by the SPSS 19.0 software package with descriptive analysis, one-way analysis of variance, and paired t test.

Results: The rate of adherence to a study diet was 100% at day 28. Among 3 groups above, SBP, DBP, FBG and PBG values declined significantly over the intervention period (P<0.05). The changes in SBP are more favorable for both 100g-NOG group and 50g-NOG group than the diet group (P<0.05). The improvements in FBG were better in 100g-NOG group than in diet group (P<0.05). The 100g-NOG group had the most significant reduction of PBG values (P<0.05 for all comparisons among 3 groups).

Conclusions: Comparison between 50-100g/day NOG replacement to structured diet and diet alone suggests that the former intervention (especially at a dose of 100g/day) provided better benefits to patients with hypertension associated with type 2 DM in their disease management and cardiovascular disease risk control.

THE CONTROL OF BLOOD GLUCOSE AND COMPLICATIONS AMONG TYPE 2 DIABETES MELLITUS PATIENTS BASED ON THE DYNAMIC CHANGES OF DIETARY INTAKE DURING THE FOLLOW-UP SURVEY PERIOD

[1]Li, Yong; [2]Fan, Rui; [2]Xu, Meihong; [2]Wang, Junbo.

[1]Prof. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; [2]PhD. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191.

Background and objectives: Centralized intervention can provide a balanced diet on glycemic control among patients with Type 2 diabetes mellitus (T2DM), but most individuals may not follow the recommended diet guidelines in the long run. The real dietary behavior and its outcomes during the follow-up periods are scarce. Therefore, how the dietary behavior changed and what were the outcomes brought during the follow-up survey were reported for the first time in this study.

Methods: One hundred and seventy-five elder participants with T2DM for more than 2 years who previously been randomized to receive centralized intervention were included. We analyzed the association between the blood glucose and each nutrients intake through logistic regression, the effects of dynamic changes of dietary intake had been evaluated based on glycemic control and complication prevalence in three years.

Results: The optimal diet assistant decreasing blood glucose characterized as low fat (<25%), standard-protein (25%), high complex carbohydrate and high fiber (>18 g/1000kcal). The participants adhering to this diet showed a satisfactory outcomes in three years. Compared with the baseline, Hemoglobin A1c (HbA1c), fasting plasma glucose (FPG) and 2h-plasma glucose (2h-PG) decreased from 8.3%, 9.62 mmol/L and 18.28 mmol/L to 7.3%, 7.81 mmol/L, and 11.3mmol/L, respectively. Additionally, they also exhibited a decrease in nephropathy prevalence, and their prevalence of diabetic foot ulcer and neuropathy remained unchanged.

Conclusions: The obviously control of blood glucose, HbA1c as well as the prevalence of complications occurred on those elder participants persisted in the optimal diet. Therefore, this study will provide strategies to guide clinicians with their dietary prescription to control complications and is promising with regard to further exploration of comprehensive diabetes care.

THE POSITIVE EFFECTS OF NAKED OAT ON GLYCEMIA AND BLOOD LIPID RISK FACTORS FOR CARDIOVASCULAR DISEASE IN PATIENTS WITH TYPE 2 DIABETES AND METABOLIC SYNDROME: ONE YEAR RESULTS OF A RCT

(1)Li, Yong; (2)Li, Ye; (2)Xu, Meihong; (2)Fan, Rui.

(1)Prof. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; (2). Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191.

Background and objectives: Patients with type 2 diabetes and metabolic syndrome are at increased risk for cardiovascular complications. Comprehensive cardiovascular risk reductions are critical for this high-risk population. The aim of this study was to evaluate the effects of long-term naked oat consumption on cardiovascular disease risks in patients with type 2 diabetes and metabolic syndrome.

Methods: 244 participants met type 2 diabetes and metabolic syndrome criteria were selected from a randomized clinical trial who completed the one year dietary program. They were randomly allocated to four groups: control group; diet group; 50g-NOG group and 100g-NOG group. Participants in the control group continued their usual diet. The diet group had structured diets. The participants in the 50g-NOG group received structured dietary intervention and replaced some of the staple foods with 50g NOG. And the 100g-NOG group also received structured dietary intervention while the daily substitute of staple foods was 100g NOG. At baseline and 12 months, physical examinations and blood tests were carried out and food-frequency questionnaires were administered to investigate changes from baseline and compliance with the dietary intervention.

Results: After 1 year intervention, HbA1c, FPG and PG were significantly decreased compared to the control group particularly at 100g-NOG group (-1.0±1.7%, -2.1±3.2mmol/l, and -6.9±5.9mmol/l, respectively, P<0.05). Reductions were also achieved in TG (-0.2±1.1mmol/l to -0.6±1.6mmol/l), TC (-0.2±1.1mmol/l to -0.5±1.2mmol/l), and LDL-c (-0.2±0.8mmol/l to -0.4±0.8mmol/l) in the intervention groups (P<0.05). The groups differed significantly with respect to the percent of patients who reached the treatment goals in glycosylated hemoglobin, cholesterol and triglycerides (P<0.05). Glycemic control was better in patients of 100g-NOG group with 23.8% having HbA1c below 6.5%. And more patients reached lipid goals in the NOG group. 44.4% of patients in the 100g-NOG group had cholesterol below 4.5mmol/l, and 57.1% had triglycerides below 1.7mmol /l. No adverse events were reported throughout the study period.

Conclusions: The results of the present study suggest the beneficial effects of naked oats on cardiovascular disease risk factors, especially on glycemic regulation and lipid metabolism in patients with type 2 diabetes and metabolic syndrome.

Keywords: naked oat; cardiovascular disease; diabetes mellitus, type 2; metabolic syndrome

EFFECTS OF MEAL INTERVENTION COMBINED WITH WALKING ON EXERCISE ABILITY AND PHYSIQUE OF MIDDLE - AGED AND OLD PEOPLE

(1)Li, Yong; (2)Chen, Qihe; (2)Mao, Ruixue; (2)Xu, Meihong.

(1)Prof. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; (2)PhD. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191.

Background and objectives: To investigate the effects of vigorous walking and diet intervention on exercise capacity and physical fitness of middle-aged and elderly people.
Methods: According to the different physical condition of the middle - aged and old people, the data were divided into 93m / min, 100m / min, 107m / min, 110m / min, 114m / min 5 by comparing their own before and after the test. Blood pressure, heart rate, heart rate, body weight, waist circumference, hip circumference, systolic blood pressure, diastolic blood pressure, heart rate, BMI and other data were collected in the intervention group with the maximum exercise load of 50%.
Results: Compared with the baseline, the 6-min walking distance, cardiac recovery rate, systolic blood pressure, diastolic blood pressure, body weight, hip circumference and BMI of the subjects were significantly improved (P <0.05). Have different degrees of improvement.
Conclusions: Jianbu walking and take the joint dietary intervention in the exercise capacity of the elderly and physical fitness has significant effect, it is recommended to promote.
Keywords: vigorous walking; diet; 6min walking test; blood pressure; heart rate; circumference

THE INTERPLAY BETWEEN MOTHER'S KNOWLEDGE, ATTITUDE AND PRACTICE , BMI AND INFANTS' NUTRITIONAL STATUS IN DELTA STATE, NIGERIA

(1)Ofili, Oghenefego; (2)Fadupin, Grace T.

(1)PhD Student, Department of Human Nutrition, University of Ibadan; (2)PhD, Nutritionist, Senior Lecturer, Department of Human Nutrition, University of Ibadan.

Background and objectives: The health and nutritional status of an infant is largely dependent on the mother's knowledge, attitude and practice (KAP) of certain widely researched guidelines such as GOBIFFF and the Essential Nutrition Actions (ENA). This report is from the baseline survey conducted as part of an intervention project aimed at improving the KAP of mothers on

infant nutrition and health care practices through behavior change communication in Delta State, Nigeria. This study seeks to gather evidence for policy advocacy on nutrition behavior change communication as a key strategy to improving infant health and nutrition in Nigeria.

Methods: A baseline assessment as part of formative research was conducted to review the situation and gaps in knowledge, skill or other issues related to infant nutrition and health of mothers in Delta State. A semi-structured questionnaire was used to gather information on demographic characteristics, nutritional status of mother-child pair and KAP of infant nutrition and health care strategies in 6 communities in Delta State. Knowledge, attitude and practice scores were determined by the number of correctly answered questions.

Results: 68.3% of infants in this study population were severely stunted, 15% were wasted, while 28.6% of infants in Delta State were found to be severely underweight. Infants whose mothers were overweight or obese had more tendency to have normal weight-for-age than infants whose mothers were underweight or normal. Results: **Conclusions:** The nutritional status of an infant is strongly linked to the mother's KAP of infant nutrition and health care strategies. Also, the ability of a mother to maintain a healthy BMI does not necessarily result in an infant with a healthy/normal nutritional status. There needs to be more intervention programs in the area of nutrition education at the community level.

THE PREVALENCE, AWARENESS, TREATMENT, AND CONTROL OF HYPERTENSION AMONG CHINESE ADULTS IN 2012

[1]Zhao, Yanfang; [2]Wang, Zhuoqun; [2]Yang, Jing; [3]Zhao, Wenhua.

[1]MD.National Center for Chronic and Noncommunicable Disease Control and Prevention. Chinese Center for Disease Control and Prevention. China.; [2]National Center for Chronic and Noncommunicable Disease Control and Prevention. Chinese Center for Disease Control and Prevention. China.; [3]National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China.

Background and objectives: Unreasonable dietary rich in saturated fatty acid and salts may increase the risk of many chronic diseases.The dietary structure of Chinese population has changed greatly during the recent decades and the problem of related chronic diseases becomes more and more serious. Hypertension is a major risk factor for cardiovascular disease and treatment and control of hypertension reduces risk. The study aims to evaluate the prevalence, awareness, treatment and control of hypertension among China adults.

Methods: Data were extracted from the report of Chinese national nutrition and chronic disease status issued by National Heath and Family Planning Commission of China in 2015, in which the data were calculated based on the National Health and Nutrition Examination Survey 2010-2013.The surveillance included about 200 thousand adults aged 18 and over, which were sampled from 150 surveillance points by Multi-stage cluster random sampling.Hypertension was defined as systolic BP of at least 140mm Hg and diastolic BP of at least 90 mm Hg, self-reported use of antihypertensive medications, or both. Hypertension control was defined as systolic BP values of less than 140 mm Hg and diastolic BP values of less than 90 mm Hg.

Results: The prevalence of hypertension among Chinese adults aged 18 and over was 25.2% in 2012, 26.2% and 24.1% among men and women, respectively; 26.8% and 23.5% among urban and rural adults, respectively, and 10.6%, 35.7%and 58.9% among the groups of 18–44, 45-59, and 60 years old and over, respectively. Among adults with hypertension in 2012, 46.5% were aware of their hypertension, 41.1% were currently taking medication to lower their blood pressure, and 13.8% were controlled hypertension. Compared with 2002, the prevalence of hypertension increased by 6.4%, and the awareness, treatment and control of hypertension increased by 16.3%, 16.4% and 7.7%, respectively.

Conclusions: The prevalence of hypertension among Chinese adults has remained at a high level and has showed a rapid rising trend. Although the rates for awareness, treatment, and control of hypertension have improved markedly, they are still at a low level. These findings suggest that it is necessary to strengthen the health education and comprehensive management of hypertension in China.

COMPARISON OF TWO APPROACHES OF NUTRITIONAL EDUCATION IN THE MANAGEMENT OF DIABETES

[1]zeghari, lotfi; [2]zeghari, lotfi; [2]Aboussaleh, Youssef.

[1]PhD; [2]Laboratory of Nutrition, Health & Environment | Biology Department | Faculty of Science | Ibn Tofail University, PB 133 | Kenitra 14 000 | Morocco |.

Background and objectives: introduction: Nutrition education is one of the fundamental axes in the management of diabetes.

Objective: study the impact of two types of nutrition education (personalized and collective) on the glycemic control of diabetics in the province of Kenitra.

Methods: The population was composed of 184 patients (86 men, 98 women) with an average age of (51.7 ± 14.0) and an age range of [20 to 88.5]. Data collection was carried out using a questionnaire containing socio-demographic and anthropometric informations.

Glycemic control was based on fasting glucose (GAJ), postprandial glucose (GPP), and glycated hemoglobin (HbA1c). These analyzes were taken in three separate phases with a duration of 3 months; T0 represents the initial state (before our intervention),

t1 and t2 which represent the values of the three analyzes after our intervention.

Participants were randomized into two groups: a group that received collective nutrition education (n = 105) and another group (n = 79) had a personalized (individual) education.

BMI was the only anthropometric measure used

Results: The whole population is overweight (BMI> 25) for either women or men, also the results of glycemic control are superior to the norms in the three stages (t0, t1 or t2). Nutrition education Personalized shows statistically significant differences in the variables studied as a function of time more than those studied in collective nutrition education (p = 0.00 <0.05). Also the difference is significant between collective nutrition education and personalized nutritional education (P = 0.00 <0.05) for the means of HBA1C (%) at t1 and at t2; Fasting glucose (g / l) at t1 and t2 and post-prandial glucose (g / l) at t1 and t2.

Conclusions: The results of this study show that collective nutrition education yields significant results in terms of impact on glycemic control of theses diabetics. The number of studies on this aspect (nutrition education) remains modest, another study is desirable on a larger sample to better confirm our results

[1]PhD. Nutritionist. Hospital César Milstein.Docente University of Buenos Aires; [2]PhD. Nutritionist; [3]PhD. Nutritionist. Hospital César Milstein.; [4]PhD. Nutritionist. César Milstein Hospital. University of Buenos Aires; [5]PhD. Nutritionist. César Milstein Hospital. University of Buenos Aires.

Background and objectives: Introduction: Vitamin B12 (VB) is an essential micronutrient, its deficiency causes neurological diseases. Type 2 Diabetes Mellitus (DM2) is a rising condition, Metformin (MTF) is the most widely used drug, its use is associated with B12 deficiency (DVB). MTF competitively blocks the binding of the intrinsic factor VB complex to its receptor, this interaction rarely generates an anemia that is reversible upon discontinuation of metformin or the addition of VB. Some individuals seem more predisposed than others to this interaction. Prevalence is variable

Objective: To determine the association between the use of MTF and DVB in elderly patients with DM2.

Methods: Descriptive observational study. The sample was obtained from patients who attended the Milstein Hospital Nutrition service between May and June 2016. Folic acid (AF), VB, VCM, hematocrit (HTO) were requested. The following data were obtained from the medical records: DM years, MTF doses, years of MTF use. It was considered deficit of VB12<200 mg, partial deficiency (DP) between 201 and 300, and as pathological values of VCM>100 and HTO<35%. The sample was divided into 2 subgroups according to age: advanced age (EA) between 60 and 74 years old, elderly aged between 75 and 89 years. P<0.05 statistically significant.

Results: The sample size was 192 patients, 56% were women, the prevalence of DVB was 12.5%, a partial deficiency was 29.5, HbA1c mean 7%, MTF dose of 1.7g, with a 8 years median of use for DVB patients and 5 years for DP, we found no statistically significant differences when analyzing HTO, VCM or AF values (p 0.58), nor differences in B12 dosage when analyzed each age subgroup.

Conclusions: The DVB reveals a public health problem. HTO, VCM and AF would not provide relevant data at the time of DVB suspicion. The control of the elderly with DM2 should include VB dosing, regardless of the dose of MTF. Studies with larger sample size are required.

EFFECT OF FORMULATED DRINK AND SNACK FROM COCOA, MORINGA, COMPOSITE FLOUR AND THAUMATOCOCCUS DANIELLI AS AN ORGANIC SWEETENER ON THE NUTRITIONAL STATUS OF WISTER RATS

[1]Oyebamiji, Emmanuel; [2]Atinmo, Tola; [3]Attah, Alfred.

[1](BSc,MSc). Nutritionist. Department of Human Nutrition. University of Ibadan. Nigeria; [2]Professor. Nutritionist. Department of Human Nutrition. University of Ibadan. Nigeria; [3]PhD. Department of Pharmacognosy. University of Ibadan. Nigeria.

Background and objectives: Micronutrient deficiencies cause an estimated 1.1 million of the 3.1 million child deaths that occur each year. This study, therefore, investigates the effect of formulated nutritional supplements on the nutritional status of Wistar rats using formulated nutritional drinks and snacks from cocoa and Moringa with Thaumatococcus Danielle as an organic sweetener.

Methods: Twelve Wistar rats weighing 120g were subjected to formulated drinks and snacks to determine the nutritional effects. The rats were fed for two weeks, after the initial acclimatization, and grouped into three groups equally, the first group were given the 1mls of the formulated drink with normal rat diet, drink composed of Moringa, cocoa and spices, the second group were given formulated bread from Cocoa, Moringa, with Cassava flour and

Thaumatococcus Danielle with normal drinking water, and the control group were given normal rat diets which were the control. At the end of the two weeks, the experimental rats were weighed before they were sacrificed and there was a significant difference in their weight. Blood samples were collected to determine micronutrient (vitaminA, iron, zinc, calcium, and iodine) level in the experimental rat's blood serum.

Results: The result revealed a significant (p≤0.05) increase in the treatments in respect to the micronutrient status of the experimental rats when compared with the control group. Furthermore, there was an appreciable non-significant increase among micronutrient levels of those that were fed with the bread and drinks respectively (group two and one), except for vitamin A with 0.007.

Conclusions: Based on the results of this study, the formulated drinks and snacks had a significant effect on the growth and micronutrient levels of the experimental rats and thus can be used in combatting malnutrition.

Keywords: Malnutrition, Moringa, Cocoa, Thaumatococcus Danielle

HIGH FODMAP PRODUCTS CONSUMPTION AMONG CHILDREN WITH GASTROINTESTINAL DISORDERS

[(1)]*Boradyn, Katarzyna Mirosława;* [(2)]*Jarocka-Cyrta, Elżbieta;* [(3)]*Przybyłowicz, Katarzyna Eufemia.*

[(1)]MSc. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.; [(2)]Prof. Department of Clinical Pediatrics. University of Warmia and Mazury in Olsztyn. Poland.; [(3)]Prof. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.

Background and objectives: Gastrointestinal disorders are one of the most commonly diagnosed diseases among children. Preliminary studies indicate that FODMAP (Fermentable Oligosaccharides, Disaccharides, Monosaccharides and Polyols) improves symptoms in gut disorders. Low FODMAP diet seems to be effective diet therapy mostly in IBS but also in others functional gastrointestinal symptoms [1,2].

The purpose of this pilot study was to valuate of differences in the frequency of high FODMAP products consumption among children with various gastroenterological diseases.

Methods: Retrospective study was conducted among 67 children, age range 4-17 years, who reported abdominal pain and problems with defecations. Respondents were patients of Department of Pediatrics, Gastroenterology and Nutrition Children's Hospital in Olsztyn. Symptoms have been diagnosed as constipation, functional abdominal pain and celiac disease. A food fre-

quency questionnaire was used to collected information about consumption of high FODMAP products categorized in 6 groups: sweets and snacks, dairy products, cereal products, fruits, vegetables and drinks.

Results: The most commonly consumed high FODMAP products were dairy products (mean 2,60 times a day, 95% CI: 2,32-2,89) and the least eaten were vegetables (mean 0,69 times a day, 95% CI: 0,56-0,83). Children with functional abdominal pain consumed high FODMAP food the most often during the day (mean 9,87 times a day, 95% CI: 8,53-11,20) and patients with celiac disease the least often (mean 7,91 times a day, 95% CI: 6,70-9,12). The results showed a significantly lower intake of high FODMAP cereal products among children with celiac disease compared to the other groups.

Conclusions: The pilot study showed that children with gut disorders consumed high FODMAP products from different food groups which may induce the occurrence of symptoms of disease. More long term research conducted among children is needed to confirm this association.

ASSOCIATIONS OF WAIST-TO-HEIGHT RATIO WITH EMOTIONAL EATING, IRREGULARITY OF EATING, EATING FAST, EATING UNTIL FULL, EXTERNAL EATING AND MAKING ENVIRONMENT TO PROMOTE EATING IN JAPANESE ADULTS

[(1)]*Nakade, Makiko;* [(2)]*Aiba, Naomi;* [(3)]*Morita, Akemi;* [(4)]*Miyachi, Motohiko;* [(5)]*Deura, Kijo;* [(6)]*Watanabe, Shaw.*

[(1)]RD, PhD. Tokai Gakuin University. Japan.; [(2)]RD, PhD. Kanagawa Institute of Technology. Japan.; [(3)]MD, PhD. Koshien University. Japan.; [(4)]PhD. National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition. Japan.; [(5)]MD. Saku Central Hospital. Japan.; [(6)]MD, PhD. Life Science Promotion Foundation. Japan.

Background and objectives: Waist-to-height ratio (WHtR) has started gaining attention as a measure of abdominal obesity. While the associations between various eating behaviors and higher BMI or obesity/overweight determined by BMI have been reported, studies focused on the relationship between eating behaviors and WHtR in adults are scarce. This cross-sectional study aimed to clarify eating behaviors associated with a higher WHtR in Japanese adults.

Methods: Subjects were 2818 men and women aged 20 to 75 years who had participated in baseline assessments of a cohort study in Japan from 2009 to 2013. They underwent assessments including physical examination and answered questionnaire regarding various eating behaviors (emotional eating, irregularity of eating, eating fast, eating until full, external eating and making environment to promote eating), lifestyles, and stage of change regarding diet. The relationship between the WHtR (<0.5 as a reference) and each eating behavior was examined using multiple logistic regression analysis adjusting for age, sex, lifestyles, and stages of change regarding diet.

Results: After adjusting for covariates, the WHtR showed significant positive relationships with eating behaviors regarding all items of emotional eating, having late-night snack, eating between meals, having many occasions to go to drinking parties, eating fast, eating until full, all items of external eating and making environment to promote eating. Skipping breakfast and having dinner late did not show significant associations with the WHtR.

Conclusions: Some eating behaviors were associated with a higher WHtR in adults. Putting more emphasis on these specific eating behaviors may effectively decrease the WHtR and prevent cardiovascular diseases.

Keywords: waist-to-height ratio, eating behaviors, adults

EFFECT OF DIETARY SUPPLEMENTATION OF 25-HYDROXYVITAMIN D3 ON IMMUNE RESPONSES OF CHICKENS

[1]Chou, Pao-Chia; [2]Lai, Lih-Shiuh; [3]Chen, Shuen-Ei.

[1]PhD student. Department of Food Science and Biotechnology, National Chung Hsing University, Taichung, Taiwan; [2]PhD. Department of Food Science and Biotechnology, National Chung Hsing University, Taichung, Taiwan; [3]PhD. Department of Animal Science, National Chung Hsing University, Taichung, Taiwan.

Background and objectives: Innate immunity acts as the frontline of the host defence system against pathogens, such as bacteria and viruses. Macrophages and neutrophils can internalize and destroy pathogens and activate subsequent humoral immune responses. Obesity is associated with dyslipidemia, systemic inflammation, and a susceptibility to pathogen invasion. Vitamin D3 has been shown to ameliorate obesity-related cardiomyopathy and systemic inflammation, but the role of innate immune cells against bacterial infection in obese individuals and by the effect of vitamin D3 is elusive. The preset study aimed to investigate the effect of obesity and dietary supplementation of vitamin D3 on the invasion defense in chickens using Salmonella as a pathogen.

Methods: Hens provided with a basal control diet or with vitamin 25 OH-D3 inclusion, then were released for ad libitum (AD) feeding or continued with restricted (R) feed intake. Four weeks after treatment, hens were sampled for blood collection for peripheral leukocyte isolation in the following weeks. Freshly isolated heterophils and monocytes were analyzed for bacterial killing (5 × 105 freshly cells to 106 CFUs of opsonized Salmonella Typhimurium) or migration (2 × 106 cells/well). Fasting plasma were analyzed for glucose, triglyceride and cholesterol concentrations.

Results: Hens with AD feeding ± 25OH-D3 treatment had the highest bacterial killing activity in the monocytes, but heterophils showed AD heterphils had the highest bacterial killing activity. In both R and AD hens, cell migration rate of monocytes was increased significantly (p < 0.05) by 25OH-D3 supplementation, but not in the heterophils. AD hens had a higher plasma triglyceride levels than R hens. 25OH-D3 supplementation suppressed plasma triglyceride and cholesterol levels but slightly increased glucose concentrations in AD hens but not in R hens.

Conclusions: These results suggest a cell type- and obesity-dependent innate immune cell response to 25OH-D3.

Keywords: monocytes; heterophils; Salmonella Typhimurium; migration; pathogen invasion

A MULTI-ETHNIC AUSTRALIAN COHORT WITH CORONARY HEART DISEASE ADHERE WELL TO A MEDITERRANEAN DIET INTERVENTION AND IMPROVE PLASMA ADIPONECTIN LEVELS

[1]Mayr, Hannah; [2]Bendall, Cassandra; [3]Tierney, Audrey; [4]Kingsley, Michael; [5]Radcliffe, Jessica; [3]Itsiopoulos, Catherine; [6]Thomas, Colleen.

[1]BHsc (Hons). Accredited Practicing Dietitian. Department of Rehabilitation, Nutrition and Sport. La Trobe University. Australia.; [2]BHsc. Nutritionist. Department Rehabilitation, Nutrition and Sport. La Trobe University. Australia.; [3]PhD. Accredited Practicing Dietitian. Department Rehabilitation, Nutrition and Sport. La Trobe University. Australia.; [4]PhD. Exercise Physiologist. La Trobe Rural Health School. La Trobe University. Australia.; [5]PhD. Nutritionist. Department Rehabilitation, Nutrition and Sport. La Trobe University. Australia.; [6]PhD. Department of Physiology, Anatomy and Microbiology. La Trobe University. Australia.

Background and objectives: The AUStralian MEDiterranean (AUSMED) Heart Trial aims to determine the efficacy of a 6-month Mediterranean Diet (MedDiet) intervention, compared to a low fat diet, in reducing secondary cardiovascular events at 12 months in a multi-ethnic Australian cohort (target n=1032) of high-risk patients, with a prior coronary event. We report initial data on participant adherence to the MedDiet intervention and whether the MedDiet improves markers of cardiometabolic risk profile at 6 months.

Methods: An initial cohort of AusMed participants (n=39, mean age 64 years, 87% male) were randomised to a MedDiet (n=24) or a Low-fat diet (n=15). Participants attended appointments with a Dietitian at 0, 3 and 6 months. Haemodynamic, anthropometric and body composition were measured and blood samples were collected for biomarker analyses. In addition, at these time points, adherence to the MedDiet was assessed using a validated 14-item questionnaire and 7-day food diaries allowed dietary composition changes to be recorded.

Results: Intervention participants adhered well to the MedDiet (baseline score of 5/14 increased to 11/14 at 6 months; p<0.001). The MedDiet adherence score of Low-fat diet participants did not change significantly. MedDiet participants had a higher intake of monounsaturated fat (22.0% vs 13.6% of total energy intake p=0.01) and polyunsaturated fat (9.2% vs 7.4% of total energy intake, p=0.02) after 6-months, compared to Low-fat diet participants. Compared to the Low-fat diet, the MedDiet did not change visceral adipose tissue, waist circumference, body weight, blood pressure or lipid profile (p>0.05). Plasma levels of the anti-inflammatory and insulin-sensitising biomarker adiponectin tended to increase in response to the MedDiet compared to the Low-fat diet after 6 months (4.7±2.3 mg/ml to 5.6±3.7 mg/ml vs. 5.1±2.5 mg/ml to 3.5±1.2 mg/ml, respectively; p=0.08).

Conclusions: These preliminary findings demonstrate that Mediterranean diet intervention in a multi-ethnic Australian population with coronary heart disease can change dietary behaviour, especially increase intake of healthy fats. This dietary change positively influences plasma adiponectin concentrations, an established protective cardiometabolic risk marker, compared with a conventional low fat diet.

RANDOMISED CONTROLLED TRIAL: ARTISAN WHEAT BREAD VS. INDUSTRIAL WHEAT BREAD TO RELIEVE THE SYMPTOMS OF IRRITABLE BOWEL SYNDROME

[1]*Laatikainen, Reijo;* [2]*Koskenpato, Jari;* [3]*Hongisto, Sanna-Maria;* [3]*Loponen, Jussi;* [4]*Poussa, Tuija;* [5]*Korpela, Riitta.*

[1]M Sc, Dietician, Medical Faculty, Department of Pharmacology, Medical Nutrition Physiology, University of Helsinki, Finland.; [2]Aava Medical Centre, Helsinki, Finland; [3]Fazer Bakeries Ltd, Vantaa, Finland.; [4]STAT Consulting Ltd, Nokia, Finland; [5]Medical Faculty, Pharmacology, Medical Nutrition Physiology, University of Helsinki, Finland.

Background and objectives: Industrial wheat bread has a high gluten content, relatively high amounts of FODMAPs (Fermentable Oligo-, Di-, Monosaccharides And Polyols), is baked with yeast and usually contains dough improvers (baking additives). Wheat bread is often considered by many patients as triggering their IBS symptoms. Sourdough baking method could theoretically improve tolerabillity of wheat bread due to lower content of FODMAPs, additives and immunogenic proteins (i.e. amylase trypsin inhibitor, ATIs) of sourdough bread.

Methods: Our aim was to evaluate if sourdough wheat bread, i.e. "artisan wheat bread", that is fermented for a long time (>12 hours) and baked without baking improvers, added gluten or preservatives would be better tolerated than regular industrial wheat bread in subjects with IBS who have poor subjective tolerance of wheat. The study was conducted as a randomized double-blind controlled parallel-group study (n=26). Participants first followed a gluten-free diet run-in period for seven days and then were randomly assigned to receive regular industrial wheat bread or artisan wheat bread for seven days while maintaining the gluten-free diet. Gastrointestinal and other symptoms were assessed on a visual analogue scale (VAS).

Results: There were no differences in the gastrointestinal signs of IBS i.e. flatulence, bloating, abdominal pain, dyspepsia, and stomach rumbling etc. between the study breads. There were statistically significantly (p≤0.03) more feelings of tiredness, joint symptoms and decreased alertness when the participants ate the artisan wheat bread. The treatment differences (mm) were 16 (95% CI 4-27, p=0.01),7 (1-13, p=0.03) and 14 (5-22, p=0.003), respectively.

Conclusions: The present results do not support the hypothesis that artisan wheat bread (sourdough bread) that contains no preservatives, added gluten or improvers would be better tolerated than regular wheat bread.

Institute of Biomedicine and

Translational Medicine, Department of Biochemistry, Centre of Excellence for Genomics and Translational Medicine, University of Tartu, Estonia; [4]MD.PhD. Senior Assistant. Institute of Biomedicine and Translational Medicine, Department of Biochemistry, Centre of Excellence for Genomics and Translational Medicine, University of Tartu, Estonia; [5]MD.PhD. Associate Professor. Institute of Biomedicine and Translational Medicine, Department of Biochemistry, Centre of Excellence for Genomics and Translational Medicine, University of Tartu, Estonia; [6]PhD. Professor. Institute of Biomedicine and Translational Medicine, Department of Biochemistry, Centre of Excellence for Genomics and Translational Medicine, University of Tartu, Estonia.

Background and objectives: Cardiovascular diseases and type 2 diabetes continue to be a challenge and burden to heath. Positive shifts in well accepted risk factors of them are the key of long-term success. We aimed to establish if the targeted composition of innovative supplement Reg'Activ Cholesterol (RAC) has a positive influence to the human cardiovascular-inflammatory and diabetes-related parameters.

Methods: 45 apparently healthy participants consumed an RAC containing an antioxidative and antiatherogenic probiotic LFME-3 for 4 weeks. The parameters measured were total cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides, oxidized LDL (oxLDL), hsCRP, IL-6 and glycosylated haemoglobin (HbA1c%).

Results: Significant improvement of the cardiovascular and diabetes risk profile of the participants was established according to next data: the reduction of total cholesterol (from 6.5±1.0 to 5.7±0.9 mmol/l, p=9.90806E-11) was on the account of LDL cholesterol as the HDL cholesterol level rose from 1.60±0.31to 1.67±0.34mml/l, p=0.01; HbA1c% was reduced from 5.85±0.28 to 5.66±0.25 p=4.64E-05 and oxLDL decreased from 84±20 to 71±15 U/l, p=4.66292E-08.

Conclusions: The consumption of RAC in clinically asymptomatic volunteers with border¬line-high values of risk factors for cardiovascular disease for 4 weeks had a positive effect on blood lipoprotein, oxidative stress and inflammatory profile.

This trial was an open label pilot study within the framework of a larger special clinical trial (ISRCTN55339917).

Keywords: Blood serum lipid profile, L. fermentum ME-3, Oxidized LDL, HbA1c%, Human clinical trial

BODY MASS INDEX, HEIGHT FOR AGE AND WAIST CIRCUMFERENCE IN CHILDREN BETWEEN 2 AND 18 YEARS OF AGE WITH TYPE 1 DIABETES MELLITUS FROM THE HOSPITAL UNIVERSITARIO DEL VALLE "EVARISTO GARCÍA" IN CALI, COL

Velasco, Carlos; Matallana, Audrey Mary.

Universidad del Valle. Cali, Colombia.

Background and objectives: The American Diabetes Association recommends monitoring, among others, the nutritional status of children with type 1 diabetes mellitus (T1DM), to maintain normal metabolic control that does not contribute to the morbidity of the disease. The objective is to determine the nutritional status in children with T1DM, according to body mass index (BMI) and height for age (HA) using the WHO tables, and according to waist circumference (wc).

Methods: Prevalence study in children aged 2-18 years of the Hospital Universitario del Valle (HUV) "Evaristo García" from Cali, Colombia, who were given sociodemographic (age, sex), anthropometric variables [weight (W), height (H), wc] and were diagnosed as having malnutrition due to BMI (obesity, overweight, risk of overweight, undernutrition and severe undernutrition), altered height (low stature and severe low stature) and abdominal obesity per wc (> p90%).

Results: 147 children from HUV in Cali, Colombia; 54.4% female, 10.9±3.5 years of age, with W=39.1±17.8 kg, H=138.3±24.1 cm and wc=64.9±9.0 cm. They presented malnutrition=30.8%, altered height=10.9% and none with abdominal obesity. There was predominance of malnutrition in girls with no statistical significance (p> 0.05).

Conclusions: About 1/3 of these children presented malnutrition (undernutrition=7.5%, overweight and obesity=21.8%), few were of low height, and no abdominal obesity; without possible associations or risk factors.

Keywords: Body mass index, Height for age, Waist circumference, Type 1 Diabetes Mellitus, Children

ANTHROPOMETRY ACCORDING TO BODY MASS INDEX, HEIGHT FOR AGE AND WAIST CIRCUMFERENCE IN CHILDREN BETWEEN 2 AND 18 YEARS OF AGE WITH DOWN SYNDROME OF CALI AND BUCARAMANGA, COLOMBIA

[1]*Velasco, Carlos;* [2]*Moreno, Lina Johanna.*

[1]Universidad del Valle. Cali, Colombia; [2]Universidad Santiago de Cali. Cali, Colombia.

Background and objectives: The Down Syndrome Growing Up Study (DSGS) of the Centers for Disease Control and Preven-

tion (CDC) from United States recently published growth charts for American children with Down Syndrome (DS). The objective is to determine the nutritional status in children with DS, according to body mass index (BMI) and height for age (HA) using the DSGS/CDC tables, and according to waist circumference (wc).

Methods: Prevalence study in children between 2-18 years of age from Cali and Bucaramanga, Colombia, to whom sociodemographic (age, sex), anthropometric variables [weight (W), height (H), wc] were taken and diagnosed by BMI on malnutrition (Obesity, overweight, risk of overweight, undernutrition and severe undernutrition), altered height by HA (low height -2 and -3 SD and low severe height > -3 SD) and abdominal obesity by wc (> p90%).

Results: There were 76 children (37 Cali and 39 Bucaramanga, Colombia), 59.2% were males, 9.4±4.3 years of age, W=30.8±15.0 kg, H=122.2±19.2 cm and wc=64.8±12.4 cm. They presented malnutrition=29.0%, altered height=27.6% and abdominal obesity=4.0%. There was a predominance of malnutrition in children aged 5-12 years and altered height in male children (p>0.05).

Conclusions: About 1/3 of these children presented malnutrition (undernutrition=15.8%, overweight and obesity=11.8%) and altered height (low height=15.8%) and 4.0% of abdominal obesity; without possible associations or risk factors.

Keywords: Body mass index, Height for age, Waist circumference, Children, Down Syndrome

DAILY FOOD CONSUMPTION IN COLOMBIAN SCHOOLCHILDREN AND ADOLESCENTS WITH FUNCTIONAL GASTROINTESTINAL DISORDERS

[1]Arias, Katherine; [1]Velasco, Carlos; [2]Ramirez, Carmen Rosy.

[1]Universidad del Valle. Cali, Colombia; [2]Hospital Regional María Inmaculada. Florencia, Colombia.

Background and objectives: The prevalence of functional gastrointestinal disorders (FGDs) in Colombian children is 29.0%; being its pathophysiology multifactorial and one of the possible risk factors, feeding. The objective is to determine the prevalence and possible risk factors of daily consumption of kilocalories (Kcal), carbohydrates (CH), proteins (Prot), fats (Fat), dietary fiber (Fib), iron (Fe+), folic acid (FolAc) and vitamin A (vitA) by means of a 24-hour reminder according to the Program for the Evaluation of Diets and Management of Food (DIAL) in Colombian children with FGDs.

Methods: Prevalence study in schoolchildren (n=897) and adolescents (n=1109) between 8-18 years of age in the Colombian Andean (La Unión=476), atlantic (Cartagena=427), pacific (Cali=1220, Quilichao=356) and amazonic (Florencia=392) zone, of public school, to whom sociodemographic (age, sex), anthropometric (weight, height, waist circumference) variables and were diagnosed as malnutrition by index of body mass, low height by height/age, abdominal obesity by waist circumference, and FGDs according to Rome III Criteria in Spanish. Normal daily consumption of kcal=1750-2250 kcal/m2, CH=50-55% total caloric value

(TCV), Prot=10-15% tcv, Fat=30-35% TCV, Fib=Age + 5 grams, Fe+=9-18 mg, FolAc=300-400 µg and VitA=500-700 µg.

Results: 2006 Colombian children were included; 50.5% male, 12.8±2.2 years old, with kcal=1924.0±644.7 kcal/m2/d, CH=258.6±110.7 g/d, Prot=327.6±297.5 g/d, Fat=321.9±304.5 g/d, Fib=21.4±14.8 g/d, Fe+=72.7±74.0 mg/d, FolAc=329.8±248.2 µg/d and VitA=648.1±1492.4 µg/d, malnutrition=25.9%, low height=6.9%, abdominal obesity=3.1% and FGDs=18.2%. They presented a hypocaloric daily consumption=73.5%, hypoglycemia=40.1%, hyperprotein=70.6%, hyperlipid=43.2%, low in Fib=50.8%, Fe+=67.5%, FolAc=75.3% and VitA=68.8% deficiency and as more frequent FGDs functional constipation=8.3% and irritable bowel syndrome (IBS)=4.3%; being the possible risk factor for IBS daily hypoproteic consumption (OR=2.78, 95%CI=1.13-7.30 p=0.0127).

Conclusions: The daily consumption of these Colombian schoolchildren and adolescents with FGDs was hypocaloric, hypoglycemic, hyperprotein, hyperfat, low in fiber, deficient in Fe+, AcFol and VitA; being the hypoproteic feeding the only possible risk factor for IBS.

ESTABLISHMENT OF SIMPLE METHOD FOR EVALUATING GUT MICROBIOTA USING T-RFLP

[1]Maruyama, Tsuyoshi; [2]Hagio, Masahito.

[1]BSc. Graduate school of Life Science. Toyo University. Japan.;
[2]PhD. School of Life Science. Toyo University. Japan.

Background and objectives: Recently, it has been reported that there are close relationships between intestinal bacteria and various diseases including obesity and diabetes. One of common methods evaluating the intestinal bacterial flora is a DNA sequence analysis using a next generation sequencer, but it is not easy to do it for any laboratory from the viewpoint of experimental equipment and analytical cost. Previously, we have established simple separation method, which can quickly crash mouse feces and separate it into three layers including polar fraction, nonpolar fraction and feces. Terminal restriction fragment length polymorphism (T-RFLP) is a method which can analyze microbiota as mixed DNA fragment information of various microorganisms. In this study, by combining the above two methods, we aimed to simplify the analytical method for evaluating gut microbiota.

Methods: Fecal samples were collected from four male mice. Bacterial DNA was extracted using a stool DNA extraction kit from the separated fecal layer by simple separation method. The 16S rDNA was amplified by PCR using 6-FAM-labeled 8F primer and 1492R primer. The PCR products were reacted with restriction enzyme MspI at 37°C and 1 h, and the digested fragments were analyzed by Genetic Analyzer. Finally, the obtained data were analyzed by statistical software "R", and the similarity of the flora among individual animals were compared.

Results: It was possible to perform from the collection of feces to comparison of microflora in less than 1 day. Using the method, four mice could be grouped based on the similarity of the flora.

Conclusions: We established a simple method for evaluating gut microbiota. Using this method, it is possible to compare quickly and simply the similarity, for example circadian change, of microbiota among individual animals and to survey the sequential change of microbiota in a single animal.

Keywords: T-RFLP, gut microbiota, mouse.

SERUM 25(OH)D CONCENTRATION AND META-BOLIC SYNDROME AMONG ADULTS IN SOUTH-WEST CHINA

[1]Li, Danting; [2]Xue, Hongmei; [2]Liang, Yi; [1]Chen, Mengxue; [2]Quan, Liming; [3]Zhao, Li; [4]Gong, Yunhui; [5]Cheng, Guo.

[1]BSc. West China School of Public Health. Sichuan University. Chengdu. China.; [2]MD. West China School of Public Health. Sichuan University. Chengdu. China.; [3]West China Research Center for Rural Health Development, Sichuan University Huaxi Medical Center. Sichuan University. Chengdu. China; [4]Department of Obstetrics and Gynecology, West China Second University Hospital. Sichuan University. Chengdu. China.; [5]PhD. West China School of Public Health. Sichuan University. Chengdu. China.

Background and objectives: Vitamin D deficiency has been suggested as a risk factor for various chronic metabolic diseases. However, evidence regarding this issue among Chinese population is limited. The present study aimed to examine the association between serum 25-hydroxy vitamin D (25(OH)D) and metabolic syndrome (MS) in Chinese adults.

Methods: Serum 25(OH)D was measured in a cross-sectional sample of 920 non-diabetic adults (62.61% women) aged 25-65 years recruited from Southwest China. Data on dietary intake and physical activity were collected by validated questionnaires. MS was defined according to the criteria of Chinese Diabetes Society. Fasting plasma glucose (FPG), insulin, glycated hemoglobin (HbA1c), the homeostatic model assessment-insulin resistance (HOMA2-IR), lipid profile and blood pressure were evaluated. Anthropometry measurement included waist circumstance (WC), height and weight, and the last two were used to calculate body mass index (BMI). Data were analyzed by multivariable-adjusted regression models.

Results: We observed that 7.17% participants had MS, and the percentage of overweight or obese individuals (BMI ≥ 25kg/m2) in our study was 29.24%. Compared with the lowest tertile of serum 25(OH)D, a statistically significant 53% lower odds of metabolic syndrome was observed for adults in the highest tertile (OR: 0.47, 95%CI: 0.24-0.89), after adjusting for age, gender, personal monthly income, smoking status, energy intake, and physical activity. Moreover, we observed significant inverse associations of 25(OH)D with fasting insulin (p=0.0007), HbA1c (p=0.0001),

HOMA2-IR (p=0.0007) after adjusting for potential confounders, but not with other MS components.

Conclusions: A poor vitamin D status is significantly associated with an increased risk of having metabolic syndrome and insulin resistance among Chinese adults, warranting further investigation in large prospective studies.

Keywords: Vitamin D, 25(OH)D, Metabolic syndrome

COUNSELING ON IYCF PRACTICE TO SICK BABY (NEUROLOGICALLY DAMAGED & OTHER) TO IMPROVE BREASTFEEDING STATUS -A HOSPITAL BASED STUDY IN BANGLADESH

[1]Roy, Swapan Kumar; [2]Cubra, Khadijatul; [3]Jahan, Khurshid.

[1]MBBS, MSc, Dip in Biotech, PhD, FRCP, Senior Scientist, Chairperson, Board of Trustees Bangladesh Breastfeeding Foundation. Chairperson Nutrition Foundation. Bangladesh; [2]MSc, Divisional Officer, Bangladesh Breastfeeding Foundation. Bangladesh; [3]MSc. Director. Bangladesh Breastfeeding Foundation. Bangladesh.

Background and objectives: Specific attachment & position is effective for production and flow of breast milk. Counseling to mother on breastfeeding includes continuation of breast feeding during illness when sick baby recovers earlier. Breastfeeding is a challenge to neurologically damaged baby. Some of the baby cannot cry & cannot reflect his demand, cannot suck, most of the time it sleeps. Usually babies are kept NPO (nothing per oral) or fed expressed breast milk. The fat content of hind breast milk insulates nerve fibers and speeds electrical signals increases with breast feeding. Brain development takes place from birth. Breastfeeding helps the baby develop coordination of the muscles and nervous system. The jaw and mouth movements needed for technical help along breastfeeding.

Methods: Counseling about Breast feeding & complementary feeding was done at the pediatric ward at Rangpur Medical College Hospital in Rangpur, Bangladesh, from September 2016 to March 2017. Mothers of 144 infants at neonatal unit were taught specific attachment & position effectively for special situation of baby & mother. From total number of baby, 35 were neurologically impaired, other suffered from different illness. We taught the mothers the cross cradle position, modified cross cradle position; which is effective for flat nipple, inverted nipple, large nipple, sore nipple, nipple infection, low birth weight baby, sick baby such as: neurologically damaged, jerking problem baby & the baby who are given saline and breast fed often (8 to 12 times in 24 hours)

Results: A total of 144 sick baby were studied. About 24.3% infants were neurologically impaired baby. All neurologically damaged baby were successfully breast feed immediately, after 30 minutes, the improvement of sucking quality were visible. The rest

were kept NPO, so I gave them counseling about the technique of breast feeding of neurologically damaged baby. Babies who took less amount of breast milk had kidney infection, dysentery for giving powder milk (BIOMIL).

Conclusions: Mothers of sick baby specially neurologically damaged baby's mothers need more support & guidance about effective breastfeeding.

Keywords: Positioning, Attachment, breast feeding, sick baby

IMPACT OF PHYSICAL ACTIVITY (45 MINUTES DAILY AND 15 MINUTES THREE TIMES A DAY AFTER MEALS) ON BODY MASS INDEX OF TYPE 2 DIABETES MELLITUS FEMALE PATIENTS

(1)*Malik, Monica;* (2)*Singh, Kalyani;* (3)*Bhansali, Anil;* (4)*Sehgal, Shruti.*

(1)MSc. Foods and Nutrition. Associate Professor. Government Home Science College. Chandigarh. India.; (2)MSc. Foods and Nutrition. Faculty. Panjab University. Chandigarh. India; (3)DM. Endocrinologist. PGIMER, Chandigarh, India.; (4)MSc. Nutritionist. Fortis. Mohali. India.

Background and objectives: Type 2 Diabetes Mellitus is a chronic progressive metabolic disorder. Obesity is its major driver. Physical activity as a part of lifestyle intervention is the cornerstone for its prevention and management. Objective of the cross-sectional study was to compare impact of physical activity (walk) 45 minutes daily to 15 minutes physical activity (walk) three times a day after each meal on Body Mass Index (BMI) of type 2 diabetic females.

Methods: Female respondents (N=175) were prospectively enrolled from Endocrinology OPD of Post Graduate Institute of Medical Research (PGIMER), Chandigarh, India. Respondents were made to walk regularly for 45 minutes followed by 15 minutes post meal walk for 6 weeks each. Self designed questionnaire and WHO validated Global Physical Activity Questionnaire (version 2) were used for data collection. Data analysis was done using SPSS software (version 20).

Results: Family history of diabetes was seen among 78.9% respondents. 95.4% respondents were diabetic for more than 6 months. Mean BMI was 28.14±3.63kg/m2, 27.93±4.05kg/m2 and 27.79±4.07kg/m2 at initiation, 45 minutes walk and 15 minutes walk after each meal respectively. Mean HbA1C was 8.31±1.96, 8.09±1.93 and 7.64±1.64 at initiation, 45 minutes walk and 15 minutes walk after each meal respectively. Mean Fasting plasma glucose (FPG) was 140.99±57.13mg/dL, 133.01±41.10mg/dL and 115.26±27.46mg/dL at initiation, 45 minutes walk and 15 minutes walk after each meal respectively. Highly significant difference between BMI, HbA1C and FPG (p <0.001) was found between 45 minutes and 15 minutes post meal walk.

Conclusions: Post meal physical activity (walk) was seen to be significantly effective for diabetics in achieving health benefits as compared to one time walk daily.

EFFECTIVENESS OF HOMEMADE IMPROVED RECIPE WITH NUTRITION COUNSELLING IN THE MANAGEMENT OF SEVERELY WASTED AND SEVERELY UNDERWEIGHT CHILDREN

(1)*Roy, Swapan Kumar;* (2)*Jahan, Khurshid;* (3)*Ara, Ferdous;* (4)*Akter, Syeda Mahsina.*

(1)MBBS, MSc, Dip in Biotech, PhD, FRCP, Senior Scientist, Chairperson, Board of Trustees Bangladesh Breastfeeding Foundation. Chairperson Nutrition Foundation. Bangladesh.; (2)MSc. Director. Bangladesh Breastfeeding Foundation (BBF). Bangladesh; (3)MSc, MPhil. Senior Program Officer. Bangladesh Breastfeeding Foundation (BBF). Bangladesh; (4)M.Sc, Food & Nutrition, M.Sc, Nutrition and Health. Assistant Director. Bangladesh Breastfeeding Foundation (BBF). Bangladesh.

Background and objectives: In Bangladesh, management of Severe Acute Malnutrition (SAM) includes the use of commercially produced therapeutic foods. The study aimed to measure the impact of selected homemade improved recipes with nutrition counselling on nutritional status of SAM and Severely undernourished children.

Methods: An experimental study among 44 children aged 6 to 59 months with uncomplicated SAM was conducted in the Institute of Child and Mother Health (ICMH), Dhaka. Subjects were purposively allocated from SAM unit of ICMH after recovery from acute phase of infection. After screening, recipe trial for 10 days was conducted by providing 6 improved homemade recipes containing 100-110 kcal/kg/day for first 4 days and 130-150 kcal/kg/day for next 6 days. Nutrition counselling using IEC materials and demonstration of cooking were provided to the mothers or caregivers of the children. Daily body weight was recorded to measure the improvement of nutritional status. Children were followed-up weekly at home for 1 month to monitor dietary compliance and nutritional status.

Results: Median age of children was 9.00 (6-42) months; Weight, Height & MUAC were (mean±SD) 5.3(±1.2) kg, 64.9(±9.6) cm & MUAC 10.8(±1.0) cm respectively. Mean calorie (kcal/kg body weight) and protein (g/kg body weight) intake were 119(± 62) and 4.5(± 2.3) at 1st day and 129(±77) and 4.92± 2.87 at 7th day. Weight gain was 18.1±16.8 g/kg/day at 4th day & 12.4 (±7.3) g/kg/day at 7th day. In community follow-up, 0.5±1.5 kg (mean±SD) weight was increased in 4th follow-up from the 1st follow-up. Practice of providing appropriate complementary food was followed by 62.5% in 1st follow-up and increased to 66.7% at 4th. Providing vitamin A and animal protein rich foods were 87.5% and 62.5% at 1st follow-up while improved to 100% at 4th follow-up. Giving breastmilk substitute reduced to 25% at 4th follow-up from 46% in 1st follow-up.

Conclusions: Nutrition rehabilitation with homemade foods of improved recipe and nutrition education at both hospital and community setting was fruitful for improving nutritional status of SAM children.

Keywords: SAM, Nutrition education, homemade improved recipe

GASTROINTESTINAL SYMPTOMS, HYDROGEN EXCRETION AND GASTROINTESTINAL CONDITIONS MEASURED WITH SMARTPILL® IN IRRITABLE BOWEL SYNDROME PATIENTS - MEAL STUDY ON LOW-FODMAP AND REGULAR RYE BREAD-MEALS

[1]Laatikainen, Reijo; [2]Pirkola, Laura; [3]Hongisto, Sanna-Maria; [3]Loponen, Jussi; [4]Hillilä, Markku; [5]Linderborg, Kaisa; [5]Yang, Baoru; [5]Nuora, Anu; [2]Freese, Riitta.

[1]M Sc, Dietician, Medical Faculty, Pharmacology, Medical Nutrition Physiology, University of Helsinki, Finland.; [2]Division of Nutrition, Department of Food and Environmental Sciences, University of Helsinki, Finland.; [3]Fazer Bakeries Ltd, Vantaa, Finland; [4]Clinic of Gastroenterology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [5]Division of Food Chemistry and Food Development, Department of Biochemistry , University of Turku , Finland.

Background and objectives: Grains are often considered as triggers of irritable bowel syndrome (IBS) symptoms but less is known about effects of grain products with differing content of FODMAPs on gastrointestinal transit times, pH and intraluminal pressure in patients with IBS. In a previous study intraluminal pH was lower among IBS subjects than in healthy controls possibly demonstrating higher rate of colonic fermentation in IBS.

Methods: Our aim was to evaluate if rye bread low in FODMAPs would cause less hydrogen excretion, lower intraluminal pressure, higher colonic pH and less IBS symptoms than regular rye bread. The study was conducted as a randomized double blind controlled cross-over meal study. Female IBS patients (n=7) ate study breads on 3 consecutive meals, i.e. for breakfast, lunch and dinner and were followed for 630 minutes. Intraluminal conditions were measured by SmartPill®, an indigestible motility capsule.

Results: Postprandial hydrogen excretion, a marker of colonic fermentation, expressed as AUC(0-630 min) was [median (range)] 6300 (1785-10800) for low-FODMAP rye bread and 10 635 (4215-13080) for regular bread (p=0.028). The means of the VAS measurements of individual gastrointestinal symptoms during the follow-up (30 to 630 min) tended to be numerically lower after the low-FODMAP rye bread but did not show any statistically significant differences between the breads.

Intraluminal pressure correlated significantly with total symptom score after regular rye bread (ρ=0.786, p=0.036) and nearly significantly after low-FODMAP bread consumption (ρ=0.75, p=0.052). We found no differences in pH, contractions or gastro-intestinal transit times between the breads. Gastric emptying of SmartPill was slower than reported in previous studies.

Conclusions: Our meal study demonstrated that low-FODMAP rye bread reduces colonic fermentation but no difference could be found in median values of IBS symptoms, pH, colonic pressure of gastrointestinal tract when compared to regular rye bread. Our observation on the correlation between increased intra-colonic pressure and symptom severity warrants further studies in IBS.

Keywords: IBS, FODMAP, rye, colonic fermentation, intraluminal pressure

Conflict of Interest Disclosure: Fazer Bakeries funded the study and provided the breads. Reijo Laatikainen has written a Finnish book on irritable bowel syndrome and diet. He is also founder and owner of Booston Ltd, which provides IBS related dietetic services to IBS patients, health care professionals and various organisations. Laura Pirkola, Sanna-Maria Hongisto and Jussi Loponen are employees of Fazer Bakeries. Others have no personal interests to declare.

INFLUENCE OF PUBERTAL STAGE IN CUT OFF VALUES OF WAIST CIRCUMFERENCE ASSOCIATED TO ALTERED ANTHROPOMETRIC VARIABLES AND BLOOD PRESSURE AS CARDIOMETABOLIC RISK MARKERS IN BRAZILIANS ADOLESCENTS

[1]Alves dos Santos, Ivete; [2]Passos, Maria Aparecida; [3]Ganen, Aline; [2]Sampaio, Isa; [4]Fisberg, Mauro.

[1]MSc. Nutritionist. Mestrado Profissional em Nutrição: do nascimento à adolescência. Centro Universitário São Camilo. Brazil.; [2]PhD. Nutritionist. Departamento de Especialidades Pediátricas do Centro de Atendimento e Apoio ao Adolescente. Universidade Federal de São Paulo. Brazil.; [3]PhD. Nutritionist. Mestrado Profissional em Nutrição: do nascimento à adolescência. Centro Universitário São Camilo. Brazil.; [4]MD. Nutrologist and pediatrician. Departamento de Especialidades Pediátricas do Centro de Atendimento e Apoio ao Adolescente. Universidade Federal de São Paulo. Brazil.

Background and objectives: The adolescents' development should not be determined just by the chronological age, once it is influenced by other environmental and intrinsic factors. The pubertal stage associated with anthropometric data, such as waist circumference (WC) is considered essential for screening risk of morbidities in adolescents, especially cardiovascular disease. This measure has proved to be a useful tool for identifying nutritional status, as well as its association with chronic noncommunicable diseases. The aim of the present study was to verify the influence of pubertal stage in cut off values of waist circumference associated to altered anthropometric variables and blood pressure.

Methods: A total of 557 adolescents aged 10 to 15 years were recruited from public schools, who were classified according to pubertal stage, by Tanner criteria. The interest variables, WC and the independent variables, such as

---

gender, age and weight were evaluated. The predictive power and cut off points of WC for overweight/obesity prevention were identified using ROC curves, as well as sensibility and specificity. Indeed, it was verified the correlation between the WC, anthropometric measures and blood pressure.

Results: According to the nutritional status, the adolescents were 58% eutrophic, 25.2% overweight and 13.9% obese, there was no difference between genders. It was observed a strong correlation between CC and weight, BMI, neck circumference, arm circumference, rip circumference and WC/height ratio in both genders. In addition, it was showed a weak correlation but statistically significant between WC and systolic and diastolic pressure. The WC cutoff points to determine overweight/obesity showed high sensitivity and specificity in girls and boys in all pubertal stages, pubere being representing by 64,9, 66,45 and 70,65cm in prepubescent, Pubere and post-pubere respectively in boys and by 68,5, 69,15 and 69,45cm in female adolescents.

Conclusions: The creation of WC cutoff points according to the pubertal stage, specific for the Brazilian adolescent population, proved to be an excellent, non-invasive and low cost tool for identifying overweight/obesity and cardiometabolic risk, and it is extremely relevant, due to changes in body composition resulting from puberty events.

Keywords: adolescence, waist circumference, pubertal status, cardiometabolic risk, overweight.

THE EFFECT OF BLACK SEED POWDER ON BLOOD GLYCAEMIA, BLOOD LIPIDEMIA AND BODY COMPOSITION ON ADULTS AT RISK FOR CARDIOVASCULAR DISEASES

[1]Al Dhaheri, Ayesha; [2]Al Khatib, Dana; [2]Jarrar, Amjad.

[1]PhD. Nutrition and Health Department. College of Food and Agriculture. United Arab Emirates University; [2]MSc. Nutrition and Health Department. College of Food and Agriculture. United Arab Emirates University. UAE.

Background and objectives: In United Arab Emirates (UAE), 39.6% of the population were diagnosed with metabolic syndrome (MetS) according to a previous study, while the prevalence of the MetS in the Gulf Cooperation Council Countries (GCC) is 10-15% higher than in most developed countries. Abdominal obesity, high fasting blood glucose, high blood pressure, elevated triglycerides and reduced high-density lipoprotein cholesterol (HDL-C) are the risk factors for MetS. Traditional spices, such as black seed, are used as medications for treating some of these diseases. However, several studies have proven that black seed has antioxidant, anti-inflammatory, anti-diabetic, lipid-lowering functions and thymoquinone was found to be the active form of black seeds.

Objectives: To measure the effect of 3 grams of black seed (Nigella Sativa) powder for 12 weeks on participants at risk for cardiovascular diseases for fasting blood glucose, HbA1c levels, blood pressure, blood lipid profile levels and waist circumference.

Methods: A controlled, randomized, single blind, parallel-design study conducted on 51 participants with risk of developing heart diseases. Participants were randomly assigned to consume either 3g/day of black seed powder or placebo for 12 weeks. Each of weight, height, waist circumference, body composition and systolic and diastolic blood pressure were measured at baseline, midpoint (after 6 weeks) and endpoint (after 12 weeks). Fasting blood glucose, HbA1c, total cholesterol, LDL-C and HDL-C were tested at baseline, midpoint and endpoint.

Results: After 12-weeks consumption of black seed powder, each of waist circumference, percent body fat, cholesterol, HDL and LDL levels were highly significantly improved (p-value < 0.01). In addition, body weight and triglyceride level were significantly improved (p-value <0.05).

Conclusions: Consumption of 3g of black seed powder daily for 12 weeks have shown positive effect on fasting blood glucose, blood pressure, blood lipid profile levels and waist circumference on individuals who are at risk of developing cardiovascular diseases.

Keywords: Black seed powder, metabolic syndrome, cardiovascular diseases, blood lipidemia, blood glycaemia.

OVERWEIGHT/OBESITY: LOOKING TO EXPAND THE LIPID PROFILE

[1]Lucentini, Marcelo; [2]Sobol, Dana; [2]Riega, Eduardo; [3]Castiñeyras, Sofía.

[1]PhD; [2]Md; [3]Nutritionist.

Background and objectives: Our objectives in this work are: to establish the incidence of overweight or obesity in adult patients who perform clinical consultation for periodic health examination; describe the most frequent laboratory abnormalities observed in such patients and try the search of new biochemical parameters permitting to assess more thoroughly the insulin resistance presenting the majority of these patients.

Methods: We studied 177 patients, whose ages ranged from 18 to 75 years and who attended outpatients clinic medical of the Hospital de Clinicas, to carry out a periodic review of health, between January 1, 2010 and January 1, 2017. All patients underwent: complete clinical history, physical examination (including back of eye) and is asked the following laboratory blood tests: complete blood count; blood glucose; lipid profile (total cholesterol, HDL, LDL, triglycerides and cholesterol non-HDL; risk); apo A and apo B; T3, free T4 and TSH; Vitamin D; insulinemia; HOMA; Ultrasensitive CRP (Hscrp); full hepatograma and complete examination of urine.

Results: Of the 177 patients studied, the following results were obtained: 36,72% were overweight and 24.86% suffered from obesity. Of the total of patients, 49.7% presented alterations of blood glucose; Hypertriglyceridemia: 51.5%; hypercholesterolemia: 55.7%. The HOMA > 2.5: 41,09% ; Hscrp > 3 mg/l: 31.78%; Vitamin D < 20 ng/ml: 44,19%; TSH > 4 uUI/l: 7.75%; Non-HDL

cholesterol > 130 mg/dl: 74,42%; TG/HDL > 3.5: 26.36%; insulin values higher than 20 μU/ml were obtained in 60,47%. Of the 86 patients studied for apo A decrease, the 24.24% were below 119 mg/dl; with respect to Apo B, only 6.45% showed values higher than 163 mg/dl.

Conclusions: Emphasizes the need to strengthen the strategy of primary health care to prevent the development of Overweight/obesity and to count on a competent laboratory that encompasses the entire spectrum of the IR, in particular, the determinations of: HOMA, PCR us; dosage of vitamin D and the TG/HDL ratio. Intends this index to identify simple individuals with insulin resistance and increased risk of developing disease franchises in relation to go through a simple, economical, calculation of acceptable sensitivity and specificity, which is done with routine.

EFFECTS OF ARGININE ON THE MOBILIZATION OF ENDOTHELIAL PROGENITOR CELLS AND TISSUE INJURY IN A MOUSE MODEL OF HINDLIMB ISCHEMIA/REPERFUSION

[1]*Yeh, Sung-Ling;* [2]*Hsieh, Kuan-Feng;* [2]*Hou, Yu-Chen.*

[1]School of Nutrition and Health Sciences, College of Nutrition, Taipei Medical University; [2]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan.

Background and objectives: Acute limb ischemia is a frequent event that may be caused by arterial embolism, vascular thrombosis, injury or trauma. Endothelial progenitor cells (EPC) are unique cells circulate in the blood with the ability to differentiate into endothelial cells and can contribute to vascular repair in ischemia/reperfusion (I/R) injury. This study investigated whether administration of L-arginine (L-Arg), the precursor of nitric oxide (NO), enhances blood EPC percentages and protects against I/R-induced inflammatory response in a mouse model of hindlimb I/R injury.

Methods: There were 1 normal control (NC) and 4 I/R groups. The NC group did not undergo the I/R procedure. The mice in the I/R groups were subjected to hindlimb compression with 4.5-oz orthodontic rubber bands for 150 min. Saline (S) groups were intravenously injected with saline whereas L-Arg (A) groups injected with L-Arg (300 mg/kg body weight) before reperfusion. Mice in the I/R groups were sacrificed 24 or 48 hr after reperfusion respectively. Blood and tissue samples were collected for analysis.

Results: I/R led to a significantly lower blood EPC percentage and plasma NO levels. However, plasma interleukin-6 levels as well as the inflammatory cytokine gene expressions in muscle were elevated. Compared to the saline groups, L-Arg administration resulted in a higher EPC percentages. Also, plasma NO levels, matrix metallopeptidase-9 and vascular endothelial growth factor concentrations were upregulated whereas muscle keratinocyte-derived chemokine and monocyte chemoattractant protein-1 mRNA expressions reduced after reperfusion. Histological findings consistent with the finding that muscle injury was attenuated during I/R insult when L-Arg was administered.

Conclusions: A single dose of L-Arg administration before reperfusion increases the percentage of EPCs and reduces the inflammatory reaction locally and systemically.

Keywords: L-arginine, ischemia/reperfusion, endothelial progenitor cell, nitric oxide, inflammatory cytokine

DIETARY INTAKE AND NUTRITIONAL STATUS OF PATIENTS WITH PHENYLKETONURIA IN TAIWAN

[1]*Weng, Hui-Ling;* [2]*Hwu, Wuh-Liang;* [3]*Lee, Ni-Chung;* [4]*Cheng, Chin-Pao;* [3]*Chien, Yin-Hsiu.*

[1]MD.Dietitian; [2]PhD. Professor. Department of Medical Genetics and Pediatrics, National Taiwan University Hospital, Taipei, Taiwan; [3]PhD. Associate Professor. Department of Medical Genetics and Pediatrics, National Taiwan University Hospital, Taipei, Taiwan; [4]PhD. Dietitian. Department of Dietetics, National Taiwan University Hospital, Taipei, Taiwan.

Background and objectives: Phenylketonuria (PKU) is due to phenylalanine hydroxylase deficiency and is characterized by accumulation of phenylalanine (Phe). Untreated patients develop severe intellectual disabilities. Early diagnosis such as universal newborn screening and early treatment by diet instruction may maintain patients' cognitive function. However, the Phe-restriction diet treatment should be maintain for lifelong and adequate nutritional status in these patients are also important. In this study, we characterize the body composition and the growth status in Taiwan PKU patients, correlating with their metabolic control status, to know if they have nutritional disturbances due to the Phe-restriction diet treatment.

Methods: We enrolled 22 controls (8-39y; 19.73 ± 10.6, table 1), and 22 patients with PKU (8-27y; 14.96 ± 5.27) including 14 patients (64%) receiving PKU-free formula as the dietary supplement. Anthropometric features (height, weight and body mass index) and body composition were analyzed. Dietary intake was also collected. For continuous parameters, the data was expressed as median ± standard deviation and Mann-Whitney U test has been used to test the difference among the groups.

Results: All patients met dietary reference intakes (DRIs) in protein (106.79 ± 33.27% of DRIs) and energy intake (103.7 ± 21.63% of DRIs). Compared to the control, PKU patients have similar height (Z-score, -0.18 ± 1.18 v.s. 0.43 ± 0.78, p=0.72), weight (Z-score, 0.04 ± 0.97 v.s. 0.39 ± 1.08,p=0.69) and body mass index (Z-score, 0.23 ± 1.10 v.s. 0.24 ± 0.98,p=0.43). The detailed body composition analysis showed that they have similar muscle mass (73.40 ± 8.79 v.s. 75.51±7.42,p=0.45) and body fat percentage (20.75 ± 8.70 vs 8.67 ± 7.53,p=0.46). Among PKU patients, the more natural protein they consumed, the more body muscle mass

they gained (Correlation coefficient 0.5360, p=0.0101) and the less fat mass they got (Correlation coefficient -0.5370, p= 0.0082).

Conclusions: Overall, Taiwan PKU patients do not show differences in body composition and growth status in comparison with controls. A normal intellectual development is expected when adequate treatment is started early in life and continued during life.

Keywords: Phenylketonuria, dietary intake, nutritional status

DISTRIBUTION OF DIETARY CARBOHYDRATE LOADING BY KIWIFRUIT ALTERS GLYCAEMIC RESPONSE CHARACTERISTICS

Monro, John Alexander; Mishra, Suman.

Carbohydrate Digestion and Metabolism Team, New Zealand Institute for Plant and Food Research.

Background and objectives: Partial equal carbohydrate substitution of kiwifruit sugars for starch in foods co-ingested with whole kiwifruit (KF) leads to a substantial reduction in glycaemic response. The reduction in response is due to both exchange of fructose for glucose, and to the physical influence of undigested KF remnants in the foregut. As fructose consumption has been reported to promote blood glucose disposal, and KF remnants appear to retard processes that mediate absorption of starch-derived glucose from the foregut, it is possible that overall modulation of glycaemic response to starchy food by KF may be affected by the temporal proximity of the KF and starchy staple ingestion events.

Methods: To test this possibility KF (200 g = flesh of two KF) was ingested 10 h, 90 min, 30 min before, at the same time as, or 30 min after a starch-based wheaten biscuit (WB) containing the same amount of available carbohydrate, mainly starch, as the KF. Capillary blood glucose concentrations and satiety were measured after ingestion of the foods.

Results: Partial substitution of WB by KF caused a 20-30% reduction in total glycaemic response irrespective of the separation of KF and WB ingestion. However ingesting KF 30 min before WB decapitated the blood glucose "spike", whereas the reverse, WB 30 min before KF did not.

Conclusions: The results suggest that both the temporal distribution of available carbohydrate (meal slowness) and differences in composition of foods consumed at different stages in a meal may be used to manage glycaemic response.

Keywords: glycaemia, temporal distribution, kiwifruit, carbohydrates

ASSESSMENT OF URINARY SODIUM EXCRETION AMONG UAE POPULATION

[1]*Jarrar, Amjad;* [2]*Al Dhaheri, Ayesha;* [3]*Cheikhismail, Leila.*

[1]MSc. Instructor. Nutrition and Health Department. UAE University; [2]Ph.D. Nutrition and Health Deprtment. UAE University; [3]Ph.D. Nutrition. Oxford University.

Background and objectives: Chronic diseases such as cardiovascular diseases (CVD), cancer, chronic respiratory diseases (CRD), and diabetes are increasing worldwide and becoming the leading cause of death. Positive relationship is found between CVD and the intake of salt, trans-fatty acid (TFA) and saturated fatty acid (SFA).

Methods: A cross sectional study was conducted from March – June 2015 in United Arab Emirates. A random sample of 476 healthy individuals were recruited, (n= 214 male, n= 262 female). A screening questionnaire was designed to collect data about demographic information, lifestyle, past medical history, medications use and the current health status in addition to anthropometric measurements were assessed using standardized procedures. A single timed 24-hr urine collection was obtained for estimation of sodium excretion, and urinary creatinine and urine volume were used to measured adequacy of 24-hr urine volume. The samples were analyzed by Inductively Coupled Plasma/Optical Emission Spectrometry (ICP-OES). Dietary information was collected using 24-hr dietary recall. Energy, carbohydrate, fat, protein, unsaturated fat, saturated fat, trans-fat, cholesterol and sodium were analyzed using ESHA Food Processor and Kuwaiti Food Composition Database.

Results: Participants mean age was 37.3 ± 12.5, 55 % were females. The majority of the participants were overweight (36.1%) or obese (23.7%). The majority of the participants reported that they add salt during cooking and while eating. Majority (68.9%) reported that they were aware that high salt intake could cause a serious health problem. The mean sodium intake from food records was 2829.1 ± 1404.9 mg while mean sodium excretion in urine was 2713.4 ± 713 mg. This amount of sodium is significantly higher (P<0.001) than the amount recommended by WHO which is above the WHO recommendations.

Conclusions: A large proportion of UAE population consumes sodium above levels recommended by WHO. This is probably the reason for the high incidence of CVD in UAE.

Keywords: Urinary sodium excretion, cardiovascular diseases, urinary creatinine, Non-communicable diseases, ESHA Food Processor

KNOWLEDGE AND MANAGEMENT OF FOOD ALLERGY AMONG PRE- SCHOOL CHILD CAREGIVERS IN OGUN STATE. NIGERIA

Wahab, Nimot.

Tai Solarin University of Education. Ijebu-Ode. Ogun state. Nigeria.

Background and objectives: Children whose mothers work outside the home are most of the time left in the hands of secondary caregivers for certain period of time. Investigating the knowledge and management of food allergy among these caregivers then becomes necessary as the severe case of this immunological response can lead to life threaten action. This study assessed the knowledge and management of food allergy among pre-school child caregivers in Ogun State, Nigeria.

Methods: Descriptive survey using multisampling technique was adopted to select eight-two (82) child caregivers from the study area. A validated Food Allergy Knowledge and Management Questionnaire (FAKMQ) was used for data collection. Knowledge and management scale of 0-10 was adopted and categorized high: ≥7, moderate: 4.0-6.9 and poor: 0-3.9. Data collected were analyzed using descriptive statistic and t test at p=0.05.

Results: The results of the findings showed that respondents possessed low knowledge in the following areas: food that can cause allergic reactions in children (2.45±0.42), signs and symptoms of food allergy (3.20±0.85), factors that increase the risk of having food allergy (2.20± 0.62), severe allergic reactions (anaphylaxis) (2.0±0.26) . Most respondents could not differentiate between food allergy and food intolerance (1.20±0.35). Results:

Conclusions: Knowledge and management of food allergy was poor among pre-schools child caregivers in Ogun State Nigeria. Regular training should be organized for caregivers to increase their knowledge on food allergy by reviewing past occurrences to identify better ways of management.

IMPACT OF TRANSTHEORETICAL METHOD INTERVENTION ON HYPERPHOSPHATEMIA AND FLUID CONTROL OF HEMODIALYSIS SUBJECTS

[1]*Hermsdorff, Helen Hermana;* [2]*Ribeiro, Priscila;* [2]*Balbino, Karla;* [2]*Epifânio, Andreza;* [1]*Moreira, Ana Vládia.*

[1]Assistant professor. PhD. Nutritionist. Department of Nutrition and Health. Universidade Federal de Viçosa; [2]MSc. Nutritionist. Department of Nutrition and Health. Universidade Federal de Viçosa.

Background and objectives: Nutritional therapy on hemodialysis (HD) is complex and a challenging for patients, since significant changes in eating habits and behavioral patterns are required. Thus, the objective of the present study was to evaluate the impact of change in food behavior on hyperphosphatemia and fluid control of HD individuals.

Methods: This intervention study based in transtheoretical method enrolled 83 HD subjects (55 men/28 women, age: 61 ± 15 years) attended at a Nephrology Center. In the nutritional intervention, three individual consultations and two group meetings were conducted during four months, to achieve improvement of metabolic disorders by change in food behavior. The stages of change were classified as pre-contemplation, contemplation, preparation, action and maintenance, grouped into active (action and maintenance) and inactive (pre-contemplation, contemplation and preparation). Serum phosphorus and interdialytic weight gain (IWG) were collected in the medical records and evaluated before and after the intervention.

Results: At the beginning of the study, 2.4% of the participants were allocated to pre-contemplation, 42.2% contemplation, 28.9% preparation and 26.5% action. After nutritional intervention, 2.4% of patients presented in the pre-contemplation stage, 10.8% contemplation, 26.6% preparation and 60.2% action. The effectiveness of the intervention on stages of change was confirmed by the observed impacts on the metabolic markers. Hyperphosphatemia significantly reduced (41.0 vs. 10.8%, p<0,001). The individuals considered inactive, in relation to the behavioral stage, presented higher IWG in relation to the actives (2.4 ± 1.0 vs. 1.9 ± 0.7 kg, respectively; p = 0.022). In addition, the active presented a reduction in the serum phosphorus concentration after the intervention, when compared to the inactive (4.8±1.4 vs. 4.1±0.8 mg/dL, respectively; p=0,006).

Conclusions: The intervention based on the transtheoretical model promoted a behavior change with increase to action stage (active condition) in HD individuals, which had direct and positive impact on the metabolic markers of important control in HD subjects. Financial support: CAPES, FAPEMIG and CNPq.

Keywords: Transtheoretical model, food behavior, serum phosphorus, interdialytic weight gain, chronic kidney disease.

QUALITY OF LIFE IN OBESITY. DO DEPRESSION-ANXIETY SYMPTOMS ARE PRESENT AMONG OVERWEIGHT AND OBESE PATIENTS MORE OFTEN THAN AMONG PATIENTS WITH PROPER BODY WEIGHT?

[1]*Przybylowicz, Katarzyna Eufemia;* [2]*Obara-Gołębiowska, Małgorzata;* [3]*Boradyn, Katarzyna Mirosława;* [4]*Morze, Jakub.*

[1]Prof. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland; [2]PhD. Department of Psychology of Development and Education. University of Warmia and Mazury in Olsztyn. Poland.; [3]MSc. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.; [4]Student. Faculty of Medical Sciences. University of Warmia and Mazury in Olsztyn. Poland.

Background and objectives: Depression, anxiety disorders, and obesity are common co-occurring disorders. Psychodietetics

in the scope of overweight therapy shows that psychological desta-bilisation leading to a decrease of individual life quality, frequently results in excessive eating [1]. Due to the scarcity of research on the depression-anxiety disorders expansion in the group of people with BMI≥25, the objective of this paper is to analyse the level of depression and anxiety in a group of obese patients of the Obesity Treatment Ward compared to the group to patients with proper body weight.

Methods: The research covered two equal research groups. The first group included 340 obese female patients of the Obesi-ty Treatment Ward (BMI 36.8, range 25.0-52.4), aged 25-67 years. The second group included 340 female primary patients (BMI 23.9, range 22.3-24.9), aged range 24-67 years. Hospital Anxiety and Depression Scale HADS was used to collect psychological in-formation.

Results: The analysis showed a significantly higher level of depression and anxiety in the HADS scale among overweight or obese persons in comparison to those with proper body weight. In the obese group there was an increase of anxiety level in 31% of patients, including 11% with anxiety at a pathological level. An increased level of depression was recorded among 33% patients, including 15% with pathologically intensified depression symp-toms. For comparison, an increased anxiety level occurred in 14% patients with proper body weight and increased level of depression in 17%. Only 1% of respondents with pathological anxiety or de-pression were recorded in this group.

Conclusions: The results showed significantly higher preva-lence of depression-anxiety disorders among obese people in com-parison to those with proper body weight. Psychological condition may be one of the factors which determine the efficiency and sus-tainability of the lifestyle change associated with the goal of dietary therapy [2]. Therefore, obese people should receive individual psy-chological support during weight loss treatment, due to the level of anxiety and/or depression.

IMPACT OF DIETARY PROTEIN INTAKE DURING FIRST TRIMESTER OF PREGNANCY ON GESTA-TIONAL DIABETES MELLITUS

[1]Liang, Yi; [1]Xue, Hongmei; [1]Li, Danting; [2]Chen, Mengxue; [1]Cheng, Guo.

[1]MD. West China School of Public Health. Sichuan University. Chengdu China; [2]BSC. West China School of Public Health. Sichuan University. Chengdu China.

Background and objectives: Dietary intervention is a con-siderable management of gestational diabetes mellitus (GDM). Al-though several dietary factors have been related to GDM risk, ma-jority of studies have previously focused on carbohydrate and fat content and in turn their subtypes, however, the association with dietary protein is still poorly characterized. The objective of the study was to investigate the association of dietary protein intake during first trimester of pregnancy with the incidence of GDM.

Methods: A prospective study was conducted among 573 chinese singleton pregnancy without diabetes from first trimester pregnancy onwards. Dietary information was assessed by using a validated food-frequency questionnaire. To screen GDM, partici-pants underwent an OGTT test during 24-28 weeks of gestation. Logistic regression were used to estimate RRs and 95% CIs for associations of the quintiles of specific protein and the source of protein intakes in early pregnancy with GDM status.

Results: 110 incident cases of GDM were documented. After adjustment for age, parity, family history of diabetes, history of GDM and prepregnancy BMI, across increasing quintiles of animal protein, RRs (95% CIs) for GDM were 1.00 (reference), 2.02 (0.98-1.10), 1.50 (0.73-3.31), 2.39 (1.18-5.07), 2.41(1.16-5.23) (P-trend <0.05) and 1.00 (reference), 1.10 (0.52-2.36), 2.06 (1.04-4.21), 2.69 (1.33-5.62), 1.43 (0.72-2.95) (P-trend <0.1) for red meat.

Conclusions: Higher first trimester of pregnancy intakes of animal protein especially red meat was associated with a greater risk of GDM.

Keywords: gestational diabetes, animal protein, first trimester of pregnancy

THE EFFECT OF NUTRITIONAL COUNSELING ON THE DIETARY BEHAVIOR CHANGES OF TYPE 2 DIABETIC PATIENTS

[1]Liu, Jen-Fang; [2]Lin, Ying-Tzu; [3]Lin, Cheng-Wei; [4]Huang, Yu-Yao; [5]Liu, Hsin-Yi.

[1]Ph.D. Professor. Department of Nutrition and Health Sciences, Research Center for Food and Cosmetic Safety, and Research Center for Chinese Herbal Medicine, College of Human Ecology, Chang Gung University of Science and Technology, Taiwan (R.O.C); [2]BS. RD. Department of Nutrition. Chang Gung Memorial Hospital. Taoyuan City. Taiwan (R.O.C.); [3]BS. MD.Division of Endocrinology and Metabolism, Department of Internal Medicine, Chang Gung Memorial Hospital. Taoyuan City. Taiwan (R.O.C.); [4]Ph.D. MD & Director. Department of Medical Nutrition Therapy, Chang Gung Memorial Hospital. Taoyuan City. Taiwan (R.O.C.); [5]MS. RD. Department of Nutrition. Chang Gung Memorial Hospital, Taoyuan City. Taiwan (R.O.C.).

Background and objectives: Diabetes care needs com-prehensive treatment including medicine, life style change and

healthy eating habit. In Taiwan, diabetic patients treated at medical institutions could participate the diabetes shared care program (DSCP) and received integrated care from physician, diabetes educator, and dietitian. The aim of this study was to investigate the effect of nutritional education during the DSCP.

Methods: A total of 2966 type 2 diabetic patients participated the DSCP in Chang Gung Memorial Hospital from 2011 to 2015 were retrospectively reviewed. There were nineteen items of dietary behaviors recorded in each nutritional counseling (total 8 times). Higher score indicated more ideal dietary behavior. The scores of dietary behaviors were considered as outcome to evaluate the effectiveness of nutritional education. These patients' clinical information and glycated hemoglobin change were also analyzed.

Results: The average summed score of dietary behaviors significantly increased after 8 times education (from 16.0 ± 2.3 to 17.6 ± 1.4). Their glycemic control (glycated hemoglobin) also had improvement along with the increased dietary behavior score (effect size: -0.036, p value < 0.001). Eighteen items of dietary behaviors had significantly increased but one item (Satisfied with food) had decreased in the end of this study. We also found that patients with younger age (≤65 years old), male gender, overweight (body mass index ≥ 24), family history of diabetes, or higher glycated hemoglobin (HbA1c > 7) had lower initial dietary behavior scores. Nevertheless, the patients of these groups with inappropriate dietary behaviors initially had more obviously improvement in scores after education program than those with good dietary behaviors.

Conclusions: Nutritional education was effective to improve the dietary behaviors of type 2 diabetic patients and therefore improve their glycemic control. Especially for those without healthy eating habit, the regularly nutritional counseling would provide most benefit.

ASSOCIATION BETWEEN DIETARY HABITS, BODY COMPOSITION INDICES AND HBA1C OF ADULT TYPE-2 DIABETES PATIENTS ATTENDING ROUTINE OUT-PATIENT CLINIC REVIEW: A CROSS-SECTIONAL STUDY

[1]Hayford, Frank Ekow Atta; [2]Issah, Ra-uf; [3]Ainuson-Quampah, Joan.

[1]PhD Candidate.Dietitian. Centre of Excellence in Nutrition. Faculty of Health Sciences. North West University. Potchefstroom, South Africa; [2]MSc. Dietetics. Department of Nutrition and Dietetics. School of Biomedical and Allied Health Sciences. University of Ghana. Ghana; [3]PhD. Dietitian. Department of Nutrition and Dietetics. School of Biomedical and Allied Health Sciences. University of Ghana. Ghana.

Background and objectives: Low intake of fruits, vegetables, excessive energy intake and reduced physical activities has been associated with type-2 diabetes (T2DM) and it associated co-mor-bidities. Unhealthy dietary patterns and increased body fat (adiposity), which are associated with increased inflammation, can also serve as a precursor for the development of co-morbidities in patients with T2DM. Good dietary habits such as increased fibre intake are associated with reduction of glycated haemoglobin (HbA1c), improved lipid profile and loss of body weight. Quantification of adiposity and its relation to dietary habits and HbA1c levels are thus important for assessing future health risks and development of T2DM co-morbidities. The objective of the study was to determine the association between dietary habits, body composition and HbA1c of T2DM patients, attending routine out-patient review clinic in Northern-western Ghana.

Methods: A cross-sectional study involving one hundred and seventeen (117) subjects, aged between 35 and 64 years. Pregnant women, subjects with concomitant debilitating illness and impaired memory or cognitive functions were excluded. Dietary habits was assessed with validated FFQ, body composition with Omron Bio-impedance analyser (OMRON HBF-516b, Japan) and % glycated haemoglobin (HbA1c) measured with Quo-lab. Data was analyzed using SPSS version 20. Associations and correlations were determined for all variables of interest using chi-square and significance set at p≤0.05.

Results: Mean age and BMI of participants were 52.9744 ± 8.74097 and 27.5845 ± 4.79002 respectively, with mean % body fat of 35.3835 ± 10.2815, indicating high adiposity. Mean %HbA1c was 9.44783 ± 4.28958 indicating poor glycaemic controls. Dietary habits represented by predictors such as type of Carbohydrate consumed,type of fibre intake and type of fat intake significantly correlated with % body fat (p<0.049) and HbA1c (p<0.041).

Conclusions: Strategies focusing on improving healthy food intake habits which could lead to prevention of excess adiposity and better glycaemic control is urgently required to prevent onset of T2DM complications and co-morbidities.

Keywords: Dietary habit, HbA1c, Type-2 diabetes. Body composition, Northern-western Ghana

Background and objectives: Circadian disruption, resulting from shiftwork, has been classified as probably carcinogenic to humans by the International Agency for Research on Cancer. The biological circadian clock is subject to environmental effects, particularly light exposure and rhythmic food intake. However, the association between circadian nutritional behaviors and cancers has never been well explored. We investigated the prospective associations between time of the last eating episode, number of eating episodes, night-time fasting duration and the nutritional quality of the last eating episode, with overall, breast and prostate cancer risks.

Methods: This prospective study included 41,389 men and women of the French population-based NutriNet-Santé cohort (2009-2016) who completed at least three 24h-dietary records during the first two years of follow-up. The risk of developing can-cer was compared across different groups using multivariable Cox models.

Results: 1,732 first primary incident cancer cases were diagnosed during follow-up, among which 428 breast cancers and 179 prostate cancers. Late eaters (last eating episode after 9:30 pm) had an increased risk of breast cancer (HR=1.48 (1.02-2.17), p=0.03) and prostate cancer (HR=2.20 (1.28-3.78), p=0.004); on the other hand, early eaters (last eating episode before 7 pm) had a lower risk of overall cancers (HR=0.78 (0.63-0.96), p=0.02). No association was observed between the number of eating episodes, night-time fasting duration and the nutritional quality of the last eating episode, with cancer risk.

Conclusions: This large cohort study suggests that circadian disruption associated with late time of last food intake may be involved in carcinogenesis at different locations. Beyond nutritional quality of food intake, targeting time of food intake might be interesting in cancer prevention.

Keywords: feeding time, cancer risk, circadian rhythm, prospective study

NUTRITION KNOWLEDGE AND DIETARY HABITS OF PATIENTS WITH TYPE-2 DIABETES ATTENDING POST MANAGEMENT REVIEW CLINIC: A CROSS-SECTIONAL SURVEY

[1]Issah, Ra-uf; [2]Hayford, Frank Ekow Atta; [3]Ainuson-Quampah, Joana.

[1]MSc. Dietitian. Department of Nutrition and Dietetics. University of Ghana. Legon. Accra. Ghana; [2]MPhil. Dietitian, Department of Nutrition and Dietetics, University of Ghana. Legon. Accra. Ghana.; [3]PhD. Dietitian. Department of Nutrition and Dietetics. University of Ghana. Legon. Accra. Ghana.

Background and objectives: Chronic diseases such as type-2 diabetes require continuous medical care and ongoing patient self-management education and support to prevent multiple complications and premature mortality. Adequate nutrition knowledge and appropriate dietary habits play key roles in the nutritional management of type-2 diabetes. Therefore, providing adequate nutrition information and skills on indicators such as good diet, adequate physical activities have been shown to improve the well-being of individuals. The objective was to assess the nutrition knowledge and dietary habits of type-2 diabetes patients attending routine clinical review at a regional hospital in Ghana.

Methods: A cross-sectional study consisting of one hundred and seventeen participants recruited using systematic random sampling technique. Structured questionnaire and validated FFQ were used to assessed nutrition knowledge and dietary habits respectively. Data was captured in excel, cleaned and then exported into SPSS version 20 for statistical analyses. Nutrition knowledge was scored using performance-rating scale.

Results: The mean BMI for the female and male participants were 28.59±4.699kgm-2 and 24.96±4.019kgm-2 respectively. Most

participants' (45.3%) nutrition knowledge was below average and generally had poor dietary habits with majority (90%) consuming sweets and high fat food source thrice (3×) daily, indicating poor nutritional status.

Conclusions: Below average nutrition knowledge was associated with poor dietary habits. Type-2 diabetic subjects therefore must be encouraged to take part in nutrition education programs in order to effectively manage their disease condition.

PERCEPTION OF CHANGES IN HEALTH CONDITIONS AND LIFESTYLE AFTER PERSONALIZED NUTRITIONAL INTERVENTION: PROCARDIO-UFV STUDY

[1]*Hermsdorff, Helen Hermana;* [2]*Almeida, Alinne;* [2]*Lopes, Lilian;* [3]*da Costa, Thiago;* [1]*da Costa, Glauce.*

[1]Assistant professor. PhD. Nutritionist. Department of Nutrition and Health. Universidade Federal de Viçosa; [2]PhD Student. MSc. Nutritionist. Department of Nutrition and Health. Universidade Federal de Viçosa.; [3]Assistant Professor. PhD. Administrator. Department of Administration and Accounting. Universidade Federal de Viçosa.

Background and objectives: Many nutrition care programs have been performed to treatment of obesity and other cardiometabolic conditions, but the evaluation of related-stages has not been reported. Thus, this study evaluated the perception of the suitability of nutritional treatment activities and lifestyle changes in users of the Cardiovascular Health Care Program, Universidade Federal de Viçosa, Minas Gerais, Brazil (PROCARDIO-UFV).

Methods: The PROCARDIO-UFV is a nutritional intervention program for individuals with cardiometabolic risk who have some connection with the UFV (ReBEC – Id:RBR-5n4y2g). The study included 53 users of the program (31 women/ 22 men, 43.5-15.9 years), all of them with cardiometabolic risk. The subjects answered an evaluation questionnaire based in the Likert Scale regarding to: Process (diet meal plan, orientations and educational actions for health promotion) and Results (information comprehension, lifestyle changes and clinical and metabolic improvement) of the program, according to with the method proposed by Donabedian.

Results: Among the users, 96.2% (n=51) reported having received and understood the diet meal plan passed on during the nutritional treatment; 81.1% (n=43) said that the diet meal plan was adapted to their reality and disease and 94.3% (n=50) said they received some kind of educational material to encourage the adoption of healthy food. In addition, 96.2% (n=51) considered the nutritional treatment to be effective and satisfactory. Finally, the users reported having acquired knowledge about food and healthy lifestyle (94.3%, n=50) as well as having presented clinical-metabolic improvement (88.7%, n=47) and changes in lifestyle (84.9%, n=45), after the nutritional intervention offered by PRO-CARDIO-UFV. Interestingly, there was a negative correlation between the perception of clinical-metabolic improvement by users and reductions of body weight (r=-0,333; p=0,036), waist circumference (r=-0,458; p=0,003) and BMI (r=-0,333; p=0,036) after three months of intervention.

Conclusions: The users have evaluated as satisfactory the methods using by PROCARDIO-UFV in nutritional treatment and health education, at the same time they presented a perception of improvement in clinical-metabolic conditions and lifestyle, with emphasis on a healthier diet. Altogether, our results indicate the importance of personalized nutrition in the treatment of individuals with cardiometabolic risk. Financial support: FAPEMIG, CAPESe CNPq.

VITAMIN D INSUFFICIENCY AFFECTS CALCIUM ABSORPTION EFFECTIVENESS OF PREBIOTICS

[1]*Zeni, Susana N;* [2]*Seijo, Mariana;* [3]*Duran, Francisco;* [4]*Bryk, Gabriel;* [5]*Pita Martín de Portela, Maria Luz.*

[1]Metabolic Osteopaties Laboratory. Clinical Hospital. INIGEM (UBA-CONICET); [2]MD. Metabolic Osteopaties Laboratory. Clinical Hospital. INIGEM (UBA-CONICET); [3]BSc. Metabolic Osteopaties Laboratory. Clinical Hospital. INIGEM (UBA-CONICET); [4]PhD. Metabolic Osteopaties Laboratory. Clinical Hospital. INIGEM (UBA-CONICET); [5]PhD. Nutrition Department. School of Pharmacy and Biochemistry. University of Buenos Aires.

Background and objectives: Low Ca intake (CaI) is related to osteoporosis among others pathologies. Passive and active intestinal Ca absorption (Abs) is regulated by vitamin D within limits, which compensate for the lesser CaI. Prebiotics also positively affect Ca Abs by selectively increasing acid lactic bacteria's which releases short-chain fatty acids which improve Ca salts solubility by lowering intestinal pH, and favor colonic epithelial cell proliferation. The aim of the present report was to evaluate the effectiveness of prebiotic to absorb Ca in adult rats feeding a low Ca diet and vitamin D insufficiency. Objectives: The effectiveness of Galacto-oligosaccharides/Fructo-oligosaccharides (GOS/FOS®) mixture to increase CaAbs was evaluated in a model of VD insufficiency (-VD) and established osteopenia.

Methods: Female adult Wistar rats were ovariectomized and fed a commercial diet during 15 days postsurgery. Then, rats were divided: 32 fed a diet VD-free (0 IU%) during 45 days to become VD insufficient (-VD) and 16 fed a normal VD diet (100 IU%) (+VD). At day-60, +VD were subdivided in 2 groups and received during 45 days: AIN´93 (control diet)(+VD Ca0.5%); AIN´93 containing 0.3%Ca and 2.5% GOS/FOS® (9:1) (+VD Ca0.3%Prebiotics); -VD were subdivided in 4 groups and received during 45 days: VD free-AIN´93 (-VD Ca0.5%); VD free-AIN´93 contain-

ing 0.3%Ca (-VD Ca0.3%); VD free-AIN´93 containing 0.3%Ca and 2.5% prebiotics (-VDCa0.3% Prebiotics) or VD free-AIN´93 containing 0.3%Ca and prebiotics 5% (-VDCa0.3%:Prebioticsx2). Food intake and faeces (F) were collected to determine Ca intake (CaI) and Ca en feces (CaF). Ca Abs% = CaI – CaF/ CaI x 100.

Results: Ca Abs % as mean±SD: -VDCa0.5%: 32.71±1.74; -VDCa0.3%: 38.33±2.33;

-VD0.3%Prebiotics: 44.71±1.84; -VD0.3%x2Prebiotics: 56.40±1.39; +VD0.3%Prebiotics: 87.45±1.82; +VD0.5%: 67.80±2.21. As expected, VD insufficiency reduced Ca Abs%

(-VDCa0.5% and –D0.3% vs. +VDCa0.5%; p<0.001). Moreover, GOS/FOS® effectiveness was negatively affected (-VD0.3% Prebiotics vs. +VD0.3% Prebiotics; p<0.001). Ca Abs% of free-VD diets containing GOS/FOS® mixture was improved by increasing prebiotic % in the diet (-VD0.3% Prebiotics vs. -VD0.3:2xP; p<0.01).

Conclusions: Under our experimental conditions VD nutritional status affected the effectiveness of prebiotics on Ca Abs.

CARDIOMETABOLIC PREDISPOSITION AT ESCUELA AGRÍCOLA PANAMERICANA ZAMORANO 2016

[1]Di iorio, Adriana; [2]Hernández, Adriana; [3]Espinal, Raul; [4]Fuentes, José isidro.

[1]MS.c. Investigación en atención primaria de la salud. Universidad Miguel Hernández. España; [2]DSP. Doctorado en salud Publica. Universidad de San Carlos. Guatemala; [3]PhD. Grain Science and Post-Harvest Technology. Kansas State University; [4]BsC. Agroindustria Alimentaria. Escuela Agrícola Panamericana Zamorano. Honduras.

Background and objectives: In the bodily composition, fatty components show a tight bond with obesity and the development of non-transmissible chronic diseases. The posed objectives were:

- Assess blood glucose level, cholesterol and blood pressure
- Determined the BMI, % visceral fat, muscle mass and body water
- Link levels of income and physical activity

Methods: It is a descriptive study with a sample of 30-years-old and older 80 voluntary employees (56% female) with three years or more of seniority in Zamorano. An equipment of bioelectric impedance mBCA SECA 514 was used. The sample was estimated with a reliability of 99%, precision of 3% for a bilateral hypothesis adjusted to 5% lost.

Results: Age and seniority averaged 43±9.92 y 15.6±2, respectively. 67% of the women and 63% of the men showed prediabetes. 9% of females and 15% of males presented high levels of CT. 16%

of women and 9% of the men showed diabetes and hypertension. Higher physical activity was linked with higher levels of TAS (r=-0.273, p=0.016). 82% of females and 89% of males presented android obesity, males reported visceral fat percentages of 4.05% in comparison to females (2.69%) (p=0.0022). The muscle media was 25.38Kg in women and 33.5 Kg in men inducing to a Sarcophenic obesity. 77% of the population registered optimum levels of hydration as compared to high levels of hydration in physically active employees. Higher levels of income correlated to a higher T.E.E r=0.8472 p<0.001 and r=0.453 p=0.001and a low physical activity. Lower incomes reported higher P.A.E.E.

Conclusions: The BMI glucose, cholesterol, visceral fat and P.A.E.E revealed that employees are at a high risk of cardio metabolic disease not only affecting their quality of life but also their work performance.

HOST TRANSCRIPTIONAL RESPONSES FOLLOWING EX VIVO RE-CHALLENGE WITH MYCOBACTERIUM TUBERCULOSIS AMONG A MALNOURISHED POPULATION

[1]Yu, Elaine A; [2]John, Serene H.; [1]Tablante, Elizabeth C.; [2]Kenneth, John; [3]Russell, David G.; [1]Mehta, Saur.

[1]Division of Nutritional Sciences, Cornell University, Ithaca, New York; [2]Division of Infectious Diseases, St. John's Research Institute, Bangalore, Karnataka, India; [3]Department of Microbiology and Immunology, College of Veterinary Medicine, Cornell University, Ithaca, New York.

Background and objectives: The identification of immune correlates that are predictive of disease outcome for tuberculosis remains an ongoing challenge. To address this issue, we evaluated gene expression profiles from peripheral blood cells following ex vivo challenge with Mycobacterium tuberculosis (M. tb), among participants with active TB disease (ATBD), latent TB infection (LTBI), and previous active TB disease (after successful treatment; PTBD), relative to controls.

Methods: Study participants with TB were recruited at a rural hospital in India, which has a clinical population with a high prevalence of malnutrition (median body mass index 18.7 kg/m2 [interquartile range 16.8, 22.1]). Peripheral blood mononuclear cells from participants with ATBD (n=10), LTBI (n=10), and PTBD (n=10), and controls (n=10) were infected with live M. tb. Differential gene expression profiles were assessed by suppression-subtractive hybridization, dot blot, real-time polymerase chain reaction, and the comparative cycle threshold methods.

Results: Comparing ATBD to control samples, greater fold-increases of gene expression were observed for a number of chemotactic factors (CXCL1, CXCL3, IL8, MCP1, MIP). ATBD was also

associated with higher IL1B gene expression, relative to controls. Among LTBI samples, gene expression of several chemotactic factors (CXCL2, CXCL3, IL8) were similarly elevated, compared to individuals with PTBD.

Conclusions: Our results demonstrate that samples from participants with ATBD and LTBI have distinct gene expression profiles in response to ex vivo M. tb infection. These findings indicate that there is value in further characterizing the peripheral responses to M. tb challenge as a route to defining immune correlates of disease status or outcome, particularly among populations with a high burden of malnutrition.

TRIGLYCERIDE–GLUCOSE INDEX (TYG INDEX) AS AN INDICATOR OF CARDIOMETABOLIC RISK IN OVERWEIGHT MAN APPARENTLY HEALTHY

[1]Caldas, Ana Paula; [2]Alves, Raquel Duarte Moreira; [3]Bressan, Josefina.

[1]MSc. Nutritionist. Department of Nutrition and Health. Universidade Federal de Viçosa. Brazil.; [2]PhD. Nutritionist. Department of Nutrition. Univiçosa. Brazil.; [3]PhD. Nutritionist. Department of Nutrition and Health. Universidade Federal de Viçosa. Brazil.

Background and objectives: The detection of insulin resistance in apparently healthy individuals represents an important clinical tool in the prevention of cardiovascular diseases. Recently, the Triglyceride-glucose index (TyG index) was considered a promising marker of insulin resistance associated with the occurrence of cardiovascular events regardless of the presence of other risk factors. This way, the objective of present study was use TyG index for evaluate the insulin resistance and your association with other cardiometabolic risk factor in overweight man apparently healthy.

Methods: This was a cross sectional study performed with 64 overweight man (BMI: 26 - 34,9 kg/m2; 18–50 years) apparently healthy that, after informed consent, gave blood in fasting condition. The volunteers were submitted the anthropometric and cardiometabolic markers measurements. TyG index {TyG= Ln [fasting triglyceride (mg/dL) × fasting plasma glucose (mg/dL)]/2} was used as a measure for to assess the degree of insulin resistance

Results: The volunteers had on average 27,5 ± 0,9 y and BMI 29,7 ± 0,3. Altogether, 61% (n = 39) were overweight and the rest were obese. According to TyG index TyG, 50% (n=32) of the volunteers were insulin resistant (TyG > 4,65). There were significant correlations between the TyG index and fasting glucose (r= 0,640, p<0,001), fasting insulin (r=0,600, p<0,001), total cholesterol (r=0,256, p=0,041), triglycerides (r=0,988, p<0,001), HDL-c (r= -0,450, p<0,001), VLDL-c (r=0,987, p<0,001), LDL-c:HDL-c (r=0,488, p<0,001), total cholesterol:HDL-c (r= 0,685, p<0,001) and Non-HDL cholesterol (r=0,459, p<0,001). There were no correlations between TyG index and weight, BMI or waist circumference. When grouped in resistant and non-insulin resisting using to TyG index, insulin resistant individuals had higher values of BMI (p=0,026), waist circumference (p=0,014), fasting glucose (p<0,001), fasting insulin (p<0,001), total cholesterol (p=0,007), triglycerides (p<0,001), HDL-c (p=0,002), VLDL-c (p<0,001), LDL-c:HDL-c (p<0,001), total cholesterol:HDL-c (p<0,001) and Non-HDL cholesterol (p<0,001) In relation to non-insulin resistant individuals.

Conclusions: The present study demonstrated the efficiency of the TyG index in the identification of insulin resistance associated with cardiometabolic risk in apparently healthy overweight men.

Keywords: Cardiometabolic markers, Overweight man, TyG index.

K36, A SYNTHETIC CAFFEAMIDE DERIVATIVE, IMPROVES THE PATHOLOGY OF ALZHEIMER'S DISEASE IN STREPTOZOTOSIN AND HIGH FAT DIET-INDUCED TYPE 2 DIABETIC RATS

[1]Shen, Szu-Chuan; [1]Wu, Pei-Chin; [1]Tu, Meng-Shiuan; [1]Tu, Rong-Shiuan; [1]Lin, Shih-Shiang; [2]Kuo, Yeuh-Hsiung; [3]Chang, Wen-Chang; [3]Ting, Yu-Wen; [3]Wu, James Swi-Bea; [1]Wu, ChHao.

[1]National Taiwan Normal University; [2]China Medical University; [3]National Taiwan University.

Background and objectives: Type 2 diabetes mellitus (T2DM) is a metabolic disease accompanied with hyperglycemia and hyperinsulinemia. T2DM, which is major caused by obesity, characterized with insulin resistance, may result in the metabolic disorder. Epidemiology studies showed that T2DM is a high risk factor of Alzheimer's disease (AD). Previous studies confirmed that caffeamide may improve serum glucose and insulin resistance in diabetic animals. This study aims to investigate the protective effect of caffeamide derivative compound K36 on pathology of AD in the streptozotosin (STZ)-high fat diet (HFD)-induced T2DM rats.

Methods: The male Wistar rats fed HFD (60% fat of calorie) for 4 weeks, then were intraperitoneally (ip) injected STZ (30mg/kg b.w.). After injection, the rats were served HFD continuously for 8 weeks to induce T2DM, and then orally administered with

K36 (15mg/kg b.w.) once a day for 13 weeks. The rats were received cognition test before sacrificing. The blood biochemical analysis was conducted after the rats were scarified. The expression of cerebral hippocampus and cortex insulin signaling, synaptic function protein and synaptic expression related protein were analyzed by western blotting.

Results: The results showed that rats exhibit hyperglycemia (216.8 mg/dl) and hyperinsulinemia (1.53 μg/mL) after STZ injection and HFD feeding for 8 weeks, indicating the induction of T2DM. The serum total cholesterol (TG, p<0.05), serum triglyceride (TC, p<0.05), free fatty acid (FFA, p<0.01) is significantly decreased in K36 treated T2DM rats compared to the T2DM rats (p<0.05). The results from Morris Water Maze task indicated K36 significantly improves the cognition ability in T2DM rats (p<0.05). Western blotting analysis revealed that the protein expression of cerebral insulin receptor substrate-1 (IRS-1), brain-derived neurotrophic factor (BDNF), postsynaptic density protein 95 (PSD-95) in K36 treated T2DM rats were increased compared to the T2DM rats (p<0.05).

Conclusions: In addition, K36 also suppresses the expression of amyloid bata precursor protein (βAPP) and amyloid beta (Aβ) in T2DM rats. According to the above results, we suggest that caffeamide derivative K36 may prevent AD progression via alleviating cerebral insulin resistance and ameliorating synaptic plasticity in STZ-induced T2DM rats.

Keywords: caffeamide derivative, Alzheimer's disease, type 2 diabetes mellitus, cerebral insulin resistance.

ALPHA LIPOIC ACID ALLEVIATES HYPERLIPIDEMIA AND INFLAMMATION OF VISCERAL ADIPOSE TISSUE IN HIGH FAT DIET PLUS STREPTOZOTOCIN -TREATED RAT MODEL

[1]Shen, Szu-Chuan; [1]Tu, Meng-Shiuan; [1]Wu, Pei-Chin; [1]Tu, Rong-Shiuan; [1]Lin, Shih-Shiang; [1]Chang, Yu-Yuan; [2]Chang, Wen-Chang; [2]Ting, Yu-Wen; [2]Wu, James Swi-Bea; [1]Wu, ChHao.

[1]National Taiwan Normal University; [2]National Taiwan University.

Background and objectives: Hyperlipidemia is a symptom commonly occurred in type 2 diabetes mellitus (T2DM). Studies suggest that individuals with both T2DM and hyperlipidemia may increase the risk of cardiovascular disease (CVD)-related complications, such as coronary artery disease. The dysfunction of visceral adipose tissue (VAT) is considered to be associated with insulin resistance and subsequently may result in the lipid metabolism abnormality in T2DM. Evidence indicates that inflammatory related markers are associated with the high serum lipid level. Alpha lipoic acid (ALA) is an endogenous cofactor located in mitochondria. Previous studies reported that ALA has therapy potential on improving hypoglycemia in diabetic rats. This study investigates the effect of ALA on hyperlipidemia in high-fat-diet (HFD) plus STZ-induced diabetic rats.

Methods: Male Wistar rats were fed HFD (60% fat of calorie) for 4 weeks followed by single intraperitoneal injection of streptozotocin (STZ, 30mg/kg), and then served HFD continuously for 8 weeks to induce hyperglycemia. The HFD-STZ-induced diabetic rats were orally administered with ALA once a day at a dosage of 200 mg/kg for 13 weeks. After rats were sacrificed, the serum lipid profiles were measured, the VAT (epididymal and perirenal adipose tissues) was picked up and weighed, and the pro-inflammation related cytokines of VAT were analyzed.

Results: Our results showed that HFD plus STZ treatment results in markedly hyperlipidemia and hyperglycemia in rats. The administration of ALA significantly reduced the levels of fasting serum insulin, total cholesterol, low density lipoprotein, triglyceride and free fatty acid by 55%, 39%, 73%, 68% and 53%, respectively, whereas significantly increased high density lipoprotein level by 1.54 fold in diabetic rats (p<0.05), suggesting the reduction on the risk of CVD-related complications. The relative VAT weight was significantly decreased by 40% in ALA treated diabetic rats (p<0.05), indicating the suppression of lipid accumulation. Moreover, ALA also significantly decreased the levels of pro-inflammatory cytokines such as interleukin 6, tumor necrosis factor-alpha in serum and IL-1β in VAT of diabetic rats (p<0.05).

Conclusions: In conclusion, the present study demonstrates that ALA may have benefits on preventing the progression of hyperlipidemia via ameliorating blood lipid profiles and inflammation of VAT in HFD-STZ-induced diabetic rats.

Keywords: alpha lipoic acid, hyperlipidemia, inflammation, type 2 diabetes mellitus, visceral adipose tissue

EFFECT OF DIFFERENT DIETARY OIL COMBINED WITH LYCIUM BARBARUM POLYSACCHARIDE EXTRACT ON LIVER FIBROSIS INDUCED BY CCL4 IN RATS

[1]Chao, Jane; [2]Chiang, Yun-Yun.

[1]PhD. Professor. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan; [2]MSc. Student. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan.

Background and objectives: The effective therapy for liver fibrosis is still elusive. Olive oil and Lycium barbarum polysaccharides were considered to act as hepatoprotective activity. This study investigated anti-inflammatory and anti-fibrotic effects of olive oil and Lycium barbarum polysaccharide extract (LBE) on CCl4-induced liver fibrosis in rats.

Methods: Male Sprague-Dawley rats were divided into 7 groups: normal diet (N), soybean oil diet (S), olive oil diet (O), soybean oil/olive oil diet (mix oil, M), soybean oil diet + LBE (S+L), olive oil diet + LBE (O+L), and soybean oil/olive oil diet + LBE (M+L). The LBE-treated groups were given 50 mg/kg/day LBE. Except for the N group, other six groups were injected with CCl4 intraperitoneally for 8 weeks.

Results: The results showed that CCl4 caused more severe liver fatty change, necrosis, and fibrosis, and increased plasma activities of aspartate aminotransferase and alanine aminotransferase (ALT), while the groups treated with mix oil or LBE decreased plasma ALT activity compared with the S group or corresponding group without LBE. Compared with the N group, liver interleukin (IL)-10 level was significantly lower in the S, O, and S+L groups, but liver tumor necrosis factor-α (TNF-α) level was not changed in the S group. The mix oil group restored liver IL-10 level compared with the S group, and the LBE-treated groups decreased liver TNF-α level. The N group had significantly higher matrix metalloprotein (MMP)-2 level than other groups. The S group had significantly higher tissue inhibitors of metalloprotein (TIMP)-1 level than the N group, and olive oil or LBE decreased liver TIMP-1 level compared with the S group. Liver hydroxyproline was significantly higher in the O, M, and S+L groups compared with the N group, and olive oil reduced hydroxyproline when LBE was given.

Conclusions: Mix oil and LBE decreased liver injury and inflammation. Olive oil or mix oil combined with LBE inhibited inflammation but improved liver fibrosis partially.

Keywords: olive oil, Lycium barbarum polysaccharides, inflammation, liver fibrosis

EFFECTS OF ORAL BALANCED NUTRITIONAL SUPPLEMENT ON INFLAMMATION AND OXIDATIVE STRESS IN HEMODIALYTIC PATIENTS

[1]Chao, Jane; [2]Un, Teng-Hong.

[1]PhD. Professor. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan; [2]MSc. Student. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan.

Background and objectives: According to the United States Renal Data System 2015 Data Report, Taiwan had the highest prevalence of end-stage renal disease (ESRD) in the world. Inflammation and oxidative stress are risk factors of cardiovascular disease in ESRD patients. Insufficient data show whether intake of oral balanced nutritional supplement can improve inflammation and oxidative stress in hemodialytic patients. Therefore, this study evaluated the effect of oral balanced nutritional supplement on inflammation and oxidative stress in hemodialytic patients.

Methods: One hundred hemodialytic patients were recruited and divided evenly into two groups. The subjects in the control group were kept on their regular diet without supplement. The subjects in the treatment group were assigned one or two packages (43 g per package) of oral balanced nutritional supplement (200 kcal energy, 48% carbohydrate, 32% fat, and 20% protein per package) containing arginine (0.7%, w/w) and glutamine (4.8%, w/w)

daily for 12 weeks based on the recommended energy requirement. Serum interleukin-6 (IL-6), interleukin-10 (IL-10), tumor necrosis factor-α (TNF-α), C-reactive protein (CRP), malonaldehyde (MDA), and total antioxidant capacity (TAC) were measured at weeks 0, 6, and 12.

Results: Serum IL-10 and TAC levels in the treatment group were increased significantly at week 12. Moreover, serum IL-6, TNF-α, CRP, and MDA levels in the treatment group were decreased significantly at week 12. There were no significant differences for inflammatory and oxidative stress markers in the control group at weeks 0, 6, and 12. Increases in serum IL-10 level in the treatment group were significantly greater than those in the control group at week 12 compared with the baseline. Furthermore, decreases in serum TNF-α and CRP levels in the treatment group were significantly greater than those in the control group at week 12 compared with the baseline.

Conclusions: Our results suggest that oral balanced nutritional supplement is effective for anti-inflammation and antioxidation in hemodialytic patients.

EFFECTS OF MELATONIN ON GLUCOSE HOMEOSTASIS, ANTIOXIDANT ABILITY AND ADIPOKINE SECRETION IN NA/STZ-INDUCED DIABETIC ICR MICE

[1]Chien, Yi-Wen; [2]Lo, Chung-Cheng; [3]Yang, Ting-Hsuan; [3]Ou, Tzu-Hsuan.

[1]PhD. , RD; [2]MS,Department of Nutrition and Health Science, Taipei Medical University, Taipei, Taiwan ROC; [3]Department of Nutrition and Health Science, Taipei Medical University, Taipei, Taiwan ROC.

Background and objectives: The relationship between the melatonin and diabetes has been previously investigated. Moreover, supplement of melatonin on obese diabetic rats can improve their metabolic syndromes, such as blood glucose, plasma lipid and adipokine. The aim of this study was to investigate the effects of different dosage of melatonin on glucose hemostasis, oxidative state and adipokine secretion in diabetic ICR mice.

Methods: Mice were divided into five groups, including: control (C), diabetic (D), three dosage melatonin-treated group. Treated group were subdivided into L, M and H that given melatonin respectively 10, 20, 50 mg/kg. Melatonin was dissolved in vehicle (ethanol aqueous solution). After the diabetes induction, the mice were given melatonin or vehicle orally between 17:00-19:00 daily. Oral glucose tolerance test (OGTT) was performed at week 0 and 6. After the six-week-intervention, hepatic and plasma lipid, malondialdehyde (MDA), and anti-oxidative enzyme were analyzed by colorimetric method. Plasma insulin, leptin and adiponectin were measured.

Results: Although none of melatonin-treated group performed reduced glucose level, H group performed significant less increased glucose level and higher insulin level compared to diabetic group (p < 0.05). Treating melatonin could reduce diabetes-increased MDA level in liver and plasma and increase superoxide dismutase activity in liver. Moreover, there were no significant differences in relative fat mass between D and treated group, but melatonin-treated group revealed significant higher adiponectin and lower leptin and leptin/adiponectin ratio compared to diabetic group, especially in H group.

Conclusions: High dosage of daily oral melatonin administration ameliorates the glucose tolerance, oxidative stress and adipokine without affecting fat mass in NA/STZ-induced diabetic mice.

Keywords: melatonin, diabetes, leptin, adiponectin and insulin resistance

Japan; [7]BSc.The University of Tokyo Hospital. Japan; [8]MD. Chief. Departamento de Medicina Transfusional. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. México; [9]BSc. Nutritionist. Clínica de Obesidad y Trastornos de la Conducta Alimentaria. Departamento de Endocrinología y Metabolismo. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. México; [10]PhD, MD. Institut für Ernährungsmedizin. Universität Hohenheim. Stuttgart. Germany.

Background and objectives: According to the WHO Expert Consultation, current BMI cut-offs should be retained as an international classification. It is therefore important to consider the impact of race/ethnic differences on clinically meaningful body composition at these cut-offs.

The aim of the study was to analyze ethnic differences in the bioelectrical impedance analysis (BIA) outcome measures fat mass index (FMI), fat-free mass index (FFMI), skeletal muscle mass (SMM), visceral adipose tissue, extracellular/total body water (ECW/TBW), bioelectrical vector analysis (BIVA) and phase angle.

Methods: Body composition was measured (seca mBCA 514/515) in 3,069 healthy adults with a wide range of age and BMI (18-78 y, BMI 13.9–44.3 kg/m²) from Germany, Japan and Mexico (1,048 Caucasians, 995 Japanese and 1,026 Mexican). Regression analyses between BIA outcome variables and BMI were used to predict ethnic-specific reference values for different WHO-BMI cut-off points.

Results: Caucasian men and women had the highest fat free mass (FFM) per fat mass (FM) whereas Japanese and Mexican populations had a lower and similar amount of FFM per FM at an underweight and normal weight BMI. However in obesity, the Japanese phenotype corresponds more closely to the Caucasian body composition. In the Japanese population, phase angle was lower compared with Caucasians (compatible with lower SMM/FFM and higher ECW/TBW) and BIA vector was shorter compared with Mexicans.

Conclusions: Ethnic-specific relationships between BMI and body composition vary with weight status and emphasize the need for ethnic-specific normal values for the diagnosis of obesity, sarcopenia or disturbed hydration.

Keywords: Ethnicity, body composition, BIA, BIVA, reference values

LONG-TERM DITYROSINE ADMINISTRATION INDUCES MYOCARDIAL DYSFUNCTION BY OXIDATIVE STRESS

[1]Le, Guowei; [2]Zhao, Qi; [2]Li, Zhuqing; [2]Shi, Yonghui.

[1]PhD. School of food science and technology, the research centre of nutrition and functional factors. Jiangnan Univercity. China.; [2]MSc. School of food science and technology, the research centre of nutrition and functional factors. Jiangnan Univercity. China.

Background and objectives: Cardiovascular disease is connected with inflammation and oxidative stress. Previous studies indicated administration of oxidized protein impairs antioxidant system in organs. Dityrosine is an oxidative biomarker of acute myocardial infarction and generated during food processing and storage. This studies aim to explore the role of dityrosine in cardiac diseases.

Methods: The rats were administered with dityrosine for 24 weeks. Blood pressure and heart rate were measured. T-AOC, GSH-Px and other oxidative stress markers as well as CK-MB, LDH, AngII, NO, FFA were examined. The ultrastructural features of heart mitochondria were examined under a transmission electron microscope. And quantitative PCR was carried out to examine the expression level of related genes.

Results: Dityrosine administration increases DBP and SBP, but no change in heart rate. CK, CK-MB, LDH, ICTP, PIIINP and FFA were upregulated by dityrosine and NO was downregulated. With dityrosine administration for 24 weeks, the biomarkers of oxidative stress in myocardium such as MDA, AOPP, DT were increased, while T-AOC and GSH-Px were decreased, indicating impaired antioxidant capacity by dityrosine administration. Transmission electron microscopic result suggested the alternation of heart mitochondria ultrastructure induced by dityrosine. Finally, Dityrosine upregulated TNF-α, IL-6 and P38 expression level and downregulated PPARα expression level in myocardium of rats.

Conclusions: These results indicated dityrosine induce oxidative stress in myocardium and reduce myocardial collagen degradation rate, which lead mitochondrial dysfunction and myocardial energy generation.

Keywords: Dityrosine, Oxidative stress, Myocardial dysfunction

Conflict of Interest Disclosure: There are no competing financial interests in relation to the work.

ESTABLISHMENT OF HEMOGLOBIN MEASURING METHOD FOR THE PREVENTION OF SPORTS ANEMIA IN FEMALE ATHLETES

[1]Abe, Hirotoshi; [2]shirai, Anna; [2]Matsumoto, Megumi.

[1]Master of student; [2]Nihon University.

Background and objectives: For a female athlete, iron deficiency and anemia is one of the symptoms which remarkably lowers performance, and could cause health impairment. Athletes frequently undergo anemia due to rigorous training, reducing food intake for weight control and destruction of erythrocyte by repeated sole impulse. In addition, menses make it difficult for females to improve anemia.

In this study, we focused on the collegiate female athletes of land jump, volleyball and fencing who often complain anemia, and tried to establish the simple method of measuring the hemoglobin concentration in blood using non-invasive fingertip sensor, in order to monitor the status of iron nutrition easily.

Methods: Subjects were composed of each 27 collegiate female athlete of land jump, volleyball and fencing. The hemoglobin concentration was measured at before training using measuring instrument of non-invasive fingertip sensor (Pront-7). Furthermore hearing investigation was performed to record the physical condition and food intake frequency of one week.

Results: In hearing investigation, the athletes who complained symptom of anemia were70%, 40% and 35% in land jump, volleyball and fencing, respectively. The score of anemia condition negatively correlated with hemoglobin concentration. Hemoglobin concentrations were 12.4±0.2 g/dL, 12.1±0.4 g/dL and 12.9±0.2 g/dL athletes of land jump, volleyball and fencing, respectively. As a result of surveying the meal intake frequency in the athletes of jumping events of athletic competition, there was a positive corre-

lation between the amount of iron, protein or zinc intake per day and hemoglobin level. (iron: r = 0.575, protein: r = 0.630 and zinc: r = 0.661, respectively)

Conclusions: The measurement of hemoglobin using fingertip sensor might be useful option for monitoring the status of iron nutrition to prevent sports anemia.

Keywords: sports anemia, hemoglobin, non-invasive fingertip sensor, protein, iron

ASSISTING THE MANAGEMENT OF NUTRITION CARE WITH COMPUTER SYSTEMS

[1]Chen, Jiyuen-Tieng; [1]Lin, Shu-Chi; [2]Tsai, Hsiao-Jung; [2]Jen, Kai-Lin.

[1]MSc. Dietitian. Department of nutrition. Taiwan Adventist Hospital. Taiwan.; [2]BSc. Dietitian. Department of nutrition. Taiwan Adventist Hospital. Taiwan.

Background and objectives: In the treatment of cancer patients, it is necessary to provide adequate nutritional support. Traditionally, patients' conditions are recorded on paper by physicians, and screening for a nutrition consultation was done manually. However, patients' needs were often neglected due to the lengthy work process. In order to simplify the nutrition consultation process, and further avoid the possibility of missing cancer patients' needs, we set up computer systems to better assist the management of nutrition care.

Methods: The nutrition consultation standard for gastrointestinal tract cancer patients was developed in 2013. The "ICD Code Consultation Standard" for gastrointestinal tract cancer was established as the main consultation guide. When a doctor assigns a patient with a cancer ICD code, the computer system screens and sends a nutrition consultation notice immediately. Dietitians then advise the patient according to the resulting consultation list, providing nutrition care and advice based on the assessment. The nutrition recommendations and intake of these patients are recorded to analyze the effectiveness of nutritional care.

Results: 826 patients were counseled with gastrointestinal cancer nutrition care within 48 hours after consultation from 2013 to 2016. When enteral nutrition (EN) support was inadequate, parenteral nutrition (PN) support was provided as alternative nutritional intervention. The actual calorie intake of patients through EN or PN was recorded and analyzed. During hospitalization, the average percentage of recommended calorie intake increased from 53% to 75% (2013 to 2016), and recommended protein intake increased from 58% to 74% (2014 to 2016).

Conclusions: With improvement in nutritional consultation delivery supported by technology, cancer patients can receive early nutrition intervention, and get better nutrition care.

DIET QUALITY SCORES AND LUNG CANCER RISK: A CASE-CONTROL STUDY OF ADULTS MEN FROM THE NORTH-EASTERN REGION OF POLAND

(1)Hawrysz, Iwona; (2)Slowinska, Malgorzata Anna; (3)Wadolowska, Lidia; (1)Krusinska, Beata; (2)Janiszewska, Katarzyna; (4)Czerwinska, Anna; (5)Golota, Janusz Jacek.

(1)MSc. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.; (2)PhD. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.; (3)Prof. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.; (4)MD. Independent Public Complex Tuberculosis and Lung Diseases in Olsztyn. Poland.; (5)PhD. Clinic of Thoracic Surgery. Medical Center Ars Medica. Olsztyn. Poland.

Background and objectives: Lung cancer is the most common cause of cancer death in men worldwide [1, 2]. The studies describing the cumulative effect of food consumption on the lung cancer risk are limited. Objective: Assessment of the association between diet quality and risk of lung cancer in men from the north-eastern region of Poland.

Methods: The case-control study involved 339 men aged 29-83 years from the north-eastern region of Poland. Lung cancer was diagnosed in 140 men. On the basis of the food frequency questionnaire (QEB) [3] two diet quality scores were created. Pro-Healthy Diet Index-8 (pHDI-8) included 8 items: fruit, vegetables, wholemeal bread, milk, fermented milk drinks, cottage cheese, fish, legumes. Non-Healthy Diet Index-8 (nHDI-8) included 8 items: sweets, fried food, instant soups, fast foods, canned, sweetened carbonated beverages, energy drinks and alcoholic drinks. Multiple logistics regression analysis was used. Two models were created: crude and adjusted for: age, SES index, overall physical activity, sedentary lifestyle, occupational exposure, smoking, prevalence of cancers in family, BMI, weight change and waist-to-height-ratio.

Results: The odds ratios (ORs) of lung cancer prevalence in comparison to the absence of cancer (OR=1.00) were from 0.37 (95% confidence interval 95% Cl: 0.21-0.65; p<0.001; crude) to 0.25 (95% Cl: 0.12-0.51; p=0.0001; adjusted) in men in the upper tertile of the p-HDI-8. The ORs of lung cancer in comparison to the absence of cancer (OR=1.00) were 0.57 (95% Cl: 0.33-0.98; p<0.05; crude) in men in the upper tertile of the n-HDI-8, but not significant after adjustment.

Conclusions: In men from north-eastern Poland, the high diet quality score characterized by the frequent consumption of the pro-healthy foods strongly reduced the incidence of lung cancer, independently of confounders. The associations between low diet quality score and lung cancer risk was not clear and needs further research. References: [1] Vieira AR et al. POLISH ADAPTED PRO-MEDITERRANEAN DIET SCORE AND OTHER DIETARY PATTERNS AND BREAST OR LUNG CANCER RISK: A POOLED ANALYSIS OF TWO CASE-CONTROL STUDIES

(1)Krusinska, Beata; (1)Hawrysz, Iwona; (2)Wadolowska, Lidia; (3)Slowinska, Malgorzata Anna; (4)Biernacki, Maciej; (5)Czerwinska, Anna; (6)Golota, Janusz Jacek.

(1)MSc. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.; (2)Prof. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.; (3)PhD. Department of Human Nutrition. University of Warmia and Mazury in Olsztyn. Poland.; (4)PhD. Department of Surgery. University of Warmia and Mazury in Olsztyn. Poland.; (5)MD. Independent Public Complex Tuberculosis and Lung Diseases in Olsztyn. Poland.; (6)PhD. Clinic of Thoracic Surgery. Medical Center Ars Medica. Olsztyn. Poland.

Background and objectives: Results: **Methods:** This pooled analysis of two case-control studies involved 560 subjects (280 men and 280 women) aged 40-75 years from north-eastern Poland. Breast cancer in 140 women and lung cancer in 140 men were diagnosed. The food frequency consumption for selected 21 food groups was collected using the FFQ-6 [2]. Three DPs were identified in Principal Component Analysis: 'Prudent', 'Non-Healthy' and 'Dressings and sweetened-low-fat dairy'. The 8-items Pro-Mediterranean diet (Pro-MED) score (range: 0-8 points) included: vegetables, fruit, whole grain, fish, legumes, nuts and seeds, ratio of vegetables oils to animal fat, red and processed meat. Multiple logistics regression analysis was used. Two models were created: crude and adjusted for: age, sex, type of cancer, BMI, SES index, overall physical activity, smoking status and abuse of alcohol.

Results: The odds ratios (ORs) of both cancers prevalence in comparison to the cancer absence (OR=1.00) were 0.37 (95% confidence interval 95%Cl:0.21-0.64;p<0.001; adjusted) and 0.35 (95%Cl:0.21-0.58;p<0.0001; crude) in the top category (6-8 points) of the Pro-MED score and in the upper tertile of the 'Prudent' DP was 0.62 (95%Cl:0.41-0.94;p<0.05; crude), not significant after adjustment. The cancer ORs in comparison to the cancer absence were 1.65 (95%Cl:1.05-2.59;p<0.05; adjusted) and 1.89 (95%Cl:1.25-2.86;p<0.01; crude) in the upper tertile of the 'Non-Healthy' DP. The cancer ORs for the 'Dressings and sweetened-low-fat dairy' DP were not significant.

Conclusions: In Polish adults from northern-eastern Poland, the high adherence to the Mediterranean diet significantly low-

ered the chance of the breast or lung cancer, independently of confounders. The beneficial effect of the Mediterranean diet was stronger than the 'Prudent' pattern. The high adherence to the 'Non-Healthy' pattern increased chance of the breast or lung cancer. References: [1]Schwingshackl L., Hoffmann G. THE ASSOCIATION BETWEEN DIETARY CHOLESTEROL INTAKE AND DYSLIPIDEMIA PREVALENCE AMONG ADULTS IN CHINA: FINDINGS FROM THE CHINA HEALTH AND NUTRITION SURVEY

[1]*Wang, Zhihong;* [2]*Huang, Feifei;* [3]*Wang, Huijun;* [4]*Zhang, Jiguo;* [5]*Zhang, Bing.*

[1]PhD. Professor. National Institute for Nutrtition and Health, China CDC; [2]MS. Research Assistant. National Institute for Nutrition and Health, China CDC; [3]MS. Professor. National Institute for Nutrition and Health, China CDC; [4]PhD. Research Associate. National Institute for Nutrition and Health, China CDC; [5]PhD. Professor. National Institute for Nutrition and Health, China CDC.

Background and objectives: There is still controversy about deleting the recommendation of no more than 300mg/d dietary cholesterol for the healthy person. This study aims to examine the dose-response association between dietary cholesterol intake beyond 300mg/d and serum lipids-profile in Chinese adults.

Methods: Data from China Health and Nutrition Survey in 2009, 6,521 adults aged 18 to 65 who had complete diet data, serum lipids and sociodemographic data were selected as the analysis sample. Dietary cholesterol intake was assessed with consecutive 3-d 24-h recall and classified into 6 levels (0-<100mg/d, 100-<200mg/d, 200-<300mg/d, 300-<400mg/d, 400-<500mg/d and ≥400mg/d). The adults were defined as dyslipidemia (including high triglycerides, high total cholesterol, high LDL-C and low HDL-C) according to Guidelines for prevention and treatment of dyslipidemia in Chinese adults revised in 2016.

Results: About 36.4% of the men and 28.3% of the women had at least one abnormal serum lipid and only 21.9% of the men and 26.7% of the women had ideal level of the lipids-profile. The prevalence of high triglycerides, high total cholesterol, high LDL-C and low HDL-C in Chinese adults was 19.3% (men 22.9%

vs. women 16.0%, P<0.05), 8.6%, 10.1 and 10.7% (men 14.1% vs. women 7.5%, P<0.05), respectively. Multivariate Logistic regressions showed that the odds of having high TC and high HDL-C among the adults with dietary cholesterol intake higher than 500mg/d were 1.81 times (95%CI: 1.03, 3.22, p-trend>0.05) and 1.70 times (95%CI: 1.02, 2.81, P-trend>0.05) the odds in the adults with dietary cholesterol intake of 200-300 mg/d after adjusting for all potential covariates, respectively. However, the levels of dietary cholesterol intakes were not associated with the prevalence of high TG and low HDL-C.

Conclusions: it was found that the impact of dietary cholesterol intake on the prevalence of high TC and high LDL-C in Chinese adults may be threshold, rather than linear trend, at the level of 500mg/d or higher instead of limit of 300mg/d Prospective study in this field is needed to confirm the findings.

INTAKE OF ADDED SUGARS AND SATURATED FAT IN HEART FAILURE

[1]*Cardoso, Luciana;* [2]*Rosa, Maria Luiza;* [3]*Couto, Camilla;* [4]*Yokoo, Edna.*

[1]BSc. Nutritionist. Collective Health Institute. Federal Fluminense University. Brazil.; [2]PhD. Physician. Collective Health Post-Graduation Program. Collective Health Institute. Federal Fluminense University. Brazil.; [3]BSc. Nutritionist. Collective Health Post-Graduation Program. Collective Health Institute. Federal Fluminense University. Brazil.; [4]PhD. Nutritionist. Collective Health Post-Graduation Program. Collective Health Institute. Federal Fluminense University. Brazil.

Background and objectives: Heart failure (HF) has high rates of hospitalization and mortality. There is no consensus in the literature whether diets rich in saturated fat and added sugars contribute to the incidence and progression of HF. This study aimed to evaluate if the intake profile of saturated fat and added sugars would be associated with HF.

Methods: The study used data from DIGITALIS, study that estimated the prevalence of HF in the population assisted by the Family Medical Program in Niterói, Rio de Janeiro - Brazil. It was applied FFQ to evaluate the intake of added sugars and saturated fat. HF was diagnosed by clinical examination, electrocardiogram, echocardiogram and B-type natriuretic peptide and the population classified as: healthy (0), no symptomatic with risk factor (A), no symptomatic with functional/structural alterations (B), symptomatic with functional/structural alterations (C) and frequent symptomatic (D). ANOVA test was performed for continuous variables and Chi-Square test for categorical variables, considering p≤0.05 for statistical significance. The intake was evaluated by the recommendation, 10% and 7% of total energy intake for added sugars and saturated fat, respectively, and by quintiles.

Results: Around 59% and 70% of the sample exceeded the recommendation for added sugars and saturated fat, respectively. The analyses for recommendation and last quintile for added sugars and saturated fat together, showed there was no statistically significant difference between HF categories and healthy individuals (p=0.905 and 0.127, respectively). The result was similar in the individualized analysis for grams per day (p=0.115 and p=0.331, respectively) and quintiles (p=0.245 and 0.144, respectively).

Conclusions: The incidence and progression of HF were not associated with intake of added sugars or saturated fat, either above the recommendation or in the last quintile of intake in this population.

Keywords: heart failure, added sugar, saturated fat

LOW HDL IS ASSOCIATED WITH REDUCED GLOMERULAR FILTRATION RATE IN CHILDREN WITH OVERWEIGHT/OBESITY

[1]Alonso, Elizabeth; [2]Muzzio, María Luz; [3]Kabakian, Laura; [4]Scricciolo, Romina; [5]Lando, Inés; [5]Brovarone, Lucrecia; [5]Peredo, Maria Soledad; [5]Fernández, Jorgelina; [6]Santucci, Pía; [2]Meroño, Tomas.

[1]MD, Pediatric Specialist. Servicio de Diabetes y Nutrición Infanto-Juvenil, Complejo Médico Churruca-Visca.; [2]PhD. Biochemist. Central Laboratory. Complejo Médico Churruca-Visca. Buenos Aires. Argentina.; [3]MD. Pediatric Specialist. Servicio de Diabetes y Nutrición Infanto-Juvenil. Complejo Médico Churruca-Visca. Buenos Aires. Argentina.; [4]Biochemist. Central Laboratory. Complejo Médico Churruca-Visca. Buenos Aires. Argentina.; [5]Nutritionist. Servicio de Diabetes y Nutrición Infanto-Juvenil. Complejo Médico Churruca-Visca. Buenos Aires. Argentina.; [6]MD. Endocrinology Specialist. Servicio de Diabetes y Nutrición Infanto-Juvenil. Complejo Médico Churruca-Visca. Buenos Aires. Argentina.

Background and objectives: Several longitudinal studies have found an association between childhood overweight/obesity and the risk of kidney disease. Indeed, the increasing prevalence of kidney disease in children suggests that obesity-related glomerulopathy might begin at early stages of life. Renal hyperfiltration is postulated as one of the early events in obesity-related glomerulopathy. However, decreased, instead of increased, glomerular filtration rate (GFR) has been recognized in some series of children with overweight/obesity. The aim of this study was to evaluate the correlation between the GFR and biomarkers of the nutritional status in children with overweight/obesity.

Methods: Prospective study carried out in 35 children [age: 11(9-13)years] with overweight/obesity who attended the Pediatric Nutrition Unit of the "Complejo Médico Churruca-Visca", Buenos Aires, Argentina. Anthropometric measures were recorded. Z-scores were calculated according to the World Health Organization (WHO) growth charts. GFR was estimated using the Zappitelli combined formula which includes creatinine and cistatin C measurements. Routine laboratory measurements and biochemi-

cal evaluation of selected micronutrients were performed. Differences were evaluated by T or U test and correlations by Pearson or Spearman Correlation test, according to data distribution.

Results: Out of the 35 children studied (18 males), 25 were obese and 10 were overweight. Mean GFR was 97±15 ml/min.1.73m2, range: 76–132 ml/min.1.73m2. GFR was lower in males than females (-15%,p<0.01). Neither insulin resistance markers nor plasma levels of ferritin, vitamin B12 and vitamin D were correlated with GFR. GFR was only significantly correlated with HDL-C (r=0.41,p<0.01). Children with low HDL-C (n=23) presented higher Z-BMI (+16%,p<0.05), triglycerides (+33%,p<0.01) and cistatin C (+22%,p<0.01), as well as lower GFR (-21%,p<0.01) and Vitamin B12 (-30%,p<0.01) than children without low HDL-C. No differences in sex distribution were observed between the children with or without low HDL-C.

Conclusions: In this study of children with overweight/obesity we did not observe GFR values compatible with hyperfiltration (>135 ml/min.1.73m2). Instead, a trend towards lower GFR values was observed in this population. HDL-C was inversely correlated with the GFR. Children with overweight/obesity and low HDL-C may be at increased risk of renal dysfunction. Longitudinal studies are needed to confirm this hypothesis.

NUTRITION SCREENING FOR OVER NUTRITION IN ADULTS AGED 18-49 YEARS IN URBAN CITY OF KAMPALA, UGANDA

Ssenyondo, Muzafaru; Ainomugisha, Prudence; Nyakake, Lynn.

BSc. Department of Food Technology & Nutrition. Makerere University. Uganda.

Background and objectives: Background: According to WHO findings, Non-communicable diseases (NCDs) primarily cardiovascular diseases, cancers, chronic respiratory diseases and diabetes, are responsible for 63% of all deaths worldwide (36 million out of 57 million deaths), which could easily be prevented through nutrition education and early screening. About 80% of all NCD deaths occur in low and middle income countries in which Uganda belongs. The lack of nutrition education and direct disease screening programs for communities in urban areas, has been a critical gap in the community and national response to lifestyle diseases, especially nutrition related NCDs. Objective: To create awareness on NCDs, bring screening services closer to the urban population in order to promote an economically productive and non-communicable disease free population through Mobile Nutrition clinics; which provide effective community nutrition

screening and education; to ensure early detection, referral and treatment of nutrition- related NCDs in the community.

Methods: A three-day Urban Public Nutrition clinic (4th to 6th/09/2016) was organized by the Human nutrition students at Kampala Railway ground. Services provided included screening for 1) Malnutrition using anthropometry, 2) Random blood sugar test to screen for diabetes and 3) Blood pressure measurement. 4) Nutrition education using IEC materials, food demonstrations using the food pyramids, counseling and referrals.

Results: A total of 534 (77.7%, Males & 22.3%, Females) adult participants assessed, 41.7% had BMI above normal (>24.9 Kg/m2). Of these, 66.7% had high blood sugar levels and 49.6% had raised systolic blood pressure. They were counseled and referred to hospitals for treatment.

Conclusions: Conclusion: High incidence of NCDs among overweight urban population living in Kampala. Bringing services closer to Kampala urban population would help create awareness, educate and identify NCDs cases early and save lives.

Keywords: non- communicable diseases, mobile nutrition clinic, screening, Urban areas and over nutrition.

POTENTIAL RENAL ACID LOAD: A DIETARY PREDICTOR OF SERUM URIC ACID

[1]Esche, Jonas; [2]Krupp, Danika; [3]B.M. Mensink, Gert; [4]Remer, Thomas.

[1]MSc. DONALD Study Center Dortmund. IEL - Nutritional Epidemiology. University of Bonn. Dortmund, Germany; [2]Dr. Nutritionist. DONALD Study Center Dortmund. IEL - Nutritional Epidemiology. University of Bonn. Dortmund. Germany.; [3]Dr. Nutritionist. Robert Koch-Institute. Department of Epidemiology and Health Monitoring. Berlin. Germany; [4]Prof. Nutritionist. DONALD Study Center Dortmund. IEL - Nutritional Epidemiology. University of Bonn. Dortmund. Germany.

Background and objectives: Experimental studies indicated that a reduction of dietary acid load, e.g., by an increased consumption of fruits and vegetables, leads to increased renal uric acid excretion and reduced serum uric acid (SUA) levels. Against this background we examined the association between dietary potential renal acid load (PRAL) and SUA in a representative sample of the German adult population.

Methods: Cross-sectional analyses were performed in n=6894 participants (18-79y) of the German Health Interview and Examination Survey for Adults (DEGS1). Dietary intake was assessed by a food frequency questionnaire (FFQ). Nutritive acid load and the intake of uric acid equivalents (UAE) were characterized by assigning PRAL and UAE values, respectively, to the reported food consumption. Multiple linear regression models were used to analyze the association of PRAL, UAE and relevant food groups with SUA. Multiple logistic regressions were used to calculate the odds ratio (OR) for hyperuricemia comparing lower (T1) and upper (T3) tertiles of the predictors.

Results: After adjusting for relevant confounders, PRAL (p=0.003), alcohol (p<0.0001), UAE (p=0.03) and meat intake (p=0.003) were positively associated with SUA whereas the intake of fruits & vegetables and of milk products was inversely associated (both p<0.0001). Subgroup analyses among participants without interacting medication use largely confirmed these results. Additionally, participants with lower PRAL had lower odds for hyperuricemia (OR=0.60, 95% CI: 0.43-0.83).

Conclusions: Apart from substantiating known dietary influences on SUA, a low PRAL shows itself as a potentially SUA-reducing dietary pattern. This strengthens the importance of dietary alkalization as a future nonpharmacological tool to treat elevated SUA levels and gout.

Department of Nutrition. University of Buenos Aires. Food and Diet Therapy Service. Acute General Hospital Juan A. Fernández of Buenos Aires. Argentina.

Background and objectives: Cardiac rhythm abnormalities are well known to be predictors of severe, life-threating, cardiac arrhythmias, especially in patients with underlying cardiovascular diseases. In recent years, it has been suggested that eating habits may affect cardiac rhythm and the chance of developing rhythm abnormalities. However, evidence are controversial and inconclusive. The aim of the present study was to inspect relationships among lifestyle, dietary patterns, and anthropometrics with heart rhythm (Heart Rate Variability (HRV), Premature Ventricular and Atrial Complexes (PVC and PAC)), in patients undergoing Holter monitor.

Methods: The Heart Rhythm and ObeSity Prevention (HEARS) study is a cross-sectional investigation enrolling sub-

jects undergoing Holter monitor. Socio-demographic characteristics, body composition (full-body bioimpedentiometry), 24-h dietary recall, and quality of life were assessed. Generalized Additive models, considering a Zero Adjusted Gamma distribution (accounting for outcomes' skewness), were estimated to assess the relationship between outcomes of interest and variables collected.

Results: The study enrolled 121 patients, showing a median of 33 PVC (1-400; I-III quartiles) and 39 PAC (9-224; I-III quartiles), registered by Holter monitor. At multivariate analysis, fruit consumption was directly associated with HRV (p-value 0.044), while higher BMI was associated with lower HRV. PVC showed significant direct association with age (p-value 0.005), intake of grain-based product (p-value 0.001), snacks (p-value 0.063), and sugars (p-value 0.013); while fruit intake was significantly inversely associated with PVC (p-value 0.024). Regarding anthropometrics, mass of body fat was in a direct relationship with PVC (p-value <0.0001). Aging and cardiovascular comorbidities were significantly associated with PAC. Regarding dietary intake, condiments and sauces raised the likelihood of PAC (p-value 0.01), while protein food consumption was significantly inversely associated to PAC (p-value <0.0001).

Conclusions: These findings highlighted that anthropometrics, lifestyle, and nutrition are associated with cardiac rhythm abnormalities, and that factors importance changed according with outcome considered. Despite the need of further studies to better characterize the contribution of such factors to cardiac rhythm abnormalities, these findings might be useful to improve the management of patients attending cardiac rhythm labs, in order to tailor ad hoc prevention strategies (modification of lifestyle and eating habits) based on Holter parameters.

Botucatu Medical School. Brazil.

Background and objectives: HIV-associated lipodystrophy (HALS) is characterized by morphological changes due to fat tissue heterogeneous disorders, with body fat redistribution associated or not to metabolic alterations. Such alterations are consequences of the chronic inflammatory state due the viral infection and the usage of specific therapy to treat the sickness. The HALS is described as a syndrome which consider the fat loss and/or accumulation, classified in three subtypes. The impairments due these metabolic and morphological alterations go beyond esthetic consequences, once there may be an increased risk to the development of other disturbances, such as the Metabolic Syndrome (MS). Considering the existence of body composition differences per gender, the objective of the present study was to verify, among genders, the clinical-nutritional and anthropometric differences of people living with HIV/AINDS with clinical diagnoses of HALS.

Methods: The study was observational and transversal, with its sample selected by convenience and performing clinical immunological characterization, anthropometric assessment, nutritional diagnosis, body composition of PLHA during the follow-up of specialized outpatient service in infectiology with a clinical HALS diagnosis from July 2015 to July 2016, in regular ART use for at least a year, ranging from 18 to 60 years old. Pregnant women, people with chronic kidney failure, nephrotic syndrome, B and C virus chronic infection, uncontrolled hypothyroidism were excluded from the study.

Results: Forty individuals were distributed equally by gender, with age of 45,5 ± 8,2 years, diagnostic time of 15,3 ± 6,2 years and antiretroviral therapy usage time of 13,8 ± 5,7 years. The results showed significant difference on lipid profile to female gender, with increased values, exce-pt for HDL-cholesterol. No statistical differences were observed for fasting blood glucose and clinical-immunological parameters between genders.

Conclusions: Despite the lack of differences, body fat and anthropometric indicators presented higher alterations among women living with HIV/AIDS. Lipid profile significant alterations and high body fat values (even without statistical significance) among women suggests an increased risk for cardiovascular diseases when compared to men in the aforementioned population, highlighting the importance to adopt different follow up strategies for those patients.

Keywords: People living with HIV/aids, lipodystrophy, body composition, metabolic syndrome.

THE ASSOCIATION BETWEEN DEPRESSION AND FOOD INSECURITY STATUS IN TWO IRANIAN ETHNIC GROUPS LIVING IN NORTHWEST OF IRAN

Rezazadeh, Arezoo; Omidvar, Nasrin; Eini-Zinab, Hassan.

Department of Community Nutrition. National Nutrition and Food Technology Research Institute. Faculty of Nutrition and Food Technology. Shahid Beheshti University of Medical Sciences and Health Services. Iran.

Background and objectives: Studies approve that Food insecurity (FI) influences on mental health. Minor ethnic group may experience higher level of FI and this situation may be related with higher depression prevalence. The aim of this study was to determine the association of depression with general and central obesity in major (Azeri) and minor (Kurd) ethnicities living in Urmia, West Azerbaijan, Iran.

Methods: In this cross-sectional study, 723 participants (427 women and 296 men) aged 20–64 year old, from two ethnic groups (445 Azeri and 278 Kurd) were selected through a multi stage cluster systematic sampling. Depression rate was assessed by "Beck" short form questionnaire (validated in Iranians) through interviews. Household food insecurity status (HFIs) were measured using adapted household food insecurity access scale through face-to-face interviews at homes. Multinomial logistic regression was used to estimate odds ratios (OR) of depression across HFIS.

Results: Higher percent of Kurds had moderate and severe depression in comparison with Azeri group (73[17.3%] vs. 86[27.9%]). There was not any significant differences between the two ethnicities in mild depression. Also, of all the subjects, moderate-to-sever FI was more prevalent in Kurds (28.5%), compared to Azeri group (17.3%) [P<0.01]. IN Kurd ethnic group who were food secure or with mild HFI had lower chance to have sever depression (OR=0.097; 95% CI: 0.02-0.47) in comparison to those with sever FI. However, there was no significant association between depression and HFI in Azeri group.

Conclusions: Findings revealed that the severity of HFI was related with severity depression in minor studied ethnic groups. However in Azeri ethnicity as a major group other confounders may have influence on the relation with depression and FI that not controlled in the present study.

Background and objectives: Currently 170 million people worldwide are infected with the hepatitis C virus, the biggest cause of viral hepatitis. The objective of our study was to evaluate the differences between the anthropometric and biochemical profile of patients with hepatitis C diagnosis and controls from the Polyclinic Piquet Carneiro (Rio de Janeiro, Brazil).

Methods: Case-control study. Patients were recruited at the time of the diagnostic examination of hepatitis C. We included 99 adult patients with positive diagnosis. The 50 controls were recruited among people without hepatitis C at the time of routine exams. The individuals were weighed and measured. Blood samples were collected for the determination of total cholesterol, HDL cholesterol, LDL cholesterol, triglycerides, total bilirubin (TB) and direct bilirubin (DB), glutamic oxalacetic transaminase (GOT), glutamic pyruvic transaminase (GPT) and iron.

Results: Most of the subjects were overweight and obese, 40.8% and 24.5% of the patients, and 36.9% and 27.2% of controls respectively. total cholesteroland LDL were significantly higher in control subjects (Md 196.00 mg/dL -IQ 123.00-343.00) and (Md 118.00 mg/dL-IQ 43.00-256.00), when compared to patients with hepatitis C (Md 170.50 mg/dL-IQ 108.00-314.00) and (Md 93.00 mg/dL-IQ 31.60-225.00). The levels of TB, DB, AST, ALT and iron were lower in the controls when compared to patients with hepatitis C. In the final model, adjusted for age and presence of comorbidities, TB (p 0.02), DB (p 0.02), AST(p <0.01) and Iron (p 0.04) remained significantly lower in the controls.

Conclusions: Overall, These results demonstrated that patients do not have significant anthropometric alterations at the

time of diagnosis of hepatitis C, but already present significant alterations in the biochemical markers. These results reinforce the importance of the composition of biochemical and anthropometric indicators for a correct diagnosis.

Background and objectives: In some cases, bariatric surgery may be an alternative treatment for obesity, which may contribute to weight loss and control comorbidities, but may also lead to food intolerances. The objective of this study was to evaluate the nutritional characteristics and quality of life of patients undergoing bariatric surgery.

Methods: 39 patients who are in treatmente in a multidisciplinary center and who met these inclusion criteria were enrolled: consent to participate in the research, performance of Gastric bypass Roux-en-Y technique and age between 18 and 59 years. Personal and clinical data were obtained through interview and consultation in medical records and anthropometric measures and dietary reviews were do by a nutritionist. The quality of life evaluation was done by the BAROS protocol.

Results: 87.2% of the participants were females and a mean age of the population was 37.2 ± 8.7 years. The mean preoperative body mass index was 45.1 ± 7 kg / m² and a percentage of preoperative weight adequacy corresponded to $204.3 \pm 25.9\%$ for women and 236.4 ± 47, 3% for men. Of the 22 patients who reported comorbidities on preoperative, 91% had disease resolution. The mean percentages of excess weight loss according to the postoperative period were, respectively, $24.9 \pm 8\%$ (up to 3 months), $52 \pm 13\%$ (4 to 11 months) and 62.3 ± 15, 9% (1 year or more). The median postoperative time was 7 months and the minimum and maximum values were 1 to 24 months, respectively. All patients underwent multidisciplinary treatment before and after surgical intervention. The dietary assessment indicated that 23% of the individuals presented intolerance to red meat, 18% did not accept chicken meat and 5.1% had difficulty consuming fish. The vegetables were not accepted by only 2 participants (5.1%). 53.8% of the participants obtained the maximum score in the BAROS Protocol, classifying their quality of life as excellent.

Conclusions: Surgery promotes progressive weight loss and resolution of comorbidities, and although there are certain food intolerances, especially with animal protein items, quality of life is considered excellent by the majority of the patients operated on.

ENTERAL NUTRITION IN CRITICALLY ILL ADULTS: ARE THE PRESCRIPTION AND THE NUTRIENT DELIVERY ACCORDING TO THEIR REQUIREMENTS?

Villa, Roberto.

MD. PhD. Professor of Medicine. Terapia Intensiva Adultos. Obra Social para la Actividad Docente. Argentina.

Background and objectives: Identify factors that impede the delivery of enteral nutrition, and assess the amount of nutrients prescribed, required, and actually delivered for critically ill adults.

Methods: In a prospective cohort study 55 consecutive patients aged 58.2 ± 11.4 years, who received enteral nutrition for > 2 days through gastric or post-pyloric tubes, were followed from admission until the first 15 days of nutritional delivery. The amounts of prescribed / delivered energy were recorded daily and compared with basal metabolic rate (goal energy) according to the recommendations of WHO (1). The reasons for cessation of enteral feeding were evaluated. The prognostic score The Acute Physiology and Chronic Health Evaluation (APACHE II) (2) and Simplified Acute Physiology Score (SAPS II) was used at admission.

Results: The mean caloric intake was 19.5 ± 8.8 kcal/kg/day, 60% of the median caloric amount required, and 85% of the prescribed. The ratio delivery/required was > 90% of the goal energy in only 44% of enteral nutrition days (164/370). Low prescription rate was the predominant reason for not achieving the goal energy in the first five days of enteral nutrition; after this study point, other factors were associated. In bivariate analysis, factors significantly associated with low energy delivery were: APACHE II > 14, gastrointestinal complications, use of adrenergic vasoactive drugs regardless of the dose with which the patient is. When the logistic regression model was applied, only the use of adrenergic vasoactive drugs was a independent and significant factor (p=0,043).

Conclusions: The prescription and delivery of energy were not appropriated in > 50% of enteral nutrition days. Among the factors analyzed, a low rate of enteral nutrition prescription and the use of adrenergic vasoactive drugs showed association with low energy delivery.

ENTERAL NUTRITION IN SEPTIC SHOCK IN THE ELDERLY: DO THE TIME ELAPSED UP TO THE START AND THE ACHIEVED BASAL ENERGY EXPENDITURE INTERFERENCE IN MORTALITY?

[1]Villa, Roberto; [2]Clochiatti, Natalia; [2]Vargas, Erick.

[1]MD. PhD. Professor of Medicine. Terapia Intensiva Adultos. Obra Social para la Actividad Docente. Argentina.; [2]MD. Physician. Terapia intensiva. Obra social para la actividad docente. Argentina.

Background and objectives: The earliest start point of the enteral nutrition (EN), as well as the basal energy expenditure (BEE) achieved in a time space as short as possible seem to benefit a good amount of critical patients.

Objectives: To analyze the time to start the EN and the BEE achieved in the elderly interned with a septic shock diagnose and to verify the association with mortality in these patients.

Methods: Prospective cohort hold within 32 months and with 67 patients over 65 years-old in ICU with septic shock where 59 of those had EN. The APACHE II score was carried out in every patient. The following variables were analyzed in this group: the time taken to start the NE, the BEE (achieved or not), the time to reach the BEE in those who got it. These variables were correlated with death and it was still observed if there was correlation between the start time point of EN and the achieved BEE. The statistics tests used were: T test and chi-square, considering 5% as the significance level.

Results: The average age was 80 + 7 (min.= 66, max.= 96), the APACHE II average was 18 + 5 (min.= 8, max.= 28), and the time average to start EN was 80 ± 53 h (min. de 12 h e max. de 240 h). The achieved BEE occurred in 69,5% (n= 41) of the patients and the time average to reach it was 115 ± 56 h (min. de 72 h e max. de 360 h). Death was associated with time to start EN (p= 0,001) and with the non-achieved BEE (p< 0,001). However, there was no correlation with time to reach BEE (p= 0,22). The time to start EN did not show association with the achieved BEE (p= 0,08).

Conclusions: The EN initiated as soon as possible and the BEE when achieved in this group of patients showed some benefit. The time to achieve the BEE seems not to have correlation with mortality in these patients. The time to start NE did not have association with the BEE achieved in this sample.

Teikyo University School of Medicine. Japan.

Background and objectives: To determine the association between dietary patterns identified via a validated food frequency questionnaire (FFQ) and the risk of impaired glucose tolerance in community-dwelling adults.

Methods: We followed 798 participants who did not take medication for diabetes treatment and less than 5.4% of HbA1c, completed a self-administered questionnaire at baseline, and participated at least one identical follow-up health check-ups, and who did not develop diabetes (start of medication for diabetes and/or HbA1c 6.5% or more) during the follow-up period. In this study, impaired glucose tolerance was defined as HbA1c concentrations of 5.4-6.4%. The association of dietary patterns with impaired glucose tolerance was examined logistic regression analysis with adjustment for potential confounding variables.

Results: During the follow-up period, we identified 378 incident cases of impaired glucose tolerance. Using principal component analysis and dietary data collected through a FFQ, we identified three major dietary patterns: Japanese, high protein, and western breakfast. After adjustment for potential confounding variables, the highest quartile of the high protein pattern was 1.59 times higher risk of developing impaired glucose tolerance (95% confidence interval 1.06-2.40). Other dietary patterns were not appreciably associated with impaired glucose tolerance.

Conclusions: Our findings suggest that high protein dietary pattern may be related to increasing the risk of impaired glucose tolerance in Japanese populations.

Keywords: dietary pattern, impaired glucose tolerance, community-dwelling adults

SYSTEMIC RESPONSES OF METHIONINE RESTRICTION IN MICE WITH HIGH FAT DIET BY METABOLOMIC STUDIES

[1]Shi, Yonghui; [2]Yang, Yuhui; [3]yan, biao; [4]Wang, Yanan; [4]Zhang, Jiahong; [4]Guo, Haitao; [3]Le, Guowei.

[1]MSc. The State Key Laboratory of Food Science and Technology. School of Food Science and Technology. China. Jiangnan University. China.; [2]MSc. School of Food Science and Technology. Jiangnan University. China.; [3]PhD. School of Food Science and Technology. Jiangnan University. China.; [4]BSc. School of Food Science and Technology. Jiangnan University. China.

Background and objectives: Dietary methionine restriction shows many beneficial effects on health including extends mean and maximum lifespan, improves insulin sensitivity and reduces adiposity, and reduces reactive oxygen species generation and oxidative stress. However, the systemic responses of high fat diet mice to dietary methionine restriction remain largely unknown. This study aims to investigate the effects of dietary methionine restriction on the systemic metabolism of high fat diet C57BL/6 mice.

Methods: Mice were fed with a high fat diet containing either 0.86% methionine or 0.17% methionine for 22 consecutive weeks. We analyzed the metabolic alterations in mice plasma and urine using 1H NMR-based metabonomics approaches and coupled with multivariate data analysis methods.

Results: We found that dietary methionine restriction caused significant level elevation for albumin, 3-hydroxybutyrate, acetoacetate, citrate, glycerophosphorylcholine, propionate, isobutyrate, ethanol and decline for tyrosine, 1-methylhistidine, lipids (-CH2-, CH2C=C, =CCH2C=), unsaturated lipids, α-glucose, β-glucose, trimethylamine-N-oxide, N-acetyl glycoprotein, O-acetyl glycoprotein in mice plasma. Dietary methionine restriction also caused elevation of citrulline, 3-hydroxybutyrate, acetoacetate, acetone, succinate, α-ketoglutarate, lactate, propionate, valerate, sarcosine, succinimide, taurine in mice urine together with depletion of 2-keto-isovalerate, urea, N-methylnicotinamide, trimethylamine, trimethylamine-N-oxide, allantoin, indoxyl sulfate, 4-hydroxyphenylpyruvate, 2-(4-hydroxyphenyl) propanoate.

Conclusions: These observations indicated that dietary methionine restriction caused widespread systemic metabolic changes, including reduced catabolism of amino acids, increased energy expenditure (enhanced fatty acid oxidation, glycolysis and tricarboxylic acid cycle metabolism), reduced oxidative stress and inflammation, altered gut microbiota functions, reduced the risk of atherosclerosis and vascular disease, and improved learning and memory. These findings provide a comprehensive insight into the biochemical consequences and metabolic responses to dietary methionine restriction in high fat diet mice.

EFFECTS OF METHIONINE RESTRICTION ON THYROID HORMONES AND SKELETAL MUSCLES MITOCHONDRIAL CONTENT AND FUNCTION IN HIGH-FAT DIET MICE

[1]Zhang, Jiahong; [1]Wang, Yanan; [1]Guo, Haitao; [2]Le, Guowei; [3]Shi, Yonghui.

[1]BSc . School of Food Science and Technology. Jiangnan University. China.; [2]PhD. The State Key Laboratory of Food Science and Technology, School of Food Science and Technology, Jiangnan University. China.; [3]MSc. The State Key Laboratory of Food Science and Technology, School of Food Science and Technology, Jiangnan University. China.

Background and objectives: Dietary methionine restriction (MR) limits fat deposition and expends lifespan without food restriction. Our objective was to investigate the effects of methionine restricted high-fat diet on thyroid hormones and skeletal muscle mitochondria content and function in mice.

Methods: A total of twenty-seven male C57BL/6 mice were randomly divided into control feeding diet (CON), high-fat diet (HFD) and methionine restricted-high fat diet (MR-HFD). In 22th week, the energy metabolism was measured by comprehensive laboratory animal monitoring system (CLAMS). Thyroid gland histological analysis was performed by microscopy. The plasma levels of lipids, thyroid hormones and the skeletal muscle levels of deiodinase 2 (Dio2) activity, mitochondrial membrane potential (MMP), ATP content were detected. Mitochondrial DNA copy number, relative mRNA expression of Dio2, mitochondrial biogenesis related genes PGC-1α, Tfam and ATP6 were determined by quantitative reverse transcription-polymerase chain reaction.

Results: Compared to HFD group, the average body weight was significantly decreased by methionine restriction (P<0.05), while the level of energy intake and energy expenditure were significantly increased (P<0.05). In plasma, methionine restriction significantly decreased the level of lipids (P<0.05), while the level of thyroid hormones was significantly increased (P<0.05). In skeletal muscle, the level of Dio2 activity, MMP, ATP, mitochondrial DNA copy number and the mRNA expression of Dio2, PGC1α, Tfam, ATP6 were significantly increased in MR-HFD group than those in HFD group (P<0.05).

Conclusions: Methionine restriction may enhance skeletal muscle mitochondria content and function by increasing T3 profited from both improvement of thyroid gland function and the high expression of skeletal muscles Dio2 in high fat diet mice. As a consequence, the energy metabolism of skeletal muscle was accelerated and the weight of mice was reduced.

COMBINED INTERVENTION OF METHIONINE RESTRICTION AND COLLAGEN PEPTIDES ON LIPID METABOLISM AND OXIDATIVE STRESS IN HIGH-FAT DIET-FED MICE

[1]*Wang, Yanan;* [2]*Yan, Biao;* [1]*Zhang, Jiahong;* [1]*Guo, Haitao;* [3]*Shi, Yonghui;* [4]*Le, Guowei.*

[1]BSc . School of Food Science and Technology. Jiangnan University. China.; [2]PhD . School of Food Science and Technology. Jiangnan University. China.; [3]MSc. The State Key Laboratory of Food Science and Technology, School of Food Science and Technology, Jiangnan University. China.; [4]PhD. The State Key Laboratory of Food Science and Technology, School of Food Science and Technology, Jiangnan University. China.

Background and objectives: Methionine restriction and collagen peptides are different dietary intervention that both reduces adiposity and improves oxidative stress. Our present objective was to elucidate the combined intervention of methionine restriction and collagen peptides on lipid metabolism and oxidative stress in high-fat diet-fed mice.

Methods: Thirty-six male C57BL/6 mice were randomly equally divided into normal diet (ND) group, high-fat diet (HF) group, high-fat with methionine-restricted diet (MR) group, or MR diet supplemented with 1% collagen peptides (PMR) group, respectively. Mice were fed for 22 weeks. Plasma lipid profiles were examined. The concentrations of total cholesterol (TC) and triglyceride (TG), the levels of total antioxidant capacity (T-AOC), glutathion peroxidase (GSH-Px), malondialdehyde (MDA) and reactive oxygen species (ROS) in liver were determined. The mRNA expressions of FAS, ACC-1, SREBP1c, CYP7A1, CPT1 and PPARα in liver were assayed by real-time PCR.

Results: Compared to HF, MR significantly decreased the body weight, the concentrations of TG and TC in plasma and liver, the levels of MDA and ROS in liver, the expressions of FAS, ACC-1 and SREBP1c in liver. MR significantly increased T-AOC and GSH-Px activity in liver, the expressions of CYP7A1, CPT1 and PPARα in liver. Compared to MR, PMR significantly decreased the body weight, the concentrations of TG and TC in plasma, the concentration of TG in liver, the expressions of SREBP1c and ACC-1 in liver. Meanwhile, the activity of GSH-Px and the expressions of PPARα and CPT1 in liver were increased.

Conclusions: Dietary methionine restriction can significantly decrease plasma lipid profiles and liver fat content, enhance antioxidant capability in high-fat diet-fed mice. Combined intervention of collagen peptides and methionine restriction can more effectively increase the antioxidant capacity, decrease plasma lipid profiles and liver fat content.

Keywords: Methionine restriction, Collagen peptides, Lipid metabolism, Oxidative stress

NON-PROCESSED RED MEAT CONSUMPTION IS ASSOCIATED WITH A LOWER RISK OF A FIRST CLINICAL DIAGNOSIS OF CENTRAL NERVOUS SYSTEM DEMYELINATION

[1]*Bowe, Gabrielle;* [2]*Sherriff, Jill;* [3]*Pereira, Gavin;* [4]*Lucas, Robyn;* [5]*Black, Lucinda;* [6]*Investigator Group, Ausimmune.*

[1]BSc. Master of Dietetics student. School of Public Health. Curtin University. Australia.; [2]PhD APD. Associate Professor. School of Public Health. Curtin University. Australia.; [3]PhD. Senior Research Fellow. School of Public Health. Curtin University. Australia.; [4]PhD. Professor. National Centre for Epidemiology and Population Health. The Australian National University. Australia.; [5]PhD. Research Fellow. School of Public Health. Curtin University. Australia.; [6]Ausimmune Investigator Group.

Background and objectives: The evidence associating red meat consumption and risk of multiple sclerosis (MS) is inconclusive. We tested associations between non-processed and processed red meat consumption and risk of a first clinical diagnosis of CNS demyelination (FCD), a common precursor to MS.

Methods: We used food frequency questionnaire data from the 2003-2006 Ausimmune Study (272 cases, 519 controls), an incident case-control study examining environmental risk factors for FCD. We calculated non-processed (beef, veal, lamb, pork) and processed (ham, bacon, salami, sausages) red meat density as grams of meat intake per 1000 kcal of energy intake per day. Red meat density was categorised into quartiles based on the thresholds for control participants. Logistic regression models were adjusted for age, sex, geographical region, smoking, vitamin D status, history of infectious mononucleosis, education and dietary misreporting (n=746).

Results: Compared with those in the lowest quartile of non-processed red meat density, the risk of FCD was 5% lower for those in the second quartile (OR=0.95; 95%CI 0.63,1.45; p=0.826), 39% lower for those in the third quartile (OR=0.61; 95%CI 0.39,0.95; p=0.030), and 38% lower for those in the highest quartile (OR=0.62; 95%CI 0.39,0.98; p=0.041). The results suggest a non-linear protective association between non-processed red meat density and risk of FCD, with beneficial effects for non-processed red meat density above 35 g per 1000 kcal/day, and similar effects for the top two quartiles. For a diet consisting of 2000 kcal/day, the strongest FCD risk reduction (approximately 40%) equates to a non-processed red meat consumption of at least 70 g/day. We found no statistically significant associations between processed red meat consumption and risk of FCD.

Conclusions: Our results suggest a possible protective effect of higher non-processed red meat consumption and risk of FCD. Further investigation is warranted to understand the important components of a diet that includes at least 70 g of non-processed red meat per 2000 kcal for lower FCD risk.

EFFECTS OF ALLIUM HOOKERI LEAF ON PLASMA GLUCOSE AND LIPID PROFILE IN STREPTOZOTOCIN INDUCED DIABETIC RATS

[1]*Kim, Myung Wha;* [2]*Han, Hye Kyoung;* [3]*Park, Su Min.*

[1]PhD. Professor. Dept of Food and Nutrition. Duksung Women's University. Seoul Korea.; [2]PhD. Lecturer. Dept of Food and Nutrition. Duksung Women's University. Seoul Korea.; [3]BCs. MSc student. Dept of Food and Nutrition. Duksung Women's University. Seoul Korea.

Background and objectives: Diabetes mellitus has been one of major health risks in industrialized countries. The first burden of disease is diabetes mellitus in Korea. Allium hookeri (AH) has been used as food and medicine in Southeast Asia. We used AH leaf grown in Korea as an experimental material. This study was designed to examine the effects of AH leaf on plasma glucose and lipid profile in streptozotocin (STZ) induced diabetic rats.

Methods: Diabetes mellitus was induced in male Sprague-Dawley rats through injection of STZ dissolved in citrate buffer into tail veins at a dose of 45 mg/kg body weight (BW). Sprague-Dawley rats were fed an AIN-93 recommended diet and the experimental groups were fed a modified diet containing 5% and 10% of AH leaf powder for 4 weeks. The experimental groups were divided into four groups, consisting of a normal control group, STZ-control group, and diabetic groups fed with AH 5% & 10%. Rats' body weights, organ weights, plasma glucose, total cholesterol, HDL-cholesterol, triglyceride (TG), and free fatty acid (FFA) values in plasma were measured along with hematocrit (Hct) values and aminotransferase activities.

Results: The organ weights/100g BW of kidney and liver in the STZ-AH 5% and 10% diabetic groups were significantly decreased compared to the STZ-control group. Plasma glucose was significantly reduced in the STZ-AH 10% diabetic group. HDL-cholesterol significantly increased while FFA significantly decreased in the STZ-AH 10% diabetic group.

Conclusions: These results indicate that supplementation with Allium hookeri leaf maybe beneficial in management of diabetes mellitus as a potential therapeutic candidate.

Keywords: Allium hookeri, STZ diabetic rats, plasma glucose, lipid profile.

THE EFFECT AND MECHANISM OF OAT BETA-GLUCAN ON TYPE 2 DIABETES MELLITUS BASED ON GUT MICROBIOTA

[1]*Xu, Meihong;* [2]*Li, Yong;* [3]*Mao, Ruixue;* [4]*Wang, Junbo.*

[1]Peking University; [2]liyongbmu@163.com; [3]mxmao@163.com; [4]bmuwjbxy@bjmu.edu.cn.

Background and objectives: It's aims to evaluate the relationship between oat beta-glucan and the rats with T2DM from the gut microbiota's point of view.

Methods: A model of SD rats with high fat diet-induced combined low dose STZ was used. AIN93G diets containing 0.275%, 0.55% and 1.1% oat beta-glucan were supplied to normal or diabetic rats for 10 weeks. The proinflammatory and inflammatory markers such as serum lipopolysaccharide, TNF-a, IL-6 were measured using commercially availbale ELISA kits. Expression of CD14 and Toll-like receptor in serum and skeletal were measured by western blot analysis. Gut microbiota were assessed by stand plate counting method and 454 genesanalysis.

Results: After 10 weeks feeding, comparing with the model control, the food consumption of 1.1g/kg*bw oat beta-glucan rats was significantly decreased (P<0.05), whereas urine volume was relatively reduced without significant difference (P>0.05). Oat beta-glucan intervention significantly reduced the blood glucose (P<0.05) and improved insulin resistance (P<0.05). Besides, oat beta-glucan intervention was found to reverse the elevated serum and hepatic lipid profiles in diabetic rats (P<0.05). There were clearly structural differences of gut microbiota between model control and normal control group at both the phyla and genus levels. Bacteroidetes were significantly decreased in diabetic rats compared to normal control group, with Firmicute and Proteobacteria elevated. Our research showed oat beta-glucan supplement could change the diabetic-disrupted gut microbiota to a healthier state by increasing the abundance of Bacteroidetes and reducing the abundance of Firmicute. Results: **Conclusions:** This study verified that oat beta-glucan had an benefits effect on T2DM, by reducing blood glucose and decreasing insulin resistance, and Modulation of gut microflora may be one potential mechanism.

Keywords: oat beta-glucan, type 2 diabetes mellitus, gut microbiota

Background and objectives: While many cancer patients are affected by weight loss, others tend to gain weight, which may impact prognosis and risk of recurrence and of second cancer. The aim of this prospective study was to investigate weight variation between before and after cancer diagnosis and socio-demographic, economic, lifestyle and clinical factors associated with moderate-to-severe weight gain.

Methods: 1051 incident cases of first primary cancer were diagnosed in the NutriNet-Santé cohort between 2009 and 2015. Weight was prospectively collected every 6 months since subjects' inclusion (i.e. an average of 2y before diagnosis). Mean weights before and after cancer diagnosis were compared with paired Student's t-test. Factors associated with moderate-to-severe weight gain (≥5% of initial weight) were investigated by age and sex-adjusted logistic regression.

Results: Weight loss was observed in men (-3.54±4.39kg in those who lost weight, p=0.0002) and in colorectal cancer patients (-3.94±4.40kg,p=0.001). Weight gain was observed in breast and skin cancers (2.83±3.21kg,p=0.04, and 2.96±2.75kg,p=0.04 respectively). Women (OR=1.75[1.06-2.87],p=0.03), younger patients (2.44[1.51-3.70],p<0.0001), those with lower income (OR=1.30[1.01-1.72],p-trend=0.007), lower education (OR=1.32[1.03-2.70],p-trend=0.03), excess weight before diagnosis (OR=1.64[1.12-2.42],p=0.01), lower physical activity (OR=1.28[1.01-1.64],p=0.04) and those who stopped smoking (OR=4.31[1.99-9.35],p=0.005]) were more likely to gain weight. In breast cancer patients, induced menopause was associated with weight gain (OR=4.12[1.76-9.67]), but no association was detected for tumor characteristics or treatments.

Conclusions: This large prospective cohort provided original results on weight variation between before and after cancer diagnosis, highlighting different weight trajectories. Socio-demographic and economic factors appeared to influence the risk of weight gain, illustrating social inequalities in health.

Keywords: Weight gain, weight loss, cancer diagnosis, breast cancer, socio-demographic factors

EFFECTS OF METHIONINE RESTRICTED DIET ON BONE FORMATION IN MICE

(1)Guo, Haitao; (1)Wang, Yanan; (1)Zhang, Jiahong; (2)Shi, Yonghui; (3)Le, Guowei.

(1)BSc . School of Food Science and Technology. Jiangnan University. China.; (2)MSc. The State Key Laboratory of Food Science and Technology, School of Food Science and Technology, Jiangnan University. China.; (3)PhD. The State Key Laboratory of Food Science and Technology, School of Food Science and Technology, Jiangnan University. China.

Background and objectives: To investigate the effects of methionine restricted diet on the bone strength and microstructure of the femur in mice and the mechanisms by using the oxidative stress status and micro-CT.

Methods: Mice were fed with normal diet (CON) with methionine content of 0.86% and methionine restricted (MR) diet with metnionine content of 0.17% for 22w. After feeding, the femur length, femur dry weight, BMC, BMD, microstructure, bone strength and redox state of femur were determined.

Results: Compared with CON group, femur length, femur dry weight and bone mineral density (BMD) of MR group have no difference. BMC, cancellous bone volume and trabecular thickness significantly increased, oxidative stress significantly decreased, while the bone strength significantly decreased.

Conclusions: 22w MR diet can significantly increase the BMC and trabecular thickness, improve the microstructure of bone tissue, significantly reduce the body weight of mice and bone strength. There is a tendency to reduce fat cell content of femur, but there is no significant difference in bone strength/body weight.

IMPACT OF SOCIOECONOMIC STATUS ON ONE-CARBON METABOLISM IN PRE-ELDERLY AND ELDERLY: THE LIFELINES COHORT AND BIOBANK STUDY

[1]Minovic, Isidor; [2]van Zon, Sander K.R.; [3]Reijneveld, Sijmen A.; [4]Kootstra-Ros, Jenny; [5]Feskens, Edith; [6]Navis, Gerjan; [7]Eggersdorfer, Manfred; [4]Kema, Ido; [6]Bakker, Stephan J.L.

[1]PharmD. Isidor Minovic. Department of Nephrology. University Medical Center Groningen. The Netherlands.; [2]MSc. Department of Health Sciences. University Medical Center Groningen. The Netherlands.; [3]MD PhD. Department of Health Sciences. University Medical Center Groningen. The Netherlands.; [4]PhD. Department of Laboratory Medicine. University Medical Center Groningen. The Netherlands.; [5]PhD. Division of Human Nutrition. Wageningen University. The Netherlands.; [6]MD PhD. Department of Nephrology. University Medical Center Groningen. The Netherlands.; [7]PhD. Nutritional Products. DSM. Switzerland.

Background and objectives: Low socioeconomic status (SES) is an established risk factor for cardiovascular disease and for low intake of micronutrients, such as B-vitamins. The latter could adversely affect one-carbon metabolism, especially in populations at increased risk of inadequate nutritional intake, such as pre-elderly and elderly. We therefore evaluated folic acid, vitamin B12, vitamin B6, and homocysteine in plasma of pre-elderly and elderly with high and low SES.

Methods: From the population-based LifeLines Cohort and Biobank Study (N=167,729), 1,600 individuals between 60 and 75 years were included to create two gender-matched groups (both N=800) with different socioeconomic status (SES). Since education is more differentiating than income in the egalitarian Dutch population, SES-groups were defined according to highest completed education as high (university degree) and low (no or only primary education)). Parameters of one-carbon metabolism were measured using validated routine assays. Differences between groups were tested with linear regression analysis.

Results: Mean±SD age and BMI were 65±4 years and 25.7±3.6 kg/m2 in the high-SES group, compared to 67±4 years and 28.2±4.2 kg/m2 in the low-SES group, respectively (both P<0.001). For high- and low-SES groups, we found similar prevalences of smokers, 86 (11%) versus 105 (13%), and energy intakes, 1865±488 versus 1871±555 kCal/day (P=0.42 and 0.89, respectively). Conversely, concentrations of folic acid, vitamin B12, and vitamin B6 were significantly lower and homocysteine higher in the low SES group, 14.4 [9.7-22.7] nmol/L, 275 [218-347] pmol/L, 48.8 [34.0-72.8] nmol/L, and 14 [12-16] μmol/L, compared to the high-SES group, 18.4 [12.7-27.4] nmol/L, 303 [234-380] pmol/L, 60.0 [40.7-91.2] nmol/L, and 13 [11-15] μmol/L, respectively (all P≤0.001). These differences were independent of potential confounders, such as age, BMI, smoking, and energy intake.

Conclusions: Pre-elderly and elderly with low SES have a significantly worse folic acid, vitamin B12, vitamin B6, and homocysteine status compared to those with high SES, independent of potential confounders. This could contribute to their increased cardiovascular risk, and could provide a logical target for nutritional intervention in this vulnerable group.

Keywords: Socioeconomic Status, One-Carbon Metabolism, Vitamins, Elderly, Cardiovascular risk.

NEITHER SELF-REPORTED ATOPY NOR IGE MEDIATED ALLERGY ARE LINKED TO INCREASED GASTROINTESTINAL SYMPTOM BURDEN IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

[1]Nybacka, Sanna; [2]Öhman, Lena; [3]Störsrud, Stine; [3]Böhn, Lena; [4]Willpart, Katarina; [5]Bengtsson, Ulf; [6]Winkvist, Anna; [5]Törnblom, Hans; [5]Simrén, Magnus.

[1]MSc. Dietician. Department of Internal Medicine and Clinical Nutrition. University of Gothenburg. Sweden.; [2]PhD. Department of Microbiology and Immunology. University of Gothenburg. Sweden.; [3]Dietician. PhD. Department of Internal Medicine and Clinical Nutrition. University of Gothenburg. Sweden; [4]MD. Department of Internal Medicine and Clinical Nutrition. University of Gothenburg. Sweden; [5]MD. PhD. Department of Internal Medicine and Clinical Nutrition. University of Gothenburg. Sweden.; [6]Nutritionist. PhD. Department of Internal Medicine and Clinical Nutrition. University of Gothenburg. Sweden.

Background and objectives: It has been proposed that the presence of atopic disease may correlate with more severe symptoms among patients with Irritable Bowel Syndrome (IBS), but few studies have investigated this. We therefore assessed if the presence of self-reported atopic symptoms and serum IgE in patients with IBS was associated with increased symptom severity.

Methods: The levels of total and specific IgE in serum were measured in 223 patients with IBS and 47 non-IBS controls. Participants also completed questionnaires assessing the presence of atopic disease (i.e eczema, asthma, and rhinoconjunctivitis), gastrointestinal symptom burden (IBS severity scoring system, IBS-SSS), food intolerance, and somatic (The Patient Health Questionnaire, PHQ-15) and psychological symptoms (Hospital Anxiety and Depression scale, HAD).

Results: Presence of atopic disease was reported in 123 (55%) patients with IBS compared to 19 (40%) of the non-IBS controls (N.S.). IBS patients with atopic manifestations had higher median serum IgE levels (31 vs. 16 kU/L, P<0.001) and higher prevalence of self-reported food intolerance than non-atopic IBS patients (28% vs. 9%, P=0.002), but no major difference in gastrointestinal or psychological symptom burden was noted. However, having severe somatic symptoms was more common among atopic than non-atopic IBS patients (38% vs. 27%, P=0.028). Specific IgE to common food allergens was rare and was unrelated to the IBS symptom pattern and self-reported food intolerance.

Conclusions: Atopic disease is a common comorbidity in patients with IBS, but our data do not support major differences in

IBS symptoms between atopic and non-atopic IBS patients, except for slightly increased prevalence of self-reported food intolerance and more somatic symptoms in atopic IBS patients.

Keywords: Irritable bowel syndrome, atopy, IgE, food intolerance

Dirección de Alimentación y Nutrición, Hospital Nacional de Clínicas, Facultad de Ciencias Médicas. Universidad Nacional de Córdoba, Argentina.; [7]PhD. Nutritionist. Escuela de Nutrición, Facultad de Ciencias Médicas. Universidad Nacional de Córdoba, Argentina.

Background and objectives: Abdominal adiposity is associated with metabolic risk profile such as dyslipidemia and low grade systematic inflammation. Dietary unsaturated fatty acids (FA) could influence metabolic alterations associated with visceral adipose tissue. We aimed to analyze food sources of n-3 and n-6 and n-9 FA and their association with cardiometabolic risk markers in patients with abdominal adiposity.

Methods: Participated 47 adults, between 40-80 years old, both sexes, with central adiposity determined by waist circumference (WC), attended in Cardiology Division, National Hospital of Clinics, Córdoba, Argentina, 2014-2016. Medical history and validated food frequency questionnaire were applied. Food information was processed by Interfood v.1.3. nutritional software. FA food sources were classified in: n-9 FA (olive oil, avocado and olives), 20:4 n-6 FA (red meat, chicken and eggs), 18:2 n-6 FA (corn, soybean, sunflower and mixed oil), 20:5 and 22:6 n-3 FA (fish and seafood), and 18:3 n-3 FA (nuts and seeds). Anthropometric measures, serum lipid profile (total cholesterol, LDL-col, col-HDL and triglycerides), glycemia and hs-CRP were determined. Lineal regression adjusted by age, sex, total energy intake, body mass-index, smoking, and physical activity was development to analyze associations between FA food source and biochemical markers.

Results: Medium age was 60.4 ± 9.8 in men and 57.1 ± 9.3 years old in women. 40% showed overweight and 41% obesity. According WC, 26% had high-risk and 74% very high risk. Medium total cholesterol was 185.4 ± 37.3 mg/dL, LDL-c 108.6 ± 30.6 mg/dL, HDL-c 50.6 ± 13.1 mg/dL, triglycerides 145.1 ± 65.2 mg/dL, glycemia 113.1 ± 26.2 mg/dL, and PCR-us 4.0 ± 2.5 mg/L. About dietary intake, the consumption for n-9 food was 13.1 ± 12.6 g/day, 20:4 n-6 FA 226,4 ± 122,6 g/day, 18:2 n-6 FA 22.4 ± 16.2 g/day, 20:5-22:6 n-3 FA 13.5 ± 14.2 g/day and 18:3 n-3 FA 11.6 ± 18.6 g/day. Significant positive association was observed between intake of 20:4 n-6 FA and triglycerides concentration (β=0,25; p=0,04) and between 20:5-22:6 n3 FA and HDL-c (β=0,35; p=0,03).

Conclusions: These preliminary results show the influence of diet in lipid profile. Dietary intervention are an important tool in patients with cardiometabolic risk factors.

Keywords: Food source, fatty acids, markers, cardiometabolic risk.

University of Barcelona.; [6]PhD. Doctor. Department of Internal Medicine. Hospital Clínic. Institut d'Investigació Biomèdica August Pi i Sunyer. Universitat de Barcelona, Spain.

Background and objectives: Several epidemiological studies suggest that moderate wine consumption have beneficial effects on cardiovascular risk, related to appearance and progression of the atherosclerosis. No previous studies have analyzed the beneficial effects of aged wine (AW), a type of Spanish white wine, on cardiovascular risk factors. The aim of this study was to evaluate the effects of AW and gin on circulating endothelial peripheral cells (EPC) and circulating biomarkers, related to appearance and progression of the atherosclerosis, in high cardiovascular risk subjects.

Methods: A total of 38 high-risk male volunteers, between 55-80 years, who received at random 30g of ethanol per day in form of AW or gin. The study was an open, randomized, controlled, cross-over trial that aims to compare the effects of moderate consumption of AW and gin after 3 weeks of intervention, in which the diet and physic at activity was monitored. After a run-in period and after interventions, we assessed changes on the expression of EPC and biomarkers related to atherosclerosis.

Results: A significantly increased the circulating EPC 39.63% (P=0.03) was observed after intervention AW. We observed a significantly decreased the systolic and diastolic blood pressure (P= 0.033 and P=0.030 respectively) and increased HDL cholesterol after AW intake. On the other hand, we observed a significantly increased the LDL cholesterol (P=0.005) and glucose (P=0.025) after the gin intake. However, when analyzed other biochemical and anthropometric parameters, we observed a significantly increased for Apolipoprotein A (P=0.001; both) and protombine time (P=0.022, P=0.018) for both beverages, without changes in triglycerides, homocysteine, fibrinogen or body mass index. Finally we observed a significantly increased for calcium (P=0.001; both), potassium (P=0.006) iron (P=0.044) and folic intracellular (P= 0.050) after AW intake.

Conclusion: Fermented alcoholic beverages, such as AG, appear to confer greater cardioprotective effects than distilled beverages (gin), probably due to their higher content of polyphenols. Interventions with AW, showed beneficial changes on cardiovascular risk biofactors, and increases the number of circulating EPC in peripheral blood that increases the ability to repair and maintain endothelial integrity.

Keywords: Aged wine; cardiovascular risk; diet; polyphenol.

INTAKE OF FATTY ACIDS AND ITS CORRELATION WITH RENAL FUNCTION IN CHILDREN WITH OVERWEIGHT/OBESITY

[1]Peredo, Maria Soledad; [2]Scricciolo, Romina; [3]Alonso, Elizabeth; [4]Lando, Inés; [4]Brovarone, Lucrecia; [4]Fernández, Jorgelina; [5]Muzzio, María Luz; [6]Santucci, Maria Pia; [5]Meroño, Tomas; [3]Kabakian, Maria Laura.

[1]Nutricionist; [2]Biochemist; [3]Physician, Pediatric Nutricionist; [4]Nutritionist; [5]PhD Biochemist; [6]Physician, Nutricionist.

Background and objectives: Polyunsaturated fatty acids (PUFA) are defined as the sum of ω3 and ω6-fatty acids (FA). Their impacts on health are mainly attributed to anti-inflammatory effects and to the activation of the peroxisome proliferator-activated receptors(PPAR)-γ. In dietary interventions for obesity the substitution of saturated fatty acids (SFA) by PUFA is encouraged. Only few studies addressed the impact of PUFA intake over the glomerular filtration rate (GFR) in patients without renal disease. Our aim was to evaluate the association between dietary FA and GFR in children with overweight/obesity.

Methods: Prospective study which included 35 children [age: 11(9-13)years] with overweight/obesity who attended the "Servicio de Diabetes y Nutrición Infanto-Juvenil" of the "Complejo Médico Churruca-Visca", Buenos Aires, Argentina. Anthropometric measures were determined and Z-scores were calculated (WHO). Nutritional assessment was performed by the 24-hour dietary recall method using the tables from the "Sistema de Análisis y Registros Alimentarios" (SARA, Ministerio de Salud). GFR was estimated using the Zappitelli formula using serum creatinine and cistatin C levels. Serum lipids and levels of selected micronutrients were recorded. Correlations were evaluated by Pearson or Spearman Correlation tests, according to data distribution.

Results: Out of the 35 children studied (18 males), 25 were obese and 10 were overweight. Mean BMI Z-score was 1.9±0.5. None of the children were taking dietary supplements. Median intake of SFA, monounsaturated fatty acids (MUFA) and PUFA were, median(interquartile range), 14.1(10.2-24.7)g/day, 17.6(11.3-20.7) g/day and 4.5(1.9-10.0)g/day, respectively. Mean GFR was 97±15 ml/min.1.73m2. Intakes of SFA and MUFA were only correlated with waist circumference (r=0.36,p<0.05; r=0.37,p<0.05, respectively). PUFA intake was correlated with cistatin C (r=-0.47,p<0.01) and GFR (r=0.41,p<0.01). In order to correct by individual differences in total FA intake the ratio PUFA/totalFA was calculated. The ratio PUFA/totalFA was inversely correlated with Z-BMI (r=-0.37,p<0.05), cistatin C (r=-0.58,p<0.001) and GFR (r=0.52,p<0.005). The correlation between GFR and PUFA/totalFA ratio was independent of age but not sex-independent.

Conclusions: In this study of children with overweight/obesity the GFR was associated with PUFA intake. Nutritional advice to substitute SFA by PUFA might be useful to prevent the obesity-associated decline in renal function. Longitudinal studies are needed to confirm this hypothesis.

Keywords: Children, obesity, glomerular filtration rate.

Background and objectives: Background: Epidemiological studies have shown that deficiency of Vitamin D is associated with higher incidence of cardiovascular disease. This deficiency has been related to low sun exposure, reduced intake of some foods, and higher alcohol consumption.

Aims: The aim of this study was to determine the possible relationship between consumption of foods rich in vitamin D, adherence to Mediterranean Diet (MeDiet) and consumption of wine or beer in a population with high cardiovascular risk.

Methods: PREDIMED trial is a 5-year parallel group; multicenter, randomized, controlled clinical trial aimed to evaluate the effects of a MeDiet supplemented with extra virgin olive oil (EVOO) or nuts on incidence of cardiovascular disease. We analyzed baseline data from the Food Frequency Questionnaire with 137-items that included the amount and type of alcoholic beverage consumed and foods rich in vitamin D. A validated 14-point score of adherence of MeDiet was also tested.

Results: We included data from 7,447 high-risk participants. The mean age was 67.88 ± 6.08 years, 27.7% were males, and the mean BMI was 30.20 ± 4.0 kg/m2. Wine and beer drinkers showed a significant increased in food rich in vitamin D consumption compared with non-drinkers 5.96 ± 0.81 vs 5.44 ± 0.67 µg/d, p< 0.001). Among different foods rich in vitamin D analyzed, cured cheese, fat fish, and seafood were the more frequently consumed. In the other hand, drinkers showed higher score of baseline adherence of MeDiet compared to non-drinkers (8.79 ± 0.04 vs 8.39 ± 0.04, p< 0.001).

Conclusions: Wine and beer drinkers showed a higher intake of foods rich in vitamin D, and a higher adherence to MeDiet than non-drinkers. Therefore, moderate alcohol consumers in the Mediterranean area report a healthier lifestyle compared to drinkers from other cultures.

Keywords: Mediterranean diet; foods; cardiovascular risk; alcohol beverages; vitamin D.

NUTRITIONAL MANAGEMENT OF AN ADULT PATIENT BEFORE, DURING AND AFTER LIVER PARTITION (ALPPS) FOR DIFFUSE HEPATIC EPITHELIOID HEMANGIOENDOTHELIOMA

[1]Cascarón, María Fernanda; [2]Dietrich, Ailen; [2]Quesada, Eliana; [3]Resio, Nicolas.

[1]Medica especialista en nutrición; [2]Licenciada en nutricion; [3]Cirujano.

Background and objectives: 54-year-old female patient.
Diagnosis: multifocal hepatic epithelioid hemangioendothelioma, treated with two-stage hepatectomy.
- Medical history
Hypertension
Dyslipidemia
Class I obesity
Hepatic steatosis
Thyroid failure
Parathyroid insufficiency
Appendectomy
Thyroidectomy + Parathyroidectomy

Objectives

This study shows that nutritional support in the perioperative period reduces nutritional complications, shortens hospital stay and improves post-surgical recovery.

Methods: Nutritional assessment at an outpatient clinic 60 days prior to surgery. Height: 1.60 m; weight: 79 kg; medium build; class I obesity; no weight loss.
Hospital stay:
First stage of surgery: liver transection + right portal vein ligation + metastasis resection from segments II-III. FLR/TLV: 27%.
Postsurgical period:
Day 1: parenteral nutrition with SMOF lipid.
Day 2: liquid diet + TPN.
Day 3: bland diet + TPN.

Day 4: hepatoprotective diet + TPN.

Day 6: TPN is interrupted due to fever and replaced by oral diet. Hypertrophy: 42% of total increase. FLR/TLV: 38%.

Day 7: right hepatic trisectionectomy + cholangiojejunostomy. Fasting.

Second stage of surgery:

Day 3: liquid diet. Poor tolerance, vomiting.

Day 6: TPN.

Day 7: trophic EN via NGT (semi-elemental formula) + TPN.

Day 10: oral bland diet + EN + reduced PN.

Day 11: TPN is interrupted and replaced by EN and bland diet.

Day 13: NGT is removed, oral feeding + hypercaloric supplement.

Day 18: food intake improvement. Dietary plan to be followed on hospital discharge is created.

Results: Parameters   Before surgery: 79 kg,hemoglobin (Hb)13,1 , albumin 3,6

Between surgeries: 77kg, Hb 10,9, Lymphocytic cells 1280, Albumin 2,9, total protein 5,6, nitrogen balance +6

At discharge: 76,5 kg, Hb 12,2,lymphocytic cells 1158, albumin 3,3, Total protein: 5,8

Conclusions: An interdisciplinary approach is essential for managing highly complex, elective surgical procedures. Timing nutritional interventions to the surgical planning improves therapeutic results.

Keywords: nutritional support, hepatectomy, ALPPS.

EFFECT OF OMEGA-3 FATTY ACIDS ON EN-DOTHELIAL FUNCTION IN METABOLIC SYN-DROME: A SYSTEMATIC REVIEW

[1]Bertorello, Natalia Belén; [2]Lerda, Daniel; [3]Eynard, Aldo Renato; [4]Defagó, Maria Daniela.

[1]BS. Nutritionist. Licenciatura en Nutrición - Facultad de Medicina-Universidad Católica de Córdoba; [2]PhD. Biochemical. Facultad de Medicina. Universidad Católica de Córdoba; [3]PhD. MD. INICSA- CONICET. Córdoba, Argentina; [4]PhD. Nutritionist. INICSA- CONICET. Escuela de Nutrición. Facultad de Ciencias Médicas. Universidad Nacional de Córdoba Córdoba, Argentina.

Background and objectives: Omega-3 polyunsaturated fatty acids (ω3-PUFA) are increasingly being used in the management of several metabolic pathologies, due to its anti-inflammatory role. The aim was summarize the findings on the effects of ω3-PUFA on endothelial function in patients with metabolic syndrome.

Methods: An electronic literature search from 2004-2015 in Medline, Lilacs, Cochrane Library and Scielo, was conducted. We combined search terms related to the exposure (i.e. ω3-PUFA, syndrome metabolic) and outcomes of interest (blood pressure, endothelial dysfunction, endothelial markers). Randomized-controlled interventional trials without language restrictions were considered. PRISMA guidelines were employed. Methodological quality, i.e. study design, sample size, bias, and statistical analysis, was assessed by Jadad scale.

Results: 273 references were identified, of which 25 were finally included. Articles were classified in food pattern modification (i.e. mediterranean-style diet, prudent food pattern, n=7), ω3-PU-FA supplementation (i.e. fish oil, flaxseed oil, EPA/DHA capsules, n=10) and mixed interventions (food pattern modification and ω3-PUFA supplementation, n=8). Five articles with food pattern modification, reported significantly reduction in systolic (SBP) and diastolic blood pressure (DBP), and four studies observed lower levels in C-reactive protein (CRP) with diet change. In clinical trials with ω3-PUFA supplementation, three studies observed a significant decrease in SBP with reduced circulation levels of CRP, sICAM-1, PAI-1 and IL-6. About mixed interventions, two studies reported lower levels of SBP, DBP, CRP and IL-6.

Conclusions: Dietary interventions and supplementation with ω-3 PUFA in metabolic syndrome are a relevant strategy to the maintenance of cardiovascular health and prevent future complications.

Keywords: ω-3 fatty acids, metabolic syndrome, blood pressure, endothelial dysfunction

CORRELATIONS OF SERUM 25(OH) VITAMIN D LEVELS WITH THE METABOLIC PARAMETERS IN SUBJECTS WITH DIFFERENT BODY MASS INDEX

[1]Nikolova, Maria; [2]Boyanov, Mihail; [3]Penkov, Alexandar.

[1]Medical Doctor. Department of Hygiene, Medical Ecology and Nutrition. Medical University of Sofia. Bulgaria; [2]Professor. MD. Phd. Clinic of Endocrinology. Department Internal Medicine. Alexandrovska University Hospital. Medical University of Sofia. Bulgaria; [3]Assoc.Professor. MD. Phd. Department of Hygiene, Medical Ecology and Nutrition. Medical University of Sofia. Bulgaria.

Background and objectives: We triedto describe the correlation between serum 25(OH) vitamin D and metabolic parameters in men and womenwith different BMI.

Methods: 264 subjects participated – 109 men and 155 women aged 20-60 years.Body weight and height, waist circumference, systolic and diastolic blood pressure were recorded. Body composition was assessed by bioelectrical impedance (Tanita BC 420 MA, Tanita Inc., Japan).Serum 25(OH)D Total and insulin were measured by electro-hemi-luminescence (Elecsys 2010 analyzer, Roche Diagnostics, Switzerland). High-sensitivity C-reactive protein was measured by an immune turbo-dimetrical method(Cobas Integra 400+ analyzer)together with total, HDL-cholesterol (direct)and triglycerides. Statistical analysis was performed on a SPSS 23.0 for Windows (SPSS Inc., Chicago, IL).

Results: 27.2 % of the participants had normal weight, 24.6 % - overweight, 29.2 % -class I obesity, and 18.9 % – class II or III. 33.3 % had vitamin D deficiency, 40.2 % - insufficiency. Vitamin D was weakly and inversely correlated to many variables in the group as a whole. The most powerful correlations were with weight, WC, WC/Height, % body fat and HOMA-IR index (r=-0.231, -0.283,

-0.307, -0.339, -0.328 respectively, all p<0.001). Fewer correlations were registered in men than in women. Splitting the subjects according to BMIled to loss of significance. Backward analysis revealed Total-C / LDL-C ratio, and LDL-C/HDL-C ratio as strongest predictors (p=0.001; R2=0.204).

Conclusions: The association of vitamin D with blood pressure,plasma lipids, glucose and insulin is very weak on an individual level.It might be demonstrated in large surveys.

Keywords: Body composition; Obesity; Metabolism; Vitamin D

IMPORTANCE OF DIETARY COUNSELING TO PATIENTS WITH DIABETES MELLITUS TYPE 2 FROM AN OUTPATIENT CLINIC IN SÃO PAULO

[1]Barros Pereira Ferreira, Natália; [1]Parise Polo, Gabriela; [1]Silva Gregório, Amanda; [1]Lekevicius Consolin, Brunna; [1]Fonseca Gonçalves, Daniel; [2]Garcia Peloggia de Castro, Adriana.

[1]Nutrition Student. Centro Universitário São Camilo. Brasil.; [2]PhD. Nutritionist. Centro Universitário São Camilo. Brasil.

Background and objectives: A healthful eating pattern and regular physical activity are extremely important components of type 2 diabetes mellitus management. For many individuals with type 2 diabetes mellitus, the most difficult part of the dietetic plan is to decide what to eat. Dietary therapy has been recognized as an essencial strategy for helping patients with type 2 diabetes mellitus, improving self-management, developing nutritional education and providing an eating plan. In this context the purpose of this work is to correlate the eating habits of patients who received professional guidance with those who did not receive any guidance.

Methods: This is a cross-sectional, descriptive study with primary data collection, sampling done by convenience, approved by the Ethics and Research Committee of Centro Universitário São Camilo, Brazil. A structured questionnaire to characterize food intake was developed for this research and applied to 82 patients with type 2 diabetes mellitus, both male and female, attending an outpatient clinic in São Paulo. Data analyses were performed using descriptive statistic, the Qui-square test with a level of significance of p<0.05.

Results: Regarding the interviews, the mean age was 63 ± 10.6 years characterizing an elderly population (64.6%). The majority of respondents (80%) received specific dietary guidance for type 2 diabetes mellitus but only 30% admitted to follow the guidance given by the health professional. It is noteworthy that the main health professionals who carried out dietary counseling were nutritionists (50%) and physicians (46%). People who received guidance showed a slightly more varied diet than those who did not receive guidance. Nevertheless, this result was not statistically significant (p=0.26). The most consumed types of food were: fruits, vegetables and greens (74%), pasta, breads and biscuits (66%) and food of animal origin (59%).

Conclusions: Patients who received professional guidance on diet present a more varied food profile in relation to those who did not receive it. Therefore, the professional counseling in this population is extremely important for an adequate management of the disease and quality of life.

PLASMA GLUCOSE KINETICS FOLLOWING INGESTION OF TWO CEREAL PRODUCTS DIFFERING BY THEIR SLOWLY DIGESTIBLE STARCH CONTENT IN HEALTHY MALES AND FEMALES

[1]Meynier, Alexandra; [2]Péronnet, François; [3]Rabasa-Lhoret, Remi; [4]Mignault, Diane; [5]Normand, Sylvie; [5]Sauvinet, Valérie; [6]Laville, Martine; [7]Vinoy, Sophie.

Canada.; [4]Institut de Recherches Cliniques de Montreal. Canada.; [5]PhD. CRNH Rhône-Alpes. Lyon. France.; [6]MD. PhD. CRNH Rhône-Alpes. Lyon. France.; [7]PhD. Nutrition Research Department. Mondelez France R&D. Saclay. France.

Background and objectives: High postprandial plasma glucose concentrations have been implicated in the development of chronic metabolic diseases. Cereal products with a high content in Slowly Digestible Starch (SDS) elicit lower glycemic responses than those with a low SDS content. This has been shown when ingested in a breakfast. The objective of the present study was to describe the kinetics of glucose provided by two cereal products differing by their SDS content and consumed alone in healthy males and females.

Methods: Fourty-one young healthy males and females volunteered to consume in a random order ~ 45g of two cereal products differing by their SDS content: co-extruded cereals (0.2% SDS – Lo-SDS) or biscuits (19% SDS – Hi-SDS). Carbohydrate in these products were intrinsically labelled with 13C and plasma glucose kinetics were measured using [6,6-2H2]glucose infusion along with plasma glucose, insulin, Non-Esterified Fatty Acides (NEFA) and glucose-dependent insulinotropic peptide (GIP) concentrations.

Results: When compared to the Lo-SDS co-extruded cereals the rate of appearance of exogenous glucose (RaE) was lower with the Hi-SDS biscuits in the first part of the postprandial period. This was reversed 2h following the ingestion of the product with the RaE observed with the biscuits higher than with the co-extruded cereals. The same kinetics was observed for the rate of disappearance of exogenous glucose. This resulted in lower plasma glucose levels in the first 2h of the postprandial period and higher levels in the next 3h following ingestion of the biscuits than the co-extruded cereals. Plasma insulin was also lower with the biscuits than the co-extruded cereals over the first 2h of the postpran-

dial period. No difference was observed between the two products for plasma NEFA and GIP concentrations.

Conclusions: Substituting Lo-SDS co-extruded cereals with Hi-SDS biscuits slows down the availability of glucose from the cereal product and its appearance in peripheral circulation, reduces the early peak of plasma glucose and distributes the glucose ingested over a longer period following the meal.

SIGNIFICANCE OF SUPPLYING OF INFORMATION ABOUT THE CHANGE OF POTASSIUM CONTENTS IN VEGETABLES BY COOKING DURING THE COURSE OF NUTRITIONAL GUIDANCE FOR DIALYSIS PATIENTS

[1]Toda, Yohko; [2]Sugawa-Katayama, Yohko; [3]Matsumoto, Sadahiro; [4]Kasahara, Harumi; [5]Hasegawa, Hirohito.

[1]Nutritionist. Osaka Aoyama University . Japan; [2]PhD. Osaka Aoyama University. Japan; [3]Nurse. Kasahara clinic. Japan; [4]MD. Kasahara clinic. Japan; [5]MD. Kasahara clinic. Japan.

Background and objectives: During the nutritional guidance for dialysis patients, it is important to be aware of how much they know about potassium and how much they pay attention to cut down its dietary intake in each meal. In the present study, we performed a survey to investigate the patients' awareness of potassium and its dietary control. Furthermore, we determined potassium concentrations in some vegetables to answer the patients' questions such as whether vegetables in season or greener vegetables have higher contents of potassium in comparison to those out of season or less greener vegetables, respectively.

Methods: A questionnaire survey was conducted to investigate the patients' knowledge about potassium contents in vegetables and their practical trials to cut down dietary intake of potassium on 41 dialysis outpatients (27 males and 14 females, 65±14 years of age, and 128±123 months of dialysis treatment). In order to improve our knowledge as nutritional advisers to help the patients, we determined potassium contents in some vegetables such as cabbages in and out of season and broccoli and cauliflower as a typical pair of green and white vegetables.

Results: There were positive correlations between their knowledge on potassium and their endeavor to cut down their dietary potassium intake and between their lengths of dialysis treatment history and their degrees of concern about dietary intake of phosphate. Potassium determination results: There were no significant differences between the vegetables in and out of season or between

those green and white vegetables, but when they were boiled, broccoli lost potassium faster than cauliflower.

Conclusions: Supplying the dialysis patients with those potassium determination data may be helpful therapeutically from the view point of nutritional guidance.

Keywords: dialysis patients, dietary management, potassium determination

WEIGHT LOSS AND LONG TERM WEIGHT MAINTENANCE WITH A NON-DIETING APPROACH

[1]Anger, Vanesa Erica; [1]Anger, Vanesa Erica; [2]Rovira, Sergio; [1]Giannini, Martin; [1]Katz, Mónica.

[1]MD. Centro Katz; [2]BPhEd. Centro Katz.

Background and objectives: Classical models of weight loss interventions achieve short-term success, but regain is common. Our objective was to evaluate the efficacy of a non-dieting approach intervention in weight loss and long term weight loss maintenance.

Methods: Overweight and obese adult outpatients, who consulted for individual treatment, were enrolled. After completed basal evaluation (t0), they underwent to a non-dieting approach weight loss program during at least 6 months (t1). At t0 and t1 weight, height, frequency of physical activity (PA), physically active condition (10,000 steps / day), unhealthy eating patterns (UEP) and emotional eating (EE), were assessed. At least 18 months after ending interventional period (t2), patients were interviewed by phone, about weight, PA, physical active condition, UEP and EE. Weight loss (WL) was defined as a reduction > 3% of baseline weight (BW).

Results: Ninety-four patients completed interventional period (44.8 ± 1.5 years of age; 78.7% females, mean BMI 33.4 kg/m2). Mean weight reduction rate (WRR) was 5.9 ± 5.5% of t0 weight; 71.3% lost weight (34% between 5 and 9.9%, and 21.3% ≥10% of t0 weight). Participants significantly lost weight and reduced BMI between t0 and t1, (89.9 ± 18.5 kg vs 84.5 ± 17.7 kg, and 33.4 ± 5.5 kg/m2 vs 31.3 ± 5.4 kg/m2, respectively; p < 0.001). Difference was significant for PA and physically active condition (7.4% vs 57.4% and 16.0% vs 42.6%, respectively; p < 0.001). Forty-two patients answered the telephone interview; time elapsed was 30.6 ± 7.4 months; weight and BMI were significant lower compared to baseline (p < 0.05); WRR was 7,6 ± 8,1%; 45,2% of patients reduce more than 10% of t0 weight, and compared to baseline, there was a significant difference related to PA (16.0% vs 68.9%; p < 0.0001), physically active condition (7.4% vs 64.4%; p < 0,0001), UEP (94.7% vs 62.2%; p < 0,001), and EE (86.2% vs 71,1%; p = 0.033).

Conclusions: A non-dieting approach intervention can be considered a long term effective method to treat obese and overweight patients. More studies are needed to confirm this preliminary data.

Department of Physiology and Institute of Nutrition and Food Technolgy "José Mataix". University of Granada. Granada. Spain; [7]MD. Sport Medicine. Andalusian Centre of Sport Medicine. Granada. Spain.

Background and objectives: Celiac disease (CD) is an autoimmune disorder characterized by inmunologically mediated intolerance to gluten, which is managed with lifelong gluten free diet (GFD). Several dietary surveys had suggested high intakes of saturated fat and sucrose and inadequate intakes of fiber and micronutrients (thiamin, riboflavin, niacin, folate, iron, calcium) in subjects with CD following a strict GFD (Öhlund et al., 2010). Furthermore, some studies have shown a higher rate of cardiovascular disease in patients with CD (Ludvigsson et al., 2011; Assa et al.,2017). Therefore, the objective of this study was to assessment the association of CD with lipid metabolism markers, considered as risk cardiovascular factors, and GFD consumption.

Methods: 25 children (range 3-15 years) diagnosed as CD and consuming GFD for at least one year, were evaluated for their lipid hematological profile. The diagnosis, according to accepted criteria, and analysis were made at Pediatric Gastroenterology and Nutrition Unit, Virgen de las Nieves University Hospital, in Granada, Spain. Blood was collected from fasting patients by venipuncture into EDTA-containing vacutainer tubes. Samples were centrifuged at 1700 x g for 15 min at 4°C to obtain plasma. Total plasma-cholesterol (Total-Col), serum high-density lipoprotein cholesterol (HDL-Col) and triglyceride (TG) concentrations were measured by enzymatic colorimetric methods using commercial kits (Spinreact, Barcelona, Spain). LDL-Col was calculated using the Friedewald equation: LDL-C=total cholesterol–(HDL-C)–(triglycerides/5), mg/dL. Study was approved by the Ethics Committee of the University of Granada. The data obtained were processed with the SPSS 20.0 software.

Results: Blood lipid concentrations (mean value ± standard deviation) determined were: 176.83 ± 26.34 mg/dl Total-Col, 56.63 ± 12.91 mg/dl HDL-Col, 105.6 ± 26.98 mg/dl LDL-Col and 68.04 ± 17.75 mg/dl TG. These values are between de reference values (140-200 mg/dl, 40-60mg/dl, 100-130 mg/dl and 89-150 mg/dl respectively), although Total-Col and LDL-Col levels are in the limelight of cardiovascular disease.

Conclusions: As hyperlipidemia, particularly elevated LDL cholesterol, is an established risk factor for cardiovascular disease (Murphy et al., 2010) and total cholesterol level is an important determinant of the Framingham risk score for cardiovascular disease, our data suggest that blood lipid levels should be monitored in CD.

MINIMUM EFFECTIVE DOSE OF COMMONLY CONSUMED BEANS REQUIRED TO SIGNIFICANTLY LOWER POST PRANDIAL BLOOD GLUCOSE RESPONSE

[1]Ramdath, Dan; [2]Renwick, Simone; [3]Hawke, Aileen; [4]Wolever, Thomas.

[1]PhD. Research Scientist. Guelph Research and Development Centre. Agriculture and Agri Food Canada. Canada; [2]BSc Student. Guelph Research and Development Centre. Agriculture and Agri-Food Canada. Canada.; [3]BSc. Research Technician. Guelph Research and Development Centre. Agriculture and Agri-Food Canada. Canada.; [4]MD. PhD. President. Glycemic Index Laboratory. Toronto. Canada.

Background and objectives: Beans elicit a low glycemic response compared to other starchy foods. However, previous studies have tested serving sizes that may not be achieved in a usual meal. This study compared the blood glucose response of beans consumed at ¼ and ½ cup with that elicited by similar amounts of common starchy foods.

Methods: Six commonly consumed Canadian beans (pinto, black turtle, cranberry, red kidney, navy and great northern) and starchy control foods (white rice, macaroni, instant potato and corn) were consumed by healthy volunteers in a using an open-label, randomized cross-over trial. Foods were consumed at either ¼ cup (n=16 to 24) or ½ cup (n=12 to 18) after an overnight fast and blood glucose response was measured over a 2hr period. Incremental area under the blood glucose (iAUC), relative glycemic response and insulin (at ½ cup only) response curves were calculated and analyzed for treatments effects.

Results: Overall beans consumed at ¼ cup servings elicited lower glycemic responses than ¼ cup servings of corn, macaroni, potato and rice, although iAUC for individual beans were not significantly different from corn. At ¼ cup serving, mean reductions in blood glucose response elicited by the beans compared to controls were: 34±4% (vs. corn); 59±3% (vs. macaroni); 51±3% (vs. potato) and 61±3% (vs. rice) (paired t-test; all p<0.05). Similarly, at ½ cup serving mean reductions in blood glucose response elicited by beans were: 38±5% (vs. corn); 64±3% (vs. macaroni); 55±5% (vs. potato) and 68±3% (vs. rice) (paired t-test; all p<0.05).

By ANOVA all 6 beans had significantly lower iAUC than the respective starchy control, except for cranberry, which had an iAUC that was not significantly different from corn eaten at ½ cup. Insulin response curve elicited by ½ cup beans was not significantly different from potato indicating that the blood glucose lowering effect of beans is not due to hyperinsulinemia.

Conclusions: Beans consumed at ¼ and ½ cup reduce blood glucose response by a minimum of 20%, which is defined as a significant effect. This information can be used for regulatory approval of a health claim for pulse and blood glucose attenuation.

FOOD INTAKE AND BODY MASS INDEX OF PATIENTS WITH TYPE 2 DIABETES MELLITUS FROM AN OUTPATIENT CLINIC IN SÃO PAULO

[1]Barros Pereira Ferreira, Natália; [1]Parise Polo, Gabriela; [1]Silva Gregório, Amanda; [1]Lekevicius Consolin, Brunna; [1]Fonseca Gonçalves, Daniel; [2]Garcia Peloggia de Castro, Adriana.

[1]Nutrition Student. Centro Universitário São Camilo. Brasil.; [2]PhD. Nutritionist. Centro Universitário São Camilo. Brasil.

Background and objectives: The prevalence of type 2 diabetes mellitus is increasing in all populations worldwide. This increase is accompanied by the rising rates of obesity and overweight observed over the past decade. For this reason, the analysis of the body mass index (BMI) may serve as a powerful tool in the assessment of the risk factor for Diabetes. As overweight is directly related to the to lifestyle and eating habits, a better understanding of food intake in patients with type 2 diabetes mellitus is essential in order to correct problems, stimulate healthy habits and foster weight loss of these population. This study objective is to classify the population using the BMI scale and correlate it to food intake.

Methods: This is a cross-sectional, descriptive study with primary data collection, sampling done by convenience, approved by the Ethics and Research Committee of Centro Universitário São Camilo, Brazil. A structured questionnaire to characterize food intake was developed for this research and applied to 82 patients with type 2 diabetes mellitus, both male and female, attending an outpatient clinic in São Paulo. BMI was classified according to the World Health Organization. Weight and height were self-reported. Data analyses were performed using descriptive statistic, the Quisquare test with a level of significance of p<0.05.

Results: Regarding the interviews, the mean age was 63±10.6 years. Mean BMI was 29.6 ± 5 kg/m2 ranging from 28.5 to 30.8 kg/m2 (for a 95% of confidence interval). When BMI was classified as underweight, normal weight and overweight it was possible to find a significant difference (p=0.04) between the groups regarding their eating habits. As for individuals with overweight the most consumed foods were: fruits, vegetables and greens (86%), pasta, breads and biscuits (82%), foods of animal origin (73%) and sweets in general (27%).

Conclusions: Most patients with type 2 diabetes mellitus are overweight and there are significant differences in food choices according to their BMI score. This insight may bring possibilities for dietary changes and may facilitate the translation of findings to public health recommendations.

Keywords: Diabetes mellitus. Body mass index. Food intake. Eating habits.

EFFECT OF GLUTEN FREE DIET CONSUMPTION ON THE CLINIC PROGRESS OF CHRONIC MUSCULOSKELETAL PATHOLOGY

[1]Nestares Pleguezuelo, María Teresa; [2]Montoya Lozano, Luis; [3]López Frías, Magdalena; [4]de Teresa Galván, Carlos.

[1]PhD. Pharmacy. Department of Physiology and Institute of Nutrition and Food Technology; [2]MSc. Physiotherapist. Lorca Clinic. Granada. Spain; [3]PhD. Pharmacy. Department of Physiology and Institute of Nutrition and Food Technology "José Mataix". University of Granada. Spain; [4]MD. Sport Medicine Doctor. Andalusian Centre of Sport Medicine. Granada. Spain.

Background and objectives: Recently, success in the treatment of some diseases has been associated with the follow-up of a gluten-free diet, in the absence of celiac disease, although there is controversy as to whether this diet is better for subjects who do not need it. Therefore, the objective of this study was to study in subjects with chronic musculoskeletal pathology the effect of consumption of the gluten-free diet on the clinical progress of their disease.

Methods: We studied 47 subjects who attended a rehabilitation medical center with more than one year of musculoskeletal pathology progression. In addition all had symptoms of digestive disorders.

The patients had: rheumatoid arthritis (10), irritable bowel syndrome associated with musculoskeletal disorder (15), fibromyalgia (10), osteoarthritis (10) and rheumatic pelvic spondylitis (2).

After informed consent, they began to follow a strict gluten-free diet for 6 months, during which they were followed up weekly with a nutritional study through a 48h reminder survey.

At the beginning and end of the study, a test for the assessment of musculoskeletal signs and symptoms (EVA pain scale, muscle weakness and joint stiffness) and extra-articular muscles (fatigue, gastrointestinal discomfort and perception of their condition) were performed. Study was approved by the Ethics Committee of the University of Granada. The data obtained were processed with the SPSS 20.0 software.

Results: The results showed that, in general, all patients improved as gastrointestinal symptoms, pain, weakness, stiffness and tiredness decreased and they perceived a better general condition. This improvement was greater in subjects diagnosed with irritable bowel syndrome. No patient worsened with dietary treatment.

Conclusions: We conclude that the non-celiac gluten sensitivity may be the underlying cause of the symptoms raised by the need to conduct a controlled clinical trial for testing.

Keywords: Gluten free diet, musculoskeletal disease, non-celiac gluten sensitivity

IS HIGH BMI AT EARLY ADULTHOOD A RISK FACTOR FOR THE EARLY INCIDENCE OF CHRONIC NONCOMMUNICABLE DISEASES?

[1]Mazzeti, Camila; [2]Cumpian-Silva, Jéssica; [3]G Carvalho, Julia; [3]Giatti, Amana; [4]Rinaldi, Ana Elisa Madalena; [5]Lisboa Conde, Wolney.

[1]MD. Nutricionist. School of Public Health. University of São Paulo.; [2]MD. Nutricionist. School of Public Health. University of Sao Paulo.; [3]Student of Nutrition. School of Public Health. University of Sao Paulo.; [4]PhD. Nutricionist. Federal University of Uberlandia.; [5]PhD. Nutricionist. School of Public Health. University of Sao Paulo.

Background and objectives: High body mass index (BMI) is the third largest modifiable risk factor for morbidity and mortality to cancer, cardiovascular disease and diabetes. The early incidence of these diseases raises costs in the health service and reduces the quality of life. To analyze the effect of BMI at the age of 25 years (USA) and 20 years (Brazil) on the early incidence of 3 major chronic noncommunicable diseases [3CND] during adult life.

Methods: American NHANES-IV data (2007-2014) [25 to 49 years old] and Brazilians of PNS data (2013) [20 to 49 years] about the age of incidence for 3DCNT, BMI at age 25 (USA) and BMI at age 20 (Brazil), ethnicity, schooling, physical activity, smoking time, and alcohol consumption were modeled in Cox regression to estimate the effect (harzard ratio [HR]) of BMIearly on the time of incidence of any of 3CND.

Results: Men with BMIearly above 25 kg/m2 had a risk of 1.78 in the USA and 1.9 in Brazil. The women presented a risk of 2.18 and 1.4, respectively. For BMIearly above 30 kg/m2 in Brazilians man the HR was 2.84 and woman was 2.1. In American man the HR was 4.2 and was 3.13 in woman. High schooling was a protective factor in Brazilian and American women, but not in American men (1.04). In both genders, belonging to the black ethnic group in the USA was a risk factor, but in Brazil non-white women presented protection. In the USA obesity anticipated in 6 years the incidence of one of the 3CND in men and 5 years for women. In Brazil, this anticipation was 10 years for men and 8 years for women, bringing the findings closer in the two countries.

Conclusions: BMI of early adulthood is a high and modifiable risk factor for the incidence of one of the 3CND. The effects of BMIearly are direct and indirect, multiplicative, and indicate the relevance of preventing excessive weight gain during and at the end of adolescence. Surveillance and intervention actions are advisable in this age group.

CATTLE OWNERSHIP, CHILDHOOD MALARIA AND ANEMIA IN UGANDA

[1]Kabunga, Nassul; [2]Duggan, Christopher; [3]Bashaasha, Bernard; [4]Agaba, Edgar; [4]Webb, Patrick; [5]Ghosh, Shibani; [6]Griffiths, Jeffrey.

[1]PhD. Research Fellow. International Food Policy Research Institute. Kampala Office. Uganda.; [2]Department of Global Health and Population. Harvard T.H. Chan School of Public Health. Friedman School of Nutrition Science and Policy. Tufts University. Boston. USA; [5]Feed the Future Innovation Lab for Nutrition. Friedman School of Nutrition Science and Policy. Tufts University. Boston. USA.; [6]Department of Public Health and Community Medicine. School of Medicine. Tufts University. Boston. USA.

Background and objectives: Agricultural interventions may improve rural household food production and consumption, income, nutrition and health. Animal source foods, such as milk, meat, fish and poultry provide critical nutrients essential to child growth and health. Livestock ownership may also predispose humans to diseases with potential implications for nutrition and health.

This study explored the linkages between cattle ownership, malaria and anemia in children below 5 years.

Methods: Panel surveys were conducted in 6 rural districts of Uganda in 2012 and 2014 obtaining comprehensive household and individual data on demographics, agricultural production, dietary consumption, water and sanitation, health, education, and income producing activities. Moreover, we measured child hemoglobin levels and tested for malaria using rapid diagnostic tests. To control for potential observed and unobserved confoundedness, multivariate analyses—including linear probability model, pooled probit and correlated random effects models with and without the control function—were conducted. Coincidentally two of the four agro-ecologically similar districts in Northern Uganda had received multiple rounds of indoor residual spraying (IRS) against malaria within the study period. To able to link our analysis to IRS, we further conducted PCR analysis to compare mosquito species variability across IRS-sprayed and non-IRS districts.

Results: Multivariate analyses that conservatively control for confounding showed that cattle ownership was significantly associated with a higher prevalence of malaria in children under five years of age. Cattle ownership was generally associated with a 3% increase in childhood malaria (p<0.05). Malaria was in turn linked to a 28% increase in anemia (p< 0.01). In the 2 IRS districts, both childhood malaria and anemia prevalence were significantly lower (p<0.001). However, in the IRS districts, cattle ownership enhanced childhood malaria prevalence by 4-8% (p<0.01) compared to the non-IRS districts. PCR analysis showed that outdoor mosquito species that feed on livestock are predominant in IRS districts while indoor mosquito species are predominant in non-IRS districts.

Conclusions: IRS, which kills indoor mosquito species, may unmask residual malaria transmission by outdoor mosquito spe-

cies, which feed on both cattle and humans. Efforts to enhance nutrition and health by the agricultural intervention of cattle promotion may need to include livestock-oriented vector control.

Keywords: Cattle ownership, malaria, anemia, indoor residue spraying, anemia

SUPPLEMENTATION OF VITAMIN D IN TYPE 2 DIABETIC PATIENTS WITH HYPERTENSION DECREASES OFFICE AND 24-H AMBULATORY BLOOD PRESSURE MONITORING

[1]de Paula, Tatiana; [2]Sperb, Luiza; [3]Moreira, Juliano; [4]de Freitas, Mauren; [5]Miller, Maria Elisa; [6]da Silva, Andressa; [7]Viana, Luciana; [8]Azevedo, Mirela.

[1]PhD. Nutricionist. Federal University of Rio Grande do Sul. Brazil; [2]Medical Student. Hospital de Clinicas de Porto Alegre. Porto Alegre. Brazil; [3]Medical Doctor. Hospital de Clinicas de Porto Alegre. Porto Alegre. Brazil; [4]Nutricionist. Hospital de Clinicas de Porto Alegre. Porto Alegre. Brazil; [5]Medical Student. Hospital de Clinicas de Porto Alegre. Brazil; [6]Nutrition Science Student. Hospital de Clinicas de Porto Alegre. Brazil; [7]Medical Doctor. Hospital de Clínicas de Porto Alegre. Brazil; [8]Medical Doctor. Hospital de Clínicas de Porto Alegre. Porto Alegre. Brazil.

Background and objectives: Background and Objectives: Data on the potential beneficial effects of supplementation of vitamin D in hypertensive patients with type 2 diabetes mellitus (DM) and hypovitaminosis D are still scarce. The aim of study was to evaluate the effect of a single dose (100.000 IU) of vitamin D on 24-h ambulatory blood pressure monitoring (ABPM) in patients with type 2 DM, hypovitaminosis D and hypertension.

Methods: In a double-blind, placebo-controlled trial, 43 hypertensive patients with type 2 DM and hypovitaminosis D were randomly assigned to vitamin D supplement group (single dose 100,000 IU) or placebo group (single dose). Blood pressure (BP) was assessed by office measurements (Omron HEM-705CP) and 24-h ABPM (Spacelabs®). Physical activity was evaluated by steps counter (pedometer – Yamax Digi-Walker®). Clinical, nutritional, and laboratory parameters were evaluated by a standardized protocol before and after the supplementation. Body composition was determinate by bioimpedance In Body®. Results were expressed as mean, median, or number of patients with the characteristic. Changes in variables during the study were analyzed by the general linear model (GLM) for repeated measures.

Results: Forty-three 43 patients (age 65.4±9.2 years; 35% males; BMI 30.6±4.4 kg/m², DM duration 12.4±7.7 years; HbA1c 7.6±1.0%) were included. Mean 25(OH)D was 14.1±4.4 ng/ml. Office systolic and diastolic BP were 147.0±17.0 and 82.8±6.8 mmHg, in placebo group and 148.9±18.1 and 84.2±13.7 mmHg

in intervention group. After eight weeks, supplementation of vitamin D caused ABPM reduction on systolic 24-h (-5.1vs.-0.9 mm Hg; P=0.025), systolic daytime (-6.3 vs.-0.3 mm Hg; P=0.004), and diastolic daytime (-4.9vs.-0.1 mm Hg; P=0.006) and office systolic BP (-6.3 vs. -3.4 mm Hg; P <0.001) measurements than observed in the control group.

Conclusions: Vitamin D supplementation in patients who had hypovitaminosis caused a clinically significant reductions in systolic office BP and ABPM values in hypertensive patients with type 2 diabetes.

Keywords: hypertension, type 2 diabtes, vitamin D, hypovitaminosis

EFFECT OF A 6-MONTH PERSONALIZED NUTRITION INTERVENTION PROGRAM IN RECENTLY DIAGNOSED BREAST CANCER PATIENTS

[1]Limón-Miro, Ana Teresa; [2]Lopez-Teros, Veronica; [3]Valencia, Mauro E.; [4]Caire-Juvera, Graciela; [5]Pacheco-Moreno, Bertha Isabel; [4]Astiazarán-García, Humberto.

[1]MSc Nutritionist. Department of Nutrition. Centro de Investigacion en Alimentacion y Desarrollo A.C. (CIAD). Mexico.; [2]PhD Associate Professor. Department of Chemical and Biological Sciences, University of Sonora. Mexico.; [3]PhD Professor. Department of Chemical and Biological Sciences, University of Sonora. Mexico.; [4]PhD Professor. Department of Nutrition. Centro de Investigacion en Alimentacion y Desarrollo A.C. (CIAD). Mexico.; [5]BSc Laboratory Technician. Department of Nutrition. Centro de Investigacion en Alimentacion y Desarrollo A.C. (CIAD). Mexico.

Background and objectives: During antineoplastic treatment, breast cancer patients' body composition can be negatively affected increasing the risk of tumor recurrence and mortality. These changes include an increase in fat mass and a decrease in their muscle mass, known as sarcopenic obesity. The implementation of a personalized nutrition intervention for breast cancer patients could prevent these consequences. The aim of this study was to evaluate the effect of a 6-month personalized nutrition intervention in body composition components of breast cancer patients.

Methods: Anthropometric data was obtained and indexes were developed. Subjects' body composition was measured using dual-energy x-ray absorptiometry and participants' total energy expenditure was estimated using an algorithm for Mexican population. When required, a caloric restriction (500-1000 kcal/d) was considered, according to each patient's nutritional status. The dietary plan followed the NIH guidelines, modifying dietary protein (1.2-1.5 g/kg/d) in order to prevent sarcopenic obesity. Socioeconomic and cultural preferences were considered to develop the personalized nutrient-specific diet. Patients were followed every 2-weeks and a different diet menu was provided by a specialized nutritionist, for 6 months.

Results: Nine volunteers have completed the intervention. At baseline, 70% were overweight or obese and after 6 months a significant weight loss of -2.8 kg was observed (p<0.01), -1.9 kg of fat mass (p<0.05), -3 cm hip circumference (p<0.01), and -1 cm arm circumference (p<0.01).

Conclusions: A 6-month nutrition intervention program based in a personalized nutrient-specific diet for breast cancer patients had a positive effect in their body composition.

Keywords: sarcopenic obesity, personalized diet, dietary assessment, food-based intervention

TOTAL POLYPHENOL INTAKE AND THE INCIDENCE OF CARDIOVASCULAR DISEASE IN A MEDITERRANEAN COHORT: THE SEGUIMIENTO UNIVERSIDAD DE NAVARRA (SUN) PROJECT

[1]Mendonça, Raquel; [2]Marçal, Adriano; [3]Gea, Alfredo; [4]Martínez-González, Miguel Ángel; [5]Bes-Rastrollo, Maira.

[1]PhD student. Nutritrionist. Universidade Federal de Minas Gerais; [2]PhD. Nurse. Department of Preventive Medicine and Public Health. University of Navarra. Pamplona. Spain. Department of Maternal-Child Nursing and Public Health. School of Nursing. Universidade Federal de Minas Gerais. Brazil; [3]PhD. Department of Preventive Medicine and Public Health. University of Navarra. Pamplona. Spain.; [4]PhD. Department of Preventive Medicine and Public Health. University of Navarra. Pamplona. Spain. Department of Nutrition. Harvard TH Chan School of Public Health. Boston. USA; [5]PhD. Department of Preventive Medicine and Public Health. University of Navarra. Pamplona. Spain.

Background and objectives: Polyphenol-rich diets have been associated with reduced risk of CVD. However, few prospective epidemiological studies have evaluated the relationship between the risk of CVD and total polyphenol intake and classes of polyphenols. To evaluate the association between total intake of polyphenol and classes of polyphenol and the risk of major cardiovascular events in the Seguimiento Universidad de Navarra (SUN) Project, a prospective Spanish cohort.

Methods: We included 17,319 Spanish university graduates who were followed-up for a mean of 10.0 years (standard deviation, 4.1 years; total person-years: 172,918). Polyphenol intake was assessed using a validated semi-quantitative 136-item food frequency questionnaire and by matching food consumption data with the Phenol-Explore database. Cox proportional hazards models were used to estimate the adjusted HR and 95%CI for incident cardiovascular events.

Results: Cherries, chocolates, coffee, apples, and olives were the major sources of polyphenols. A total of 130 incident cases of cardiovascular events were identified during the follow-up. Among the classes of polyphenol, flavonoids were inversely associated with cardiovascular events, with a 63% reduction in risk observed on comparing quintile fifth with quintile first (adjusted HR: 0.37; 95%CI: 0.17-0.84; P for trend=0.01) after adjusting for potential confounders.

Conclusions: In this large prospective Mediterranean cohort, we observed an inverse association between the intake of flavonoids and the risk of cardiovascular events.

Keywords: dietary polyphenols, cardiovascular disease, SUN cohort, prospective studies.

COFFEE INTAKE AND RISK OF BREAST AND OVARIAN CANCER: UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS

[1]Bamia, Christina; [2]Turati, Federica; [2]Guercio, Valentina; [3]Guha, Neela; [4]Loomis, Dana; [5]Tavani, Alessandra.

[1]PhD. Associate Professor of Epidemiology and Medical Statistics. Department of Hygiene, Epidemiology and Medical Statistics. National and Kapodistrian University of Athens. Medical School. Athens. Greece; [2]PhD. Department of Clinical Sciences and Community Health. University of Milan. Italy; [3]PhD. Scientist. Section of IARC Monographs. International Agency for Research on Cancer. Lyon. France; [4]PhD. Deputy Section Head. Section of IARC Monographs. International Agency for Research on Cancer. Lyon. France; [5]IRCCS – "Mario Negri" Institute for Pharmacological Research. Milan. Italy.

Background and objectives: Cancers of the breast and ovary are important among women worldwide with breast cancer being the most commonly diagnosed and the leading cause of cancer death. Coffee is one of the most frequently consumed beverages worldwide; its association with these gynecological cancers has been investigated since the 1980s but early results were inconsistent. In 2016 a Working Group (WG) for an update of the 1991 IARC Monographs classification of coffee as a possible carcinogen, reported evidence suggesting lack of carcinogenicity and inadequate evidence of carcinogenicity for coffee intake and female breast and ovarian cancer, respectively. We undertook a meta-analysis of all studies included in the WG report, to provide the most updated summary of the collective evidence regarding the association of coffee intake with breast and ovarian cancer risk.

Methods: Case-control and cohort studies were identified by searching the PubMed database as of June 2016, and by reviewing the reference lists of retrieved articles. Random effect models were used to provide summary estimates of individual associations.

Results: 40 and 32 studies including, respectively, 76,748 women with breast and 11,411 women with ovarian cancer were considered in the meta-analysis. The combined RR (95% CI) for the study-specific highest vs. lowest coffee consumption was 0.97 (0.93–1.00, I2 5.5%) for breast and 1.03 (0.93–1.14, I2 31.9%) for ovarian cancer. These associations did not differ by study design, geographical location or menopausal status (both cancer sites), ER/PR status and body mass index (breast cancer) or histological type (ovarian cancer). For decaffeinated coffee the respective RRs were 1.00 (0.93-1.08) and 0.83 (0.71-0.96) for breast (13 studies) and ovarian (9 studies) cancer. Heterogeneity was medium-to-low but higher among ovarian as compared to breast cancer studies. The association of coffee intake with ovarian cancer risk was higher among studies published before 1990, (RR 1.38 95%CI (1.11-1.71)) compared to after 1990 (RR 0.97 95%CI (0.87-1.07)) (p-heterogeneity 0.004).

Conclusions: Findings from this updated meta-analysis suggest a weak inverse association with breast cancer and no association with ovarian cancer risk. Given the high consumption of coffee worldwide these results may be of high public health importance.

Keywords: breast cancer; ovarian cancer; coffee; meta-analysis

EFFECT OF PROBIOTIC BIFIDOBACTERIUM LACTIS BL-04 ON HOST RESPONSES AND MICROBIOTA IN EXPERIMENTAL RHINOVIRUS INFECTION IN HEALTHY ADULTS

[1]Mukherjea, Ratna; [2]Turner, Ronald; [3]Latvala, Sinikka; [3]Lyra, Anna; [4]Hibberd, Ashley; [3]Lehtoranta, Liisa; [4]Stahl, Buffy; [5]Lahtinen, Sampo; [3]Lehtinen, Markus.

[1]Global Nutrition Innovation. DuPont Nutrition & Health; [2]MD. University of Virginia School of Medicine. US; [3]PhD. Global Health & Nutrition Science, Danisco Sweeteners Oy. Finland; [4]Msc. Genomics and Microbiome Science, Danisco Madison Center. US; [5]PhD. 4Pharma Ltd. ElectroCity. Finland.

Background and objectives: Ingestion of probiotics may be beneficial for reducing the risk of upper respiratory tract illnesses. Bifidobacterium animalis subspecies lactis Bl-04 (Bl-04) significantly reduced the risk of respiratory illness episodes by 27% over 5-month winter season in healthy active adults. The mechanisms of this effect is unknown. The purpose of this study was to determine the effect of probiotic Bl-04 administration on host responses to experimental rhinovirus (RV39) challenge and to assess changes in gut and nasal microbiota due to treatment or viral challenge.

Methods: 152 seronegative volunteers treated for 28 days, 73 probiotic and 79 placebo, were challenged with RV39. Administration of study treatment continued for five days during collection of specimens for assessment of host response, infection, and symptoms. Fecal samples were collected at baseline and analysed by qPCR for Bl-04 and by sequencing of 16S rRNA gene for microbiota composition.

Results: Analysis of nasal lavage IL-8 concentration revealed significantly higher concentrations on Day 0 prior to virus challenge in the probiotic group. In contrast, the IL-8 response to RV39 challenge was significantly reduced in the probiotic group (geometric mean ratio for change, probiotic : placebo=0.65, p=0.03). The administration of probiotic was associated with reduced nasal lavage virus titer and the proportion of subjects shedding virus in nasal secretions (76% probiotic group, 91% placebo group, p=0.04). There was no effect of probiotic treatment on symptom severity, lower respiratory tract inflammation (eNO) or serum antibody responses to the virus. On Day 0, the supplemented Bl-04 was detected in 69% of probiotic group participants. The overall composition and diversity of intestinal microbiota remained stable through treatment and viral challenge. Results: **Conclusions:** This study demonstrates that ingestion of Bl-04 has effects on the baseline state of innate immunity in the nasal mucosa and on the subsequent response of the host to rhinovirus challenge. The gut microbiota appears resilient to both probiotic treatment and viral challenge. These findings provide first evidence in humans on the potential mechanisms behind reduced upper respiratory illness risk in healthy active adults by the probiotic Bl-04.

Keywords: probiotic, Bl-04, respiratory tract, rhinovirus, immunity

Faculty of Pharmaceutical Sciences. University of São Paulo. Brazil.; [4]PhD. Student. Nutricionist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Sciences. University of São Paulo. Brazil.; [5]PhD Student. Nutricionist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Sciences. University of São Paulo. Brazil.; [6]Associate Professor. Biochemist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Sciences. University of São Paulo. Brazil.

Background and objectives: Diabetes is characterized by hyperglycemia that can be associated or not with insulin resistance. Although the underlying mechanisms are not fully understood, leucine supplementation has been demonstrated to improve lipid and glucose metabolism, to reduce adipose tissue inflammation and to preserve lean body mass. We investigated the effects of leucine supplementation on lipid profile and glycemic control in diabetic rats.

Methods: Five days after birth, twenty four male Wistar rats received streptozotocin (120 mg/kg of body weight), and were randomly assigned into two groups at weaning: D – diabetic rats receiving a standard chow; DL – diabetic rats fed a diet supplemented with 5% leucine for nine weeks. A control group (C) consisted of twelve non-diabetics animals that received standard chow. Fasting glucose, insulin, triglycerides (TG), total cholesterol and HDL-cholesterol levels were analyzed in serum and homeostasis model of assessment-insulin resistance (HOMAIR) was calculated.

Results: Diabetic rats presented higher serum glucose, triglycerides and total cholesterol levels, and lower serum insulin when compared to control group ($p < 0.05$). Leucine supplementation significantly reduced serum glucose (131.80 ± 11.66 mg/dl versus 174.90 ± 12.55 mg/dl), total cholesterol (63.50 ± 3.40 mg/dl versus 74.67 ± 3.70 mg/dl), and TG (59.25 ± 3.39 mg/dl versus 86.90 ± 10.16 mg/dl) levels in diabetic rats when compared to D group. The HOMAIR was significantly higher in D group when compared to C group (14.07 ± 1.32, and 8.31 ± 1.55, respectively), indicating insulin resistance in diabetic animals. The HOMAIR was significantly lower in DL compared with D (8.66 ± 1.83 and 14.07 ± 1.32, respectively), but no difference was observed in comparison with C group.

Conclusions: We conclude that chronic leucine supplementation reversed insulin resistance and reduced hyperglycemia, hypertriglyceridemia, and hypercholesterolemia without improving hypoinsulinemia in diabetic rats.

Keywords: diabetes. insulin resistance. leucine. supplementation.

FASTING AND CALORIC RESTRICTION IN ELDERLY WITH CARDIOVASCULAR DISEASE: A REVIEW

[1]Tello Casillas, Jessica Karen; [2]Lopez-Teros, Miriam; [3]Ochoa Rivera, Teresa; [4]Escalante-Izeta, Ericka; [5]Gamboa-Melendez, Marco Alberto.

[1]BSc. MD. Health Department. Iberoamerican University. Mexico.; [2]PhD. MD. Health Department. Iberoamerican University. Mexico; [3]PhD. Nutritionist. Health Department. Iberoamerican University. Mexico; [4]PhD. Phsycologist. Health Department. Iberoamerican University. Mexico; [5]PhD. QFB. Health Department. Iberoamerican University. Mexico.

Background and objectives: The main chronic diseases for the geriatric population are diabetes mellitus and cardiovascular disease, impacting quality of life and increasing the use of health resources. It has been shown that the main intervention for cardiovascular disease is a change of lifestyle, focused on weight control. The caloric restriction (CR) method has shown effectiveness in the treatment and reduction of costs of diabetes mellitus, obesity and hypertension. Also, it has been found that intermittent fasting has an important positive effect on weight, decreasing cardiovascular risk as a result. Although there are some cases and clinical trials that show the benefits obtained from fasting and CR, it has not been studied enough in elderly population. The objective of this review is to evaluate the clinical evidence of fasting and its benefits in elderly patients with cardiovascular disease.

Methods: We performed research using the PubMed database up to March 2017. We included clinical trials, metanalysis and systematic reviews. Search terms comprising Medical Subject Headings were as follows: "fasting", "caloric restriction", "cardiovascular disease", and "elderly". The included criteria were: studies of intervention in patients with cardiovascular disease (hypertension, dyslipidemia, coronary disease, and heart failure) with fasting or CR, where their outcomes were clinical parameters (blood pressure, lipid profile, weight, body mass index and fat mass). Adult men and women from 60 to 80 years and articles in English language were included in the research.

Results: We identified 27 potentially relevant studies. We excluded 10 studies for the following reasons: did not report clinical outcomes or patients of younger age. Finally, we included 11 studies, 4 systematic reviews, 2 metanalysis and 5 clinical trials, which will be evaluated for their full text. The preliminary results show that fasting and CR decreases cardiovascular risk in geriatric population, which is positively influenced by weight and serum lipid levels control.

Conclusions: Fasting as an intervention may have a benefit in geriatric patients with cardiovascular disease.

Keywords: fasting, caloric restriction, elderly, cardiovascular disease.

THE DIET ADHERENCE IN CARDIOVASCULAR RISK FACTORS PATIENTS IN THE NORTH OF IRAN   BASED ON THE MEDITERRANEAN DIET ADHERENCE

[1]Mahdavi-Roshan, Marjan; [2]Salari, Arsalan; [3]Gholipour, Mahboobeh; [3]Naghshbandi, Moona.

[1]Assistant Professor in Nutrition Sciences, School of Medicine, Guilan University of Medical Sciences, Rasht, Iran.; [2]Associate Professor in cardiology, Guilan Interventional Cardiovascular Research Center, Department of Cardiology, Heshmat Hospital, School of Medicine, Guilan University of Medical Sciences, Rasht, Iran.; [3]Assistant Professor in cardiology, Guilan Interventional Cardiovascular Research Center, Department of Cardiology, Heshmat Hospital, School of Medicine, Guilan University of Medical Sciences, Rasht, Iran.

Background and objectives: Before any nutritional intervention, it is necessary to have the prospect of eating habits of people with cardiovascular risk factors. In this study we assessed the adherence of healthy diet and related factors.

Methods: This study was conducted on 550 men and women with cardiovascular risk factors that referred to Heshmat hospital in Rasht. Information was collected by interview and reading medical history and measuring anthropometric indexes. The Mediterranean Diet Adherence Screener was used for assessing dietary adherence, this screener was modified according to religious beliefs and culture of Iran.

Results: The mean age of participants was 58±0.38years. The mean of body mass index was 27±0.01kg/m2 and the mean of waist circumference was 98±0.2cm. The mean of dietary adherence was 5.76±0.07. Forty three percent of participants had low adherence and just 2% had suitable adherence. The mean of dietary adherence in men was significantly higher that women (p=0.07). There was no significant association between smoking and body mass index and dietary adherence. Participants in rural area and high educational participants insignificantly had an unsuitable dietary adherence

Conclusions: Education to different group about dietary intake correction and using a Mediterranean dietary pattern that is similar to dietary intake in the north of Iran, for controlling cardiovascular disease is necessary.

Keywords: Dietary adherence, Mediterranean dietary pattern, cardiovascular disease.

ASSOCIATION BETWEEN DEPRESSIVE SYMPTOMS AND MEDITERIAN DIETARY ADHERENCE IN ADULTS WITH CARDIOVASCULAR DISEASE RISK FACTORS IN THE NORTH OF IRAN

[1]Salari, Arsalan; [2]Ashouri, Asieh; [3]Mahdavi-Roshan, Marjan.

[1]3-   Department of Cardiology, School of Medicine, Heshmat Hospital, Guilan Interventional Cardiovascular Research Center, Rasht, Iran.; [2]Biostatistics, School of Health, Guilan University of Medical Sciences; Rasht-Iran.; [3]phD. Nutritionist.School of Medicine, Guilan University of Medical Sciences, Rasht, Iran.

Background and objectives: Depression is prevalent in cardiovascular patients and may have important effects on patients' adherence to healthy diet that are necessary for their health. We examined the association between depression and dietary adherence in cardiovascular disease risk factors adults in the north of Iran.

Methods: This cross-sectional study was performed on 344 participants who were admitted to a tertiary hospital in Rasht. Demographic characteristics, blood pressure, anthropometrics indexes and blood factors were measured. For assessing dietary adherence, we used the 14-point Mediterranean Diet Adherence Screener (MEDAS) and for depression we used Beck Depression Inventory (BDI). All statistical tests were two-sided and P<.1 and P<.05 was used to indicate statistical significance

Results: Depressive symptoms was observed in 43% patients. Prevalence of patients with low, moderate and good diet adherence was 44%, 54% and 2%, respectively. In the univariate analysis, there was a relation between depression and diet adherence. Female sex, diabetes, higher waist circumference, higher HbA1C and lower level of hematocrit was associated with lower diet adherence. After controlling for confounders, there was no relation between depression and diet adherence (P=.249). So, odds ratio of the low diet adherence in patients with depression compared with patients without depression was 1.311 (95%CI: .827-2.079).

Conclusions: Study showed that depressive symptoms and dietary non-adherence were prevalent in our participants. Depressive symptoms were an independent predictor of dietary non-adherence. Studies are needed to increase our finding of the association between depressive symptoms and both perceived and objectively determined dietary adherence.

Keywords: Depressive symptoms, Dietary adherence, Cardiovascular risk factors, North of Iran

THE INFLAMMATORY POTENTIAL OF DIET IS ASSOCIATED WITH BREAST CANCER RISK IN DIFFERENT CONTEXTS OF URBANIZATION: A MULTILEVEL ANALYSIS

[1]Niclis, Camila; [2]Tumas, Natalia; [3]Shivappa, Nitin; [3]Hebert, James R.; [4]Aballay, Laura; [5]Becaria Coquet, Julia; [4]Reartes, Gabriela; [4]Díaz, María del Pilar.

[1]PhD. Instituto de Investigaciones en Ciencias de la Salud. Universidad Nacional de Córdoba and Consejo Nacional de Investigaciones Científicas y Técnicas. Argentina.; [2]PhD. Centro de Investigación y Estudios sobre Cultura y Sociedad. Universidad Nacional de Córdoba and Consejo Nacional de Investigaciones Científicas y Técnicas. Argentina.; [3]PhD. Arnold School of Public Health. University of South Carolina. USA.; [4]PhD. Escuela de Nutrición. Universidad Nacional de Córdoba. Argentina.; [5]BSc. Instituto de Investigaciones en Ciencias de la Salud. Universidad Nacional de Córdoba and Consejo Nacional de Investigaciones Científicas y Técnicas. Argentina.

Background and objectives: Habitual dietary choices may influence chronic inflammation and several non-communicable diseases. The dietary inflammatory index (DII) was developed to assess the inflammatory potential of diet of diverse populations. The aim of the present study was to evaluate the association between the DII and breast cancer risk in Córdoba, Argentina.

Methods: A case-control study (317 women with BC and 526 controls) was conducted in Córdoba (Argentina) throughout 2008 to 2015. Dietary inflammatory index scores were computed based on dietary intake assessed by a validated food frequency questionnaire. Multi-level logistic regression models were fit to estimate the association between dietary inflammatory index scores and breast cancer. Age, Body Mass Index, age at menarche, number of children, socio-economic status and family history of BC were included as covariates at first level and level of urbanization (Capital city, cities with >30,000 inhabitants [except Capital city], and towns/rural populations with ≤30,000 inhabitants) as the second level variable.

Results: Increasing DII score (as continuous variable) showed significant positive associations with BC risk (OR 1.15; 95%CI 1.11 to 1.19). When the DII was used as a categorical variable, women at the third tertile of DII showed a 58% higher risk of BC (1.58; 95%CI 1.42 to 1.75) compared to women at the first tertile. A median OR around 2 indicated that for persons with the same individual-level covariates but belonging to more urbanized contexts, the risk of breast cancer increases, in median, 2 times.

Conclusions: Higher DII scores, were positively associated with breast cancer occurrence, suggesting that increasing intake of more anti-inflammatory dietary components, such as plant-based foods rich in fiber and phytochemicals, and reducing intake of pro-inflammatory factors, such as processed foods, or food rich in refined carbohydrates, saturated or trans fatty acids, may be a strategy for reducing BC risk in different contexts (or degree) of urbanization.

Conflict of Interest Disclosure: On behalf of all authors, the corresponding author states that there is no conflict of interest. Disclosure: Dr. Hébert owns controlling interest in Connecting Health Innovations LLC (CHI), a company planning to license the right to his invention of the dietary inflammatory index (DII) from the University of South Carolina in order to develop computer and smart phone applications for patient counseling and dietary intervention in clinical settings. Dr. Nitin Shivappa is an employee of CHI.

144/1317

GLUCOSE, INSULIN AND METABOLIC RESPONSE TO SOY AND WHEY PROTEIN AMONG NORMAL HEALTHY WEIGHT INDIANS

[1]Kurpad, Anura; [2]Sambashivaiah, Sucharita; [3]Cope, Mark; [4]Selvam, Sumithra; [4]Thomas, Tinku; [3]Mukherjea, Ratna; [5]Kuriyan Raj, Rebecca.

[1]MD. PhD. Physiology & Nutrition. St John's Medical College; [2]MD. PhD. St John Research Institute; [3]PhD. Global Nutrition Innovation. DuPont Nutrition & Health; [4]PhD. St John Research Institute; [5]Associate Professor. India.

Background and objectives: Incidence of metabolic syndrome and type2 diabetes in developing countries is increasing. Intervention strategies including increased physical activity and healthier dietary pattern are needed to improve health status. While high quality dietary protein intake has been linked to the growth and development of lean tissue; it could also be insulinogenic. Acute effect of consumption of different sources and amounts of protein, on glucose homeostasis, in South-Asian Indians, is unknown. This population group has a greater risk of developing diabetes, and a habitually low intake of high quality protein.

Methods: Study investigated effect protein type (soy vs. whey) and dose (15% vs. 30% Energy) on glucose homeostasis and energy metabolism, among healthy normal-weight Indians. The study tested Healthy adult males (20-35 years) (n=15) received four testmeals in random order. Energy expenditure (EE) and substrate oxidation (RQ) were measured every 30 minutes for 300 minutes post-meal. Satiety was estimated using visual analogue scale (VAS) at 0, 10, 40 min, and every half hour thereafter. Blood was collected at basal (- 10,-5 min), and post-meal (15, 30, 45, 60, 90, 120,180, 240,300 min) and incremental area under the curve (AUC) was measured for plasma glucose and insulin.

Results: There were no significant differences in mean weight and BMI between four intervention arms. EE, VCO_2, RQ, VAS and glucose did not differ with protein source or dose. AUC for plasma insulin was significantly higher for whey compared to soy at 30% dose (p<0.01). There was no difference in the insulinogenic response between whey and soy at 15% dose (p=0.07). Within a specific protein, only whey demonstrated a higher insulin response with a higher dose (p<0.01).

Conclusions: At lower doses, whey and soy do not elicit different insulinogenic responses. At higher doses, whey has greater insulinogenic response compared to soy, making soy a better source for those at greater risk for developing diabetes. Soy, as a source of high quality protein that is low in fat, saturated fat and cholesterol, makes it a good protein source to improve dietary patterns that could impact the development of type2 diabetes and metabolic syndrome.

Keywords: soy, whey, protein, glucose, insulin

Conflict of Interest Disclosure: Work was funded by DuPont Nutrition & Health and RM and MC were employed at the time of the study by DuPont Nutrition and Health.

PROFILE CONSUMPTION OF SWEETENERS AND DIETETIC PRODUCTS BY INDIVIDUALS WITH TYPE 2 DIABETES MELLITUS FROM AN OUTPATIENT CLINIC IN THE CITY OF SÃO PAULO (BRAZIL)

[1]*Parise Polo, Gabriela;* [2]*Barros Pereira Ferreira, Natália;* [2]*Lekevicius Consolin, Brunna;* [2]*Fonseca Gonçalves, Daniel;* [2]*Silva Gregório, Amanda;* [3]*Garcia Peloggia de Castro, Adriana.*

[1]Nutrition Student. Centro Universitário São Camilo. Brazil;
[2]Nutrition Student. Centro Universitário São Camilo. Brazil.;
[3]PhD. Nutritionist. Centro Universitário São Camilo. Brazil.

Background and objectives: The consumption of sweeteners and dietetic products is increasing in the last few years. These products play an important role in the diet of patients with diabetes mellitus since they can provide the taste of sweetness, without adding calories. Besides, they can also improve social life, psychological acceptance of the disease and the possibility of increasing the variety of foods. Therefore, the purpose of this work is to analyze the consumption of sweeteners and dietetic products among patients with type 2 diabetes (DM2).

Methods: This is a cross-sectional, descriptive study with primary data collection, sampling done by convenience, approved by the Ethics and Research Committee of Centro Universitário São Camilo, Brazil. A structured questionnaire to characterize alternative sweeteners and dietetic products intake was developed for this research and applied to 82 individuals with DM2, both male and female, attending an outpatient clinic in São Paulo. Data analyses were performed using descriptive statistic, the Qui-square test with a level of significance of $p<0.05$.

Results: The majority of the participants consumes sweeteners (79%), usually chooses products according to its flavor (33,8%) and has the diagnosis of DM as the main determinant factor for its use (87,7%). Participants with a lower level of education presented a higher consumption of sweeteners, but this result was not statistically significant (p= 0,12). The higher consumption of sweeteners was found in the lowest-income group, however this result was also not statistically significant (p=0,78). Regarding the consumption of dietetic products, half of the individuals con-

sumes them, with gelatin (54%) and soft drinks (52%) being the most consumed products. Most reported consuming them due to the diagnosis of the disease (63,4%). Nutritionists (50%) and physicians (45,5%) were the professionals who oriented the use of sweeteners and dietetic products and almost 75% followed the guidance regarding these use.

Conclusions: The majority of individuals with DM2 consumes sweeteners and dietetic products because the diagnosis of the disease. These choices are mainly guided by a health professional, being extremely important to avoid inadequacies in food choices and to improve the quality of life of these patients.

Keywords: Diabetes mellitus. Sweeteners. Dietetic products. Nutritional education.

ASSOCIATION BETWEEN THE PERCENTAGE OF FAT MASS AND ANTHROPOMETRIC AND METABOLIC INDICATORS: IN THE SEARCH FOR CLINICAL INDICATORS FOR CHILDHOOD OBESITY

[1]*Sepúlveda Flores, Cecilia;* [2]*Cigarroa, Igor;* [3]*Villegas, Sandra;* [4]*Soto, Claudio;* [5]*Lasserre, Nicole;* [6]*Sanhueza, Karen;* [7]*Escobar, Karina.*

[1]MD. Nutritionist. Nutrition and Dietetics Department. School of Health. University Santo Tomás. Chile; [2]PhD.Physiotherapist. Physiotherapy Department. School of Health. University Santo Tomás. Chile; [3]PhD.Chemist. Basic Science Department. School of Health. University Santo Tomás. Chile; [4]MSc. Physiotherapist. Physiotherapy Department. School of Health. University Santo Tomás. Chile; [5]MSc. Nutritionist. Nutrition and Dietetics Department. School of Health. University Santo Tomás. Chile; [6]MD. Nutritionist. Nutrition and Dietetics Department. School of Health. University Santo Tomás. Chile; [7]Nutritionist. Nutrition and Dietetics Department. School of Health. University Santo Tomás. Chile.

Background and objectives: In childrens, the general and visceral obesity are associated with an increased cardiometabolic risk. The measure of fat mass is the most objective indicator to diagnose obesity, however its high cost and low availability make it necessary to have new clinical indicators for its estimation. Insulin resistance is a co-morbidity present in most obese children but its measurement is expensive.The Single Point Insulin Sensitivity Estimator (SPISE) is a tool easy to use that includes circulating lipids and the BMI to estimate insulin resistance.The aim of this study was to determine the relationship between the percentage of fat mass with anthropometric and metabolic indicators to determine which variable can best predict the percentage of fat mass.

Methods: Correlation-causal design study in 40 children (12 females, 28 males), aged from de 11 to 14 years overweight and obese from an educational center in the province of Biobío.

Anthropometric measurements (weight, height, waist circumference, body fat percentage, body mass index (BMI) and Waist to height ratio (WHtR), were performed, fasting blood glucose,

insulin and lipid profile levels (TC, LDL, HDL and TG), were measured. Insulin sensivity was calculated using SPICE and Homeostasis Model Assessment – insulin resistance (HOMA-IR). The association between variables were assessed by Pearson correlation and linear regression.

Results: The means of fat mass was 36,1±5,9, from BMI 27.5±3.6, WHtR 0.6±0.1, TC 153.1±28.2, HDL choresterol 44.7±10.6, LDL choresterol 86.2±21.4, TG 108.1±61.1, fasting blood glucose 83.3±6.8, insulin levels 16.9±7.3, HOMA-IR 3.6±1.7 and 5.9±1.2 from SPISE. The percentage of fat mass presented a high correlation with WHtR (R=0.707;p=0.000) and a significant correlation with BMI (R=0.671;p=0.000), insulin levels (R=.409;p=0.009) and SPISE index(R=-0.558;p=0.000). The other variables did not present a significant correlation. In the multiple linear regression analysis, the model that included only the WHtR was the better predictor for changes in fat mass (50%).

Conclusions: The SPICE Index present a higher correlation with fat mass than insulin levels while WHtR present a high association with fat mass achieving a high percentage in its prediction, that suggest his possible application as a clinical predictor of obesity and cardiometabolic risk in Chilean childrens.

Keywords: Waist to height ratio (WHtR), childhood obesity, body fat, body mass index (BMI), The Single Point Insulin Sensitivity Estimator (SPISE)

BOCAIUVA FLOUR (ACROCOMIA TOTAI MART.) REDUCES BODY FAT AND HEPATIC STEATOSIS OF RATS SUBMITTED TO A HYPERCALORIC DIET

[1]Marques Romeiro Santos, Mirelly; [1]Caroline Da Silva, Érica; [2]Aparecida Vinci Carlos, Suellen; [2]Monteiro Santee, Cynthia; [3]Ferreira Da Silva, Nayara; [4]Candeloro Portugal, Luciane; [5]dos Santos Freitas, Deisy; [6]Braz Alcantara, Glaucia; [7]Aiko Hiane, Priscila; [8]Freitas dos Santos, Elisvânia.

[1]Doctorate Student in the Health and Development in the Brazilian Midwestern Region Post Graduate Program. Nutritionist. Federal University of Mato Grosso do Sul. Brazil.; [2]Nutritional Science Undergraduate Student. Federal University of Mato Grosso do Sul. Brazil.; [3]Pharmacy Undergraduate Student. Federal University of Mato Grosso do Sul. Brazil.; [4]PhD. Professor of Histology. Federal University of Mato Grosso do Sul. Brazil.; [5]Chemist. Federal University of Mato Grosso do Sul. Brazil.; [6]PhD. Professor of Chemistry. Federal University of Mato Grosso do Sul. Brazil.; [7]PhD. Professor of Pharmacy. Federal University of Mato Grosso do Sul. Brazil.; [8]PhD. Professor of Nutritional Science. Federal University of Mato Grosso do Sul. Brazil.

Background and objectives: The prevalence of people suffering from obesity and overweight has increased worldwide. In 2014, there were approximately 1.9 billion overweight adults, 600 million of which were obese. Thus, the purpose of this study is to evaluate the effects of bocaiuva flour on body fat and hepatic steatosis of rats submitted to a hypercaloric diet.

Methods: A total of 38 male Wistar rats were distributed in a control group on a hypercaloric diet: HC (n=9), and treatment groups on a hypercaloric diet supplemented with 5%, 10% and 15% bocaiuva flour (BF): HC5BF (n=10), HC10BF (n=9) and HC15BF (n=10), respectively. After the animals were euthanized, fat depots were obtained and weighed: retropreperitoneal, epididymal and visceral (omental, mesenteric and perirenal). To evaluate the density of steatosis in the liver, point-counting method was used in histological slides stained with H&E (haematoxylin and eosin). The data was interpreted using analysis of variance, followed by Tukey post hoc analysis, considering statistical significance p<0.05.

Results: Regarding body fat, there was a difference between groups (p=0.01), being: HC (12.99g), HC5BF (10.96g), HC10BF (9.10g) and HC15BF (8.36g). There was a significant difference between groups HC, HC5BF, HC10BF and HC15BF analyzing the following fat depots: epididymal 4.36g, 3.51g, 2.83g and 2.65g (p=0.01); mesenteric 3.54g, 3.19g, 2.64g and 2.58g (p=0.02) and retroperitoneal 3.45g, 2.94g, 2.45g and 2.04g (p=0.04), respectively. The following values were obtained from the histological analysis of the hepatic steatosis density: HC (17.32±3.63), HC5BF (13.72±2.42), HC10BF (7.08±2.47) and HC15FB (6.96±3.33). The animals of the HC10BF and HC15BF treatment groups were statistically different from the control group, since these animals showed a reduction of 59.12% and 59.82% of hepatic fat deposition when compared to the HC group.

Conclusions: The group that received the supplementation of 15% of bocaiuva flour showed a 35% reduction in body fat and preserved hepatic tissue when compared to the control group. In conclusion, these results are extremely important, since there is no other scientific evidence associating the consumption of bocaiuva flour for controlling damages caused by obesity.

EFFECT OF MORINGA OLEIFERA LEAF POWDER ON BIOCHEMICAL AND HAEMATOLOGICAL PARAMETERS OF WEANING WISTAR ALBINO RATS

[1]Yetunde, Alozie; [2]Bassey, Emma.

[1]PhD. Nutritionist. Department of Human Ecology.Nutrition and Dietetics Unit. University of Uyo. Nigeria.; [2]MSc. Nutritionist. Department of Human Ecology.Nutrition and Dietetics. University of Uyo.Nigeria.

Background and objectives: The world is under the heavy yoke of malnutrition and in the developing world, the statistics are grim. The nutritional properties of Moringa are now so well known that there seems to be little doubt of its substantial health benefit. Nonetheless, the outcomes of well controlled and well documented clinical studies are still clearly of great value. Thus, the study was designed to evaluate the effect of Moringa oleifera

leaf powder on biochemical and hematological parameters of weaning wistar albino rats as a means of food diversification in terms of protein source.

Methods: Proximate and antinutrient components of the leaf were determined. Twenty four rats of three weeks old were obtained from the Animal House of the College of Health Sciences, University of Uyo and divided into four groups of six rats each with average weight of 52.58kg. The rats were assigned dietary treatment categorized as Moringa Diet (MD), Protein Free Diet (PF), Synthetic Diet (SD) and Normal Diet (ND) for 21 days and the effect of these diets were determined.

Results: Proximate composition of the leaf revealed protein content as 29.6%, and dietary fiber 22.6%. The presence of antinutrient showed: HCN 0.06mg/100g, Oxalate 2.85 mg/100g, Phytate 1.39 mg/100g and Tannin 0.13 mg/100g were at insignificant levels. Food intake rate of rats fed with synthetic and normal diet were significantly higher (P<0.05) than that of the rats fed moringa diet. Effect of the diet on body weight showed that rats on SD (126), ND (117.67), and MD (92.66) gained significantly (P<0.05) higher weight than those on PF 23.33). Haematological parameters showed no significant difference (P>0.05) in WBC, RBC, HGB, PCV, MCV, MCH, and MCHC of moringa diet with synthetic diet. Moreover, moringa diet was significantly (P<0.05) higher than synthetic in platelet value. However, these parameters were all significant (P<0.05) against the PF. Results: **Conclusions:** Moringa leaf powder is of high biological value and could serve as a nutritional complement against protein deficiency.

Keywords: Moringa, Proximate, Anti nutrient, Protein deficiency

OBESITY PREVALENCE IN A MIGRANT POPULATION LIVING IN CASABLANCA, MOROCCO

[1]Hibbi, Nadia; [2]Saile, Rachid; [2]Derouiche, Abdelfettah.

[1]PhD. Nutritionist. Laboratory of Biology and Health-URAC 34- Faculty of Sciences Ben M'Sik. Hassan II University. Casablanca, Morocco.; [2]Professor Laboratory of Biology and Health-URAC 34- Faculty of Sciences Ben M'Sik. Hassan II University. Casablanca, Morocco.

Background and objectives: Rural-Urban migration is known as a major factor associated with the increase of obesity prevalence in many countries. In Morocco, obesity prevalence is higher in cities.

In this study, we assess the influence of ethnicity and migration, through urbanity degree, on obesity prevalence variation, between the ethnic group of Soussi (native of the rural zone of Souss region) and Casablanca in Morocco.

Methods: We used a multi-stratified sampling including 615 subjects (305 subjects recruited in metropolitan Casablanca and 310 from the Souss region). The sampling was based on ethnicity, sex and age. We measured anthropometric parameters, using (i) body mass index (BMI), based on cut-off points recommended by the WHO, and (ii) body fat percentage (BF%), based on cut-off points taken from tables provided in the user's manual of a BIA meter (i.e., a bioelectrical impedance device)

Results: Obesity prevalence is greater in women than in men (22.5% vs. 19.8%). Women also presented an AO and a higher %BF risk than men (77.6% vs. 33.4% and 71.2% vs. 60.4%, respectively). Adjusted analysis of our data indicated that, in comparison with rural Soussi, the AO is significantly greater in the second generation migrants group (51.0%, OR=0.33, 95%CI [0.17–0.64], p<0.01); Obesity prevalence (BMI and %BF) is also more elevated in Soussi from Casablanca (21.3%, OR=0.53, 95%CI [0.30–0.92], p<0.05 and 71.3%, OR= 0.42, 95%CI [0.28 –0.76], p<0.01, respectively). Obesity prevalence and AO are higher in women from Casablanca than in women from Souss region (BMI: 31.0% %, OR= 0.54, 95%CI [0.37–0.92], p<0.05, and AO: 83.9%, OR=0.48, 95%CI [0.27–0.84], p<0.01).

Conclusions: Our study showed that anthropometric and body statuses of our study population depend on urbanity degree (second generation migrants) and ethnicity (Soussi from Casablanca) in men. However, in women, it is linked to their residence location (particularly, in Women from Casablanca).

IMPACT OF EARLY ENTERAL NUTRITION WITH IMMUNONUTRIENTS IN MORBIMORTALITY IN PATIENTS WITH TRAUMATIC BRAIN INJURY IN THE INTENSIVE CARE UNIT OF MEXICALI`S GENERAL HOSPITAL

[1]Ponce y Ponce de León, Gisela; [2]Cornejo Bravo, José Manuel; [2]Pérez Morales, María Eugenia; [3]Mayagoitia Witrón, José de Jesús; [4]Rieke Campoy, Ulises; [4]Camargo Bravo, Adriana.

[1]Universidad Autonoma de Baja California; [2]Facultad de Ciencias Químicas e Ingeniería UABC; [3]Hospital General de Mexicali Mexico; [4]Facultad de Enfermería UABC.

Background and objectives: Introduction: early enteral nutrition is initiated in the first 24-48 hours after injury or admission to the Intensive Care Unit (ICU), it is a method of nutritional support with beneficial effects for the patient that improve outcome. Traumatic brain injury (TBI) is the third cause of death in Mexico caused by accidents or violence, therefore it is considered a serious public health problem.

Objective: to determine if early enteral nutrition with immunonutrients (EENI) supplied to patients with TBI decreases morbimortality in the ICU of the General Hospital of Mexicali.

Methods: random systematic, longitudinal and comparative clinical study in 22 patients with severe TBI, 11 patients in the con-

trol group with Early enteral modular nutrition (EEMN) and 11 in the intervention group supplied with EENI, that were admitted to the ICU and complied with inclusion criteria, from August 1st, 2015 to June 30, 2016.

Results: 16 (72.7%) males and 6 (27.3%) females with a mean age of 34.7 years. The main causes of TBI were run over and motor vehicle accident in 54.6%. The group with EENI showed increase in weight (T of Student 23.737, p=.001), total proteins (T de Student 13.40, p=.001), leukocytes (T Student de 2.05, p =.002) and lymphocytes (T de Student 7.09, p=.001) at discharge from the ICU. Length of stay in the ICU, mechanical ventilation, infections, mortality and days of enteral nutrition were less in the EENI group.

Conclusions: EENI impacts in a positive way by decreasing the incidence of infectious complications as length of stay in the hospital by which it is possible to improve in less time patient`s health and diminish hospital costs.

FASTING, INTERMITTENT FASTING OR CALORIC RESTRICTION AS NUTRITIONAL MANAGEMENT OF ADULTS WITH TYPE 2 DIABETES. A SYSTEMATIC REVIEW (PRELIMINARY RESULTS)

[1]Ochoa Rivera, Teresa; [2]Lopez-Teros, Miriam; [3]Escalante-Izeta, Ericka, [4]Gamboa-Melendez , Marco Alberto; [5]Tello-Casillas, Jessica Karen; [6]Méndez-Montoya, Angel Francisco.

[1]PhD. Nutritionist. Health Department. Iberoamerican University. Mexico City. Mexico.; [2]MSc. MD. Health Department. Iberoamerican University. Mexico City. Mexico.; [3]PhD. Phsycologist. Health Department. Iberoamerican University. Mexico City. Mexico.; [4]PhD. QFB. Health Department. Iberoamerican University. Mexico City. Mexico.; [5]BSc. MD. Health Department. Iberoamerican University. Mexico City. Mexico.; [6]PhD. Theologist of Food. Religious Sciences Department. Iberoamerican University. Mexico City. Mexico.

Background and objectives: Type 2 diabetes encompasses individuals who have insulin resistance and usually have relative insulin deficiency. Pharmacological treatment usually has adverse effects on the body in addition to the high cost it produces, so alternative strategies are necessary. Intermittent fasting improves metabolic health and many other physiological and molecular markers of health in animal and humans models. Also, recently it has been studied that patients with diabetes type 2 with continues caloric restriction show metabolic improvement. However, further studies are still needed to understand the effect of fasting on the physiological, metabolic and clinical mechanisms in the diabetic patient. The aim of this systematic review is to evaluate the clinical evidence that fasting is beneficial to patients with type 2 diabetes.

Methods: We performed a research of PubMed database up to February 2017. We included clinical trials, meta-analysis and systematic reviews. Search terms comprising Medical Subject Headings (MESH) as follows: "fasting", "intermittent fasting", "caloric restriction", "diabetes type 2" and "adult".

Results: According to the criteria established for the words MESH, we found 743 articles. However, 686 were excluded after reviewing the titles of these publications for the following reasons: did not report clinical outcomes about type 2 diabetes (fasting glucose and insulin, glycosylated hemoglobin, lipid profile and measures of weight, body mass index, fat and muscle mass) or without any intervention of fasting or caloric restriction. Actually, we are reviewing the abstracts of the remaining 57 studies. Publications that do not meet the established criteria will be excluded from the systematic review, while the remaining studies will be evaluated for their full text.

Conclusions: The preliminary results show the increased in recent years of clinical trials about the study of fasting as a possible intervention in patients with diabetes without negative consequences. It is recognized the cost-benefits of this therapy. Therefore, it is necessary to perform a systematic review of these studies as a tool for decision-making in evidence-based medical practice.

Keywords: fasting, caloric restriction, adult, type 2 diabetes

OBESITY AND CLINICAL OUTCOME OF HOSPITALIZED CHILDREN UNDER TWO YEARS OLD WITH LOWER RESPIRATORY TRACT INFECTIONS

[1]Barja, Salesa; [2]Bustos, Edson; [3]Franulic, Yasna; [3]Messina, Javiera.

[1]MD. MSc in Pediatric Nutrition. Josefina Martinez Hospital. Department of Gastroenterology and Pediatric Nutrition. Division of Pediatrics. Faculty of Medicine. Pontificia Universidad Católica de Chile.; [2]Nutritionist. MSc. School of Nutrition and Dietetics. Faculty of Medicine. Universidad Finis Terrae. Chile.; [3]Nutritionist. Josefina Martinez Hospital. Chile.

Background and objectives: Obesity is associated with increased morbidity and mortality in adults with respiratory infections.

Aim: To study an association between overweight and clinical evolution in children under two years old, hospitalized for lower respiratory tract infections (LRTI).

Methods: Retrospective study with clinical records review of children younger than two years old with LRTI hospitalized in Josefina Martinez Hospital, during winter (2009 to 2015). Demographic data, anthropometry, nutritional status (WHO 2006 reference) and clinical outcome were recorded: Hospital stay (days/hours), use and length (days) of oxygen and noninvasive ventilatory support (NIV), use of corticosteroids, and antibiotics.

Results: The sample was constituted by 678 children, 10.96 ± 5.65 months old, 62.3% younger than 12 months, 55% boys. The commonest admission diagnosis was viral pneumonia (67%), 54.7% received basic care, 98.7% oxygen therapy, 35.4% NIV, 26.1 antibiotics and 47.5% corticoids. Nutritional status: 10% had malnutrition and 34.8% overweight or obesity. Boys with overweight

or obesity had higher frequency of viral pneumonia (75.4% vs. 60.2%, p = 0.014), need for more complex care (27.7% vs. 19.9%, p = 0.018) and length of NIV (Median 4.5 (3 to 5.5) vs. 3.0 (2 to 5) days, p = 0.007), than eutrophic. Boys with malnutrition had higher need of NIV than eutrophic (56.2 % vs. 34.6%, p=0.02). In girls, there was no association between nutritional status and clinical outcome.

Conclusions: In this sample of children younger than two years old, hospitalized for LRTI, boys with malnutrition had a higher need of NIV but those with overweight or obesity needed a more complex care and longer NIV than the eutrophic ones.

Keywords: Obesity, overweight, lower respiratory tract infections, children, hospital.

CAN WHO GUIDELINES FOR MALNUTRITION REDUCED THE MORTALITY IN CHILDREN RECEIVING NUTRITION REHABILITATION AT THE HOSPITAL: CLINICAL STUDY IN MOROCCAN MALNOURISHED CHILDREN

[1]*Barouaca, Hassan;* [2]*Santhanakrishnan, Vimaleswaran Karani;* [3]*Hida, Moustapha;* [4]*Squali Houssaini, Fatima Zahra.*

[1]Higher Institute of Nursing Profession and Techniques of Health; [2]Prf. Nutrigenitic. Hugh Sinclair Unit of Human Nutrition and Institute for Cardiovascular and Metabolic Research. Department of Food and Nutritional Sciences. University of Reading. UK.; [3]Prf, Head of Pediatrics. Faculty of Medicine. Paediatrics Ward Hassan II. University Hospital. Morocco.; [4]Prf. Biochemist. Faculty of Sciences. Biology Department. Biochemistry Laboratory. Nutritional Biochemistry Unit. Morocco.

Background and objectives: Protein-energy malnutrition is a major cause of mortality among young children in Africa hospital. objective was to assess the outcome of children with protein-energy malnutrition after treatment by World Health Organization guidelines.

Methods: Eighty-three children with protein-energy malnutrition (PEM) and aged from 6-60 months were admitted to the paediatric service in University Hospital Hassan II, Fez, Setting: The study was carried out in the paediatric service at Hassan II University Hospital, Fez, Morocco, from 1 January 2002 to 30 July and 30 July 2005. Eighty-three children with protein-energy malnutrition (PEM) and aged from 6-60 months were admitted to the paediatric service in University Hospital Hassan II, Fez, Morocco, from 1 January 2002 to 30 July and 30 July 2005. Children were divided in two groups oedematous malnutrition (OM) and non-edematous malnutrition (NM). The main outcomes measures were the recovery rate, relapse post-discharge and rate death during treatment. All children received nutrition rehabilitation by using the World Health Organization protocol during 21days.

Dietary treatment was based on using a formula-fed (Guigoz 2) containing 498kcal/100g of energy, 9.9g/100g of protein and 23.5g/100g of fat. At initial phase we begin with energy density of 75Kcal/kg/day and 1.2g/kg/day of protein without stopping both breast-feeding and oral micronutrient supplement. At rehabilitation phase the energy dens 100-150Kcal/kg/day and 3g/kg/day of protein were used. A plasma concentration of CRP, AAG and Hemoglobin were assessed.

Results: The overall case fatality rate was 13(15.66%) split between the NM with (6.02%) and OM with a rate of 9.63% early death and late death. The recovery rate was (84.33%) and the relapse rate post-discharge was lower (4.81%). Overall rate recovery was divided among 38(45.78%) in the non-edematous group and 32(38.55%) in the oedematous. The overall weight gain was 7.16±0.62 and 58.57% gained over 5g/kg/day. 70.73% of oedamtous malnutrition gained over.

Conclusions: Despite the case fatality rate above target levels <5% of WHO, the use WHO guidelines provided an acceptable level of care indicated by high recovery rate (84.33%), lower relapse post-discharge 4(4.81%) and over half of children (58.57%) had weight gain >5g/kg/day.

CARDIOVASCULAR RISK IN CHILDREN AND ADOLESCENTS WITH CEREBRAL PALSY

[1]*Barja, Salesa;* [2]*Le Roy, Catalina;* [3]*Sepúlveda Flores, Cecilia;* [4]*Guzmán, María Luisa;* [5]*Olivarez, Maritza;* [6]*Figueroa, María José.*

[1]MD. MSc Pediatric Nutrition. Josefina Martinez Hospital. Division of Pediatrics. Faculty of Medicine. Pontificia Universidad Católica de Chile.; [2]MD. Pediatrician. Division of Pediatrics. Faculty of Medicine. Pontificia Universidad Católica de Chile.; [3]RD. Dietitian. NINEAS Program. Padre Hurtado Hospital. Medicine Faculty. Universidad del Desarrollo. Chile.; [4]Nurse. Center of human genetics. Medicine Faculty. Universidad del Desarrollo. Padre Hurtado Hospital. Chile.; [5]Nurse. NINEAS Program. Sótero del Río Hospital. Chile.; [6]MD. MSc Pediatric Nutrition. NINEAS Program, Sótero del Río Hospital. Chile.

Background and objectives: Patients with Cerebral Palsy (CP) have a growing prevalence of overweight but evidence of associated cardiovascular risk factors is scarce.

Aim: To study metabolic complications of obesity in CP children and adolescents and look for an association to different conditions.

Methods: Cross-sectional study in 69 children with CP, under follow-up in units of special health care needs children (CSHCN) from two Public Hospitals (Padre Hurtado and Sótero del Rio, in Santiago, Chile). Demographic data were obtained, Anthropometry was performed (Brooks 2011 reference), gross motor function classification system (GMFCS) was applied and a fasting sample for measuring plasma triglycerides (TG), total cholesterol (TC), glycaemia (Gli) and insulinemia was obtened. HOMA index was

calculated. Frequency and association analysis of metabolic parameters with age, sex, neonatal history, nutritional status, GM-FCS, use of anticonvulsant drugs were studied. Approved by ethics SSMSO Committee, parents signed an informed consent.

Results: 69 patients were included, of 11.1 + 4.9 years old, 62.3% were boys. Motor function: 81.2% grade IV-V, 50.7% with enteral feeding, 83.9% receiving anticonvulsant treatment. Nutritional status (BMI /Age): 15.4% (Percentile, Pc<10), 73.8% (Pc10-75) and 10.8% (> Pc75). Metabolic parameters: 5.8% had CT≥200mg/dL, 20.3% TG≥110 or 130 mg/dL (according to age), 4.3% Gli≥100 mg/dL and 18.8% HOMA≥3. Children with a BMI > Pc90 had higher TC (ANOVA; p = 0.05), with a direct correlation between BMI and CT (Spearman, R=0.11, p = 0.036). Girls and patients with anticonvulsants had a higher prevalence of insulin resistance (p = 0, 001 and p = 0, 023) and those with less mobility, a higher prevalence of elevated TG (Chi2, p = 0.032).

Conclusions: The prevalence of hypercholesterolemia, hypertriglyceridemia and insulin resistance was high in this sample of children with CP; Hypercholesterolemia was associated with overweight, hypertriglyceridemia with immobility and insulin resistance was more frequent in girls and users of anticonvulsants.

RELATIONSHIP BETWEEN BODY MASS INDEX AND DECLINE OF COGNITIVE FUNCTION IN MIDDLE-AGED AND ELDER OBESE AND OVER-WEIGHT POPULATION

[1]Ma, Weiwei; [2]Yuan, linhong; [2]Yu, Huanling; [2]Yang, Chun; [2]Xiao, Rong.

[1]Department of nutrition and Food hygiene, School of Public Health, Capital Medical University; Beijing, China [2]School of Public Health, Capital Medical University. Beijing, China.

Background and objectives: The correlation between body mass index (BMI) and cognitive function remains controversial. This study aimed to compare the cognitive function among normal weight, overweight and obese population and to explore the relationship between obesity and cognitive impairments in the midlife obese and overweight people in China.

Methods: A total of 676 adults, aged from 35 to 60, were recruited from Beijing, China. The mini-mental state examination (MMSE) and montreal cognitive assessment scale (MoCA) were carried out to assess the cognitive function of the subjects. We then compared the cognitive function among healthy, overweight and obese population using covariance analysis. The correlation between BMI and risk of cognitive impairments was assessed using the partial correlation, linear regression and multiple logistic regression models.

Results: No significant differences in MMSE and MoCA scores and scores of all domains in males among different BMI groups (p>0.05). However, in females, the MMSE score, language ability and language use ability were obviously different in different BMI groups (p<0.05) and the MoCA score, attention and abstract thinking ability were also different among groups (p<0.05). The partial correlation analysis revealed that hip circumference was negatively correlated with language skills (p<0.05), that the waist-to-hip ratio was negatively correlated with orientation but positively associated with language skills (p<0.05), and that BMI had a negative correlation with both memory and language skills (p<0.05) in the MMSE scale. In the MoCA scale, the wasit circumference was negatively correlated with orientation but positively associated with delayed memory (p<0.05); the hip circumference was positively associated with delayed memory (p<0.05); the waist-to-hip ratio was negatively correlated with both orientation and thinking ability (p<0.05). A cross-sectional linear correlation between BMI and MMSE and MoCA scores was established in females in a univariate linear regression analysis. In a univariate logistic regression analysis, a linear correlation between BMI and MMSE and MoCA scores was found in females. In multivariate logistic regression analysis, BMI was only correlated with MMSE score in women.

Conclusions: Overweight and obesity were associated with higher risk of cognitive decline among midlife population in China.

Keywords: overweight, obesity, cognitive function, body mass index, The mini-mental state examination, montreal cognitive assessment scale

BODY COMPOSITION OF PEOPLE LIVING WITH HIV/AIDS WITH CLINICAL DIAGNOSES OH HIV-RELATED LIPODYSTROPHY SYNDROME

[1]Justina Papini, Silvia; [2]Sacilotto, Lívia Bertazzo; [3]Mendes, Adriana Lúcia; [4]Corrente, José Eduardo; [5]Manechini, João Paulo Vieira; [6]Pereira, Paulo Câmara Marques.

[1]PhD. Nutritionist. Department of Nursing. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [2]MD. Nutritionist. Department of Tropical Disease and Imaging Diagnosis. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [3]PhD professor. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [4]Adjunct professor. Department of Bioestatisc. São Paulo State University (UNESP). Institute of Biosciences. Botucatu. Brazil.; [5]MD student. University of São Paulo (USP), Ribeirao Preto Medical School, Brazil; [6]Adjunct professor. Department of Tropical Disease and Imaging Diagnosis. São Paulo State University (UNESP). Botucatu Medical School. Brazil.

Background and objectives: People living with HIV/AIDS (PLHA) may develop body composition alterations (or HIV-associated lipodystrophy syndrome - HALS), with body fat redis-

tribution related or not to metabolic alterations, classified among: lipohypertrophy (fat accumulation on abdominal area and/or localized), lipoatrophy (fat reduction in peripheral regions) and mixed lipodystrophy (association of both). The purpose was to characterize PLHA with HALS diagnoses according to their subtype, clinical-metabolic profile and body composition.

Methods: The study was observational and transversal, with its sample selected by convenience and performing clinical immunological characterization, anthropometric assessment, nutritional diagnosis, body composition of PLHA with a clinical HALS diagnosis from July 2015 to July 2016, in regular ART use for at least a year, ranging from 18 to 60 years old.

Results: Forty individuals were distributed equally by gender, with age of 45,5 ± 8,2 years, diagnostic time of 15,3 ± 6,2 years and antiretroviral therapy usage time of 13,8 ± 5,7 years. HALS mixed form was the most prevalent (n = 17; 42,5%). There was significant difference for TCD4+ cell counting (p=0,0115) when comparing mixed form and lipohypertrophy groups. The main differences found among subtypes are related to body composition and anthropometric measures: body mass index, abdominal and neck circumference comparing mixed form and lipohypertrophy groups (p = 0,0007; p = 0,0018; and p = 0,0062, respectively), as well as between mixed form and lipoatrophy groups (p < 0,0001; p < 0,0001; and p = 0,0019, respectively). Concerning body composition differences were observed for all analyzed parameters: lean body mass was different between mixed form and lipohypertrophy groups (p = 0,0252); fat body mass and percent of fat body mass were different between lipoatrophy and lipohypertrophy groups (p = 0,0008 for both variables); fat visceral area values were different both between mixed form and lipohypertrophy groups (p = 0,0025) and between lipoatrophy and lipohypertrophy (p < 0,0001).

Conclusions: The diagnoses, sub-classification and identification of metabolic alterations are important as specific strategies may be elaborated, since the body changes detected reaffirm that HALS must not be seen as an unique syndrome, but as three different impairments that should be managed in particular ways.

Keywords: People living with HIV/aids, lipodystrophy, body composition, metabolic syndrome.

TRIMETHYLAMINE N-OXIDE AGGRAVATES HEPATIC STEATOSIS THROUGH UP-REGULATION OF BILE ACIDS SYNTHESIS AND ACTIVATION OF ENDOGENOUS HEPATIC FARNESOID-X-RECEPTOR

[1]Zhu, Hui-lian Zhu; [2]Zhu, Hui-lian Zhu.

[1]PhD, Department of Nutrition, School of Public Health, Sun Yat-sen University, People's Republic of China; [2]PhD, Nutritionist, Department of Nutrition, School of Public Health, Sun Yat-sen University, People's Republic of China.

Background and objectives: Trimethylamine-N-oxide (TMAO), a gut-flora-dependent metabolite of choline, is associated with cardiovascular diseases and bile acids (BAs) metabolism. BAs played a critical role in lipid metabolism and increased plasma BAs level was found in NAFLD patients. The aim of this study was to identify potential interactions between TMAO and BAs metabolism in NAFLD.

Methods: We performed a case control study including 60 biopsy-proven NAFLD cases and 35 controls. Serum TMAO and BAs concentrations were quantified by high-performance liquid chromatography with online electrospray ionization tandem mass spectrometry (HPLC-MS/MS). The associations of TMAO and BAs with pathological progress of NAFLD were studied by covariance and receiver operating characteristic (ROC) calculation was used to elaborate the predictability of NAFLD. Male C57BL/6 mice were fed either a high-fat diet (HFD) or HFD supplemented with 0.2% TMAO in water (wt/vol) for 18 weeks. Serum biochemical parameters and genes expression were quantified and compared between groups.

Results: In the case control study, median serum TMAO level was 2.02μM (interquartile range, 1.15, 3.18) and median serum BAs level was 8.70μM (interquartile range,5.84, 12.79μM) in NAFLD patients, which were significantly higher than controls (median[interquartile range]: 0.98[0.33, 1.57]μM, 6.34[4.20, 8.63] μM, serum TMAO and BAs levels respectively). Higher scores for steatosis, inflammation and NAFLD activity were associated with greater ln-transformed levels of TMAO and BAs (all P trend <0.05). To predict NAFLD versus control, area under the ROC of serum TMAO and BAs combination was 0.767 (P<0.001). The mRNA expression of the key BAs synthetic enzyme cholesterol 7 alpha-hydroxylase (Cyp7a1) was significantly higher in NAFLD patients while the mRNA level of BAs transporters remained unchanged. In the animal study, TMAO supplemented accentuated hepatic steatosis and upregulated the mRNA levels of lipogenesis genes. Hepatic BAs level and the expression of Cyp7a1 were significantly increased in TMAO supplemented group. Increased hepatic BAs activated farnesoid-X-receptor (FXR) and resulted in the elevation of fatty-acid synthase expression.

Conclusions: Serum TMAO and BAs levels were elevated in NAFLD patients and positively correlated with disease severity in NAFLD. TMAO aggravated hepatic steatosis through up-regulation BAs synthesis and activation of FXR.

BODY COMPOSITION, ANTHROPOMETRIC MEASURES AND CLINICAL-NUTRITIONAL PARAMETERS OF PEOPLE LIVING WITH HIV/AIDS WITH CLINICAL DIAGNOSES OF HIV-ASSOCIATED LIPODYSTROPHY SYNDROME SUBDIVIDED BY GENDER

[1]Sacilotto, Lívia Bertazzo; [2]Pereira, Paulo Câmara Marques; [3]Mendes, Adriana Lúcia; [4]Corrente, José Eduardo; [5]Manechini, João Paulo Vieira; [6]Justina Papini, Silvia.

[1]MD. Nutritionist. Department of Tropical Disease and Imaging Diagnosis. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [2]Adjunct professor. Department of Tropical Disease and Imaging Diagnosis. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [3]PhD professor. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [4]Adjunct professor. Department of Bioestatisc. São Paulo State University (UNESP). Institute of Biosciences. Botucatu. Brazil.; [5]MD student. University of São Paulo (USP), Ribeirao Preto Medical School, Brazil; [6]PhD. Nutritionist. Department of Nursing. São Paulo State University (UNESP). Botucatu Medical School. Brazil.

Background and objectives: HIV-associated lipodystrophy (HALS) is characterized by morphological changes due to fat tissue heterogeneous disorders, with body fat redistribution associated or not to metabolic alterations. Such alterations are consequences of the chronic inflammatory state due the viral infection and the usage of specific therapy to treat the sickness. The HALS is described as a syndrome which consider the fat loss and/or accumulation, classified in three subtypes. The impairments due these metabolic and morphological alterations go beyond esthetic consequences, once there may be an increased risk to the development of other disturbances, such as the Metabolic Syndrome. Considering the existence of body composition differences per gender, the objective of the present study was to verify, among genders, the clinical-nutritional and anthropometric differences of people living with HIV/AIDS (PLHA) with clinical diagnoses of HALS.

Methods: The study was observational and transversal, with its sample selected by convenience and performing clinical immunological characterization, anthropometric assessment, nutritional diagnosis, body composition of PLHA during the follow-up of specialized outpatient service in infectiology with a clinical HALS diagnosis from July 2015 to July 2016, in regular antiretroviral

therapy use for at least a year, ranging from 18 to 60 years old. Pregnant women, people with chronic kidney failure, nephrotic syndrome, B and C virus chronic infection, uncontrolled hypothyroidism were excluded from the study.

Results: Forty individuals were distributed equally by gender, with age of 45,5 ± 8,2 years, diagnostic time of 15,3 ± 6,2 years and antiretroviral therapy usage time of 13,8 ± 5,7 years. The results showed significant difference on lipid profile to female gender, with increased values, except for HDL-cholesterol. No statistical differences were observed for fasting blood glucose and clinical-immunological parameters between genders.

Conclusions: Despite the lack of differences, body fat and anthropometric indicators presented higher alterations among women living with HIV/AIDS. Lipid profile significant alterations and high body fat values (even without statistical significance) among women suggests an increased risk for cardiovascular diseases when compared to men in the aforementioned population, highlighting the importance to adopt different follow up strategies for those patients.

GLYCEMIC INDICES OF STANDARDIZED TRADITIONAL COCOYAM AND CORN BASED DISHES CONSUMED IN NSUKKA LOCAL GOVERNMENT AREA OF ENUGU STATE, NIGERIA

[1]Davidson, Gloria; [2]Ene-Obong, Henrietta.

[1]PhD. Nutritionist. Department of Home Science, Nutrition and Dietetics. University of Nigeria. Nsukka; [2]PhD. Department of Biochemistry (Nutrition and Dietetics Unit). University of Calabar. Cross.

Background and objectives: Glycemic index (GI) is an important parameter of food quality that compares the hypoglycemic effect of a test meal with pure glucose. Low glycemic index diets have been recommended for diabetics. There is however scarcity of data on the glycemic index of traditional Nigerian diets. The study was to determine the glycemic indices (GIs) of standardized cocoyam and corn based traditional dishes consumed in southern Nigeria.

Methods: Focus group discussions were conducted in eight randomly selected communities in Nsukka LGA to document the variations of each dish and their recipes. These were standardized and prepared. Proximate compositions of the prepared dishes were determined using standard procedure. A serving portion of each dish containing 50g of available carbohydrate was served to ten healthy adult subjects. Glucose was used as the reference food. The postprandial blood glucose response of the test and the reference meals were measured over two hours at 30 minutes interval. Blood glucose curves were plotted, area under each curve

and corresponding glycemic index value for each dish determined. Data were analyzed using Statistical Product for Service Solution (SPSS). Analysis of variance was used to compare the means.

Results: Three variations of cocoyam-based dishes were documented: "achicha"(dried cocoyam chips, soaked and steamed) with pigeon pea", "achicha" with fresh "akidi"(fresh cowpea pod) and "achicha" with vegetable (Solanum melongena). The corn-based dish had two variations: "ayaraya oka"(coarsely ground soaked, steamed corn) with pigeon pea" and "ayaraya oka" with fresh "akidi". The dishes had appreciable proximate composition though the protein content of the cocoyam based dishes were low 0.7 – 1.0%. The GIs of the cocoyam based dishes were within the range of 38.7 and 78.1 being highest in "achicha with vegetable (78.1) and lowest in "achicha" with fresh "akidi" (38.7). "Ayaraya oka" with fresh "akidi" also had lower GI (51.0) when compared with "ayaraya oka" with pigeon pea (75.3).

Conclusions: "Achicha" with fresh cowpea pod and "ayaraya oka" with fresh cowpea pod had low and moderate glycemic indices, respectively and could be recommended for diabetics.

Keywords: Traditional dishes, glycemic index, diabetics, variation, Nigeria

NEUROPROTECTIVE EFFECTS OF VITAMIN D VIA THE MODULATION OF NLRP3 INFLAMMASOME ACTIVATION

[1]Wu, ChHao; [2]Kung, Ming-Ya; [3]Shen, Szu-Chuan; [4]Lin, Shih-Xiang; [4]Jhang, Yu-Yuan.

[1]PhD; [2]MS. School of Nutrition & Health Sciences, Taipei Medical University. Taiwan; [3]PhD. Department of Human Development and Family Studies, National Taiwan Normal University. Taiwan; [4]Department of Human Development and Family Studies, National Taiwan Normal University. Taiwan.

Background and objectives: Ischemic stroke (IS) accounts for approximately 70% of the total cases of strokes. Accumulating evidence suggests that inflammasome is involved in the pathogenesis of IR by regulating proinflammatory cytokine interleukin-1β (IL-1β) secretion following tissue ischemia. According to the link between stroke severity and vitamin D status has been clinically proven in studies. The object of this study was to investigate the neuroprotective effect of vitamin D on cerebral ischemia-reperfusion (IR) injury and the possible mechanism of action.

Methods: Eight-weeks-old male Sprague-Dawley rats were assigned to (1) control group (sham), (2) ischemia/reperfusion group (I/R) (3) vitamin D deficiency group (VDD), and (4) vitamin D supplements group (VDS). Transient cerebral ischemia was induced in rats by middle cerebral artery occlusion (MCAO) for 1 h followed by reperfusion to investigate the effect of vitamin D on brain IR injury. Cerebral infarct volume, and the levels of oxidative stress and inflammatory markers were evaluated.

Results: Results showed that vitamin D deficiency exacerbated the severity of brain damage, and the levels of IL-1β and lipid per-

oxidation. By contrast, intraperitoneal administration of vitamin D improved the brain injury and these results were accompanied by attenuated NLRP3 inflammasome signaling.

Conclusions: In conclusion, vitamin D might reduce cerebral ischemic-reperfusion injury, possibly via it anti-inflammatory activity.

Keywords: Ischemic stroke, vitamin D, inflammasome, oxidative stress, IL-1β

BODY COMPOSITION PROFILES AND METABOLIC DISEASE RISK PATTERNS IN NEW ZEALAND WOMEN - THE WOMEN'S EXPLORE STUDY

[1]Kruger, Rozanne; [2]Whitford, Amanda; [3]Richter, Marilize; [3]Breier, Bernhard.

[1]PhD. Dietitian. School of Food and Nutrition. Massey University. New Zealand.; [2]MSc. Student. School of Food and Nutrition. Massey University. New Zealand.; [3]PhD. School of Food and Nutrition. Massey University. New Zealand.

Background and objectives: In New Zealand, 31.6% of adults are obese. Significant ethnic inequalities exist where Pacific Islanders and Māori have the highest rates. Despite the association between obesity and metabolic dysfunction, there is limited research comparing body composition and metabolic health status for these groups. Understanding how their body composition relates to metabolic health will be an important part of determining avenues for improving the associated health inequalities. The aim of this study was to investigate the body compositional and metabolic health profiles of healthy NZ European, Pacific and Māori women participating in the women's EXPLORE study, and to identify ethnic specific patterns between these profiles.

Methods: In this cross sectional study we recruited 233 European, 91 Pacific and 84 Māori women. Different body mass index (BMI) and body fat % (BF%) defined body composition profiles were analysed for anthropometric measurements, body fat location, and metabolic biomarkers.

Results: Obese (BF%) Māori women had higher android fat mass than obese (BF%) NZ European women (2.53kg vs 2.23kg), with no difference in waist circumference. Non-obese (BMI) Māori women had higher waist circumference than non-obese (BMI) NZ European women (78cm vs 73.5cm) with android fat differences. Regardless of body composition grouping, no ethnic differences were found for BF%. Obese Pacific women had higher HOMA-IR (5.12-5.45) and insulin (24.28-23.28mU/L) than obese NZ Europeans (2.10-2.61 and 10.07-11.24mU/L respectively), as did obese Māori women (3.64-4.35 and 16.76-19.41mU/L respectively). Body composition measures with highest sensitivity across all biomarkers assessed were BF% ≥30 for NZ European, both BF% ≥30 and BMI ≥25 for Pacific, and BMI ≥25 for Māori women respectively.

Conclusions: Māori and Pacific women had significantly higher glucose metabolism markers than NZ Europeans despite

no differences in BF%. When comparing Māori to NZ European women, a higher waist circumference was not always related to a higher android fat mass or vice versa, suggesting that WC may not be an accurate representation of abdominal fat for Māori women. In spite of ethnic differences, BF% ≥30 and BMI ≥25 appear most sensitive to detect high biomarkers compared to abdominal measurements.

EFFECT OF INTRAVENOUS IRON SUCROSE ADMINISTRATION ON LEVEL OF ANTIOXIDANT STRESS MARKERS AMONG MODERATELY ANEMIC PREGNANT WOMEN ATTENDING A SUB-DISTRICT HOSPITAL, HARYANA

[1]Kant, Shashi; [2]Jacob, Olivis; [2]Haldar, Partho; [2]Kaur, Ravneet; [2]Dadwal, Vatsala.

[1]MD. Professor. CCM. AIIMS. New Delhi. India; [2]AIIMS. New Delhi. India

Background and objectives: Oxidative stress is known to increase during pregnancy, and also after supplementation of iron. The free iron particles released into blood following iron administration are known to produce Reactive Oxygen Species (ROS) which could lead to destruction of cells. We measured the level of antioxidant stress markers following administration of intravenous iron sucrose (IVIS) to moderately anemic pregnant women.

Methods: A total of 66 women in 2ndor 3rd trimester of pregnancy with moderate anemia (Haemoglobin level between 7.0-9.9 gm/dL) attending a Sub District Hospital, Ballabgarh, Haryana were recruited. Total iron requirement was calculated using Ganzoni's formula. IVIS was administered as 300mg in 300mL of Normal Saline over 30 minuteson alternate days till complete dose. Antioxidant stress markers were measured at the time of recruitment (baseline) and 4 weeks after the last dose of IVIS (endline) and included serum malondialehyde (MDA), serum superoxide dismutase (SOD), and ferric reducing ability of plasma (FRAP)

Results: At baseline, mean(SD) levels of MDA, SOD and FRAP were 3.5(0.9) ng/mL, 2.1(0.4) U/mL and 655.9(178.6) μM/L respectively; and the same at endline were 3.1(0.9) ng/mL, 1.6(0.5) U/mL and 761.3(166.4) μM/L respectively. Paired follow-up information was available for 37, 39, and 39 women for MDA, SOD and FRAP respectively. Mean(SD) for MDA, SOD and FRAP changed from 3.3(0.9) ng/mL, 2.2(0.4) U/mL and 679.3(188.8) μM/L at baseline and to 3.1(0.9) ng/mL, 1.6(0.5) U/mL and 745.4(166.7) μM/L respectively; and with p values 0.6009, <0.001, and 0.1284 respectively. No serious adverse effects occurred during the study period

Conclusions: A significant decline in the level of SOD was seen at four weeks after IVIS administration. There was no significant change in the levels of MDA and FRAP after the admin-istration of IVIS. Hence, IVIS could be a safe alternative for the management of moderate anemia in pregnancy

FRACTIONS FROM RUELLIA TUBEROSA L. EXTRACT IMPROVES GLUCOSE UPTAKE IN TNF-A INDUCED INSULIN RESISTANT MOUSE FL83B HEPATOCYTES

[1]Wu, ChHao; [2]Jhang, Yu-Yuan; [3]Shen, Szu-Chuan; [4]Huang, Wei-Jan; [2]Wu, Pei-Chin; [2]Tu, Meng-Shiuan; [2]Lin, Shih-Shiang; [5]Chang, Wen-Chang; [5]Ting, Yu-Wen; [5]Wu, James Swi-Bea.

[1]PhD. Department of Human Development and Family Studies, National Taiwan Normal University; [2]Department of Human Development and Family Studies, National Taiwan Normal University; [3]PhD. Department of Human Development and Family Studies, National Taiwan Normal University; [4]Graduate Institute of Pharmacognosy, Taipei Medical University, Taiwan.; [5]Graduate Institute of Food Science and Technology, National Taiwan University.

Background and objectives: Diabetes mellitus (DM) is characterized by insulin resistance, caused by inadequate production of insulin or by the ineffectiveness of insulin activity. Ruellia tuberosa L. (RTL) is a plant herb and has been used as folk medicine for the treatment of diabetes in Asian countries for decades. The previous study confirmed that ethyl acetate extract of RTL possesses hypoglycemic potential in diabetic rabbits. However, the detail mechanism was still unclear. The aim of this study was to investigate the effect of the ethyl acetate fraction (EAF) from RTL methanol extract on cytotoxicity and glucose uptake in tumor necrosis factor-alpha (TNF-α) induced insulin resistant mouse FL83B hepatocytes.

Methods: RTL was first extracted with methanol, and followed by partitioned with n-hexane and ethyl acetate, respectively. The ethyl acetate layer was then isolated into eight fractions by sephadex LH20 column chromatography. The EAF containing eluents were collected and lyophilized to be powder samples. MTT assay was conducted to measure the cytotoxicity of EAF in FL83B cells. EAF was further co-incubated with TNF-α treated FL83B cells, and flow cytometry was used to assess glucose uptake ability in cells.

Results: The results showed that no significant cytotoxicity effect was observed for eight EAFs at the concentration of 25 μg/ml in FL83B cells. Moreover, EAF2, EAF3, EAF5 significantly enhances the uptake of 2-NBDG in TNF-α treated FL83B cells.

Conclusions: In conclusion, the present study suggests that RTL may alleviate insulin resistance without cytotoxicity and has potential for developing into anti-diabetic drugs or dietary supplements.

EFFECT OF CONSUMING PRELOADS WITH DIFFERENT ENERGY DENSITY (LOW VS. HIGH) AND TASTE QUALITY (SAVOURY VS. SWEET) ON POSTPRANDIAL BLOOD GLUCOSE AND ENERGY INTAKE

(1)Forde, Ciaran; (2)Tey, Siew Ling; (2)Henry, Jeyakumar; (2)Forde, Ciaran.

(1)Clinical Nutrition Research Center, A*STAR Singapore Institute for Clinical Sciences, Department of Physiology, Yong Loo Lin School of Medicine, National University of Singapore; (2)Clinical Nutrition Research Centre, A*STAR Singapore Institute for Clinical Sciences, Singapore.

Background and objectives: Consumption of reduced energy dense foods and drink has potential to reduce energy intakes and reduce postprandial blood-glucose concentrations. Recent studies suggest a meals taste quality (e.g. savoury/sweet) may play a role in satiation and food intake. This study sought to examine the effect of consuming preloads with different energy density (low or high) and taste quality (savoury or sweet) on postprandial blood glucose response and energy intake.

Methods: Thirty-two healthy lean males participated in a randomised crossover study with four treatments: low energy dense sweet preload (50kcal), higher energy dense sweet preload (248kcal), low energy dense savoury preload (58kcal), and higher energy dense savoury preload (256kcal). On each test day, participants consumed a standardised breakfast in the morning and later received one of the study preloads an hour before eating an ad libitum lunch. Blood glucose concentrations were measured at baseline (just before preload) and 15, 30, 45, 60, 90, 120, 150, and 180 minutes after consumption. Participants left the lab 3-hours after preload consumption and completed a food diary for the rest of the day.

Results: There was a significant difference in ad libitum lunch intake between treatments (P = 0.012) with higher intake in sweet LED (763kcal) and savoury LED (762kcal) compared to sweet HED (722kcal) and savoury HED (693kcal). Energy intake at subsequent meals was not significantly different between the treatments (P = 0.284). The total daily energy intake was 2056kcal for sweet LED, 2197kcal for sweet HED, 2171kcal for savoury LED, and 2194kcal for savoury HED. The glucose response over three-hour period was 249mmol/L.min for sweet LED, 355 mmol/L.min for sweet HED, 253mmol/L.min for savoury LED, and 328mmol/L.min for savoury HED, representing a significant difference between treatments (P < 0.001).

Conclusions: Participants compensated primarily for energy differences and were less influenced by taste quality. Participants compensated for the energy in savoury LED preload, but not the energy in sweet LED preload. Consumption of high energy dense preloads resulted in a larger spike in postprandial glucose response compared with low energy dense preloads, irrespective of taste quality. Potential mechanisms and reasons for these differences will be discussed.

Keywords: Energy density. Taste. Glycaemic response. Energy intake

EFFECT OF WATER SUPPLEMENTATION ON COGNITIVE PERFORMANCES AND MOOD AMONG MALE COLLEGE STUDENTS IN CANGZHOU, CHINA

(1)Zhang, Na; (2)Du, Songming; (3)Ma, Guan-Sheng.

(1)National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention; (2)PhD. Chinese Nutrition Society. China.; (3)PhD. Department of Nutrition and Food Hygiene. School of Public Health. Peking University. China.

Background and objectives: The effect of water-supplementation on cognitive performances was investigated.

Methods: Totally 68 male college students aged 18-25 years were randomly assigned into water-supplementation (WS) and no water-supplementation (NW) group. In the test day, urine osmolality, thirst, cognitive performances and mood were measured before water-supplementation. Then, subjects in WS group were asked to drink 400 mL purified water within 5 minutes. One hour later, same tests were measured. Mixed model of repeated measures analysis of variance were analyzed.

Results: Water-supplementation has effect on dehydration, Z = -2.63, P = 0.0086, with percentage of dehydration in NW group increased 5.8% without statistically significance, whilst decreased 50% in WS group, χ^2 = 17.752, P = 0.000. There were also interactions on fatigue, depression, vigor and TMD (total mood disturbance) between time and group, $F_{(1, 61)}$ = -4.93, P < 0.0001, $F_{(1, 61)}$ = -2.06, P = 0.0438, $F_{(1, 61)}$ = 5.56, P < 0.0001, $F_{(1, 61)}$ = -2.16, P = 0.0346. Significant interactions effect on total score of digit span, digit span forward and backward were found between time and group, $F_{(1, 61)}$ = 4.27, P < 0.0001, $F_{(1, 61)}$ = 2.26, P = 0.0275; $F_{(1, 61)}$ = 3.24, P = 0.0019. The total score of NW group decreased 0.03 without statistically significance, whilst increased 1.53 in WS group after water-supplementation, t (29) = -3.64, P = 0.0011.

Conclusions: In conclusion, water-supplementation has beneficial effect on hydration status, short-term memory, fatigue, depression, vigor and TMD among male college students.

Keywords: Hydration; Water supplementation; Cognitive performances

EFFECTS OF DJULIS (CHENOPODIUM FORMOSANUM) ON COLITIS-ASSOCIATED COLON CANCER IN RATS

[1]Shih, Chun-Kuang; [2]Huang, Pin-Yu; [2]Chien, Yu-Hua.

[1]PhD. Associate Professor. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan.; [2]MD. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan.

Background and objectives: Colon cancer is a disease closely associated with diet and inflammation. Many studies have indicated that high consumption of whole grains may decrease the risk of colon cancer. Djulis (Chenopodium formosanum), a native cereal crop in Taiwan, is rich in betalains, polyphenols and dietary fiber. Previous studies showed that betalains in djulis had an anti-oxidative effect and both polyphenols and dietary fiber had anti-inflammation and anti-tumor activities. This study investigated the effect of djulis on colitis-associated colon cancer and its related mechanisms.

Methods: Experimental colitis-associated colon cancer was induced in F344 rats injected with 3 doses of 1,2-dimethylhydrazine (DMH, 40 mg/kg BW, i.p) during the first week and then fed with dextran sulfate sodium (DSS, 3% in drinking water) for 7 days. Djulis-treated groups were given AIN-93G diet containing 5, 10 or 20% djulis. Animals were sacrificed after 10 weeks of experimental period and colons were collected for analyses of preneoplastic lesions and inflammatory markers.

Results: Djulis at 5, 10 and 20% levels significantly decreased the numbers of aberrant crypt foci (ACF) and sialomucin-producing ACF (SIM-ACF). Mucin depleted foci (MDF), an advanced preneoplastic lesion of colon cancer, were also inhibited by djulis treatment. Furthermore, djulis at 5, 10 and 20% levels significantly decreased the expression of cyclooxygenase-2 (COX-2) in colonic mucosa.

Conclusions: Djulis may suppress the progression of colitis-associated colon cancer by reducing the formation of preneoplastic lesions and the expression of pro-inflammatory protein.

Keywords: djulis, colon cancer, aberrant crypt foci, mucin depleted foci, inflammation

COMBINATION OF LACTOBACILLUS ACIDOPHILUS AND DJULIS REDUCED EARLY LESIONS OF COLON CANCER IN RATS

[1]Shih, Chun-Kuang; [2]Chien, Yu-Hua; [2]Huang, Pin-Yu.

[1]PhD. Associate Professor. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan.; [2]MSc. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan.

Background and objectives: Colorectal cancer is the third commonly diagnosed cancer worldwide. Dietary pattern is strongly associated with cancer risk. Previous studies showed that synbiotics had an inhibitory effect on colon cancer. Djulis (Chenopodium formosanum) is a native cereal crop planted in Taiwan. It has been reported that djulis contains high level of prebiotic dietary fiber. The aim of this study was to investigate the anti-cancer effect of Lactobacillus acidophilus and djulis on 1,2-dimethylhydrazine (DMH)/dextran sulfate sodium (DSS)-induced colon cancer in a rat model.

Methods: Rats were randomized into 5 groups: B (AIG-93G), C (AIN-93G), D (10% djulis), DLA (10% djulis plus 0.083 g/kg of L. acidophilus) and DHA (10% djulis plus 0.83 g/kg of L. acidophilus). All rats except those in group B were given three i.p. injections of DMH (40 mg/kg) and 3% DSS in drinking water after DMH injection for one week. All rats were sacrificed after 10 weeks of feeding and colons were examined for cancer-related lesions and markers.

Results: D, DLA and DHA significantly increased the weights of cecum and its content compared with B and C. DMH/DSS treatment induced the formation of preneoplastic aberrant crypt foci (ACF), especially in the distal colon. D, DLA and DHA significantly decreased the numbers of ACF and sialomucin-producing ACF in the distal colon compared with C. In addition, DLA and DHA significantly decreased the expression of proliferating cell nuclear antigen (PCNA) in colons.

Conclusions: Combination of Lactobacillus acidophilus and djulis as synbiotics showed the best inhibitory effect on early lesions of colon cancer.

Keywords: Lactobacillus acidophilus, djulis, synbiotics, colon cancer, aberrant crypt foci

EFFECT OF MATERNAL WEIGHT AND GESTATIONAL WEIGHT GAIN ON LOW GRADE INFLAMMATION DURING PREGNANCY

(1)Kalaimani Rabindrakumar, Miruna Sudharshani;
(2)Wickramasinghe, Pujitha; (3)Arambepola, Carukshi; (4)Karunaratne, Veranja; (5)Thoradeniya, Tharanga.

(1)Department of Biochemistry and Molecular Biology, Faculty of Medicine, University of Colombo; (2)MBBS. DCH. MD. PhD. Professor in Paediatrics. Department of Paediatrics. Faculty of Medicine. University of Colombo. Sri Lanka.; (3)MSc. MD. Senior lecturer. Department of Community Medicine. Faculty of Medicine. University of Colombo. Sri Lanka.; (4)BSc. PhD. Senior Professor. Department of Chemistry. University of Peradeniya. Sri Lanka; (5)PhD. Senior lecturer. Department of Biochemistry and Molecular Biology. Faculty of Medicine. University of Colombo. Sri Lanka.

Background and objectives: Early life exposure to low-grade inflammation has received extensive attention due to its association with developmental programming and neuro-development of offspring. We aimed to study the association between low-grade inflammation, maternal body mass index (BMI) and weight gain during pregnancy.

Methods: A cohort study was conducted among 110 women aged 18-36 years who were apparently healthy and attending the first antenatal community-based clinic in Colombo, Sri Lanka. Women of >12 weeks of gestation and already on nutritional supplements were excluded. To detect low-grade inflammation, high sensitive-C Reactive Protein (hs-CRP) was assessed at recruitment, third trimester (≥34 weeks POA) and at delivery in mother, and in cord blood using sensitive immunoturbidometric assay. Personal information, BMI and weight gain were also recorded at each visit.

Results: At baseline, the mean concentration of hs-CRP in women was 3.4 mg/L. Further, the overweight (BMI >25kg/m2) women had significantly higher mean concentration of hs-CRP (4.7 ± 3.3mg/L) than the normal weight women (2.9 ± 3.1mg/L) (p=0.04).

From baseline, the hs-CPR concentration was increased significantly to 6.1 ± 5.0mg/L by third trimester (p=0.03) and to 9.2 ± 6.2mg/L (p=0.019) at delivery.

The women who gained excessive weight during pregnancy had significantly higher hs-CRP concentration at third trimester (5.9 ± 2.5mg/L; p=0.03) compared to the women with recommended weight gain (3.5±2.8mg/L) by same time point. Similarly, the women who gained excessive weight had a significantly higher hs-CRP concentration at delivery (12.9±7.0mg/L; p=0.019) compared to women with recommended weight gain (7.8±5.4mg/L). The hs-CRP concentrations of cord blood were significantly correlated with mothers' blood at third trimester (Spearmen correlation; r=0.32, p=0.04) and at delivery (r=0.46, p=0.003).

Conclusions: Women with higher BMI at early pregnancy and excess weight gain during pregnancy have an increased tendency towards low-grade inflammation, which may create an inflammatory environment and thereby adverse health outcomes to the fetus.

144/1464

EFFECT OF NUTRIENT QUALITY ON VISCERAL AND SUBCUTANEOUS ADIPOSE TISSUE MASS AND INTRAHEPATIC LIPID ACCUMULATION DURING 12 WEEKS OF ENERGY-RESTRICTION IN ABDOMINAL OBESE MAN AND WOMEN

(1)Mensink, Marco; (2)Schutte, Sophie; (3)Esser, Diederik; (4)Siebelink, Els; (5)Afman, Lydia.

(1)PhD. MD. Assistant Professor. Division of Human Nutrition. Wageningen University. Wageningen. The Netherlands; (2)MSc. PhD-student. Division of Human Nutrition. Wageningen University. Wageningen. The Netherlands; (3)PhD. Post-Doc fellow. Division of Human Nutrition. Wageningen University. Wageningen. The Netherlands; (4)RD. Dietician. Division of Human Nutrition. Wageningen University. Wageningen. The Netherlands; (5)PhD. Assistant Professor. Division of Human Nutrition. Wageningen University. Wageningen. The Netherlands.

Background and objectives: Excessive abdominal fat, e.g. visceral and subcutaneous adipose tissue (VAT and SAT), and intrahepatic lipid (IHL) accumulation are closely associated to insulin resistance and glycaemic control. Weight-loss via energy restriction (ER) results in a reduction in abdominal fat and intrahepatic fat accumulation, but whether enhancing nutrient quality of an ER-diet might further improve this is not well established.

Methods: We examined the additional effects of nutrient quality over ER on abdominal fat distribution and IHL in a 12-week intervention study, in which participants with abdominal obesity were randomized over three groups; a Western-type (WD n=40) or Targeted (TD n=40) 25%ER dietary advice group, or a control group (no advice, no energy restriction; n=30,). VAT and SAT were measured with MRI; IHL was evaluated with 1H MRS. Body weight and metabolic parameters (insulin, glucose and HOMA-IR) were assessed before and after intervention in the fasted state. The Targeted Diet aimed to improve health beyond weight-loss by including MUFA, n-3 PUFAs, soy protein and dietary fibres.

Results: Although the same level of ER was applied in both groups, weight loss was enhanced in the TD (-6.3 and -8.3 kg for WD-ER and TD-ER respectively; p<0.05), while the control group was weight stable. VAT, SAT and IHL were dramatically reduced in both ER groups, with no difference between TD and WD (VAT:-44.1 and -61.5 cm2; SAT:-45.3 and -54.1 cm2;IHL -3.5 and -4.1% of H2O peak for WD-ER and TD-ER respectively. p=NS). Also the VAT/SAT ratio was significantly reduced in both ER-groups, indicating a preferential loss of VAT over SAT, without a clear effect of nutrient quality of the diet. Reductions in VAT and IHL, but not SAT, were strongly correlated with improvements in metabolic parameters, i.e. fasting insulin, fasting glucose and insulin resistance (HOMA-IR).

Conclusions: Energy restriction is the most important factor for reducing abdominal fat and intrahepatic lipid accumulation. There was no additional beneficial effect of nutrient quality on fat accumulation beyond weight-loss. VAT turned out to be more responsive to weight-loss than SAT; and changes in VAT and IHL were associated with improvements in metabolic parameters.

THE ROLE OF YOGHURT FERMENTED BY BIFIDUS ESSENSIS IN THE PREVENTION AND TREATMENT OF OBESITY AND RELATED DISEASES

[1]*Handjieva-Darlenska, Teodora;* [2]*Handjiev, Svetoslav.*

[1]MD, PhD, Department of pharmacology and toxicology, Medical university, Sofia, Bulgaria; [2]MD, PhD, Bulgarian association for the study of obesity and related diseases (BASORD).

Background and objectives: The role of yoghurt, respectively probiotics, in the treatment and prevention of obesity has been discussed. The aim of our study was to investigate the effect of yoghurt fermented by Bifidus essensis (0.5% fat) in the treatment of patients with obesity.

Methods: A total of 57 subjects with central type obesity (21 men and 36 women) were enrolled in the study. Baseline mean subject characteristics were: age-46.2 year old, body mass index (BMI)-35.4, fat mass- 39.4%, visceral fat-14.1, waist circumference-109 cm, hip circumference-120.2, and sagittal diameter-27 cm. All obese patients underwent a dietary regimen, included 290 g yoghurt fermented by Bifidus essensis for dinner for a 6-month period. The product consisted of proteins-4.3 g, carbohydrates (lactose)-3.9 g, fat-0.5 g, and 37 kilocalories per 100 g product. At the beginning and at the end of the study several anthropometric parameters have been measured by bioimpedance device (Tanita 420).

Results: The study demonstrated a decrease of BMI with 9.8%, of fat mass with 9.6%, of visceral fat with 14% as well as a decrease of waist circumference-11.9%, hip circumference-5.8%, and sagittal diameter-10.3%.

Conclusions: The regular consumption of yoghurt fermented by Bifidus essensis (0.5% fat) in the diet of obese patients leads to improvement of the studied anthropometric parameters as well as to significant decrease in the cardio-vascular risk.

Keywords: Yoghurt, obesity, metabolic syndrome

NUTRITION-RELATED CONCERNS OF THE PRIMARY CAREGIVER REGARDING CHILDREN WITH SPASTIC CEREBRAL PALSY: A CROSS-SECTIONAL, QUANTITATIVE RESEARCH STUDY

[1]*Dolman, Robin;* [2]*Lourens, Lucinda;* [3]*Van Graan, Averalda.*

[1]PhD. Dietetics. Centre of Excellence for Nutrition. North-West University. Potchefstroom. South Africa; [2]M.Sc. Dietetics. Centre of Excellence for Nutrition. North-West University. Potchefstroom. South Africa; [3]PhD. Nutrition. South African Medical Research Council, Western Cape, South Africa.

Background and objectives: Parents with children suffering from spastic cerebral palsy (CP) face various challenges regarding their child's health, nutritional status, growth, development and quality of life (QOL). The nutrition-related challenges that these children encounter are not well described in the South African setting. These concerns, its management, current feeding practices and parental perspectives were investigated.

Methods: This cross-sectional, quantitative research study made use of a self-administered, validated questionnaire to obtain information from participants at three various facilities: the Pretoria Centre for Cerebral Palsy (PCCP), the Baby Therapy Centre (BTC) and New Hope School (NHS) situated in the Gauteng Province in South Africa. Recruitment and data collection took place over a period of three months. Data was captured and the information was statistically analysed and extracted for interpretation.

Results: Thirty-four questionnaires were completed by parents and returned. The most common nutrition-related concerns reported were constipation (47.1%), underweight (32.4%) and poor appetite (20.6%). Nutrition-related problems were mostly managed by consulting a healthcare professional (HCP). Most children were seen by a multidisciplinary team (MDT) of therapists, but only 44% consulted a registered dietitian (RD). Information pertaining to the current feeding practices showed that most children required assistance at mealtimes (61.8%). Nutritionally poor food choices such as deep fried food and sugary drinks were reported. Solids (64.7%) and pureed food (23.5%) were mostly tolerated. Most parents (55.9%) spent less than two hours daily on feeding their child. Parents lacked confidence when dealing with nutrition-related problems. Most were, however, content when preparing meals, feeding their child and with how their child was growing, developing and their overall health.

Conclusions: Nutrition-related concerns that these parents encountered with their spastic CP child were common concerns. The role of the RD in addressing and managing nutrition-related problems, advising on healthy feeding practices and parental support needs to be emphasized and remains a crucial part of treatment in this group of disabled children.

INFLAMMATORY BIOMARKERS IN CHILDREN AND ADOLESCENTS WITH AND WITHOUT DOWN SYNDROME

[1]Gutiérrez-Hervás, Ana; [2]Gómez-Martínez, Sonia; [3]Villagra, Ariel; [4]Izquierdo-Gómez, Rocío; [5]Delgado-Alfonso, Álvaro; [5]Casteo, José; [6]Santiago, Catalina; [6]Gómez-Gallego, Félix; [2]Marcos, Ascensión.

[1]PhD. Nutritionist. Nursing Department. University of Alicante. Spain; [2]Institute of Food Science, Technology and Nutrition (ICTAN). Spanish National Research Council (CSIC). Madrid. Spain.; [3]Department of Physical Education, Sport and Human Movement, Autonomous University of Madrid, Madrid, Spain.; [4]Research Department, Faculty of Education, Universidad Central de Chile. Santiago, Chile.; [5]GALENO research group. Department Physical Education, School of Education, University of Cadiz. Spain.; [6]School of Doctoral Studies & Research. European University of Madrid. Spain.

Background and objectives: Inflammation has been related to cardiovascular and metabolic diseases such as atherosclerosis and type 2 diabetes. An excess of adipose tissue is well known to produce an elevation in inflammatory biomarkers, although these alterations have been less studied among children and adolescents, particularly in a very special group such as individuals with Down syndrome. Therefore, the aim of the current study was to evaluate possible associations between inflammatory biomarkers [C3 and C4 complement factors and C-reactive protein (CRP)] and fatness in a relatively large sample of children and adolescents without and with Down syndrome (DS).

Methods: A total of 355 children and adolescents (101 with DS) aged 10–20 years-old, were recruited in the UP&DOWN study. C3 and C4 complement factors and C-reactive protein (CRP) were selected as inflammatory biomarkers. Height, weight and skinfolds were measured and waist-to-height ratio (WHtR), Body Mass Index (BMI) and body fat percentage were calculated. A multivariable analysis was executed to take confounder variables into account (age, gender, waist perimeter, birth weight, triceps and subscapular skinfolds). The relationship between the main and secondary variables was made by multivariable regression model.

Results: C3 complement factor level was higher in the whole sample of children and adolescents with a higher WHtR (p<0.001). In addition, C4 complement factor level was higher in all these subjects with a higher WHtR and BMI (p<0.001). The same result for CRP was found in relation to body fat percentage (p<0.001). However, these inflammatory biomarkers were higher in subjects with DS, independently of their percentage of body fat, WHtR or Body Mass Index (p<0.001) according to the ANOVA test.

Conclusions: These results point out that anthropometric measurements such as WHtR, BMI or body fat percentage could be a useful tool to screening possible alterations in some inflammatory biomarkers in children and adolescents. Nevertheless, in the case of DS subjects, these inflammatory biomarkers are elevated, independently of their anthropometric values, leading consequently, to be at a higher risk of chronic diseases.

THE ROLE OF SALVIA HISPANICA L AS IMMUNO-NUTRITONAL MODULATOR OF HEPATIC LIPID HOMEOSTASIS

[1]Laparra Llopis, Jose Moises; [2]Vivas Fernández, Sara; [3]Haros, Claudia Monika.

[1]PhD Pharmacy. Madrid Institute for Advanced Studies in Food (IMDEA Food). Spain; [2]PhD. Candidate. Madrid Institute for Advanced Studies in Food (IMDEA Food). Spain; [3]PhD. Chemist. Instituto de Agroquímica y Tecnología de Alimentos (IATA). Consejo Superior de Investigaciones Científicas (CSIC). Spain.

Background and objectives: Chia (Salvia hispanica L.) has been regarded as an important source of nutrients as well as several different bioactive compounds. This study aims to evaluate the potential of Salvia hispanica L (Chia) to selectively modulate innate immune TLR4-mediated signaling restraining the growth of hepatoblastoma cells and metabolic programming of macrophages.

Methods: A preclinical diet-induced innate immune toll-like receptor (TLR)-4 conditioned model was used to identify innate immune potential of Chia. Mechanistic studies were further performed using hepatoblastoma (HepG2, HB-8965®) cells and the humanized macrophage-like HB-8902® cell line to prove the TLR4 activation potential of the salt-soluble fraction (SSFch) from Chia seeds (defatted).

Results: Feeding an innovative Chia-containing bread formulation to a preclinical model with dietary iron-conditioned TLR4 signaling was shown effective to upregulate the hepatic expression of peroxisome proliferator-activated receptor-gamma (PPARγ), which has been shown to suppress inflammation and limit tumor progression in vivo. This observation was accompanied of a restrained production of hepatic hepcidin associated to TLR4 activation. HepG2 cells revealed that upregulation of TLR4 expression (mRNA) was not reflected on IL-6 production that can explain the in vivo hamp levels. Thus, salt-soluble proteins from chia prevent the impairment of hepatic fatty acid oxidation. Measurements of the oxygen consumption rate by HB-8902 cells in presence of SSFch clearly showed increased oxygen consumption by non-mitochondrial enzymes. Lipid mediator profiles (epoxyoctadecenoic acids known as leukotoxins) change with macrophage phenotype.

Conclusions: It is concluded that Chia, as ingredient in bread-making, and particularly SSFch promoted beneficial innate immune TLR4-mediated metabolic changes for the regulation of lipid mediators under inflammatory circumstances.

IMMUNONUTRITIONAL PROTEASE INHIBITORS FROM CEREALS PROMOTE LIVER INFLAMMATION AND DRIVEN POLARIZATION OF MACROPHAGES

[1]Laparra Llopis, Jose Moises; [2]Vivas Fernández, Sara; [3]Gomez De Cedrón, Marta; [4]Ramirez De Molina, Ana.

[1]PhD Pharmacy. Madrid Institute for Advanced Studies in Food (IMDEA Food). Spain; [2]PhD. Candidate. Madrid Institute for Advanced Studies in Food (IMDEA Food). Spain; [3]PhD. Plant Molecular Genetics. Madrid Institute for Advanced studies in Food (IMDEA Food). Spain; [4]PhD. Biochemist and Molecular Biology. Madrid INstitute for Advanced Studies in Food (IMDEA Food). Spain.

Background and objectives: Innate immune Toll-like receptor (TLR)-4 has been identified to play a key role in hepatocellular cancer promotion and macrophage priming. This study aims to characterize TLR4-mediated innate and metabolic changes, caused by protease inhibitors found in the salt-soluble fraction of different cereals (TA, Triticum aestivum; AS, Avena sativa and OS, Oryza sativa), in hepatoblastoma (HB-8965®) and humanized macrophage-like (HB-8902®) cells.

Methods: The salt-soluble fraction from cereals was isolated (10 mM phosphate buffer, pH 7,5, containing 0.1 M NaCl) and purified (ammonium sulphate 90% saturation) as described elsewhere. Then, isolated proteins were subjected to HPLC-RP-ESI-Ms/Ms characterization. Mechanistic studies were further performed using hepatoblastoma (HepG2, HB-8965®) cells and the humanized macrophage-like HB-8902® cell line.

Results: All tested grains contain protease inhibitors that display a relatively high similarity between their amino acid sequences (20-40%). Taking advantage of the known specificity of major proteolytic enzymes involved in the gastrointestinal digestion it was identified a key role for pepsin allowing to solubilize up to 80% of these proteins. Protease inhibitors receive clinical attention because of their innate immunogenic potential. Protease inhibitors from cereals activated TLR4 in hepatoblastoma cells mediating innate immune responses (IL-6 and TNFα) that influence tumor cell growth and migration. A mitostress assay in hepatoblastoma cells revealed significant differences in oxygen consumption rate (OCR, pmol/min) as a function of the cereal considered according to the following treatment: TA<OS<AS. Similarly, macrophages exhibited a same order in increased non-mitochondrial respiration when challenged to these treatments. These metabolic changes were associated to increased endosomal acidification due to impairment of lysosomes maturation that can promote different dimerization modes for TLR4. Innate immune TLR4 activation leads to a metabolic switch to fatty acid oxidation (FAO) required for M2 macrophage phenotype development.

Conclusions: Orally ingested protease inhibitors from dietary cereals are partially resistant to digestive enzymes and can increase hepatic inflammation by activating intrahepatic macrophages and causing metabolic changes in liver cells.

THE POSITIONAL DISTRIBUTION OF FATTY ACIDS ON THE GLYCEROL BACKBONE OF TRIACYLGLYCEROL (TAG) MOLECULES MAY AFFECT LIPID RESPONSES TO DIETARY FATS – A RANDOMISED CONTROLLED CROSS-OVER TRIAL

[1]Stonehouse, Welma; [1]Benassi-Evans, Bianca; [2]James-Martin, Genevieve; [1]Abeywardena, Mahinda; [1]Noakes, Manny.

[1]PhD. Health and Biosecurity. Commonwealth Scientific Industrial Research Organisation (CSIRO); [2]MNutrDiet. Health and Biosecurity. Commonwealth Scientific Industrial Research Organisation (CSIRO).

Background and objectives: Reducing saturated fatty acid (SFA) intake is a key recommendation for hypercholesterolaemia. But cholesterolaemic effects of SFA may be influenced not only by chain length but also by their positional distribution within the triacylglycerol (TAG) molecule. The "sn-2 hypothesis" is based on the premise that fatty acids located in the centre (sn-2) of TAG are preferentially absorbed and transported to the liver where it may influence cholesterol homeostasis differently compared to when occupying outer (sn-1,3) positions. The present study examined the hypothesis that dietary fats high in SFA, but containing mostly unsaturated fatty acids in the sn-2 position with most SFA in sn-1 and -3 (palm olein [PO] and cocoa butter [CB]) will have similar outcomes to unsaturated olive oil [OO] in terms of effects on lipid profiles.

Methods: Thirty eight (38) men and women (20-40 yr, 18.5-≤27.5 kg/m2) completed a 4-week randomised 3x3 crossover feeding intervention, separated by 2-week washout periods and preceded by a 2-week run-in phase. Participants consumed the same background diet (35%E fat, 18%E protein, 48%E carbohydrate) differing in test fats only. Test fats provided 20%E as either PO, OO or CB and were delivered through meals and snacks. Total cholesterol (TC)/HDL-C ratio (primary outcome) and other lipid variables (total cholesterol, HDL-C, LDL-C, TAG, apolipoprotein A1 [apoA1], apolipoprotein B [ApoB], ApoA1/ApoB, lipoprotein(a) [Lp(a)], non-esterified fatty acids [NEFA]) were assessed pre- and post-dietary intervention. Mixed effects longitudinal models were used to analyse the data.

Results: Changes in plasma fatty acids reflected the source fat composition confirming compliance: C18:1 (oleic) increased with OO compared to PO and CB; C16:0 (palmitic) decreased with OO compared to PO; and C18:0 (stearic) increased with CB compared to PO. No differences were seen between test fats for TC/HDL-C (mean [95%CI] change for PO, 0.08[0.00, 0.15] mmol/L; CB, 0.06[-0.05, 0.16] mmol/L; and OO, -0.01[-0.15, 0.13] mmol/L; P=0.53) or any other lipid outcome.

Conclusions: Consistent with the hypothesis, PO and CB both rich in SFA, but containing primarily unsaturated fatty acid in the

sn-2 position of TAG, did not differ from OO with regard to their effects on lipid profiles.

THE RELATIONSHIP BETWEEN P53 TUMOR SUPPRESSOR PROTEIN AND ANTI-APOPTOTIC BCL-2 PROTEIN IN COLORECTAL ADENOCARCINOMA ASSOCIATED WITH TYPE 2 DIABETES AND OBESITY

[1]Horatiu-Cristian, Popescu-Valceanu; [2]Stoicea, Mihai; [3]Enache, Valentin; [4]Dragut, Ramona Maria; [4]Rusu, Emilia; [5]Ionescu-Tîrgovişte, Constantin; [6]Radulian, Gabriela.

Bucharest Emergency Hospital. Romania.; [4]MD,PhD. Department of Diabetes Nutrition and Metabolic Diseases. "Carol Davila" University of Medicine and Pharmacy Bucharest. Romania.; [5]Department of Diabetes Nutrition and Metabolic Diseases.National Institute of Nutrition and Metabolic Diseases "Prof. Dr. N. Paulescu". "Carol Davila" University of Medicine and Pharmacy Romania.; [6]MD,PhD. Department of Diabetes Nutrition and Metabolic Diseases.National Institute of Nutrition and Metabolic Diseases "Prof. Dr. N. Paulescu". "Carol Davila" University of Medicine and Pharmacy Bucharest.Romania.

Background and objectives: The relationship between cancer and metabolic disorders (obesity, diabetes and metabolic syndrome) is well known from multiple studies Obesity is associated with various types of cancer the most common being the liver, the breast in postmenopausal women, endometrial, esophageal and colorectal cancer before the pancreatic cancer. The aim of our study was to compare the frequency of obesity associated with cancer in type 2 diabetic patients vs obese and non-obese subjects, taking as markers the colorectal p53 protein (considered to be a guard of the genome) and anti-apoptotic Bcl-2 protein.

Methods: In a retrospective study we identified 1307 cases with diagnosis of colorectal cancer hospitalized between 2012-2015 in Bucharest Emergency Hospital, from which we random selected 95 cases for immunohistochemical analysis of p53 and Bcl-2 protein from colorectal adenocarcinoma samples using an automatic platform Bench Mark XT Ventana applying the dual protocol Bcl-2-p53 in the department of histopathology of laboratory center. From this 95 cases 52 were type 2 diabetic patients (33 males /19 females, mean age 70.2 years) and 43 non-diabetics (30 males /13 females mean age 69.5 years). There were 15vs2 obese subjects in diabetic/non-diabetic patients compared to 37vs41 with normal weight.

Results: Our data showed that the hiperexpression of p53 protein has been found more often in diabetic obese patients in the 80% (12/15 of cases) comparative with non-obese diabetic patients 40.5% (15/37 cases) or non-diabetics and non-obese controls 36.6% (15/41 cases p=0.024). No changes in Bcl-2 protein expression has been found.

Conclusions: It is known that the protein p53 is a powerful transcriptor factor acting as checkpoint controlling the differentiation of the various cells including adipocytes and also possible enterocytes (explaining the higher frequency of colorectal cancer which has been associated with the increased proliferation of adipocytes number and volume characterizing the obesity). Due to the protection conferred by a normal p53 protein its upregulation could be a new target for the treatment of obesity.

Keywords: obesity, type 2 diabetes, colorectal adenocarcinoma, immunochemistry, p53 and Bcl2

ROLE OF MICRORNAS ON HEPATIC THYROID HORMONE ACTION IN DIFFERENT PROPENSITIES TO OBESITY IN MICE

[1]Cheng, Xiangrong; [2]Xia, Shufang; [3]Sun, Jing; [3]Tang, Xue; [3]Le, Guowei.

[1]Associate professor. School of Food Science and Technology. Jiangnan University. People's Republic of China; [2]Wuxi School of Medicine. Jiangnan University. People's Republic of China; [3]School of Food Science and Technology. Jiangnan University. People's Republic of China.

Background and objectives: The mechanisms that individuals on the same genetic background showed different propensities to obesity were largely unknown. Considering the role of microRNAs (miRs) in the function of thyroid hormones (THs) and TH in energy homeostasis, this study was designed to investigate the possible mechanisms of hepatic microRNAs (miRs) in regulating local thyroid hormone (TH) action and ultimately different propensities to high-fat diet (HFD) induced obesity.

Methods: C57Bl/6 male mice were randomly divided into a control (Con) group and a HFD group. In the 7th week, HFD-fed mice were designated as obesity-prone (OP) and obesity-resistant (OR). Half of the mice were sacrificed and the remaining mice were kept on feeding until the 17th week. Small RNA sequencing was used to find the differentially expressed miRs between OP and OR mice in the early phase of HFD feeding, and bioinformatics algorithms was used to screen the miRs that target on hepatic Dio1 or TRb.

Results: In the 7th week, OR mice showed significantly lower body weight and higher hepatic thyroid hormone receptor b (TRb) expression and type 1 deiodinase (DIO1) activity than OP mice. Small RNA sequencing results showed that 13 miRs in liver were dysregulated between the two phenotypes, of which 8 miRs were predicted to target on Dio1 or TRb. In the 17th week, OR mice had mild hepatic steatosis and increased Dio1 and TRb expression than OP mice, with up-regulation of T3 target genes involved in fatty acid oxidation (Pparα, Cyp7a1, and Cpt1α) and down-regulation

---

of lipid synthesis related genes (Srebp1c, Acc1, and Fasn). A stem-loop qRT-PCR analysis confirmed that the tendency of miR-383 expression was contrary to Dio1 mRNA expression between the two phenotypes, while miR-34a and miR-146b expression was opposite to TRb expression at both periods.

Conclusions: Thus, Hepatic miR-383, miR-146b, and miR-34a might act on Dio1 and TRb, leading to dysregulation of TH responsive gene expression, and ultimately the different propensities to HFD-induced obesity.

Keywords: obesity-prone, obesity-resistant, microRNA, type 1 deiodinase, TRb

PREVENTION OF GESTATIONAL DIABETES MELLITUS (GDM): WHERE WE STAND AND WHERE TO GO?

[1]Samuel, Tinu Mary; [2]Spieldenner, Jörg; [3]Silva Zolezzi, Irma.

[1]Phd. Maternal Nutrition Specialist. Department of Metabolic Health. Institute of Nutritional Sciences. Nestle Research Centre; Switzerland; [2]MD. Senior Manager. Micronutrient Plan. Nestle Research Centre; Switzerland; [3]PhD. Expert/GL Metabolic programming. Department of Metabolic Health. Institute of Nutritional Sciences. Nestle Research Centre; Switzerland.

Background and objectives: GDM develops in 1 in 25 pregnancies worldwide, affecting 1 in 7 births and is associated with pregnancy/ postpartum complications, short/long term morbidities and the transgenerational transmission of risk for type 2 diabetes, obesity and metabolic syndrome. This review provides a comprehensive assessment of intervention studies to inform GDM prevention strategies.

Methods: We reviewed studies on GDM prevention until 2017.

Results: Intervention studies have largely focused on the efficacy of dietary and/or lifestyle measures, and to a limited extent nutrients/bio actives, starting second trimester of pregnancy. Diet and/ or lifestyle based approaches, including complex large scale interventions in at risk women have shown limited success, inconsistent results, and have many limitations such as variations in intervention type, population characteristics, outcome definitions and low adherence to protocol. Recent evidence suggest a promising role for bio-actives (probiotics and myo-inositol) in reducing the incidence of GDM, however their efficacy needs to be investigated in large randomized intervention trials, involving a range of healthy women with and without known risk factors, such as overweight/obesity, family risk of diabetes and advanced age. The limited success of GDM prevention trials starting mid or late pregnancy together with the demonstrated associations between pre pregnancy and early pregnancy diet and lifestyle factors and increased GDM risk, indicates that metabolic alterations may occur prior to changes in the maternal phenotype, making the pre-conception period a critical time frame to intervene and interrupt the vicious cycle of GDM and childhood obesity and diabetes.

Conclusions: Considering the heterogeneity in GDM, large scale pre-conception prevention trials should investigate the impact of dietary, behaviour, nutrient and/or bioactive based interventions on both short and long term health outcomes in the mother and child in different ethnicities and in better defined risk groups, with an aim to identify novel and tailored preventive strategies. Additionally, such studies should adopt a single set of criteria for GDM diagnosis to enable comparisons across studies to draw meaningful inferences.

RELATIONSHIP OF VITAMIN D WITH HYPERTENSION AMONG CHILDREN FROM HIGH ALTITUDE REGIONS IN INDIA

[1]Singh, Gajendra; [2]Kapil, Umesh.

[1]PhD Scholar. Department of Gastroenterology and Human Nutrition. AIIMS. New Delhi.; [2]Professor. Department of Gastroenterology and Human Nutrition. AIIMS. New Delhi.

Background and objectives: Vitamin D deficiency (VDD) is pandemic and has recently been associated with extra skeletal health disorders. Both hypertension and VDD are highly prevalent worldwide, establishing an association between these two may potentially have major public health implications. Objective: To assess the relationship of Vitamin D with hypertension and risk factors associated with VDD amongst children.

Methods: A cross sectional study was conducted among rural school children aged 12-18y from two high altitude regions (>1000 meters) of Himachal Pradesh, India. A total of 513 children [242(47.17%) boys] were enrolled in the study. Blood pressure was measured using standard mercury sphygmomanometer and hypertension was defined as per WHO 2007 criteria. Validated questionnaire were utilized to elicit information on socioeconomic status (SES), physical activity, sunlight exposure and dietary pattern of children. Laboratory investigations were undertaken for serum 25-hydroxyvitamin D(25-OHD), parathyroid hormone (PTH), calcium, phosphorus, alkaline phosphatase (ALP) and Albumin levels using standard laboratory procedures. The relationship of 25-OHD and various parameters were assessed using statistical methods carried out on STATA (version 11) software.

Results: A total of 423(82.3%) subjects had VDD with levels less than 20ng/ml. The prevalence of pre-hypertension and hypertension was found to be 11.3% and 10.3% respectively. An increasing trend in blood pressure was observed with the increase in the severity of VDD. The correlation coefficient and p value [r(p)] between 25-OHD and SBP/DBP was noted as -0.08(0.058)/-0.13(0.002).Serum 25-OHD level was found significantly lower in subjects with pre-hypertension and hypertension compared to those having normal blood pressure. Regression model revealed that unadjusted β coefficient (95% CI) of SBP (mmHg) and DBP (mmHg) was -0.059(-0.117 to -0.001) (p=0.045) and -0.098(-0.171

to -0.026) (p<0.007), respectively. SBP and female sex had negative, whereas physical activity level, sunshine exposure and non vegetarian diet had positive impact on serum 25-OHD level as indicated in multivariable regression analysis.

Conclusions: The present study supports that Vitamin D plays an important role in the regulation of normal blood pressure homeostasis and VDD is a risk factor for the development of hypertension in children.

Keywords: Vitamin D, Hypertension, Children.

TIME-RELATED CHANGES IN HEPATIC ANTIOXIDANT CAPABILITY AND MITOCHONDRIAL ENERGY METABOLISM BETWEEN OBESITY-PRONE AND OBESITY-RESISTANT RATS

[1]Li, Yingrui; [2]Tang, Xue; [3]Sun, Yongjuan; [3]Xin, Xingan; [2]Shi, Yonghui; [2]Le, Guowei.

Affiliation: [1]BSc. The Laboratory of Food Nutrition and Functional Factors. Jiangnan University. China.; [2]PhD. The State Key Laboratory of Food Science and Technology, The Laboratory of Food Nutrition and Functional Factors. Jiangnan University. China.; [3]BSc. The Laboratory of Food Nutrition and Functional Factors, Jiangnan University. China.

Background and objectives: The role of oxidative stress in energy metabolism during obesity is still unclear. The aim of the present study is to reveal the regulation of energy metabolism by oxidative stress between obesity prone (OP) and obesity resistant (OR) rats after short-term and long-term high-fat diet (HFD) feeding.

Methods: Male Sprague–Dawley rats were randomly divided into two groups: the control group and the HFD group. Delineation of OP and OR was based on body weight gain (upper 30% for OP; lower 30% for OR) after 8 weeks on HFD. Rats were sacrificed at 8th and 20th week, and serum and liver were collected for ELISA assays and oxidative stress biomarkers determination by appropriate kits.

Results: Body weight gain and liver index, as well as triglycerides (TG) and total cholesterol (TC) levels increased significantly in OP group compared with control group and OR group during the experimental period. In the 8th week, compared with control group, OP group showed a significant decrease in oxygen consumption (VO2), energy expenditure (EE) and spontaneous physical activity, whereas OR group had a normal body weight gain and energy metabolism. In the 20th week, OR group had a significant increase in superoxide dismutase (SOD) activity, GSH/GSSG ratio and total antioxidant capacity (T-AOC) in liver as compared with OP group. A remarkable reduced production of reactive oxygen species (ROS) and malonaldehyde (MDA) content were also observed in OR group. Furthermore, OP group had higher accumulation of acetyl-CoA, with down-regulation of ATP production and NADH/NAD+ ratio and reduction of mitochondrial transmembrane potential involved in mitochondrial energy metabolism.

Conclusions: Mitochondrial function and antioxidant defense might be involved in propensities to obesity and the ability of OR rats to resist obesity was the maintance of mitochondrial energy and redox balance.

Keywords: high-fat diet, obesity prone, obesity resistant, mitochondrial energy metabolism, antioxidant capacity.

Background and objectives: The prevalence of Non-alcoholic fatty liver disease (NAFLD) is estimated at 30% on the western population being the most common cause of chronic liver disease worldwide. Moreover, this pathological condition accompanying by the presence of obesity and diabetes. In this sense, the aim of the study was to evaluate the presence of NAFLD by using non- invasive hepatic indexes as well as its association with anthropometric, biochemical and lifestyle variables in diabetic and non diabetic subjects.

Methods: We conducted a baseline cross-sectional study about 300 participants recruited in Navarra. Patients were categorized according to baseline diagnostic of diabetes based on American Diabetes Association criteria, non diabetic (n=197) and diabetic (n=116). Baseline anthropometric, biochemical and non-invasive hepatic indexes were compared. A validated food frequency questionnaire was carried out in order to measure current intake.

Results: Diabetic patients exhibited significant higher levels in serum triglyceride (p= 0.012), VLDL-c

(p= 0.013) and lower levels of HDL-c concentration (p= 0.003) compared with non diabetic patients. Non significant differences in AST, ALT and GGT levels were found. Moreover, multiple non-invasive hepatic indexes (LAP, BAAT score and TYG index) were higher in the diabetic group. Interestingly, associations between general biochemical and dietetic variables with non- invasive hepatic indexes were identified.

Conclusions: Our results show that diabetic patients are at higher risk for developing NAFLD. These non- invasive hepatic

indexes might be useful to assess the hepatic status in diabetic subjects.

Department of Nutrition, Food Sciences and Physiology Centre for Nutrition Research. University of Navarra. Spain/ CIBERobn. ISCIII. Spain; (3)MSc. Department of Nutrition, Food Sciences and Physiology Centre for Nutrition Research. University of Navarra. Spain; (4)MD, PhD. Department of Nutrition, Food Sciences and Physiology Centre for Nutrition Research. University of Navarra. Spain/ CIBERobn. ISCIII. Spain/ Navarra Institute for Health Research (IdiSNA). Spain; (5)PhD. Department of Nutrition, Food Sciences and Physiology Centre for Nutrition Research. University of Navarra. Spain/ CIBERobn. ISCIII. Spain/ Navarra Institute for Health Research (IdiSNA). Spain.

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) is a condition defined by an excessive accumulation of fat in hepatocytes, with prevalence rates of 57-98% in obesity. NAFLD treatment is based on lifestyle modifications. Nevertheless, there is no a well characterized dietary pattern and further studies are necessary. The objective of this study is to increase knowledge on nutritional/lifestyle interventions in obese patients with NAFLD.

Methods: A subsample of sixty-three overweight or obese patients with NAFLD (age: 49.33±9.33 years old; BMI; 33.9±3.95 kg/m2) following a personalized energy-restricted diet (-30% individual needs) under healthy lifestyle advice (FLiO: Fatty Liver in Obesity study), was evaluated. Blood pressure, body composition (DXA), lipid and glycemic profile, as well as liver non-invasive biomarkers and scores were measured at baseline and when all the patients achieved 5% of weight loss according to American Association for the Study of Liver Diseases (AASLD). Furthermore, liver stiffness was assessed by transient elastography.

Results: In addition to weight loss, participants showed a significant reduction in waist circumference, total and android fat, blood pressure, glucose, ALT, total-cholesterol, LDL-c as well as in LDL-c/HDL-c, HOMA-IR, AST/ALT and FLI indexes. Interestingly, a significant improvement in liver stiffness was obtained (-5.11%; p<0.01).

Conclusions: These results support that well-designed dietary lifestyle interventions and weight loss are key factors in the management of obesity and NAFLD.

Background and objectives: After an acute intestinal inflammatory episode, the specific protein requirement needed for the healing of injured areas remains largely unknown.

The objective of this study was to assess the effect of different protein intake levels on the mucosal healing (MH) process in a mouse model of dextran sodium sulfate (DSS, 3,5%, 5 days)-induced colitis.

Methods: After the inflammatory flare, mice were divided into three groups, each group receiving an isocaloric diet with different levels of whole-milk protein: 14% (P14), 30% (P30) and 55% (P55). The MH process was assessed macroscopically in colon in combination with functional approaches (permeability tests), biochemical measurements (protein and gene expressions of inflammatory and repairing factors) and histological analysis.

Results: While P14- and P30-fed mice started to regain weight after colitis induction at d7, the weight-gain was delayed in P55-fed mice. The colon inflammatory score was higher in this latter group during the resolution phase and was associated with an increased colon protein expression of IL-1β and IL-6 at d28 (vs P30). However, no difference in the histological score was noticed between groups at day 10 and 13. In contrast, DSS-induced colon permeability was reduced in P30-fed mice at d9 and d12 (vs P14), as well as the myeloperoxidase activity at d28 (vs P55). In addition, the colon gene expression of the anti-inflammatory cytokine Tgf-β1 (at d10) and of the tight junction-related protein

---

Cldn1 (at d13) was specifically increased in P30-fed mice. Moreover, high-protein intake (P30 and P55) seemed to improve restoration of goblet cells according to the observed increase in the goblet cell-associated gene expression Muc2 and Tff3 at d13 in these both groups compared to P14.

Conclusions: This study revealed that the level of protein intake might exert different effect after an acute colon inflammatory episode, P55 being rather deleterious, while P30 diet showed an apparent beneficial effect during the MH process when compared to the normoproteic diet P14. Ongoing analysis of colon epithelial restitution and adherent microbiota composition, as well as protein metabolism in different organs, will help to decipher the impact of dietary protein intake level on the MH process and the peripheral consequences.

ADVISING OVERWEIGHT PERSONS TO CONTROL WEIGHT BY LITHUANIAN HEALTH CARE PROFESSIONALS IN 2000-2014

Kriaucioniene, Vilma; Petkeviciene, Janina.

PhD. Researcher. Faculty of Public Health, Medical Academy, Lithuanian University of Health Sciences.

Background and objectives: Health care professionals are in a unique position to help patients prevent or manage chronic diseases.

The study objective is to assess changes in advising overweight persons to lose weight by health care professionals over fourteen years and to determine whether reported attempts to lose weight were associated with the advices.

Methods: The data were obtained from eight biennial cross-sectional postal surveys of Lithuanian health behaviours carried out between 2000 and 2014 using the same methodology. For every survey, a nationally representative random sample of 3000 individuals aged 20-64 was drawn from the National Population Register. In total, 8738 men and 11822 women participated in these surveys. Self-reported body weight and height were used to calculate BMI. Information on whether health professionals advised overweight or obese persons to increase physical activity or to change dietary habits was obtained. The odds of receiving advices were calculated using multiple logistic regression analyses.

Results: During fourteen years the proportion of overweight increased only in men from 50.6% to 58.6%, the prevalence of overweight in women showed decreasing trends. The prevalence of obesity in men increased from 11.3% to 19.5% and has not changed among women remaining 17.3% in 2014.

During study period proportion of overweight persons being advised by health care professionals to change their diet increased from 24.2% in 2000 to 38.4% in 2010, afterwards slightly decreasing trends were observed, reaching 29.4% in 2014. In 2014, 11.6% of overweight respondents reported that their health care professionals advised them to increase physical activity.

Older and better educated women, those having higher BMI, higher number of chronic conditions and more frequent visits to health care professional office were more likely to receive advices to lose weight.

Overweight men and women who reported receiving advices were more likely to report attempts to change diet and physical activity trying to lose weight than those who were not advised.

Conclusions: Providing advice on diet and physical activity are not yet a routine part of every Lithuanian physician. Still existing barriers to counselling need to be identified and strategies put in place to overcome them.

Keywords: overweight, weight control, health care professionals

Save the Children UK. London. UK; [4]MSc. Nutrition Advisor Save the Children UK. Nairobi. Kenya; [5]MSc. Monitoring Evaluation Accountability & Learning Coordinator. Save the Children International. Nairobi. Kenya; [6]Research Assistant. Save the Children Internationl. Wajir. Kenya; [7]MSc. Research Assistant. Save the Children UK. London. UK; [8]PhD. Research Advisor. Independent.

Background and objectives: Community Management of Acute Malnutrition (CMAM) is a proven approach in the treatment of acute malnutrition, however its effectiveness is limited by Health Workers failing to adhere to standard CMAM treatment protocol, due in part to poor monitoring and support, relying on paper based systems. A mobile health application was developed by World Vision and Dimagi and piloted by Save the Children in Wajir, Kenya to help health workers follow national CMAM treatment protocols and to provide more timely and accurate data for decision making. A cluster randomized trial was conducted to evaluate the impact of the application on CMAM reporting and treatment outcomes.

Methods: Forty health facilities in Wajir were randomly allocated to an intervention and control group. Intervention facilities received a tablet with the mobile health application adapted to the Kenyan context and CMAM protocol, control sites continued to use the paper based system. Data gathered through the mobile application from intervention health facilities for a period of twelve months was compared to data gathered from paper based registers over the same period in control facilities. Data from paper based

---

registers on treatment of acute malnutrition was also collected for all forty facilities for twelve pre intervention to serve as a baseline for comparison. Two observations of treatment were conducted in a sub sample of facilities to assess adherence to treatment protocol.

Results: Data analysis is still underway and results will be available by July 2017. These will compare data quality, completeness and timeliness for decision making, adherence to treatment protocol, and treatment outcomes between the two groups.

Conclusions: The CMAM mobile application has huge potential to improve CMAM services in Kenya and other countries. Results: **Keywords:** management of acute malnutrition, mobile health, data quality

ACUTE SLEEP RESTRICTION INCREASES ENERGY EXPENDITURE IN OBESE MEN

[1]*Zimberg, Ioná;* [2]*Del Re, Mariana;* [3]*Tufik, Sergio;* [4]*de Mello, Marco Tulio.*

[1]PhD. Departamento de Psicobiologia. Universidade Federal de Sao Paulo. Brazil.; [2]MS. Departamento de Psicobiologia. Universidade Federal de São Paulo. Brazil; [3]PhD. Departamento de Psicobiologia. Universidade Federal de São Paulo. Brazil; [4]PhD. Escola de Educação Física, Fisioterapia e Terapia Ocupacional (EEFFTO). Universidade Federal de Minas Gerais. Brazil;.

Background and objectives: In recent years, experimental studies have shown that sleep restriction is associated with a greater propensity for obesity and its comorbidities in normal weight adults. However little is known about how repeated nights of insufficient sleep influence energy expenditure in obese subjects. The present study aimed at analyzing the effect of sleep restriction on energy expenditure of normal weight and obese volunteers subjected to two protocols of sleep restriction.

Methods: Fifteen healthy obese and normal weight young adults (22.43 ± 1.72 and 24.13 ± 2.90 y; BMI: 33.11 ± 2.58 and 22.22 ± 2.54, respectively) were submitted to three crossover randomized conditions of sleep for three consecutive nights: normal sleep (11.00pm–7.00am); restriction at the beginning of the night (RBN, 3.00am–7.00am); and restriction at the end of the night (REN, 11.00pm–3.00am). Participants consumed a weight-maintenance diet with fixed meal times in each condition. Body weight was measured daily at the same time in each condition. Concentration of leptin and ghrelin were monitored hourly for 24 hours after the second night. Resting metabolic rate (RMR) was measured after the third night using an indirect calorimetry.

Results: Body weight was stable in all sleep conditions and washout period. In comparison with normal sleep, RMR was 15% higher in the obese group after REN (1973 ± 364kcal compared with 2332 ± 357kcal, ≈ 300kcal, p=0.03). Sleep restriction significantly increased the morning and afternoon plasma concentrations of leptin in the obesity group (p<0.05), especially under SBN

condition. The basal and 24h concentration of ghrelin significantly reduced during sleep restriction in normal weight group (p<0.05).

Conclusions: Acute sleep restriction, especially at the end of the night, increased RMR as well as leptin concentration in obese subjects, which suggests that sleep is involved in the acute regulation of daytime energy expenditure. These physiological findings might be relevant for better understanding the multiple metabolic pathways that link sleep restriction and obesity.

Keywords: sleep restriction, obesity, metabolism, leptin, ghrelin.

Facultad de Ciencias Médicas. Universidad Nacional de Córdoba. Argentina. INICSA-CONICET. Argentina.

Background and objectives: Dietary phenolic compounds (PC) are involved in regulation of inflammatory processes such as in cardiometabolic diseases (CMD). The aim was to analyze the association between dietary PC, inflammatory biomarkers and risk factors of CMD.

Methods: Observational and correlational study. Participated 120 adults, both sex (60 women and 60 men), attended at the Non-Invasive Cardiology Division of the National Hospital of Clinics, Córdoba, Argentina, period 2014-2016. A clinical history, a validated food intake questionnaire, a physical activity questionnaire, smoking habits, systolic (SBP) and diastolic (DBP) blood pressure, nutritional status, waist circumference (WC), triglycerides (TG), serum lipid profile (total cholesterol, HDLc and LDLc) and ultrasensitive C-reactive protein (hs-CRP) were evaluated. Interfood v.1.3 software was employed to estimate fruits, vegetables and PC (isoflavones, flavones, flavonones, flavonols, flavanones,

anthocyanins) intake. Spearman correlation test was used for the correlation analysis.

Results: Average age was 61±1.43 years old, body mass-index (BMI) 28.76 ± 0.96 kg/m2 and WC 100.50 ± 2.35 cm. About risk factors, BMI was associated with SBP and DBP (r=0.22, p <0.01, r=0.26, p <0.05, respectively), and total cholesterol and BMI with TG concentration (r=0.31, p<0.05; r=0.33, p<0.05, respectively). Fruits and vegetables intake, source of PC, was 897.62 ± 89.45 gr/day. A correlation between genistein and LDLc and TG (r=-0.49, p <0.05, r=0.47, p<0.05, respectively), was observed. Other correlations were found among isoflavones and HDLc (r=0.36, p<0.05), and between flavonols and flavanones with fruits and vegetables (r=0.71, p<0.01; r=0.38, p<0.01, respectively).

Conclusions: These results showed preliminary evidence about PC intake and CMD risk factors.

Keywords: Phenolic compounds, risk factors, cardiometabolic diseases, biomarkers

LEVELS AND VITAMIN D INTAKE IN CHILDREN AND ADOLESCENTS WITH PHENYLKETONURIA

[1]Leiva Rodriguez, Carla Andrea; [2]Cornejo Espinoza, Verónica; [3]Bravo Jimenez, Paulina; [4]Toledo Astudillo, Juan.

[1]Msc. Nutricionista. Carrera de Nutrición y Dietética. Facultad de Medicina. Pontificia Universidad Católica de Chile.; [2]MSc. Nutricionista. Instituto de nutrición y tecnología de los alimentos. Universidad de Chile. Chile.; [3]MSc. Médico Pediatra. Universidad de los Andes. Chile.; [4]Medico General. Médico General de Zona. Servicio de Salud Metropolitano.

Background and objectives: Vitamin D has a broad role on bone metabolism, cardiovascular, neurological and immunomodulation. Active vitamin D [1,25 (OH) 2 D3] can be provided from the diet or skin. It has been reported that children with phenylketonuria are at risk for vitamin D deficiency and the same applies in Chilean population. The objetives of the study was to study the levels of 25-OH Vit D and vitamin D intake in patients with phenylketonuria, mild hyperphenylalaninemia and control group.

Methods: The study was conducted in the laboratory of the Institute of Metabolic Diseases and Nutrition Food Technology (INTA), the variables collected for each patient included levels of 25-OH-VIT D and intake of vitamin D. The study included a total of 48 Chilean patients, aged 6-23 years, of both sexes; 16 patients were included for group. The Kruskal-Wallis statistical test was applied.

Results: Were statistically significant differences (p <0.05) levels of 25-OH-vitamin D between PKU and HFA group (PKU: 38.9 ng / ml; HFA: 28 ng / ml) (VN> 32 ng / ml). The PKU group consumed 440 IU of Vit D, the HFA: 150 IU / day and control group: 145 IU / day, with statistically significant differences between the PKU group and groups HFA and control.

Conclusions: This study showed that the vitamin D intake in the PKU group was bigger than the control and HFA group, be-

cause PKU consume special formulas from birth to 25 years. They contain 400-500 IU/100 g of product and are delivered by the Ministry of Health. HFA and control group consumed a low amount of Vitamin D, because dietary sources of vitamin D are scarce and the Chilean market has not fortified foods. Thus adequate intake of vitamin D protects of vitamin D deficiency in PKU patients. Is important to create a protocol of fortification for domestic consumption, as it has been documented a high prevalence of vitamin D deficiency in the Chilean population.

Keywords: Vitamin d, Phenylketonuria

THE EFFECTS OF POLYUNSATURATED FATTY ACIDS AND RUMINANT TRANS FATTY ACIDS ON ALLERGIC DISEASES IN EARLY LIFE: A SYSTEMATIC REVIEW AND META-ANALYSIS

[1]Wu, Weijia; [1]Lin, Lizi; [2]Jing, Jin; [2]Cai, Li.

[1]MSc. School of Public Health. Sun Yat-sen University. China.; [2]PhD. School of Public Health. Sun Yat-sen University. China.

Background and objectives: The nutrition status in early life could influence the future development of allergic diseases. Although both polyunsaturated fatty acids (PUFAs) and ruminant trans fatty acids (R-TFAs) modulated immune functions in allergic subjects, their effects on allergic diseases in early life remained unclear. Thus, we conducted a systematic review and meta-analysis to determine whether PUFAs and R-TFAs could reduce the risk of allergic diseases in early life.

Methods: We searched PubMed, EMBASE, PsycINFO, Scopus, the Cochrane Library, and ClinicalTrials.gov from inception through January 2, 2017 for relevant full-text articles in English. Observational studies were selected if they examined the effects of PUFAs or R-TFAs on allergic diseases (eczema, asthma, wheeze and allergic rhinitis) or sensitization in early life. The period of early life is restricted to the first 1,000 days from conception to age 2 years. We excluded studies if they included participants with medical conditions. The quality of studies was examined by Newcastle-Ottawa Scale for assessing risk of bias, and a best evidence synthesis (BES) was applied. Random-effects models were used in the meta-analysis.

Results: Among the 3434 identified articles, we included 23 observational studies, and seven of them showed high quality. BES suggested that a moderate evidence for the protective effect of vaccenic acid on eczema in early life, while insufficient or no evidences were found in the relationship of other R-TFAs and PUFAs with allergic diseases. In the meta-analysis of 18 cohort studies, vaccenic acid was inversely associated with the risk of eczema (pooled odds ratio [OR] =0.43, 95% confidence intervals [95% CI]: 0.26-0.72). A-linolenic acid and linoleic acid also showed protective effects on allergic rhinitis and sensitization (pooled OR=0.77, 95% CI: 0.60-0.98; 0.86, 95% CI: 0.76-0.99). Meanwhile, higher n-6/n-3 PUFAs ratio and linoleic acid were associated with higher risk of eczema (pooled OR=1.08, 95% CI: 1.01-1.16; 1.08, 95% CI: 1.01-1.15).

Conclusions: Our systematic review and meta-analysis suggested that vaccenic acid showed benefit on decreasing the risk of eczema in early life, while PUFAs and other R-TFAs showed limited effects on allergic diseases because of insufficient evidences. More robust studies especially for R-TFAs are required in the future.

Keywords: polyunsaturated fatty acids, ruminant trans fatty acids, allergic disease, meta-analysis

ASSOCIATION OF DIET QUALITY WITH ANTIOXIDANT CAPACITY OF PLASMA OF WOMEN WITH BREAST CANCER BEFORE AND AFTER ANTINEOPLASTIC TREATMENT

[1]Rockenbach, Gabriele; [2]Santos, Elaine da Silva; [1]Hinnig, Patrícia; [1]Vieira, Francilene Gracieli Kunradi; [1]de Assis, Maria Alice; [2]de Liz, Sheyla; [3]da Silva, Edson Luiz; [1]Di Pietro, Patricia Faria.

[1]PhD. Assistent Professor, Department of Nutrition, Centre of Health Sciences, Federal University of Santa Catarina, Brazil; [2]MSc. Nutritionist, Department of Nutrition, Centre of Health Sciences, Federal University of Santa Catarina, Brazil; [3]PhD. Assistent Professor, Department of Clinical Analyses, Centre of Health Sciences, Federal University of Santa Catarina, Brazil.

Background and objectives: Reactive oxygen species (ROS) are important in regulating normal cellular processes, but deregulated ROS contributes to the development of diseases, including cancers. In addition to maintain body weight, a balanced diet rich in antioxidant nutrients can positively affect the effectiveness of antineoplastic treatment by reducing the physiological and oxidative damage caused by treatment. It is suggested that a diet rich in fats can stimulate lipid peroxidation, favoring the increase of ROS in cancer patients. The objective of this study was to verify the association between diet quality and antioxidant capacity of plasma in women with breast cancer before and after antineoplastic treatment.

Methods: Sociodemographic, clinical, anthropometric and therapeutic data of 70 women were collected. Food consumption was assessed by food frequency questionnaire. The diet quality was evaluated using the Brazilian Healthy Eating Index Revised (BHEI-R) and its components. The antioxidant capacity of plasma was evaluated biochemically from the determination of iron reducing antioxidant potential (FRAP). Food consumption assessment and antioxidant capacity of plasma were conducted before and after the treatment. Multiple linear regression was used to assess the relationship between diet quality and FRAP before and after treatment. Logistic regression model was used to verify the association between change in diet quality and change in FRAP during treatment.

Results: The median total score of the BHEI-R before and after treatment was similar (p=0.684) (median=76.2 e 76.5, respectively). No association was found between the FRAP before and after treatment (μ=629.5, DP=19.1 and μ=573.8, DP=22.7, respectively

p=0.051). Patients classified in the third tertile of diet quality (better quality) significantly increased the FRAP (β=106.78, p=0.019) before the treatment, however no association was found after the treatment. In prospective analyses, the association between change in diet quality and change in FRAP was not statistically significant (p= 0.260).

Conclusions: Women with breast cancer with better quality of diet had better concentrations of plasma antioxidants before treatment. However, the diet did not change the antioxidant capacity of plasma after treatment. Increase quality of diet is not enough to improve the antioxidant capacity of plasma in patients undergoing treatment for breast cancer in this sample of Brazilian women.

Keywords: oxidative stress; breast cancer; diet quality

IMPORTANCE OF C-REACTIVE PROTEIN (C-RP) DETERMINATION AS A PREDICTOR OF RISK IN AN OVERWEIGHT OR OBESE POPULATION

[1]Presner, Natalia; [2]Pandolfo, Marcela; [3]Dupraz, Hernán; [3]Weisstaub, Adriana Ruth; [3]Felipoff, Ana Lía; [4]González, Claudio D.; [5]Cúneo, Aldo; [5]Rivera, Santiago; [3]Zago, Liliana; [5]González Infantino, Carlos A.

[1]Nutritionist; [2]Biochemist. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Departamento de Bioquímica Clínica. Argentina.; [3]PhD. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Nutrición. Argentina.; [4]MD. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Argentina.; [5]MD. Universidad de Buenos Aires. Facultad de Medicina. Hospital de Clínicas "José de San Martín". División Nutrición. Argentina.

Background and objectives: To analyze the ability of C-RP to predict death or cardiovascular events (myocardial infarction or stroke) or development of diabetes, after 3 years, in an overweight or obese population, with or without metabolic syndrome (MS) defined by ATPIII and IDF.

Methods: In the framework of a research project on the relationship between nutritional deficiencies and obesity, 175 overweight or obese adults (mean age: 52.3 + 13.8), both genders were studied. We evaluated C-RP and the presence of MS at time 0 (T0). These patients then entered a weight loss program characterized by healthy eating and exercise guidelines for 6 months. After 3 years, 109 of the patients were contacted again by telephone and major events they suffered during that period were recorded.

Results: Among the 13 patients who had events, 53.8% had MS, and 46.15% lacked this condition. The difference was not statistically significant (p=0.5524).

In T0 it was observed that, among patients with and without MS, there was no statistically significant difference in the C-RP value (p=0.2352 and p=0.1478 defined by ATPIII and IDF, respectively).

Among patients who developed events, a prevalence of elevated C-RP was observed. We performed the ROC curve between

C-RP and event development and observed an AUC of 0.734. Analyzing the cut-off points it was found that a C-RP > 5 predicted the occurrence of events in a statistically significant way (p=0.0095; RR: 4.388, CI: 95%: 1.444 to 13.277; Sensitivity: 69.2%; Specificity: 70.8%).

Among the 109 patients who were contacted after 3 years, 24.32 % of the ones who had C-RP > 5 developed events; and just 5.55 % of the ones who had C-RP <5 developed events.

Conclusions: MS did not predict the occurrence of events in this population; on the other hand, C-RP > 5, did.

The definition of MS according to ATPIII and IDF is associated with insulin resistance and obesity, but is not necessarily related to C-RP levels. Therefore, seeing that events are significantly related to a C-RP > 5, we consider that a better definition of MS as a prognostic marker should incorporate it.

Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; (4)MD-PhD. Department of Gastroenterology and Hepatology. University Medical Center Groningen. The Netherlands.

Background and objectives: Proton-pump inhibitors (PPI) are commonly prescribed in renal transplant recipients (RTR) to prevent gastro-intestinal complaints and complications from immune-suppressants. However, chronic PPI use may induce magnesium and iron deficiencies and increase the risk of mortality. We investigated the association of PPI use with magnesium- and iron- status and mortality in a large single-center cohort of RTR.

Methods: We included 706 RTR with a functioning graft ≥ 1 year. Medication use was verified from medical records. Magnesium intake was assessed using a FFQ. Serum ferritin, magnesium and 24-h urinary magnesium excretion were measured with standard methods. Associations of PPI use on magnesium and ferritin were analyzed by linear regression. Logistic regression was used to assess association with iron deficiency (serum ferritin <100 µg/l) and magnesium insufficiency (<0.75 mmol/l). Cox regression was used to analyze the association of PPI use with mortality.

Results: At a median[IQR] of 5.4 [1.9-12.0] years after transplantation, mean±SD age was 53±13 years, 56.8% were male and 53% used PPI. Mean magnesium intake was 330±85 mg/day and was similar between users and non-users of PPI (P=0.204). PPI use was inversely associated with magnesium excretion (St.β:-0.21, P<0.001), serum magnesium (St.β:-0.08, P=0.046) and serum ferritin (St.β:-0.16, P<0.001), independent of age, gender, BMI, CRP, renal function and calcineurin inhibitor use. Iron deficiency and magnesium insufficiency were present in 208 (29.7%) and 26 (3.7%) RTR, respectively. PPI use was associated with iron deficiency (OR 1.98; 95%CI 1.44-2.73, P<0.001) and magnesium insufficiency (OR 3.25; 95%CI 1.26-8.39, P=0.015). During median follow-up of 5.4 [4.8-6.1] years, 152 RTR died. PPI use was associated with higher risk of mortality (HR 2.0; 95%CI 1.43-2.8, P<0.001), independent of potential confounders (HR 1.94; 95%CI 1.32-2.88, P=0.001).

Conclusions: PPI use is associated with low urinary magnesium excretion and serum magnesium, reflecting magnesium status, despite similar intake between PPI-users and non-users. It also seems to adversely influence iron status, together indicating impaired gastro-intestinal absorption, potentially related to the reduced gastric acid secretion. Moreover PPI use appears independently associated with increased risk of mortality in RTR, suggesting PPI use is not without danger in RTR and treatment indication may need to be revisited.

Keywords: proton pump inhibitors, magnesium, iron, all-cause mortality, renal transplantation.

EFFECTS OF LOW FAT DIET ON BODY COMPOSITION AND BLOOD PARAMETERS IN NON-ALCOHOLIC FATTY LIVER DISEASE: A PILOT STUDY

(1)İlhan, Merve; (2)Goktas, Zeynep.

(1)BSc. Dietitian. Department of Nutrition and Dietetics. Hacettepe University. Ankara. Turkey.; (2)PhD. Dietitian. Department of Nutrition and Dietetics. Hacettepe University. Ankara. Turkey.

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) is the most widespread reason of chronic liver diseases in Western countries. Enhanced diet and increased physical activity is crucial for the treatment of NAFLD. The purpose of this study is to determine the effects of nutrition on body composition and some biochemical parameters in non-alcoholic fatty liver disease.

Methods: A total of 9 sedentary adults aged between 19 to 64 years participated in this study. Subjects were evaluated at the beginning of the study and 4 weeks later. Data collected during each visit included height, weight, body fat mass, fat free mass, total body water and waist, hip and neck circumference. Anthropometric measurements were collected using bioelectrical impedance analysis (TANITA TBF-215). Serum blood samples were obtained from participants at the beginning and after 4 weeks to assess liver enzymes. During these measurements subjects were instructed to be fasted for at least 10 hours prior to testing. Diet which

compatible with NAFLD was prescribed to each participant at the beginning. 2-day food records and physical activity records were collected from participants each week. Statistical significance was set at p<0.05.

Results: A total of 6 female and 3 male subjects participated in this pilot study. Energy intakes of participants were found 1357±337 kcal/day. 3 of 9 subjects were exceed the daily fat limit. A statistically significant reduction in body weight (-2,32±2,19 kg, p<0,05), body mass index (-0,91±0,85 kg/m2, p<0,05), fat mass (-1,87±1,91 kg, p<0,05), waist circumference (-3,33±2,92 cm, p<0,01), waist to hip ratio (-0,03, p<0,05) and neck circumference (-1,00 cm, p<0,05) was observed after 4 weeks of diet treatment. Also there is a decline in liver enzymes (Alanine aminotransferase (ALT): -21,20±13,41 U/L, p<0,05; Aspartate aminotransferase (AST): -8,40±4,39 U/L, p<0,05; Alkaline phosphatase (ALP): -11,60±20,74 U/L, p>0,05; Gamma-glutamyl transferase (GGT): -28,00±33,79 U/L, p>0,05), however difference in ALP and GGT levels were not statistically significant.

Conclusions: In conclusion, low fat diet can provide weight reduction, improvement in body composition and enhance in liver enzymes in NAFLD.

Keywords: NAFLD, body composition, low fat diet

AN EXPERIMENTAL STUDY OF SUBSTITUTING SUGAR IN INDIAN TRADITIONAL SWEET WITH DRY FRUITS

[1]Modem, Sai leela; [2]N, Chaitra Moulika.

[1]Associate Professor.St.Joseph's college for Women(Autonomous).Visakhapatnam; [2]Assistant Professor. St.Joseph's college for Women(Autonomous).Visakhapatnam. India.530004.

Background and objectives: Ramaiah et al 1990 suggested that in an epidemiological study of diabetes in Asians of the Indian sub continent, steady migration of people from rural to urban areas coinciding with the economic boom, corresponding lifestyle changes are leading to steady rise in incidence of Type II Diabetes. Moreover an ethnic susceptibility to diabetes among Indians was quoted. Thomas (2015) reported an all time high prevalence of T2DM. In this context the food and dietary patterns have undergone changes leading to consumption of predominantly high glycemic foods, one of which is the sweets,made of cane sugar or sugar syrup.

Objective of the study: To experiment on developing a low glycemic sweet by incorporating fresh and dry fruits in the place of cane sugar.

Methods: A traditional sweet Gulab jamun was selected for the experiment. The standard recipe of the sweet suitable for four servings was chosen from recipe book. In the experiment , the cane sugar alone was substituted with banana fruit and dry grapes, to keep the sweetness as close as possible to original sweet. Both the recipes were administered to a panel of diabetic patients, dieti-

tians and normal subjects people, to evaluate the acceptance of the sweet without cane sugar.

Results: The nutritive value of the original and experimental recipe of the sweet Gulab jamun was calculated. It was observed that the energy value of the experiment recipe reduced by 120 K. calories while the carbohydrate content reduced by 30%. The acceptance of the recipe was satisfactory with excellent scoring by 50% dietitians,70% diabetics and 80 % normal subjects.

Conclusions: The experiment recipe of the sweet Gulab Jamun was well accepted and was observed to be an encouraging alternative for the diabetic subjects who crave for the consumption of sweets in parties,weddings , festive occasions etc. which are very common in the Indian society.

Keywords: Type 2 Diabetes Mellitus , recipe , glycemic index, Indian sweet, Gulab jamun,energy, carbohydrate, dietitians.

Conflict of Interest Disclosure: This is to disclose that the study is a dissertation work undertaken by the co-author during Graduate study under my supervision.

LOW VEGETABLE INTAKE IS ASSOCIATED WITH HIGH RISK OF NEW-ONSET DIABETES AFTER RENAL TRANSPLANTATION

[1]Gomes Neto, António; [2]Osté, Maryse; [3]van den Berg, Else; [3]Gans, Rijk O. B; [4]Soedamah-Muthu, Sabita S; [3]Bakker, Stephan J.L.; [3]Navis, Gerjan.

[1]University Medical Center Groningen; [2]Bsc. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; [3]MD. PhD. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; [4]PhD. Division of Human Nutrition. Wageningen University & Research. Wageningen. The Netherlands.

Background and objectives: New-Onset Diabetes After Transplantation (NODAT) occurs in 4-25% of renal transplant recipients (RTR) and increases risk of cardiovascular disease, graft failure and mortality in this population. NODAT is generally attributed to adverse effects of immune-suppressants (i.e. steroids and tacrolimus). Little is known about whether the risk of NODAT is modifiable by dietary factors, such as fruit and vegetable intake. We investigated whether fruit and vegetable intake is associated with risk of NODAT in RTR.

Methods: In this prospective observational study we included adult RTR with a functioning graft for ≥ 1 year. Dietary intake was assessed using a validated Food Frequency Questionnaire consisting of 177 food items. RTR with a medical history of diabetes or diabetes at baseline or RTR missing dietary data were excluded, leaving 473 RTR eligible for analyses. RTR were considered to have NODAT when ≥ 1 of the following criteria was met: repeated fasting plasma glucose ≥ 7.0 mmol/l, HbA1c ≥ 6.5%, or anti-diabetic drug use

Results: Mean ± SD age was 51.3 ± 13.2 years, 57% were male. Median [IQR] vegetable and fruit intake was 108 [72-154] and 99

[44-192] g/d, respectively. Only 11% met the recommended intake for vegetables (200g/d), and only 22% met the recommended intake for fruit (200g/d). During median follow-up of 5.3 years, 52 RTR (7%) developed NODAT. Vegetable intake was inversely associated with NODAT (HR 0.77 [95%CI 0.63-0.94] per 2log g/d). When divided in tertiles, RTR in the lowest tertile of vegetable intake (median intake: 54 [34-72] g/d) had higher risk of NODAT compared to RTR in the highest tertile (median intake: 175 [153-216] g/d) independent of age, sex, time after transplantation, total energy intake and physical activity (HR 2.2 [95%CI 1.11-4.52]) . Fruit intake was not associated with risk of NODAT (HR 0.91 [95%CI 0.80-1.04] per 2log g/d).

Conclusions: The majority of RTR do not meet the recommended intake of vegetable and fruit. Low vegetable intake is associated with higher risk of NODAT. Stimulating vegetable intake may reduce the risk for NODAT in RTR. This study shows that even in the context of allegedly iatrogenic diabetes, dietary factors are important.

Keywords: New Onset Diabetes After Transplantation. Renal Transplant Recipients. Vegetable Intake. Fruit Intake.

PREVALENCE OF THE METABOLICALLY HEALTHY PHENOTYPE IN PEDIATRIC OBESITY AND ITS ASSOCIATION WITH CLINICAL, METABOLIC AND FAMILY HISTORY PARAMETERS

[1]Patricia Lucía, Casavalle; [2]Laura Soledad, Romano.

[1]Pediatrician. Pediatrics Department. Hospital de Clínicas José de San Martín. Buenos Aires University. Argentina; [2]Nutritionist. Food Department. Hospital de Clínicas José de San Martín. Buenos Aires University. Argentina.

Background and objectives: Identifying the presence of the metabolically healthy (MH) phenotype and the factors to which it is associated in pediatric obesity, allows early detection of those who have a lower risk of future cardiometabolic complication and treatment adequation. Therefore, the objective of this study is to estimate the prevalence of MH phenotype in overweight/obesity children and adolescents and its association with clinical, metabolic and family history parameters.

Methods: 203 patients were studied, age range 8-14 years, both sexes, overweight (n=59) and obese (n=144), according to z score BMI (OMS), in the section of Pediatric Nutrition, February 2005-October 2016. Exclusion criteria: patients with endogenous obesity. The design was descriptive, observational, prospective, cross-sectional and comparison of independent samples. Evaluated variables: age, sex, z score BMI, pubertal development, HOMA-IR, family history (FH) of obesity, type 2 diabetes, arterial hypertension, dyslipidemia and early acute myocardial infarct. The MH phenotype was defined by the absence of any components of the metabolic syndrome (MS) according to the criteria of the Argentine Society of Pediatrics. Fisher's test was performed and p-value <0,05 was considerared statistically significant.

Results: 70,9% (CI 95% 64,1-77) were obese, 50,2% (CI 95% 43,2-57,3%) pubescent and 50,7% (CI95% 43,7-57,8%) females. MS frequency was 15,3% (CI 95% 10,8-21,1%). Prevalence of MH phenotype was 31% (CI 95% 24,8-38) and its was associated significantly with age range 11-14 years: 39,8% (CI 95% 29,9-50,5) vs 8-10 years: 23,6% (CI 95% 16,3-32,9) (p =0,01), overweight: 67,8% (CI 95% 54,2-79) vs obesity: 16% (CI 95% 10,6-23,2) (p=0), HOMA-IR< 3: 41,7% (CI 95% 32,7-51,3) vs HOMA-IR ≥ 3: 17% (CI 95% 10,2-26,9) (p=0,0001) and absence FH of type 2 Diabetes: 38% (CI 95% 28,6-48,3) vs presence FH of type 2 Diabetes: 24,3% (CI 95%16,6-33,9) (p=0,024). The non-associated parameters were sex (p=0,443), pubertal development (p=0,287), FH of obesity (p=0,089), FH of arterial hypertension (p=0,396), FH of dyslipidemia (p=0,435) and FH of early acute myocardial infarct (p=0,539).

Conclusions: The MH phenotype was present in 1 out of 3 patients with overweight/obesity. It was significantly associated with age range 11-14 years, overweight, HOMA- IR < 3, and absence FH of type 2 diabetes.

Keywords: children, adolescents, obesity, metabolically healthy phenotype.

HIGHER ADHERENCE TO THE MEDITERREAN DIET IS ASSOCIATED WITH LOWER RISK OF GRAFT FAILURE IN RENAL TRANSPLANT RECIPIENTS

[1]Gomes Neto, António; [2]Osté, Maryse; [2]Sotomayor, Camilo G.; [3]van den Berg, Else; [4]Gans, Rijk O. B; [5]Soedamah-Muthu, Sabita S; [6]Bakker, Stephan J.L.; [6]Navis, Gerjan.

[1]University Medical Center Groningen; [2]Bsc. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; [3]MD. PhD. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; [4]MD PhD. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.; [5]PhD. Division of Human Nutrition. Wageningen University & Research. The Netherlands; [6]MD. PhD. Department of Internal Medicine. University Medical Center Groningen. The Netherlands.

Background and objectives: Renal transplantation is considered the preferred treatment in end-stage renal disease. Despite improved short-term graft survival over recent years, long-term graft survival after renal transplantation has not improved. Research in this field is traditionally dominated by immunological evaluation and treatment, however non-immunological causes including diet and lifestyle are often overlooked. In the general population the Mediterranean Diet is associated with better cardiovascular and renal outcomes. We investigated whether adherence to the Mediterranean Diet is associated with graft failure in a large cohort of renal transplant recipients (RTR).

Methods: In this prospective observational cohort study we included all adult RTR with a functioning graft for ≥ 1 year who

visited the outpatient clinic. Dietary intake was assessed using a validated Food Frequency Questionnaire of 177 food items. RTR missing dietary data were excluded, leaving 632 RTR eligible for analyses. Adherence to the Mediterranean Diet was calculated using the nine-point Mediterranean Diet Score (MDS) by Trichopoulou based on intake of legumes, nuts, soy products, cereals, fruit, vegetables, meat , dairy, fish, alcohol and fat. Cox regression was used to analyze the association of MDS on death-censored graft failure.

Results: Mean ± SD age was 53 ± 13 years, 57% were male. Mean MDS was 4.7 ± 1.7. During median [IQR] follow-up of 5.3 [4.5-6.0] years, 76 RTR developed graft failure. MDS was inversely associated with graft failure (HR 0.88 [95%CI 0.77-0.99] per MDS-point increase). Adjustment for potential confounders including age, sex, time after transplantation, primary renal disease, eGFR, urinary protein excretion, smoking status and physical activity did not materially alter this association (HR 0.84 [95%CI 0.73-0.98] per MDS-point increase). When divided in tertiles, risk of graft failure was twice as high in RTR in the lowest tertile of MDS compared to RTR in the highest tertile of MDS (HR 2.0 [95%CI 1.05-3.84]), independent of potential confounders.

Conclusions: Higher adherence to the Mediterranean Diet is associated with lower risk of graft failure, independent of potential confounders. These findings suggest increasing Mediterranean Diet adherence may be a novel measure to improve long-term graft survival in RTR.

Keywords: Renal Transplantation. Graft Failure. Mediterranean Diet.

that responds to both iron status and inflammation in the regulation of iron absorption and sequestration. Our objective was to determine if enteric inflammatory activity is associated with an increase in systemic inflammation and hepcidin concentrations.

Methods: Serum and fecal samples were collected from 435 children aged 22-34 months. Hepcidin, C-reactive protein (CRP), and alpha-1-acid glycoprotein (AGP) concentrations were quantified in serum, while the EED biomarkers neopterin (NEO), alpha-1-antitrypsin (AAT), and myeloperoxidase (MPO) were analyzed in stool. We also measured serum ferritin, soluble transferrin receptor, hemoglobin and the presence of a hemoglobinopathy (β-thalassemia or Hemoglobin E) and considered these factors in multivariable adjusted models.

Results: In this sample, 8.0% had inflammation (CRP≥5mg/L or AGP≥1), 11.0% had anemia (Hb< 110g/L), and 27.2% were iron deficient (serum ferritin < 12 μg/L, corrected for inflammation). The median concentrations of NEO, AAT, and MPO were 581 nmol/L, 0.3 mg/g, and 2584 ng/mL, respectively, and the median hepcidin concentration was 13.4 ng/mL. Using a generalized linear mixed model, and adjusting for serum ferritin, age, and sex, we found no associations between hepcidin and any of the fecal inflammatory biomarkers. Though hepcidin was positively correlated with systemic inflammatory biomarkers CRP and AGP, none of the fecal inflammatory biomarkers was associated with CRP or AGP.

Conclusions: These data suggest that these markers of EED were not associated with a strong enough systemic inflammatory response to stimulate a response in hepcidin. Further research is needed to better understand whether EED may influence iron absorption through other pathways

Keywords: Environmental Enteric Dysfunction, iron, hepcidin

FECAL INFLAMMATORY BIOMARKERS OF ENVIRONMENTAL ENTERIC DYSFUNCTION ARE NOT ASSOCIATED WITH HEPCIDIN CONCENTRATIONS IN YOUNG BANGLADESHI CHILDREN

[1]Byrd, Kendra; [2]Lin, Audrie; [3]Rahman, Md. Ziaur; [3]Ali, Md. Shahjahan; [4]Arnold, Charles D.; [5]Jannat, Kaniz; [6]Luby, Stephen P.; [5]Rahman, Md. Mahbubur; [7]Dewey, Kathryn; [7]Stewart, Christine.

[1]PhD. University of California, Davis. USA; [2]PhD. Division of Epidemiology. School of Public Health. University of California, Berkeley. USA.; [3]MS. International Center for Diarrheal Disease Research. Dhaka. Bangladesh.; [4]MS. Program in International and Community Nutrition. University of California, Davis. USA.; [5]MBBS. International Center for Diarrheal Disease Research. Dhaka. Bangladesh.; [6]Infectious Disease and Geographic Medicine. Stanford University. USA.; [7]Program in International and Community Nutrition. University of California, Davis. USA.

Background and objectives: Environmental Enteric Dysfunction, or EED, is an inflammatory condition of the gut that afflicts many infants and children in low- and middle-income countries. EED is characterized by increased inflammatory cell activity in the small intestine, a reduced absorptive capacity, and reduced barrier function. Hepcidin is an iron-regulatory hormone

RED MEAT CONSUMPTION AND SELECTED GASTROINTESTINAL CANCERS MORBIDITY IN POLAND IN THE YEARS 1990-2014

[1]Jarosz, Miroslaw; [2]Rychlik, Ewa; [3]Sekula, Wlodzimierz.

[1]MD, PhD. Physician. Department of Nutrition and Dietetic with Clinic of Metabolic Diseases and Gastroenterology. National Food and Nutrition Institute in Warsaw. Poland; [2]PhD. Nutritionist. Department of Nutrition and Dietetic with Clinic of Metabolic Diseases and Gastroenterology. National Food and Nutrition Institute in Warsaw. Poland; [3]PhD. Economist. Department of Nutrition and Dietetic with Clinic of Metabolic Diseases and Gastroenterology. National Food and Nutrition Institute in Warsaw. Poland.

Background and objectives: Red meat is a source of some compounds which could promote carcinogenesis. It is characterized by high haem content that increases levels of N-nitroso compounds in the body. Processed meat contains nitrite that can react with the degradation products of amino acids to form N-nitroso compounds. During cooking at high temperate heterocyclic amines or polycyclic aromatic hydrocarbons can be formed. Red

meat is also rich in animal fat and high consumption of such products can lead to obesity.

The aim of the study was to examine the relationship between trends in red meat consumption after the economic transformation and some cancers (colorectal, pancreatic and oesophageal) morbidity in Poland.

Methods: The study was based on colorectal, pancreatic and oesophageal cancer incidence rates derived from the National Cancer Registry in 1990-2014. Data on red meat consumption (in kg/person/year) were derived from the national food balance sheets. Analysis includes the consumption of pork, beef, lamb and goat from domesticated animals. Spearman correlation coefficients were used to estimate the relationship between the examined variables.

Results: In 1990-2014 red meat consumption in Poland decreased from 56.1 to 41.3 kg/person/year. In the analyzed period the incidence of pancreatic and oesophageal cancer increased initially, however since the mid-90s of the twentieth century a marked decline began to be observed.

The colorectal cancer morbidity continues to grow, but to a lesser degree than in previous years.

Positive correlations were found between red meat consumption and pancreatic (0.74 for males and 0.48 for females) and oesophageal cancer (0.64 for males, correlation coefficient not statistically significant for females) incidence rates. There was no positive correlation between red meat consumption and colorectal cancer morbidity during analyzed period.

Conclusions: The decrease in red meat consumption in Poland could favourably affect some gastrointestinal cancers such as pancreatic and oesophageal cancer morbidity in Poland and probably was one of the reasons of the observed decline in these cancers incidence in recent years.

Furthermore smaller proportion of red meat in the diet could influence on the reduction in the rate of increase of colorectal cancer incidence.

Keywords: red meat, gastrointestinal cancers, morbidity

RELATIONSHIP BETWEEN NUTRITIONAL STATUS AND CARDIOVASCULAR RISK IN PATIENTS WITH CHRONIC HEPATITIS C AND METABOLIC SYNDROME

[1]Dragut, Ramona Maria; [1]Rusu, Emilia; [1]Enache, Georgiana; [1]Cursaru, Raluca; [2]Rusu, Florin; [3]Gheorghita, Andra; [3]Radulian, Gabriela.

[1]University of Medicine and Farmacy Carol Davila; Romania [2]Emergency Military Hospital Carol Davila; Romania [3]National Institute of Diabetes Nutrition and Metabolic Diseases "N Paulescu". Romania

Background and objectives: The objective of this study was to evaluate the nutritional status of patients with chronic hepatitis C virus (HCV) and metabolic syndrome (MetS) by various methods, and assessment of nutritional status and mutual relations of cardiovascular risk in this population.

Methods: This study is transversal and included 171 patients with HCV 60 HCV infected patients without MS and 111 patients with HCV and MetS. The nutritional status was assessed using body mass index (BMI) score MNA (Mini Nutritional Assessment), nutritional assessment score instantly - (instant nutritional assessment - INA) and nutritional risk index (NRI). We also calculated a combined score thus malnutrition: MNA results have merged, NRI, INA and BMI in a single combined score. We considered patients with malnutrition rezutatul based on the combined score, so it is considered malnourished individual score indicates if any is present. The diagnosis of MS was established using a modified IDF definition. Cardiovascular risk was assessed for each patient using software UKPDS-CHD.

Results: The age of patients with malnutrition and MetS was higher than that of the MetS without malnutrition (57.75±6.16 years vs. 51.85±9.65 years, p=0.125). Using the combined score of the total number of patients, malnutrition was present in 18 patients (10.5%). Of these, 12 patients (66.7%) belong to the group of those with MetS. The combination of malnutrition - moderate cardiovascular risk level, was observed in a small number of patients, most of the malnutrition associating with a low cardiovascular risk (n=2). Cardiovascular risk among those with only 6 patients had moderate malnutrition, and among those at high risk, only 4 associated malnutrition. The presence of Obesity was present in 122 patients (71.3%) - 58 women and 64 men. Of these, 8 patients (4.7%) had malnutrition based on the combined score.

Conclusions: Assessment of nutritional status in patients with HCV and MetS brings significant benefits by identifying malnutrition risk and to which they are exposed. Assessing the relationship of cardiovascular risk - malnutrition, has placed patients with malnutrition among those with low cardiovascular risk (n=2) or moderate (n=6), only a small number of people with malnutrition (n=4) with a high cardiovascular risk .

COFFEE CONSUMPTION AND SELECTED GASTROINTESTINAL CANCERS MORBIDITY IN POLAND

[1]Jarosz, Miroslaw; [2]Rychlik, Ewa; [3]Sekula, Wlodzimierz.

[1]MD, PhD. Physician. Department of Nutrition and Dietetic with Clinic of Metabolic Diseases and Gastroenterology. National Food and Nutrition Institute in Warsaw. Poland; [2]PhD. Nutritionist. Department of Nutrition and Dietetic with Clinic of Metabolic Diseases and Gastroenterology. National Food and Nutrition Institute in Warsaw. Poland; [3]PhD. Economist. Department of Nutrition and Dietetic with Clinic of Metabolic Diseases and Gastroenterology. National Food and Nutrition Institute in Warsaw. Poland.

Background and objectives: Coffee has been shown to induce the endogenous defense system, DNA repair capacity and to reduce the expression of genes involved in inflammation.

According to recent reports higher consumption of coffee probably protects against liver cancer. Some data from the literature suggest that it may reduce also the risk of gallbladder and colorectal cancer.

The aim of the study was to examine the relationship between trends in coffee consumption and liver, gallbladder and colorectal cancer morbidity in the past decades in Poland.

Methods: The study was based on liver (in 1980-2014), gallbladder (in 1970-2014) and colorectal (in 1960-2014) cancer incidence rates derived from the National Cancer Registry. Coffee consumption was determined on the basis of data on imports of coffee derived from the national statistics and converted into kg / person/year quantities.

Spearman correlation coefficients were used to estimate the relationship between the examined variables.

Results: In 1960-2014 imports of coffee to Poland increased from 0.13 to 3.02 kg/person/year.

Liver cancer incidence rates were rather stable in the decade of the 80's of the 20th century, whilst since the beginning of the 90's downward trends were observed. Gallbladder cancer incidence rates were stable between 1970 and the half of the 90's of the 20th century and then the decrease was noted. The colorectal cancer morbidity has increased over the whole period, but since the mid-90s of the 20th century to a lesser degree than in previous years.

Adverse correlations were found between coffee consumption and liver (-0.68 for males and -0.80 for females), and gallbladder cancer (-0.71 for males and -0.74 for females). There was no adverse correlation between coffee consumption and colorectal cancer morbidity during analyzed period.

Conclusions: The increase in coffee consumption in Poland could favourably affect some gastrointestinal cancers such as liver and gallbladder cancer morbidity rates in Poland and probably was one of the reasons of the observed decline in these cancers incidence in recent years.

Furthermore positive (growing) trends in coffee consumption could influence the reduction in colorectal cancer incidence rate.

Keywords: coffee, gastrointestinal cancers, morbidity

RELATION OF THE PERCEPTION AND SATISFACTION OF BODY IMAGE OF CHILDREN AND ADOLESCENTS WITH DOWN SYNDROME

[1]Manochio Pina, Marina Garcia; [2]Pansani Maniglia, Fabíola; [3]Haddad Caleiro Pereira, Cláudia; [4]Bagatini Saud Ferro, Élen Lúcia; [5]Boiani, Mariana Barbosa.

[1]Doutora.Nutricionista.Universidade de Franca.Brasil; [2]Mestre. Nutricionista.Pontifícia Universidade Católica de Campinas. Universidade de Franca.Brasil; [3]Mestre.Nutricionista. Universidade do Sagrado Coração.Universidade de Franca. Brasil; [4]Mestre.Nutricionista.Universidade de Franca.Brasil; [5]Nutricionista.Universidade de Franca.Brasil.

Background and objectives: Due to the greater predisposition to weight gain and excess body fat in children and adolescents with Down Syndrome (DS), care regarding feeding and weight gain should be doubled. When this process does not happen naturally, it can contribute to young people assessing yourselfel in an inaccurate way, these changes contribute to the body image also being reformulated. The objective of this study to identify the perception and satisfaction of body image of children and adolescents with DS and to associate it with anthropometric characteristics of this population.

Methods: It deals with a cross-sectional and observational study with 27 children and adolescents aged 7 to 18 years old with DS, in an interior town in São Paulo state. It was applied the Figure Rating Scale and it was realized the nutritional assessment using anthropometry, electrical impedance analysis.

Results: It was possible to observe that the classification of body weight by age showed the following result: 11.11% underweight, 48.14% of adequacy and 40.74% above the recommended weight. The ratio of height for age showed that 55.5 % of youth had adequate linear growth. The average waist circumference was 86.33cm. The examination of electrical impedance analysis showed good hydration, muscle mass below the minimum limit and body fat above the recommended maximum. Regarding the perception of body image, there was no statistically significant difference (p>0.05), while the satisfaction of body image, indicated statistical difference (p<0.05) between the actual BMI and the desired BMI. By correlating the waist circumference was statistically different (p<0.0001).

Conclusions: Children and adolescents with DS are not satisfied with their body image because they wish to have a slimmer body and how bigger the waist circumference is much bigger they will notice them self's. It is necessary to have further studies in order to add new values and knowledge of the perception and satisfaction with body image of individuals with DS.

Background and objectives: Depression will be the second leading cause of disability globally by 2020. There is increasing evidence that dietary patterns play a role in depression but recent reviews have failed to find consistent associations and have speculated that this might be due to differences in study designs and assessment methods.

We aimed to examine the association between dietary patterns and depression across a number of cohorts using a standardised protocol, and to meta-analyse the findings of these studies.

Methods: We developed a standardised protocol to assess the association between four a priori dietary patterns: AHEI-2010 (Chuive et al); Mediterranean diet score (Panagiotakos 2007); DASH diet (Fung 2008); The MooDFOOD diet.

Included were data of more than 20,000 participants from seven cohorts that have measured both diet and depression at different time points: InCHIANTI (Italy), LASA , NESDA, HELIUS (all three Netherlands), ALSWH (Australia), Whitehall and NSHD (both UK). Four cohorts had repeated measures allowing prospective analysis (Whitehall, InCHIANTI, ALSWH, NSHD).

Predictor and outcome variables were standardised to enable comparison between studies. The association between dietary pattern and continuous depressive symptom scores was investigated using linear regression analysis and the association with a dichotomous 'depression' outcome using logistic regression. Analyses were conducted by researchers from the individual cohorts and meta-analyses were conducted centrally.

Results: Analyses will be completed by the end of May 2017. Preliminary findings of cross-sectional data show a statistically significant protective effect of the Mediterranean diet score on continuous depressive symptoms in most cohorts. Random effects meta-analysis also yielded a statistically significant protective effect, standardized B -0.08 (95%CI -0.12; -0.04, p-value<0.01).

Conclusions: There are indications that healthy dietary patterns are associated with fewer depressive symptoms. The full findings of this study will provide important insights that can help answer the question "Can diet contribute to the prevention of depression?"

HYPERTENSION, NUTRITION STATUS, DIETARY INTAKE AND PHYSICAL ACTIVITIES OF KENYATTA UNIVERSITY EMPLOYEES: THE ROLE OF NUTRITION AND PHYSICAL ACTIVITY IN CATCHING UP THE SILENT KILLER

[1]Samburu, Betty; [2]Waudo, Judith; [3]Kimiywe, Judith; [4]Kuria, Elizabeth.

[1]Msc. Programme Manager Maternal Infant and Young Child Nutrition. Ministry of Health Nutrition and Dietetics Unit. Kenya.; [2]PhD.Prof. Nutrition. Department of Foods Nutrition and Dietetics. Kenyatta University. Kenya; [3]PhD. Assistant Prof. Nutrition. Department of Foods Nutrition and Dietetics. Kenyatta University. Kenya; [4]PhD. Kenyatta University. Department of Foods Nutrition and Dietetics. Kenyatta University. Kenya.

Background and objectives: Background: Non communicable diseases contribute to 59% deaths worldwide annually of which 16.7% are as a result of cardiovascular diseases. It was estimated that, in 2000, up to 80 million African were hypertensive and this figure is expected to double by the year 2025. In Kenya 23.8% adults are hypertensive and out of these 91.8% are not on medication. Hypertension is referred to as a "Silent Killer" as it often goes unrecognized and undiagnosed. It may drain the country to economic and social stagnation due to related mortality, costs of treatment and absenteeism from work.

Objectives: To determine the prevalence of hypertension, nutrition status and dietary intake and its relationship to socio demographic characteristics among Kenyatta University (KU) Employees.

Methods: The target respondents were employees aged 25 to 75 years. A total of 236 subjects were selected using multistage sampling. A self administered questionnaire was used to collect data. Blood pressure (BP) and weight were measured in the respondent's offices.

Results: of the 236 employees, 39.4% had hypertension (BP≥140/90mmHg/taking antihypertensive medicine). However, 36.7% of respondents with hypertension were unaware. 35.6% were overweight, 16.9% were obese 1 and 3.4% were obese 2. Diets of most employees (70%) needed improvement, whereas 10% had a good diet while 20% had poor dietary intake. Only 14.6% met the daily recommended allowances for 6 key micronutrients. Majority of subjects rarely participated in sporting activities and 95% were never involved in leisure time activities. Mean diastolic BP of moderately active normal weight men (118mm/Hg) as well as the moderately active overweight men (119mm/Hg) were lower than the BP of inactive normal weight (130mm/Hg) and overweight men (137mm/Hg). There was a strong positive relationship between obesity and hypertension p value 0.000 at 95% confidence interval

Conclusions: Conclusion: Employee's dietary intake is wanting and therefore institutions should take action to protect health of their populations. The low intake of micronutrients and physical activity is a health risk and preventive measures need to be put in place. Despite being overweight, physical activity is key in controlling BP.

Keywords: Key words: hypertension, diastolic, systolic

THE EFFECT OF HIGH AND LOW DAIRY CONSUMPTION ON CARDIO-METABOLIC RISK FACTORS IN OVERWEIGHT ADULTS

[1]Eelderink, Coby; [2]Rietsema, Susan; [3]Van Vliet, Iris M. Y.; [4]Boer, Theo; [5]Singh-Povel, Cecile M.; [5]Geurts, Jan; [6]Corpeleijn, Eva; [7]Bakker, Stephan J.L.

Background and objectives: Dairy products contain many nutritious components that benefit health. An inverse dose-response relationship between dairy consumption and the risk of metabolic syndrome was recently reported based on a meta-analysis. There are indications that dairy intake decreases the risk for type 2 diabetes and improves glucose metabolism and insulin sensitivity which is generally disturbed in overweight and obese individuals. This study aimed to investigate the effects of high and low dairy intake on cardio-metabolic health parameters.

Methods: 47 overweight males and postmenopausal females [age 58.7 ± 4.5 y, BMI 27.9 ± 1.9 kg/m2 (mean±SD)] completed this randomized, cross-over, intervention study. Each person consumed an isocaloric high and low dairy diet (HDD (5-6 portions) and LDD (≤1 portion), respectively; 200 g semi-skimmed yoghurt, 30g low-fat (30+) cheese, 250 mL semi-skimmed milk and buttermilk) for 6 weeks in a cross-over design, with a wash-out period of 4 weeks. After each 6-week intervention period blood pressure was measured, and blood samples were collected, both fasted and during challenge tests. The tests were a 75 g OGTT (13C-labeled and combined with 2H-labeled glucose infusion to study glucose kinetics) and a subsequent fasting challenge.

Results: After HDD compared to LDD there were significant decreases in blood pressure [127/79 mmHg vs 132/82 mmHg, respectively $(p<0.01)$] and uric acid [0.29 ± 0.06 vs 0.31 ± 0.07 mM, respectively $(p<0.001)$]. Fasting glucose concentrations were similar, whereas fasting insulin concentrations were lower after the LDD [10 ± 4 mU/L after HDD vs 9 ± 4 mU/L after LDD $(p<0.05)$]. In addition, there was a small difference in HDL concentrations [1.40 ± 0.34 mM after HDD, 1.44 ± 0.38 mM after LDD, $(p<0.05)$],

but the cholesterol/HDL-ratio was not different after the intervention periods [4.0 vs 3.9 (p=0.14)]. Postprandial glucose and insulin responses as well as glucose kinetics were similar after both diets.

Conclusions: High dairy intake had a positive effect on blood pressure, which may be related to the decreased plasma uric acid concentration. Results: **Keywords:** Dairy consumption, metabolic syndrome, cardio-vascular health, blood pressure, overweight

DIETARY SUPPLEMENTATION OF OMEGA-3 POL-YUNSATURATED FATTY ACIDS MANIPULATE LIPID HOMEOSTASIS VIA BROWNING OF WHITE ADIPOSE IN ALREADY INDUCED OBESE MICE

(1)Zhuang, Pan; (2)Jiao, Jingjing; (3)Wang, Wenqiao; (1)Wang, Jun.

(1)BSc. Department of Food Science and Nutrition, College of Biosystems Engineering and Food Science. Zhejiang University. China.; (2)PhD. Nutritionist. Department of Nutrition. School of Public Health. Zhejiang University School of Medicine. China.; (3)MD. Department of Nutrition. School of Public Health. Zhejiang University School of Medicine. China.

Background and objectives: Obesity and related metabolic disorders has reached pandemic levels. Previous studies have showed the ameliorative effect of omega-3 fatty acids on the development of obesity. But it is still unclear how omega-3 fatty acids improve lipid homeostatic imbalance in already existing obesity. Here we assessed the biological effects of eicosapentaenoic acid (EPA; 20:5n3) and docosahexaenoic acid (DHA; 22:6n3) from long-term dietary intake on lipid and energy homeostasis in high-fat-diet (HFD) induced obese (DIO) mice.

Methods: Four-week-old C57Bl/6 mice were fed with HFD (45% fat) for 10 weeks to introduce obesity. The HFD fed mice were then trisected and fed with DHA or EPA enriched HFD (HFD+DHA or HFD+EPA; 1% wt/wt) or HFD for 15 weeks. Systemic adiposity, hypothalamic feeding regulators, browning process of adipocytes and risk factors of hepatosteatosis were investigated. In vitro, 3T3-L1 adipocytes at different stages of differentiation were treated with EPA or DHA, and expressions of browning programme markers and mitochondrial biogenesis were investigated.

Results: After long-term supplementation with EPA or DHA in DIO mice, the body weight of mice did not decline (HFD+DHA or HFD+EPA vs. HFD) whereas DHA-fed female mice gained more weight if compared with the mice in HFD group. Interestingly, DHA or EPA administration improved hypercholesterolemia but aggravated hypertriglyceridemia. Nonetheless, DHA significantly reduced subcutaneous fat of male mice and both DHA and EPA improved fatty liver in female mice via down-regulating expressions of triglyceride synthesis genes and promoting β-oxidation relative genes expression. Moreover, EPA inhibited the appetite of female mice by controlling hypothalamic inflammation. Importantly, DHA or EPA significantly lowered the respiratory exchange

ratio of DIO mice, suggesting enhanced lipid mobilization. These effects may result from promoted thermogenesis of brown adipose tissue in all mice except DHA-fed female mice. In vitro, preadipocytes treated with DHA induced a phenotypic white-to-brown shift whereas EPA elevated uncoupling protein 1 expression and mitochondrial biogenesis in 3T3-L1 adipocytes at differentiation and also in mature adipocytes.

Conclusions: Our findings reveal the effect of DHA and EPA on lipid and energy homeostasis in already existing obesity and further clinical investigations are warranted to formulate recommendations of DHA and EPA intakes for obese subjects.

CONSUMPTION OF MACRONUTRIENTS BY CELIAC CHILDREN AND COMPOSITION OF MIXES GLUTEN FREE FLOURS

(1)Wright, Ricardo A.; (2)Dyner, Luis; (3)Ferretti, Martina; (4)Olivera Carrión, Margarita.

(1)PhD Student, Nutritionist. Center for Nutrition and Child Development Studies. Commission for Scientific Research, Argentina.; (2)PhD, Buenos Aires University, Faculty of Pharmacy and Biochemistry, Food Science Department. Argentina; (3)Biochemist, Buenos Aires University, Faculty of Pharmacy and Biochemistry, Food Science Department, Argentina; (4)PhD, Buenos Aires University, Faculty of Pharmacy and Biochemistry, Food Science Department; Argentina.

Background and objectives: The gluten-free diet is the only treatment indicated for people with celiac disease. International studies indicate high intake of carbohydrates with protein and dietary fiber deficiencies. Since in Argentina there are no topic information, it was considered of interest to highlight the intake of macronutrients in celiac children and the composition of mixes gluten free flours (GFF).

Methods: We studied 40 children (group A: 22 children 6-8 years, group B: 18 children 9-11 years), who attended in a public hospital. Food consumption was recorded for two days and macronutrient intake was calculated using national composition tables. Simultaneously it was analyzed the composition of 4 commercial mixes GFF most commonly used by families to make bread, pasta, cookies, cakes, etc. Protein, total fat, dietary fiber, carbohydrate by difference and energy were determined.

Results: Intake for groups of children A and B were respectively: 1670 and 2348 Kcal; 236 and 311 g carbohydrates; 59 and 91g protein; 55 and 76g fat and 9 and 13g dietary fiber. When comparing these values with the recommendations of the Institute of Medicine, National Academies of Sciences (2005), high consumption of carbohydrates and proteins, adequate amount of fats and low of fiber was evidenced.

The analytical results of mixes GFF showed low protein content (3.1-8.5%), fat (0.2-5.4%), fiber (2.1-5.0%) and high carbohydrate

content (72,1 - 82.4%) and energy (348-359Kcal%). The ingredients used in the mixes formulation were similar with prevalence of starchy compounds (maize starch, rice flour and potato starch / cassava).

Conclusions: The diversification of the formulation of mixes GFF with high fiber ingredients, would favor the intake of a more balanced diet in celiac children with a decrease in high carbohydrate intake and increase in dietary fiber.

NUTRITIONAL STATUS IN RECENTLY DIAGNOSED HIV-INFECTED PEOPLE

[1]Peralta, Leticia; [2]Slobodianik, Nora H.; [3]Feliu, Maria Susana; [3]Stambullian, Marcela.

[1]PhD student; [2]PhD. University of Buenos Aires, School of Pharmacy & Biochemistry. Dept. Nutrition & Food Science. Argentina.; [3]PhD.

Background and objectives: Despite the benefits from highly active antiretroviral therapy (HAART), malnutrition remains as a problem among HIV-infected individuals specially in newly diagnosed, in whom HAART does not start o just started few weeks ago. Objective: To assess nutritional risk and/or nutritional status from different indicators, in a group of HIV patients.

Methods: Cross-sectional, descriptive study. Patients diagnosed with HIV infection no more than 6 months ago were included. Malnutrition screening tool (MST) was performed. Anthropometry: weight, height and mid-upper arm circumference. BMI, % of involuntary weight loss (UWL) and significantly UWL, were calculated. It was considered BMI at risk between 18,5-20 kg/m2 (Wanke MD, et al. 2004). Total cholesterol (TC) and albumin levels were collected from medical records. Transferrin and ultrasensitive C-reactive protein were determined by quantitative radial immunodiffussion on plates and immunoturbidimetry, respectively. Nutritional assessment (NA) was performed by 2 registered dietitian specialized in HIV infection. Values were considered statistically significant at p<0.05. Software STATA 11,1.

Results: 53 patients were included. Regarded MST, 28% presented moderate and 16% had high nutritional risk. In relation to BMI, 6% were between 18,5-20kg/m2 and 4% were <18,5kg/m2. Nutritional assessment diagnosed 30% at nutritional risk and 14% with undernutrition. 36% showed a significant UWL. There is statistical significantly association between NA and MST (p≤0.0001) and BMI (p≤0.001) but not all undernourished people were identified by BMI. 73.4% of patients with BMI in normal range were diagnosed with undernutrition by NA. Biochemical analysis showed, a media of TC of 142mg/dL (IQR 102,7;192.2) and transferrin of 205,8mg/dL (RIQ 167,2;240,4), but albumin level in normal range: 3,9g/dL (RIQ 3,5;4,4). The average value of CRP was 27,4g/L. (RIQ 14,4;47,0)

Conclusions: There are several malnourished patients to consider in the first 6 months since diagnosis. BMI is the nutritional indicator most commonly used by physicians. MST detected a number of people at risk similar to the diagnoses of nutritional assessment not BMI. So, BMI could underdiagnose malnourished people by delaying an opportune nutritional care in persons suffering HIV infection.

Keywords: HIV, nutritional assessment, MST, BMI, malnutrition.

Endocrinology and Nutrition Service, Hospital Clínic, IDIBAPS), Spain / CIBER Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Instituto de Salud Carlos III (ISCIII), Spain.

Background and objectives: Nuts are long known to have a cholesterol-lowering effect. Because nuts are fat-rich, energy-dense foods, there is a widespread concern that their regular consumption may lead to unwanted weigh gain, but there are no long-term (>24 weeks) data on lipids and adiposity changes after nut-supplemented diets. We hypothesized that incorporating daily doses of walnuts to the habitual diet of older free-living individuals for 2 years would lower blood cholesterol without adverse effects on adiposity.

Methods: WAHA is a dual-center randomized controlled trial aimed at assessing the effects of walnuts on age-related diseases in individuals aged 63 to 79 years. In the Barcelona node, 352 participants (108 men/244 women) were assigned to either usual

diet without nuts (control group, CG) or usual diet with walnuts at ≈15% of energy (30-60 g/day depending on energy requirements) (walnut group, WG). Fasting serum lipids, body weight, waist circumference and body fat distribution by DEXA were assessed at baseline and at the end of the trial. We used changes in the red blood cell proportion of alpha-linolenic acid (ALA) as a biomarker of adherence to the intervention. Differences in outcomes were assessed by ANCOVA adjusting for sex, age, and baseline values; lipid changes were additionally adjusted for in-trial changes in statin treatment.

Results: 2-year data were available for 329 subjects (165 WG, 164 CG). RBC ALA increased in the WG by 0.236 % (95% confidence interval [0.219 to 0.263]; P<0.001 vs. CG). LDL-cholesterol changes in the WG and CG were -8.36 [-11.90 to -4.82] vs. -2.90 [-6.55 to 0.75] mg/dl, respectively (P=0.036). No between-group differences were observed for other lipids, body weight, body mass index, waist circumference, or body fat distribution.

Conclusions: 2-y supplementation with walnuts decreased LDL-cholesterol. This concurs with prior evidence observed in smaller trials conducted in younger individuals treated for up to 24 weeks. The results help dispel the notion that nuts are obesogenic foods, a still common constraint to recommend their consumption as a cost-effective strategy to prevent cardiovascular disease.

Keywords: adiposity, cholesterol, walnuts.

NUTRITIONAL STATUS REGARDING IRON AND ZINC IN CELÍAC CHILDREN AND MINERAL CONTRIBUTION OF MIXES FLOURS

[1]Wright, Ricardo A.; [2]Dyner, Luis; [3]Rosa, Diana; [4]Cagnasso, Carolina; [4]Olivera Carrión, Margarita.

[1]PhD Student, Nutritionist. Center for Nutrition and Child Development Studies. Commission for Scientific Research.; [2]PhD, Buenos Aires University, Faculty of Pharmacy and Biochemistry, Food Science Department. Argentina; [3]PhD. National University of La Plata. Faculty of Veterinary Medicine. Mineral Nutrition Laboratory. Argentina; [4]PhD, Buenos Aires University, Faculty of Pharmacy and Biochemistry, Food Science Department.

Background and objectives: In order to mitigate iron (Fe) deficiency in Argentina, 3 mg / 100g of Fe is added to wheat flour (WF). Nevertheless, Gluten Free Flours (GFF) are not added to Fe. Deficiencies of Fe and zinc (Zn) have been reported in celiac people even though they may consume red meat.

In this paper we studied Fe and Zn reserves in celiac children attending a public hospital and mineral content of the mixes GFF most commonly used at home.

Methods: As reserve indicators, serum Ferritin and Zn were determined in 40 children (age 8.8 ± 2.0 years, 67.5% female,

32.5% male). In 4 most used commercial mixes GFF, Fe and Zn were analyzed by atomic absorption spectrometry.

Results: The serum ferritin concentration was 23.0 ± 15.0 µg/L, where 37.5% (n=15) presented levels below the limit (≤15 µg/L), while 62.5% (n=25) presented normal iron deposits (> 15 µg/L).

For Zn, serum levels were 121.7 ± 36.0 µg/dL, where 12.5% (n = 5) presented deficiency (<0.82 µg/dL) while 87.5% (n=35) had adequate reserves (>0.82 µg/dL).

In commercial mixes GFF, Fe concentration was very low: not detectable in two samples and low in the remaining (0.10 ± 0.06 mg%, 0.60 ± 0.04 mg%). These values were very low compared to enriched WF (3mg / 100g)

Regarding Zn, the range found in mixes GFF (0.30 ± 0.01 - 0.70 ± 0.01 mg%), exceeded the results found in WF (not detectable - 0.36 ± 0.04 mg%).

Conclusions: In the studied population, the third part presented deficiency respect to the Fe, and the tenth part respect to the Zn. Compared to WF, the mixes GFF were very poor Fe contributors and adequate in Zn. This would indicate the importance of Fe addition to GFF flours.

NUTRITIONAL STATUS OF FEMALE PATIENTS WITH BREAST CANCER ATTENDING THE RADIOTHERAPY DEPARTMENT OF THE UNIVERSITY COLLEGE HOSPITAL, IBADAN, NIGERIA

[1]Fadupin, Grace T.; [2]Lawal, Hadiyah I.; [2]Ogunkunle, Morenike.

[1]PhD. Nutritionist. University of Ibadan, Ibadan, Oyo State, Nigeria; [2]M.Sc. Nutritionist. University of Ibadan, Ibadan, Oyo State, Nigeria.

Background and objectives: Nutritional status of cancer patients can be compromised in direct response to tumor induced alterations in metabolism. There is dearth of information on the nutritional status of female Nigerian patients with breast cancer. This study was carried out to access the nutritional status of female patients with breast cancer attending the Radiotherapy Department of the University College Hospital, Ibadan, Nigeria.

Methods: Thirty-five female patients with breast cancer were assessed. A semi-structured interviewer administered questionnaire and food frequency questionnaire were used to obtain information on the socio-demographic characteristics, medical history and frequency of food consumed by the patients. The body mass index (BMI in kg/m2) of the patients was determined. Data were analyzed using descriptive statistics and chi-square at p<0.05.

Results: The mean age of the patients was 47.3± 9.58 years. Most (70.2%) of the patients were Yoruba, 60.0% had secondary or tertiary education, 91.4% were married and 82.9% had ≥ 3 children. Majority (80.0%) were diagnosed with breast cancer less than 2 years. Their main sources of staple were cereals, grains,

roots and tubers and their protein sources were meat fish and legumes. Fruits were only consumed occasionally as snacks and vegetables were only consumed as accompaniment to staples. The mean height (m), weight (kg) and BMI (kg/m2) of the patients were 1.57±0.040m, 69.57±11.56kg/m2 and 29.15±4.79kg/m2. None of the patients was underweight, 20.0% had normal weight while others were overweight (45.75%), obese (31.4%) or grossly obese (2.9%). A significant association was observed between the patient BMI and occurrence of breast cancer.

Conclusions: Overweight and obesity were prevalent among the patients. The patients need proper nutritional counseling on adequate consumption of fruits and vegetables as well as maintenance of normal body weight for better health.

CD36 GENOTYPE DOES NOT AFFECT FAT SENSITIVITY IN NONOBESE SUBJECTS

[1]Chmurzynska, Agata; [2]Galinski, Grzegorz; [3]Mlodzik, Monika.

[1]PhD. Nutritionist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland. International Society of Nutrigenetics/Nutrigenomics (ISNN).; [2]PhD. Nutritionist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland; [3]MSc. Biotechnologist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland.

Background and objectives: A single nucleotide polymorphism of the CD36 gene (rs1761667; A/G) has been proposed to be one of the main determinants of fatty acid sensitivity. The relationships between fat intake, sensitivity to fat, and body weight and composition are still debatable. The aim of this study was to analyze whether the CD36 genotype affects oral fatty acid sensitivity and whether fat intake or body composition may modify this relation.

Methods: 131 people (88 women and 43 men) aged 20–40 were enrolled in the so-called Fat Taste Project. Body weight was measured using the electronic scale and body composition was analyzed using a BodPod (Cosmed, Italy). Food intake was assessed with dietary records and the intake of nutrients was calculated using the Dieta 5.0 program (National Food and Nutrition Institute). The ability to discriminate samples containing different amounts of fatty acids was investigated using salad dressings with different concentrations of canola oil. An ascending forced-choice triangle procedure was applied. The subjects were divided into three subgroups: with low, medium, and high sensitivity. The CD36 genotype (rs1761667) was analyzed using hybridizing probes.

Results: In women, the mean body mass was 62.1 ± 1.1 kg, the mean BMI was 22.4 ± 0.3 kg/m2, and the mean percentage body fat was 26.7% ± 1.0%; in men, these parameters were respectively 81.2 ± 2.3 kg, 25.1 ± 0.7 kg/m2, and 25.4% ± 1.4%. The average daily fat intake was 78.6 ± 3.0 g in women and 77.8 ± 3.0 g in men. The average percent energy from fat was 32.3% ± 0.6% in women and 32.2% ± 1.1% in men. The CD36 gene frequencies were 0.5 for both alleles. The CD36 genotype did not affect the ability to discriminate fat content in the test samples, irrespective of body composition. People with the AA genotype, who are genetically less sensitive to fat, were able to detect lower concentrations of fat when their diets contained more fat, this tendency was however not statistically significant.

Conclusions: The CD36 genotype does not affect oral fatty acid sensitivity in nonobese adults.

Keywords: fat taste, CD36, body composition, fat intake

QUALITY NUTRITIONAL COMPARISON OF PRE-HISPANIC DIET, DASH DIET, FAST METABOLISM DIET, GLUTEN FREE DIET & ALCALINE DIET AS A CONTRIBUTORY TREATMENT OPTION FOR CANCER

[1]Cárdenas García, Maura; [2]Hernández Caballero, Marta Elena; [3]Guerrero Africani, Marcela Lucía; [4]Jiménez Hernández, Diana; [4]Zambrano Zacaula, Zurisadai.

[1]D.C. Maura Cárdenas García. Facultad de Medicina. Benemérita Universidad Autónoma de Puebla. México; [2]D.C. Facultad de Medicina. Benemérita Universidad Autónoma de Puebla. Mexico.; [3]M.C. Facultad de Medicina. Benemérita Universidad Autónoma de Puebla. Mexico; [4]L.N.C.P. Laboratorio de Fisiologia Celular y Molecular. Facultad de Medicina. Benemérita Universidad Autónoma de Puebla. Mexico.

Background and objectives: During the development of this task quality nutrition was made of different diets which have been recommended as nutrition treatment contributories in patients who suffer from cancer, and also from energy protein nutritional deterioration on account of losing weight, emaciation, stress and malnutrition. Therefore, nutritional treatment is an essential pillar due to the nutritional requirements that are more specified and must be complemented.

Methods: Five different diets were selected taking into consideration five dietary events for a week with an estimated energy waste 30-35 kilocalories gram per day for 20-40 year-old adult woman with cancer. From the elaborated menus a calculi was made for each nutriment according to food composition table for Mexicans, taking into account the main nutrient compounds for cancer. The 7 weekdays results were achieved and was compared with the suggested diary ingested established for the healthy Mexican population according to age and gender.

Results: Cancer patient diet must include important nutriments as dietetic fiber, 25 – 35 grams per day, monounsaturated fatty acids, polyunsaturated, antioxidants, vitamins as ascorbic acid 75 mg/per day, retinol 800 μg - 1.000 μg, gamma tocopherol 15

mg/ día, phytoestrogens like isoflavons, oligometals like selenium, calcium and polyphenols. Diet with majority of these nutriments is prehispanic diet, which meets diary ingested requirements in comparison to alcaline, despite being richer in antioxidants but it does not meet the suggested requirements especially in macro nutriments. Obtained aminoacids quantities suggest epigenetic action as genomic modificators, acting as anti- cancerigen for supresor actions of tumoral genes.

Conclusions: It was observed that not all suggested menus meet the nutritional requirements for the oncologic aspects as a possible treatment. It is important to do more nutritional research to meet treatments and patient benefits. Nowadays, there are many diets with different characteristics, however, a diet it cannot be generalized for a nutritional treatment, it must be individualized according to patient to provide a more completed and specific nutritional support.

Keywords: nutrition, clinical, nutrition quality, diets, cancer

HIGH 24-H URINARY SULFATE EXCRETION IS ASSOCIATED WITH LOW RISK OF GRAFT FAILURE IN RENAL TRANSPLANT RECIPIENTS

[1]Said, Yusof; [2]Post, Adrian; [3]Minovic, Isidor; [4]van Goor, Harry; [5]Postmus, Douwe; [6]van den Berg, Else; [7]Navis, Gerjan; [7]Bakker, Stephan J.L.

[1]MD. PhD candidate. Department of Nephrology. University Medical Center Groningen. The Netherlands.; [2]BSc. Department of Nephrology. University Medical Center Groningen. The Netherlands.; [3]PharmD. Department of Nephrology. University Medical Center Groningen. The Netherlands.; [4]PhD. Department of Pathology and Medical Biology. University Medical Center Groningen. The Netherlands.; [5]PhD. Department of Epidemiology. University of Groningen. The Netherlands.; [6]MD. PhD. Department of Nephrology. University Medical Center Groningen. The Netherlands.; [7]MD. PhD. Department of Nephrology. Groningen Kidney Center. University Medical Center Groningen. The Netherlands.

Background and objectives: Hydrogen sulfide (H_2S) is a cytoprotective compound, which is an intermediate in the metabolic pathway between dietary sulfur-containing amino acids and the end-metabolite of this pathway, sulfate. High 24-h urinary excretion of sulfate (UExS) may therefore reflect high H_2S bioavailability and thereby be associated with protection against organ damage. We therefore aimed to investigate the association of UExS is associated with graft failure in renal transplant recipients.

Methods: We included 687 stable RTR that were recruited at least 1 year after transplantation. UExS was measured from 24-h urine samples at baseline. Cox regression analyses have been performed to study association of UExS with outcome.

Results: In our cohort, median age was 55 years, 57% were males, mean eGFR was 45 ml/min, and median time between transplantation and baseline was 5.5 (interquartile range 4.5 –

6.0) years. Median 24-h UExS was 17.1 mmol/24-h. Over a median follow-up of 5.3 (interquartile range: 4.5 – 6.0) years 81 RTR experienced graft failure. UExS was significantly associated with decreased graft failure (HR: 0.44 per log2 increment, 95% CI: 0.33-0.59, P<0.001). The association remained significant (HR: 0.50 per log2 increment, 95% CI: 0.27-0.95, P=0.03) after adjustment for age, sex, eGFR, proteinuria, BMI, physical activity, protein intake, alcohol intake, smoking behavior, transplantation-related factors (e.g. cold ischemia time, early rejection), immunosuppressive drug usage, antidiabetic drug usage, antihypertensive drug usage, and blood urea level. Additional adjustment for 24-h urinary creatinine excretion (reflecting muscle mass) did not materially change the association, although it became slightly less significant (HR: 0.52 per log2 increment, 95% CI: 0.27-1.00, P=0.05).

Conclusions: The results of this study demonstrate a significant inverse association of UExS with graft failure in RTR and suggests a protective effect of increased sulfur intake. An underlying mechanism of this association may be increased H_2S pathway activity. Additionally, the association may be explained by beneficial effects of increased muscle mass related to higher sulfuric amino acid intake and in general higher dietary protein intake. For future research, it is interesting to study what the effects are of specific dietary sources of sulfate on graft failure.

Keywords: sulfate; graft survival; renal transplantation, amino acids

RELATIONSHIP BETWEEN FAT MASS AND WAIST CIRCUMFERENCE WITH THE TRANS FATTY ACIDS INTAKE ON WOMEN OF CHILDBEARING AGE. PRELIMINARY STUDY

[1]Morínigo Martínez, Macarena; [2]Mereles Ceuppens, Laura Graciela; [2]Coronel Mendez, Eva Eugenia; [2]Wiszovaty, Lourdes; [2]Caballero, Silvia; [2]Piris, Patricia; [2]Michajluk, Javier Boris; [3]Araujo Pino, Silvia Stella; [3]Aguilar Rabito, Ana Carolina; [3]Gonzalez Cespedes, Laura Elizabeth.

[1]Nutritionist. Department of Nutrition Research. Faculty of Chemical Sciences. National University of Asuncion. Paraguay; [2]Departamento de Bioquímica de Alimentos. Dirección de investigaciones. Facultad de Ciencias Químicas. Universidad Nacional de Asunción. Paraguay; [3]Departamento de Nutrición. Dirección de investigaciones. Facultad de Ciencias Químicas. Universidad Nacional de Asunción. Paraguay.

Background and objectives: The childbearing years are an important life stage for women, where the obesity can have health consequences in the medium and long term. Intake of trans fatty acids (TFA) from diet has been associated with the development of abdominal obesity and consequently with cardiovascular disease and diabetes, these are currently considered risk factors. The aim of the work was to explore the relationship between the consumption of TFA and fat mass (FM), visceral fat (VF) and waist circumference (WC) on a population of childbearing women from

Facultad de Ciencias Químicas (FCQ) of the Universidad Nacional de Asunción.

Methods: Three outcome measures have been examined in women students (n=56): The percentage of FM and VF, by the Omrom BF500 Body Composition Monitor with Bioimpedance (NIH/WHO guidelines for BMI- Gallagher et al). The WC, following the WHO Physical Measurement Guide. (3) Consumption of TFA per day (g/TFA/day) by a Food Consumption Frequency (FCA) survey. For statistical analysis; the Spearman correlation was applied and the Kolmogorov-Smirnov and Kruskal-Wallis Z tests were used for the comparison of means.

Results: The mean age was 21.8±2.4 years. The median of caloric intake by TFA was 3.3% of total energy (IC95%: 3.11-4.5%) and 7.3g g/TFA/day (IC95%: 6.9-9.8 g/TFA/day). The mean of the anthropometric measurements was 31.5% (IC95%: 30.8-33.9%) for FM, 3.7 (IC95%: 3.4-4.0) for VF and 72.8cm (IC95% 70.8-74.8cm) for WC. The mean TFA consumption was increasing according to the FM classification, 8.4gTFA/d (Normal), 7.1gAGT/d (High) and 8.8gAGT/d (Very high), although the differences was not significant (p=0.278). The mean consumption of TFA was 6.8gTFA/day in women with WC not increased, whereas 9.5 gTFA/day with WC increased (p=0.092). All evaluated women had adequate VF. TFA consumption showed a proportional trend with FM (r=0.001) and WC (r=0.104), although not significant (p≤0.05).

Conclusions: A trend between FM, WC and the TFA intake was observed.

Keywords: Childbearing women, fat mass, waist circumference, trans fatty acids, intake.

THE EFFECT OF CORNELIAN CHERRY AND HONEYSUCKLE ADDED TO DIET ON SELECTED BIOCHEMICAL PARAMETERS IN WISTAR RATS

[1]Bronkowska, Monika; [2]Lozna, Karolina; [2]Figurska-Ciura, Danuta; [2]Orzel, Dagmara; [2]Styczynska, Marzena; [3]Kucharska, Alicja; [4]Sozanski, Tomasz; [2]Piotrowska, Ewa.

[1]Associate Professor, Head of Department of Human Nutrition, Wrocław University of Environmental and Life Sciences, Poland; [2]Dr, Department of Human Nutrition, Wrocław University of Environmental and Life Sciences, Poland; [3]Departament of Fruit, Vegetable and Plant Nutraceutical Technology, Wrocław University of Environmental and Life Science Poland; [4]Department of Pharmacology, Wrocław Medical University, Poland.

Background and objectives: Fruits of cornelian cherry (Cornus mas L.) and berries of honeysuckle (Lonicera caerulea L. var. kamtschatica) are a valuable source of phenolic compounds (1). These compounds show many properties beneficial for human organism (2). The fruits can also contain other biologically active compounds, like iridoids, which exhibit antibiotic, anti-inflammatory or hypertensive activities (3).

Methods: The experiments were conducted on 60 male Wistar rats divided into 8 groups. Rats were fed with diets: group 1- C – a control diet; group 2 - CC– a control diet with Cornelian cherry powder (300 mg/100 g); group 3 - HLC– a control diet with honeyberry Lonicera caerulea powder (300 mg/100 g); group 4 – CC+HLC - a control diet with HLC powder (300 mg/100 g) and CC powder (300 mg/100 g); group; 5 – HF- a high fat diet containing 15% of animal fat (lard); group 6 – HF+CC– a HF diet with CC powder (300 mg/100 g); group 7 – HF+HLC– a control diet with HLC powder (300 mg/100 g); group 8 – HF+CC+HLC - a control diet HLC (300 mg/100 g) and CC powder (300 mg/100 g).

Results: CC and HLC did not significantly affect on morphological parameters in blood in experimental rats. It significantly affected on liver enzyme activity ALAT, which decreased significantly in CC+HLC animals regardless of fat content in diet (41.3 vs 33.8 U / l). Comparing the effect of CC vs HLC a higher reduction in addition of honeyberry were observed. Similar results in blood TG levels were observed. The addition of one of dried fruits caused TG reduction - 11% for CC, 19% for HLC and 38% for both of them. Polyphenols have a protective effect on the liver, which is related to its ability to block both inflammatory processes in the liver and activation of stellate cells. Addition of CC and HLC caused lowering Phosphorus, Calcium and Sodium level. The effect of the supplement is independent of the fat content in the diet.

Conclusions: Cornelian cherry and honeyberry Lonicera caerulea can be addet as an element of functional food to protect liver and reduce TG level.

Keywords: Cornelian cherry honeysuckle Lonicera caerulea, biochemical parameters, rats

EXPERIMENTAL, PROSPECTIVE, RANDOMIZED AND DOUBLE BLIND STUDY ABOUT SAFETY AND EFFICACY OF MAZINDOL AS A TREATMENT AGAINST OBESITY

[1]Scacchi, Fabricio; [2]Quintans, Rubén; [3]Sánchez, Natalia; [4]D'Onofrio, Francesca; [2]D'Onofrio, Francisco.

[1]Phd. Nutrition Team investigator. Argentina; [2]Bsc Dietitian at Nutrtion Team. Argentina; [3]Bsc, Professor at National University of Tucuman. Argentina.

Background and objectives: Background: since 1980, obesity has more being increasing in all over the world. It is an incurable but controllable chronic metabolic disease, aggravating other conditions, which is currently the major public health problem in many countries. At present, pharmacological therapy is one of the most used tools along with diet and exercise. Mazindol (MZ1mg) is a drug approved by the FDA and ANMAT, in therapy as anorexigenic.

Objective: to evaluate for the first time in our country, the efficacy and safety of the MZ1 1mg (Laboratory Produmedix Argentina SA) as an adjuvant in the treatment of obesity in the staff

of the Police of Tucumán (18-60 years) with a diagnosis of obesity (BMI ≥30).

Methods: We conducted a randomized double-blind study of 100 patients, divided in placebo group (GP) and active drug group (AD) for a period of 3 months. Previously patients were evaluated clinically and through laboratory screening as method of exclusion by having other diseases and/or pregnancy. The drug was administrated as one pill daily and subjects controlled every 15 days from the clinical-nutritional and mental health point of view.

Results: AD reflected an average loss of weight of 9kg, with a 9% reduction in fat mass percentage. On the average BMI was reduced to 4 points and the circumference of the waist was 9cm for men and 11cm in women. The insulin in blood was reduced by 8 units and the homeostasis model assessment (HOMA) 2 units. GOT were reduced 8 units and the GPT 9 units. Systolic pressure decreased 12 units and diastolic pressure 6 units in women; in men was 7 and 3 respectively. Hemoglobin, glycemia, TC, HDL, LDL, and TG did not reflect significant reductions.

Ultrasound Hepato-biliary reported: Of 22 patients with fatty liver, 30% recovered normal function while 12 AD patients recovered its 50% of their normal hepatic function. There were no adverse effects of importance during the study.

Conclusions: The use of Mazindol among Policy members of Tucuman, Argentina, improved their quality and life expectancy by the weight reduction with the reduction the risk factors in relation with the overweight and obesity.

DIETARY MAGNESIUM RESTRICTION PROMOTES INSULIN RESISTANCE IN RATS FED A HIGH-FAT DIET

[1]Batista da Rocha Romero, Amanda; [2]Machado Cavassana, Vitor; [2]Fragal, Beatriz; [3]De Carli, Eduardo; [4]Rodrigues Lobo, Alexandre; [5]Colli, Celia.

[1]MSc. Nutricionist. Department of Food and Experimental Nutrition. University of São Paulo. Brazil.; [2]Undergraduate student. Department of Food and Experimental Nutrition. University of São Paulo. Brazil.; [3]PhD. Nutricionist. Department of Food and Experimental Nutrition. University of São Paulo. Brazil.; [4]PhD. Nutricionist. Department of Food and Experimental Nutrition. University of São Paulo. Brazil. Municipal Secretary of Education. Pirai do Sul. Parana. Brazil.; [5]PhD. Pharmacist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Sciences. University of São Paulo. Brazil.

Background and objectives: Magnesium (Mg) deficiency has been related to pre-diabetic conditions in experimental and human studies. Here, we evaluated in rats, for 24 weeks, the effects of dietary Mg restriction (90% of recommendations) and lipid-overload (a recognized dietary experimental model of obesity) on Mg status and whole body insulin sensitivity.

Methods: Male Wistar rats (n = 24; initial body weight 97-123 g) were fed ad libitum semipurified AIN-93-based control (CT) or high-fat (HF) diets (adequate or Mg-restricted; 500 [Mg500] and 50 [Mg50] mg Mg/kg diet, respectively). Magnesium concentrations in plasma, erythrocyte, bone, muscle, urine and feces) were measured by atomic absorption spectrophotometry. An intraperitoneal insulin tolerance test (ipITT) was performed at weeks 8, 12, 16 and 24. TRPM6 expression in the kidney was analyzed by Western-blot.

Results: HF intake increased adiposity and body weight gain ($p < 0.05$), irrespective of Mg restriction. Also as expected, Mg concentrations were decreased in plasma ($p < 0.01$), urine ($p < 0.01$) feces ($p < 0.001$) and bone ($p < 0.001$) of rats fed Mg-restricted diets. However, HF [Mg50] rats presents higher concentration of Mg erythrocyte. Compared to controls, HF Mg [50] rats developed insulin resistance ($p = 0.007$ and $p = 0.02$ at 16 and 24 weeks, respectively). Preliminary results indicate that dietary Mg restriction enhances kidney expression of TRPM6, regardless of insulin sensitivity.

Conclusions: In our experimental model, whole body insulin resistance altered the Mg compartimentalization in response to its dietary restriction without modifiy the kidney abundancy of the major Mg reabsortion channel. The evaluation of the insulin signaling pathway and other Mg channels in key compartments linked to Mg homeostasis (kidney, intestine) may elucidate the relationship between insulin resistance and Mg status.

Keywords: Magnesium deficiency. Lipids. Insulin sensitivity. TRPM6.

ADHERENCE TO THE MEDITERRANEAN AND THE CENTRAL EUROPEAN DIETS IN RELATION TO WEIGHT LOSS CHANGES IN POSTMENOPAUSAL WOMEN WITH DIAGNOSED METABOLIC SYNDROME

[1]Bajerska, Joanna; [2]Chmurzynska, Agata; [3]Muzsik, Agata; [4]Menclewicz, Katarzyna; [5]Krzyżanowska, Patrycja; [6]Walkowiak, Jarosław.

[1]PhD. Dietician. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland; [2]PhD. Nutritionist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland. International Society of Nutrigenetics/ Nutrigenomics (ISNN).; [3]MSc. Nutritionist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland; [4]MSc. Dietician. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland; [5]MD. PhD. Medical biologist. Department of Pediatric Gastroenterology and Metabolism. Poznan University of Medical Sciences. Poland; [6]Professor. MD. PhD. Pediatric Gastroenterologist. Department of Pediatric Gastroenterology and Metabolism. Poznan University of Medical Sciences. Poland.

Background and objectives: It has been demonstrated that the Mediterranean diet (MED) can improve body weight and reduce the incidence of diabetes mellitus and metabolic syndrome. On the other hand, it has also been stated that the adoption of this dietary regimen by populations other than Southern European is difficult, on account of the high cost and limited availability of these unfamiliar food items, as well as cultural differences in food preference. The aim of this study was to assess the level of adherence to MED and the Central European diet (CED) and to examine its association with weight loss changes.

Methods: Data were used from 130 free-living postmenopausal women with diagnosed metabolic syndrome (mean (SD); age: 61.0 (5.0) years; body mass index: 33.5 (4.6) kg/m2) participating in 16-week randomized dietary interventions aimed at comparing the effect of hypocaloric MED or CED with different macronutrient compositions on body weight loss. Dietary adherence was calculated as a difference between the reported and recommended distributions of energy intake from macronutrients using a Mahalanobis distance equation. This equation generates an adherence score that represents the degree of deviation from the prescribed goals for macronutrients intake; lower scores show better adherence and higher scores indicate greater non-adherence.

Results: In both groups, the adherence to dietary regimen tended to worsen over time. The 16-week body weight changes in the most and least adherent participants, irrespective of assigned dietary intervention were -9.4 ± 3.7 and -5.8 ± 3.2 kg (p < 0.001).

Conclusions: Adherence to the dietary regimen is a stronger predictor of weight loss success than the diet used.

Keywords: Adherence, Central-European diet, Dietary intervention, Mediterranean diet, Weight loss,

Conflict of Interest Disclosure: The authors declare that they have no conflict of interest.

EFFECTS OF A 16-WEEK DIETARY INTERVENTION WITH EITHER A MEDITERRANEAN DIET OR A CENTRAL EUROPEAN DIET ON ANTHROPOMETRIC PARAMETERS IN OBESE POSTMENOPAUSAL WITH DIAGNOSED METABOLIC SYNDROME

[1]Bajerska, Joanna; [2]Chmurzynska, Agata; [3]Muzsik, Agata; [4]Menclewicz, Katarzyna; [5]Krzyżanowska, Patrycja; [6]Walkowiak, Jarosław.

[1]PhD. Dietician. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland; [2]PhD. Nutritionist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland. International Society of Nutrigenetics/Nutrigenomics (ISNN).; [3]MSc. Nutritionist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland.; [4]MSc. Dietician. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland.; [5]MD. PhD. medical biologist. Department of Pediatric Gastroenterology and Metabolism. Poznan University of Medical Sciences. Poland.; [6]Professor. MD. PhD. Pediatric Gastroenterologist. Department of Pediatric Gastroenterology and Metabolism. Poznan University of Medical Sciences. Poland.

Background and objectives: The high-vegetable-fat Mediterranean diet (MED) is associated with a lower risk of diabetes mellitus and metabolic syndrome. In the Central European region, we can also find traditional beneficial foods items (i.e., apples, plums, black chokeberries, herring, linseed, rapeseed oil, oats, buckwheat, and rye bread), which may have a favorable effect on all features of metabolic syndrome. The aim of this study was to compare the effects of MED and the Central-European diet (CED), based on local healthy foods items, on changes in anthropometric parameters associated with metabolic abnormalities.

Methods: One hundred and forty-four free-living postmenopausal women with diagnosed metabolic syndrome (mean (SD); age: 61.0 (5.0) years; body mass index: 37.7 (4.9) kg/m2) were randomly assigned to the hypocaloric MED or CED for 16 weeks. The nutrient goals for the compared diets were: MED: 40% energy from fat, 20% energy from protein, and 45% energy from carbohydrates; CED: 25% energy from fat, 20% energy from protein, and 55% energy from carbohydrates. Body weight, body composition, and waist circumference were assessed before the intervention and 4, 8, 12 and 16 weeks after it.

Results: One hundred and thirty participants completed the study (MED, n = 67; CED, n = 63). At 16 weeks, both groups experienced similar reductions in body weight (MED -7.57 (3.6) kg; CED, -7.59 (4.2) kg; P = 0.94 time × group interaction), waist circumference (MED, 9.20 (3.7) cm; CED, -9.31 (4.5); P = 0.15 time

× group interaction) and fat mass (MED, -7.03 (3.4) kg, CED, -7.01 (3.7) kg; P = 0.91 time × group interaction and fat mass).

Conclusions: The results of this study show that both MED and CED diets result in significant reductions in body weight, waist circumference, and fat mass over 16 weeks of dietary intervention trial.

IMPACT OF THE CONSUMPTION OF TAMARIND FLOUR (TAMARINDUS INDICA L.) IN METABOLIC SYNDROME AMONG TYPE 2 DIABETIC PATIENTS

[1]Vergara, Clarice; [2]Martins, Diego; [3]Passos, Tatiana; [1]Matos, Maria Rosimar; [1]Sampaio, Helena; [4]Carioca, Antonio Augusto; [1]Bezerra, Ilana; [1]Arruda, Soraia; [1]Lima, Gláucia; [1]Maia, Carla Soraya.

[1]PhD. Nutritionist. Center for Health Sciences. Ceará State University. Brazil.; [2]BSc. Nutritionist. Center for Health Sciences. Ceará State University. Brazil.; [3]PhD. Nutritionist. Center for Health Sciences. Estacio University Center of Ceará. Brazil.; [4]PhD. Nutritionist. Center for Health Sciences. University of Fortaleza. Brazil.

Background and objectives: To investigate the effect of the consumption of tamarind flour on the components of metabolic syndrome (MS) among patients with type 2 diabetes mellitus treated by a reference health center of the Brazilian Unified Health System.

Methods: This is a randomized, double-blind clinical trial, placebo controlled. Of the 164 randomly treated diabetic patients, 152 were diagnosed with MS and divided into two groups: placebo and intervention group that received tamarind flour for consumption for a period of 4 weeks. A semi-structured questionnaire was applied to evaluate demographic, socioeconomic, anthropometric, biochemical and food consumption data. SPSS version 20.0 was used for data analysis with descriptive level of test of 0.05.

Results: The usual diet of the participants was inadequate with an excess of cholesterol and sodium and low amount of fiber. Regarding the indicators of MS, it was observed a reduction in the waist circumference (p = 0.003) and in triacylglycerol levels (p = 0.016) in the intervention group. Comparing placebo and intervention group, patients who received tamarind flour presented reduction in their triacylglycerol levels.

Conclusions: The consumption of tamarind flour was effective in improving two important indicators of MS, with a reduction in WC and in triacylglycerol. This fact evidences a potential role of tamarind meal as an adjuvant in the management of MS indicators among diabetic patients.

Keywords: metabolic syndrome. diabetes mellitus. tamarind. cardiovascular diseases.

GLUTEN-FREE NOODLES MADE WITH REGIONAL FLOURS: CONTENT, DIALYZABILITY AND POTENTIAL CONTRIBUTION OF IRON CALCIUM AND ZINC

[1]Macías, Sara; [2]Generoso, Silvina; [3]Binaghi, María Julieta; [4]Costa, Karina; [4]Rosas, Domingo; [4]Lescano, Natalia; [5]Villarreal, Myriam.

[1]PhD. Biochemistry. Facultad de Agronomia y Agroindustrias. Universidad Nacional de Santiago del Estero. Argentina; [2]PhD. Bichemistry. Facultad de Agronomía y Agroindustrias. Universidad Nacional de Santiago del Estero. Argentina; [3]PhD. Bichemistry. Universidad de Buenos Aires. Argentina; [4]Food Engineer. Facultad de Agronomía y Agroindustrias. Universidad Nacional de Santiago del Estero. Argentina; [5]PhD. Food Engineer. Facultad de Agronomía y Agroindustrias. Universidad Nacional de Santiago del Estero. Argentina

Background and objectives: Today, celiac disease is the most frequent chronic intestinal disease in Argentina; the official statistic is 1 in 79 for children. The need to have a diet without T.A.C.C. is imperative for celiacs, as well as the incorporation of natural and industrialized apt foods, with good contribution of nutrients. This work aimed to determine the mineral content in noodles made with regional flours without gluten and cooked, as well as dialyzability and potential contribution of them.

Methods: MyM: Four prototypes of noodles made with rice flour, control (C) and three formulations, cooked 5 and 7 minutes respectively, were analyzed; In the proportions of flours that are detailed:

F1: Rice flour 66.00%, Quinoa 20.00%, Amaranth 10.00%, Algarroba 3.00%.

F2: Rice flour 66.00%; Quinoa 10.00%, Amaranth 20.00%, Algarroba 3.00%.

F3: Rice flour 56.00%, Quinoa 20.00%, Amaranth 20.00%, Algarroba 3.00%.

Results: The total mineral concentration was determined by atomic absorption spectrometry. The mineral bioaccessibility (D%) was determined in vitro under controlled conditions of pH, after a digestion that simulates the physiological processes. The potential contribution (AP) of minerals was calculated. The determinations were made in quadruplicate, and the statistical analysis was performed using ANOVA, with Tukey's test as a posteriori test. According to the results obtained it was observed that the D% for Fe is higher in F2; For Zn and Ca F1 and F3 with all formula-

tions being greater than C. The AP of Fe was higher in F2 (1.299 ± 0.032 mg%); For Zn there were no significant differences between the three formulations, however the AP was significantly higher than C. Regarding the AP of Ca there was no significant difference between F2 and F3 (33.28 ± 0.55 mg%).

Conclusions: From the above, it is concluded that F2 is the formulation that presents the best contribution of the minerals studied. All the proposed formulations constitute a valid alternative to supply the micronutrients Fe, Ca and Zn since they show significant differences with C.

Keywords: minerals - bioaccessibility - regional flours - noodles

NUTRITIONAL STATUS AND QUALITY OF LIFE OF BREAST CANCER PATIENTS ATTENDING A TERTIARY HOSPITAL IN IBADAN, SOUTHWEST NIGERIA

[1]*Morenike, Ogunkunle;* [2]*Chiedozie John, Ezenwanne.*

[1]MSc. Nutritionist/Dietitian. Department of Human Nutrition. Faculty of Public Health. University of Ibadan. Ibadan. Nigeria; [2]BSc. Nutritionist/Dietitian. Department of Human Nutrition. Faculty of Public Health. University of Ibadan. Ibadan. Nigeria.

Background and objectives: Cancer diagnosis in Nigeria is similar to death sentence as survival rates are very low. Attention is mostly focused on the treatment with little or no attention is paid on long term survival and quality of life of the breast cancer patients. Hence, this study was designed to evaluate the relationship between the nutritional status and quality of life (QOL) of the breast cancer patients.

Methods: The descriptive cross-sectional study was carried out at the University College Hospital, Ibadan, Southwest, Nigeria among 120 breast cancer patients. Data on sociodemographic and medical history was collected using semi-structured interviewer-administered questionnaires. Weight and height were measured and body mass index (BMI) was determined. Dietary intake was assessed using 24-hour dietary recall. QOL was evaluated using EORTC QLQ-C30 and BR23. Data obtained on dietary intake was analysed using the Total Dietary Assessment software. Chi square test, student-t test and ANOVA were used as appropriate to determine the relationship between variables at $p < 0.05$.

Results: The mean age of the participants was 51.7 ±10.9 years, 48.3% were at premenopausal stage, 81.7% were married, 5% had no formal education and 80.0% were employed. About 38.0% were in stage I and 58.7% were in stage II. Approximately 54.0% had chemotherapy + radiotherapy + surgery, 23.7% had surgery only, 10.2% had chemotherapy only while 11.9% had chemotherapy + surgery. Many of the participants were either overweight (32.7%) or obese (38.4%). BMI was observed to have significant relationship with the stage of the disease, treatment option and menopausal status ($p < 0.05$). QOL of the participants was also found to have significant relationship with treatment option, BMI, menopausal status and stage of the disease ($p < 0.05$). Daily energy, protein and fibre intakes were inadequate among 64.7%, 37.26% and 70.6% respectively and vitamin A, C, folate, zinc, calcium and iron intakes were also inadequate among 33.3%, 60.8%, 66.7%, 54.9%, 96.1% and 23.5% respectively.

Conclusions: QOL has relationship with BMI, menopausal status, treatment option and the stage of the disease. Dietary intake is mostly inadequate among the participants.

THE PREVALENCE OF OBESITY IN A MIGRANT POPULATION LIVING IN CASABLANCA, MOROCCO

[1]*Hibbi, Nadia;* [2]*Saile, Rachid;* [2]*Derouiche, Abdelfettah.*

[1]PhD. Nutritionist. Laboratory of Biology and Health-URAC 34- Faculty of Sciences Ben M'Sik. Hassan II University. Casablanca, Morocco.; [2]Professor Laboratory of Biology and Health-URAC 34- Faculty of Sciences Ben M'Sik. Hassan II University. Casablanca, Morocco.

Background and objectives: Rural-Urban migration is known as a major factor associated with the increase of obesity prevalence in many countries. In Morocco, obesity prevalence is higher in cities.

In this study, we assessed the influence of ethnicity and migration, through urbanity degree, on obesity prevalence variation, between the ethnic group of Soussi (native of the rural zone of Souss region) and Casablanca in Morocco.

Methods: We used a multi-stratified sampling including 615 subjects (305 subjects recruited in metropolitan Casablanca and 310 from the Souss region). The sampling was based on ethnicity, sex and age. We measured anthropometric parameters, using (i) body mass index (BMI), based on cut-off points recommended by the WHO, and (ii) body fat percentage (BF%), based on cut-off points taken from tables provided in the user's manual of a BIA meter (i.e., a bioelectrical impedance device).

Results: Obesity prevalence is greater in women than in men (22.5% vs. 19.8%). Women also presented an AO and a higher %BF risk than men (77.6% vs. 33.4% and 71.2% vs. 60.4%, respectively). Adjusted analysis of our data indicated that, in comparison with rural Soussi, the AO is significantly greater in the second generation migrants group (51.0%, OR=0.33, 95%CI [0.17–0.64], p<0.01); Obesity prevalence (BMI and %BF) is also more elevated in Soussi from Casablanca (21.3%, OR=0.53, 95%CI [0.30–0.92], p<0.05 and 71.3%, OR= 0.42, 95%CI [0.28 –0.76], p<0.01, respectively). Obesity prevalence and AO are higher in women from Casablanca than in women from Souss region (BMI: 31.0% %, OR= 0.54, 95%CI [0.37–0.92], p<0.05, and AO: 83.9%, OR=0.48, 95%CI [0.27–0.84], p<0.01).

Conclusions: Our study showed that anthropometric and body statuses of our study population depend on urbanity degree (second generation migrants) and ethnicity (Soussi from Casablanca) in men. However, in women, it is linked to their residence location (particularly, in Women from Casablanca).

ALCOHOL CONSUMPTION AMONG ALTERNATING SHIFT WORKERS IS INFLUENCE BY WORK SCHEDULE AND ABDOMINAL OBESITY: A LONGITUDINAL STUDY

[1]*Furlan, Luisa;* [2]*Rosa, Dayane;* [3]*Fisberg, Regina;* [4]*Crispim, Cibele.*

[1]MSc Student. Faculty of Medicine. Federal University of Uberlandia. Brazil; [2]PhD Candidate.Pharmaceutical.Faculty of Medicine. Federal University of Uberlandia. Brazil; [3]PhD. Nutritionist.Faculty of Public Health. University of Sao Paulo. Brazil; [4]PhD.Nutritionist.Faculty of Medicine. Federal University of Uberlandia. Brazil.

Background and objectives: Some evidences from the literature have showed that shift workers consume high alcohol intake to compensate for sleep difficulties associated with work schedules. However, the pattern of alcohol consumption and its association with obesity is little explored between shift workers. The purpose of the study was to investigate the effects of different work schedules, rest periods and abdominal obesity on alcohol consumption in rotating shift workers.

Methods: The study included 30 males shift workers (37±5.68 years old; 90% working in shifts for more than 5 years). The working schedule was organized in the following sequence: two first days working in the morning shift (8:00a.m|.- 4:00p.m.); two days in evening shift (4:00p.m. – 0:00a.m.), one day in a break after evening shift, two days in night shift (0:00a.m. – 6:00a.m.) and 72 hours of rest. Height, weight, abdominal circumference (AC) and blood pressure were measured. The alcohol consumption was assessed using the 24-hour recall questionnaire for all shift days and days off (total=10 days). Generalized estimating equations (GEE) was used to examine the association between alcohol consumption, work schedule and abdominal obesity.

Results: GEE analyses showed a higher daily alcohol consumption in the days off (51.07g), when compared with day, evening, break between evening/night and night shifts (22.09g, 1.42g, 1.50g, 12.26g, respectively (p<005). Individuals who had high abdominal circumference consumed more alcohol than those who had normal abdominal circumference in the evening shift as well as in the break between evening/night shifts (p<0.05). Also, very high abdominal circumference individual consumed more alcohol than those with normal abdominal circumference in the break between evening/night shifts (p<0.05).

Conclusions: Rotating shift-work schedules and abdominal circumference had an effect on alcohol consumption among shift workers. These results should be confirmed in future studies.

Keywords: Shift-work, abdominal circumference, alcohol consumption.

HEMODIAFILTRATION: IMPACT ON PROTEIN-ENERGY WASTING AMONG DIALYSIS PATIENTS

[1]*Philippi, Romina;* [2]*Luxardo, Rosario;* [2]*Crucelegui, Soledad;* [2]*Bedini Rocca, Mariela Ines;* [2]*Morales Andreau, Leandro David;* [2]*Fabriani, Damian Orlando;* [2]*Ocampo, María Lorena;* [3]*Escalante, Griselda;* [3]*Coli, María Luisa;* [2]*Rosa Diez, Guillermo Javier.*

[1]Nutritionist. Servicio de Nefrología. Hospital Italiano de Buenos Aires. Argentina.; [2]MD. Servicio de Nefrología. Hospital Italiano de Buenos Aires. Argentina.; [3]RN. Servicio de Nefrología. Hospital Italiano de Buenos Aires. Argentina.

Background and objectives: Hemodiafiltration (HDF) therapy is used in end stage renal disease (ESRD) patients under dialysis and combines the mechanisms of diffusion and convection, unlike conventional hemodialysis, based on diffusion transport. This therapy allows, among other things, an improvement in the hemodynamic stability, a lower resistance to the use of erythropoiesis stimulating agents (ESA) and a better clearance of inflammatory markers. There are no Latin American reports that assess nutritional parameters in this group of patients. Therefore we aimed to determine if HDF could have any impact on the protein-energy wasting characteristic of this population evaluated through biochemical and anthropometric nutritional variables.

Methods: We performed a retrospective study with a total of 45 patients, comparing albumin, cholesterol, transferrin, hemoglobin, phosphorus, C-RP, erythropoietin resistance index (ERI) and dialysis dose (Kt/V) at the beginning of HDF treatment and

six months later. 39 of these patients were also measured with high frequency bioimpedanciometry in order to determine the lean tissue index and the fat tissue index.

Results: We analized data of 30 men and 15 women >18 years, with a mean age of 52.9 ± 18.22 years, and with a dialysis time of 57.6 ± 46.8 months.

No statistically significant differences were found at baseline and six months after HDF treatment was started for the analyzed nutritional variables. Statistically significant differences were found for Kt/V and ERI (p<0.05).

Conclusions: According to what is published internationally, HDF improves the dialysis dose and decreases the use of erythropoiesis-stimulating agents, but no significant impact was observed in the protein-energy wasting of this population.

NUTRITIONAL PROFILE OF PATIENTS IN THE SECONDARY PREVENTION OF CARDIOVASCULAR DISEASES

[1]Simony, Rosana; [2]Montone Mantovani, Luisa; [2]De Souza Mota, Luís Gustavo; [2]Flammia de Barros Costa, Giovanna; [2]Burmeister, Georgea; [2]Meirelles, Aline; [3]Ragne Torreglosa, Camila; [4]Cymrot, Raquel; [5]Weber, Bernardete.

[1]PhD Nutritionist Assistant Professor of Nutrition Courses from Center for Biological and Health Sciences at Mackenzie Presbyterian University, Sao Paulo, Brazil.; [2]Graduate Student in Nutrition from Center for Biological and Health Sciences at Mackenzie Presbyterian University, Sao Paulo, Brazil.; [3]Nutritionist of the research Institute of Heart Hospital Center of Sao Paulo.; [4]Master in Biostatistics Professor of Engineering School at Mackenzie Presbyterian University, Sao Paulo, Brazil.; [5]PhD Nutritionist Lead researcher at Heart Hospital Center of Sao Paulo.

Background and objectives: Aging is accompanied by several pathological conditions, such as chronic noncommunicable diseases (CDNT) and, in particular, cardiovascular diseases. The objective of the study was to describe the nutritional, laboratory, food consumption and risk factors of patients who suffered from a cardiovascular event at the collaborating Heart Hospital Center (HCor).

Methods: This was a descriptive cross-sectional study in which secondary data from 50 cardiac subjects were used in the study "Effect of the Cardioprotective Food Program on the reduction of events and risk factors in secondary prevention for cardiovascular disease: A Randomized Clinical Trial", known as DICA Br, a project coordinated by the Research Institute of the Heart Hospital and the Support Program for Institutional Development of SUS (PROADI-SUS) of the Ministry of Health.

Results: Regarding the nutritional status, 36% (n=18) of the evaluated individuals presented obesity, 18% (n=9) overweight and 6% (n=3) underweight. The majority of the evaluated patients had hypertension, followed by dyslipidemia. In addition, 48% (n=24) of cardiac patients are former smokers and 55% (n=26) lead sedentary lives. Waist circumference values were increased for both genders (100,87cm and 105,28cm for women and men, respectively), as were means of fasting glycemia (103,89mg/dL; EP=4,37 and 108,44mg/dL; EP=4,25) and triglycerides (168,3mg/dL; EP=28,0 and 170,6mg/dL; EP=29,10). The mean cholesterol level for women was high (172.8mg/dL; EP=15.6) compared to men (145.39; EP=5.33), presenting a significant difference (p=0.045). In addition, the value of HDL was very low for women (42,13mg/dL; EP=2,91), being below the recommended level. Men seem to consume more fatty acid omega 3 and omega 6, sodium, fiber, calcium, selenium and energy when compared to women.

Conclusions: Apparently, there was no change in the improvement of the nutritional status of the patients analyzed after the occurrence of a cardiovascular event. It is necessary to carry out more studies aimed at this type of public, for better interventions for treatment secondary to cardiovascular diseases.

IMPACT OF OVERWEIGHT ON LDL OXIDATION AND PLASMA LEVELS OF VITAMIN D IN OLDER PEOPLE IN TERTIARY PREVENTION OF CVD

[1]Santos, Elisa Maia dos; [2]Costa, Mariana Ribeiro; [3]Peçanha, Daniela; [3]Souza, Paula; [4]Cardoso, Carolina Alves; [5]Huguenin, Grazielle Vilas Bôas; [6]Weber, Bernardete; [7]Moreira, Annie Seixas Bello.

[1]Msc. Nutritionist. National Institute of Cardiology. Health ministry. Brazil; [2]Msc. Nutritionist. State University of Rio de Janeiro. Brazil.; [3]Msc student. Nutritionist. State University of Rio de Janeiro. Brazil.; [4]Msc. Nutritionist. Federal University of Rio de Janeiro. Brazil.; [5]PhD. Nutritionist. National Institute of Cardiology. Brazil.; [6]Ph.D. Nutritionist. Hospital do Coração (HCor). Brazil.; [7]Ph.D. Nutritionist. State University of Rio de Janeiro. National institute of Cardiology. Brazil.

Background and objectives: The identification of cardiovascular risk factors is fundamental for clinical practice and development of cardiovascular disease (CVD) prevention strategies. The objective of this study is evaluate classic and emerging cardiovascular risk factors (vitamin D and oxidized LDL) in the elderly with and without overweight in tertiary prevention for CVD.

Methods: A cross-sectional study with 93 elderly people with a mean age of 68.9 ± 6.9 years of both sexes, participants of a multicenter randomized clinical trial that studies the effects of a Brazilian Cardio protective Food Program on reduction of events and risk factors in prevention of CVD. The data were collected in the beginning of the nutritional intervention. Anthropometric evaluation (weight, height, waist-perimeter-PC) and blood collection were performed for analysis of lipid profile, plasma concentration

of 25-hydroxy-vitamin D and levels of oxidized LDL (LDL-ox). The elderly included did not use nutritional supplements. Data expressed in frequency and medians (p25-75), analyzed in SPSS 21.0, considering a significance level of 5%.

Results: 65,5% were male, 93,5% hypertensive, 92,3% dyslipidemic, 63,4% diabetics and 66,7% had a history of a heart attack. The mean BMI was 28,7 ± 4,5 kg/m² and 82,2% were overweight. Eutrophic individuals had no differences in LDL-C levels when compared to "overweight" [93,5 (77,5-113,0) mg/dl)] vs 89,5 (72,7-116,0) mg/dl; p=0,9] respectively, but LDL-ox concentrations were higher in the overweight elderly [6.691,0 (5.058,0 – 9.584,0) mU / mL vs 5.409,0 (3.411,7-7.572,5) mU/mL; p=0,032]. Overweight was associated with lower plasma levels of 25OH vitD, [62,0 (50,7-80,8) mmol/l vs 74,2 (62,3-97,3) mmol/l; p=0,06]. No significant differences were found in the evaluation of food consumption and had no correlations between LDL-ox and 25OH vitD.

Conclusions: Overweight had higher lipid peroxidation even reaching the established lipidic goals, and tends to lower plasma levels of 25OH vitD. These results shows the importance of non-pharmacological therapeutic measures aimed at lifestyle modification should be intensified, in order to contribute to reduction of the risk of a new cardiovascular event.

NUTRITIONAL STATUS IN CHILDREN WITH CYSTIC FIBROSIS IN PARAGUAY

[1]Sanabria, Marta; [2]Ortiz, Lourdes; [3]Gonzalez, Laura; [4]Ascurra, Marta.

[1]MsC Facultad de Ciencias Medicas; [2]MsC Dr Ministerio de Salud Pública y Bienestar Social. Programa de Detección Neonatal.; [3]Facultad de Ciencias Químicas. Universidad Nacional de Asunción.; [4]Ministerio de Salud Pública y Bienestar Social. Programa de Detección Neonatal.

Background and objectives: Introduction: Adequate nutritional status is essential in patients with Cystic Fibrosis (CF) due to its influence on lung function and mortality.

Objective: To characterize the nutritional status of children and adolescents with Cystic Fibrosis (CF) who attend the National Neonatal Detection Program, under the Cystic Fibrosis Program, under the Ministry of Public Health and Social Welfare (MSPyBS), from February to November 2016 .

Methods: Material and method: A cross-sectional, observational, descriptive study with an analytical component with con-

firmed CF diagnosis. Socio-demographic variables, clinical form at diagnosis and presence of pancreatic sufficiency, anthropometric variables and nutritional status, biochemical, dietary and lung function variables (FEV1) were studied.

Results: A total of 84 children, 56% were female. The mean age was 7.5 ± 4.7 years; 64% diagnosed ≤6 months of life). Thirty-one percent had a mixed clinical form at diagnosis and 22% had neonatal screening. The standardized mean values of z weight, z height and z BMI were -0.6, -1 and - 0.2 respectively. In <2 years, 11% presented moderate acute malnutrition. At ≥ 2 years (n = 75), 60% had adequate nutritional status, 11% overweight and 3% obesity (BMI/Age). 17.3% of the total showed low height and 42% fulfilled the nutritional goal in CF; 41% presented chronic colonization by Pseudomonas Aeruginosa. Mean pulmonary function (FEV 1) was 77.8%; 58.1% had some degree of pulmonary involvement; the most affected were those with malnutrition or at risk (p = 0.0266, Student's t test). Children/adolescents with Pseudomona Aeruginosa had significantly lower BMI than those who did not (p = 0.0324, Student's t test) and those with a lower BMI had lower lung function (Pearson correlation positive and significant p = 0.001).

Conclusions: Conclusion. In children older than 2 years, 6 out of 10 have an adequate nutritional status. The height was compromised in more than half of the children.

Keywords: cystic fibrosis, nutritional status

GLYCEMIC INDEX AND GLYCEMIC LOAD ARE ASSOCIATED WITH PROSTATE CANCER RISK IN CÓRDOBA, ARGENTINA: A MULTILEVEL ANALYSIS

[1]Niclis, Camila; [1]Román, María Dolores; [2]Aballay, Laura; [3]Haluszka, Eugenia; [3]Dávila, Valentina; [4]Massobrio, Esteban; [4]Barale, Adrián; [1]Muñoz, Sonia; [2]Díaz, María del Pilar.

[1]PhD. Instituto de Investigaciones en Ciencias de la Salud. Universidad Nacional de Córdoba and Consejo Nacional de Investigaciones Científicas y Técnicas. Argentina.; [2]PhD. Escuela de Nutrición. Universidad Nacional de Córdoba. Argentina.; [3]Student. Escuela de Nutrición. Universidad Nacional de Córdoba. Argentina.; [4]BSc. Escuela de Nutrición. Universidad Nacional de Córdoba. Argentina.

Background and objectives: The dietary glycemic index (GI) and glycemic load (GL) would increase the risk of diverse cancers, including prostate cancer (PC). The aim of the present study was to evaluate the association of dietary GI and GL with the risk of PC occurrence in male population, assessing the urban–rural context variability in Córdoba province in 2008-2015 period.

Methods: A case-control study of PC including 163 cases and 324 controls -matched by age and residence- was conducted. All subjects were interviewed with a validated food frequency questionnaire. The average daily dietary GI for a subject was computed by summing the products of the GI value of each food times the

amount of available carbohydrate (CH); then divided by the total amount of available CH consumed daily. The average GL was calculated by summing the products of the GI value of each food times the amount of available CH consumed daily divided by 100. Multilevel logistic regression models were estimated including GI or GL, age, Body Mass Index, energy and fat intake as covariates at the individual level, and level of urbanization of subject's residence as clustering factor (<29,999; 30,000-200,000; >200,000 inhabitants), with the disease status (presence/absence of PC) being the response variable.

Results: Odds of PC increased linearly with increasing GI and GL (OR 1.04; 95%CI 1.02-1.05 and OR 1.01; 95%CI 1.003-1.01). Moreover, men at the third tertile of GI showed a higher risk for PC occurrence (OR: 1.51; 95%CI 1.30-1.75) compared to men in the first tertile. The promoting effect was stronger when comparing the highest vs. the lowest tertile of GL (OR 2.06; 95%CI 2.01-2.11). There was not aggregation linked to the level of urbanization.

Conclusions: Our results suggest that a diet with high GI and GL is associated with an increased risk of PC. Hence, more attention must be given to the quality of dietary carbohydrates when promoting healthy dietary habits in men.

LEVEL OF CARE AND FREQUENCY OF NUTRITION VISITS FOR PATIENTS HOSPITALIZED IN PRIVATE HOSPITAL FROM CURITIBA - PR

[1]Gebara, Telma; [2]Camargos, Bibiane; [3]Thomaz, Ana Cláudia; [4]Tarzia, Andréa; [5]Mastella, Paula; [6]Theiss, Petra.

[1]BSc. Nutritionist. Department of Biological and Health Sciences. Tuiuti University of Parana. Brazil; [2]BSc.Nutritionist. Department of Biological and Health Sciences. Tuiuti University of Parana. Brazil.; [3]BSc. Nutritionist. Department of Biological and Health Sciences. Tuiuti University of Parana. Brazil.; [4]PhD. Nutritionist. Department of Biological and Health Sciences. Tuiuti University of Parana. Brazil.; [5]PhD. Department of Biological and Health Sciences. Tuiuti University of Parana. Brazil.; [6]MSc. Nutritionist. Department of Biological and Health Sciences. Tuiuti University of Parana. Brazil.

Background and objectives: The patient's impact on hospitalization may not only aggravate his/her general condition but it may also complicate him/her through loss of appetite, difficulty in proper dietary intake or due to imposition of fasting procedures. According to the Brazilian Nutrition Association (ASBRAN), the triage identifies the nutritional risk aiming at performing early intervention and its application is indicated within 24 hours from the admission of the patient at the hospital level and at the first consultation at the ambulatory and home level. The objective of this research was to verify the frequency of the nutritional care levels of patients triaged and the adequacy of the number of nutritionist visits, received by patients during hospitalization.

Methods: Retrospective, descriptive study made through analysis of electronic patient records from a private hospital in the city of Curitiba-PR.

Results: Data were collected from January to December 2015, totaling 5962 medical records, 54% of female patients and 46% of male patients aged 63,5±18,2 years old. The average length of hospital stay was 9,5±6,3 days and 97% of the surveyed patients were classified in secondary and tertiary level. Regarding the time of nutritional triage, 65,2% (n=3893) of the patients were triaged within 24 hours of hospital admission. When comparing the level of care with the number of visits during hospitalization, it was observed that 28.7% (n = 1714) of the patients did not receive the recommended number of visits. It is suggested that the possible causes for this inadequacy may be the limited number of professionals or the fact that patients are not available at routine schedules for nutritionists, due to specific surgical procedures and/or tests. According to CFN Resolution No. 380/2005, a nutritionist is recommended for caring 60 patients at the primary level, or up to 30 patients at secondary level or to care up to 15 patients at tertiary level.

Conclusions: The adequate number of professionals allows applying and maintaining recommendations and protocols regarding professional care.

Keywords: Nutritional care level, triage, nutritional monitoring.

NUTRIGENOMIC AND PHARMACOGENETIC PROTOCOL IN THE CONDUCT IN THE TREATMENT OF BREAST CANCER

[1]Aparecido da Silva, Silvano; [2]Renata dos Santos Barros, Cláudia; [3]Ferreira Ribeiro, Caroline; [4]de Souza Cordeiro, Heloisa; [3]Antonio Marassi Guariento, Vitor; [3]Oliveira Silva, Willian.

[1]PhD Student. Pharmacist. Institute of Scientific and Technological Research. Catholic University of Santos. Brazil.; [2]PhD. Physical Educator. Institute of Scientific and Technological Research. Catholic University of Santos. Brazil.; [3]BCs. Student. Nutricionist. Institute of Scientific and Technological Research. Catholic University of Santos. Brazil.; [4]BCs. Student. Pharmacist. Institute of Scientific and Technological Research. Catholic University of Santos. Brazil.

Background and objectives: Breast cancer is one of the most common diseases among women, and has a high incidence and mortality, especially in developing countries. The therapeutic success of this type of cancer can be better conducted when considering pharmacogenetic aspects and drug interactions. Another approach is to observe an optimized diet to avoid changes in this pharmacokinetics. The presence of bioactive compounds with inhibitory or cytochrome-inducing action involved in the treatment may interfere with drug metabolism. This approach may prevent possible adverse reactions, with discontinuation of treatment or failure of therapy. Objectives: To develop a protocol of dietary and

pharmacological behavior considering the aspects of drug interactions, interactions between nutrients, pharmacogenetics and cytochrome metabolism in the treatment of breast cancer.

Methods: The protocol was developed using the databases of PharmGKB (The Pharmacogenomics knowledgebase), CIPIC (Clinical Pharmacogenetics Implementation Consortium) and USDA (United States Department of Agriculture) National Agricultural Library.

Results: Single nucleotide polymorphisms (SNPs) in transporters such as ABCB1 (3435C> T) were shown to have low disease control in the use of taxanes. Dihydropyrimidine dehydrogenase has SNPs that affect the effectiveness of the metabolism of Fluoropyrimidines such as 5-fluorouracil, capecitabine, and tegafur increased its toxicity. The metabolism of tamoxifen in CYP2D6 can be affected by several SNPs, changing their concentrations. The use of other drugs concurrently inhibiting CYP2D6 and the presence of bioactive compounds such as garden cress, kale and resveratrol should be avoided as there is a high risk of relapse of the disease. Other compounds such as green tea, black tea and cruciferous vegetables also act inhibiting CYP2D6.

Conclusions: Genotypic analyzes of transporters and metabolizers in the treatment of breast cancer allow a better management of recommended drugs. In addition to avoiding drugs that act concomitantly on the same cytochromes and provide dose adjustments, the practice of developing a warning diet, either in the neoadjuvant phase or in the metastatic phase, that does not inhibit important cytochromes, cooperates for success of treatment and cure of the disease.

Keywords: Breast Cancer; Pharmacogenetics; Nutrigenomics; Bioactive Compounds; Tamoxifen.

BRANCHED CHAIN AMINO ACIDS IMPROVE CELL VIABILITY BUT DO NOT INCREASE NITRIC OXIDE PRODUCTION IN LPS-STIMULATED RAW 264.7 MACROPHAGES

Background and objectives: BCAAs have a unique place in protein synthesis stimulation, serving as energetic substrates for synthesis of intracellular signaling molecules. However, in inflammation and intense catabolic state, such as sepsis and cancer, the supply of these amino acids must be increased to preserve individual's immunocompetence. In vitro studies have demonstrated that immune cells use isoleucine, valine and especially leucine as substrates for production of cytokines and antibodies, besides having a modulating effect on cellular functions, as in nitric oxide synthesis. Also, studies have found that the absence of any of these amino acids in culture medium results in complete suppression of protein synthesis and cell proliferation. The aim of this study was to investigated the effect of BCAAs supplementation on cell viability and nitric oxide production in LPS-stimulated RAW 264.7 macrophages.

Methods: Cells were cultured in DMEM (with 2 mM glutamine, 10% FBS and 1% penicillin-streptomycin). After reaching 90% confluence, cell cultures were distributed into five groups: CTL - without supplementation with BCAA; LEU - supplemented with leucine (2 mmol/L); ISO - supplemented with isoleucine (2 mmol L); VAL - supplemented with valine (2 mmol/L) and LIV - supplemented with leucine (2 mmol/L), isoleucine (2 mmol/L) and valine (2 mmol/L). The inflammatory state was induced by LPS (1 μg/ml) for 24 hours and then cell cultures were supplemented with the respective amino acids for another 24 hours. The cell viability assay was performed by MTT test and the indirect nitric oxide was measured by Griess reaction.

Results: The LIV group presented higher percentage of cell viability in comparison to CTL group (p <0.05). There was no statistical difference between other groups related to macrophage viability, evidencing that the sinergy among BCAAs is the responsible

for increasing cell viability. Regarding production of nitric oxide, there was no significant difference between groups.

Conclusions: Supplementation with BCAAs association shows to be more effective in increasing cellular viability of LPS-stimulated cells compared to supplementation with isolated BCAAs. In addition, there was no difference in nitric oxide synthesis by macrophages in any of the supplemented groups.

Keywords: branched-chain amino acids, macrophages, inflammation, cell viability, nitric oxide.

THE EPIDEMIOLOGY OF HELICOBACTER PYLORI INFECTION IN EUROPE AND THE IMPACT OF LIFESTYLE ON ITS NATURAL EVOLUTION TOWARDS STOMACH CANCER: A SYSTEMATIC REVIEW

[1]Huybrechts, Inge; [2]Venneman, Kimberly; [3]Gunter, Marc J; [4]Vandendaele, Lieve; [5]Van Herck, Koen.

[1]PhD. Nutritional epidemiologist. International Agency for Research on Cancer (IARC). Lyon. France; [2]MsC. Medical doctor. Ghent University. Department of Public Health. Ghent. Belgium; [3]PhD. Molecular epidemiologist. International Agency for Research on Cancer (IARC). Lyon. France; [4]PhD. Ghent University. Department of Public Health. Ghent. Belgium; [5]PhD. Medical Doctor. Ghent University. Department of Public Health. Ghent. Belgium.

Background and objectives: Helicobacter pylori is a recognized cause of stomach cancer. This systematic review (1) summarizes the prevalence of infection with this bacterium in Europe, and (2) reviews the possible impact of particular lifestyle factors towards the progression of the associated cancer.

Methods: A systematic literature search was conducted in two databases by two independent investigators. Studies relating infection prevalence among European healthy adult populations and worldwide studies relating the impact of lifestyle factors in association with Helicobacter pylori on stomach cancer risk were included.

Results: Data throughout time showed variable Helicobacter pylori infection outcomes depending on region. Data showed the lowest infection prevalence rates in Northern Europe while the highest infection rates were found in Eastern and Southern Europe, up to 84% in Portugal and Poland. Studies on smoking, salt and meat consumption demonstrated increased risks of developing stomach cancer among Helicobacter pylori infected individuals, while studies relating the intake of fruit, vegetables and vitamins demonstrated decreased risks but the levels of significance differed importantly between studies. No significant interaction could be found for alcohol consumption or physical activity.

Conclusions: Recent data showed still high Helicobacter pylori infection rates in several European regions. Moreover, this systematic review suggests that the following correctable lifestyle factors could impact the disease progression towards Helicobacter pylori associated stomach cancer: the consumption of salt, (processed) meat, fruits, vegetables, vitamins and smoking. However, more qualitative studies are required to draw justified conclusions.

Keywords: helicobacter pylori, stomach cancer, prevention, dietary intervention, nutrition

ASSOCIATION BETWEEN BREAKFAST CONSUMPTION AND CHRONOTYPE IN BRAZILIAN UNDERGRADUATE STUDENTS

[1]Mota, Maria; [2]Teixeira, Gabriela; [2]Furlan, Luisa; [3]Crispim, Cibele.

[1]PhD Student. Nutricionist. Federal University of Uberlândia, Uberlândia, Minas Gerais. Brazil.; [2]Master Degree student. Nutritionist. Federal University of Uberlândia, Uberlândia. Minas Gerais. Brazil.; [3]PhD. Nutritionist. Federal University of Uberlândia, Uberlândia. Minas Gerais. Brazil.

Background and objectives: Current studies have demonstrated that chronotype – which reflects diurnal preferences for the times of rest and activities, and usually classified into "morning","intermediate" or "evening" types –, may influence feeding behavior of individuals. However, the relationship between these variables and the consumption of breakfast – which is currently considered a marker of health – is little explored by studies. The aim of this study was to investigate, in undergraduate students, the association chronotype and overweight and food consumption, with special focus on breakfast.

Methods: The study included 721 undergraduate students (68% female) from a Brazilian public university. Chronotype was determined by Horne and Ostberg (witch score was expressed as a continuous variable and lower score indicate a preference for eveningness). Dietary intake was assessed by applying a 24-hour recall. The usual consumption of breakfast and mealtimes were identified in the 24-hour recall and, subsequently, confirmed by specific questions to the volunteers. Body weight, height and waist circumference were measured by trained researchers. For determination of whether chronotype was associated with food intake and overweight, linear and logistic regression was performed while controlling for confounding factors.

Results: After adjustments for confounding variables it was found a negative association between chronotype and: caloric (kcal/kg/day) (β=-0.23, p=0.007); carbohydrate (g/day) (β=-0.19, p=0.04) and lipids intake (g/day) (β=-0.18, p = 0.04) in the breakfast skippers. Evening (OR=1.8, CI=1.1–2.8, p=0.01) and overweight individuals (OR=2.3, CI=1.3–3.6, p=0.001) presented a significant odds ratio of being a skipper breakfast.

Conclusions: These results suggest that students who tend to eveningness consumed a highest amount of calories, carbohydrates and fats. In addition, skip the breakfast is associated with a higher risk of overweight and eveningness. Future studies are needed to confirm these findings, which could justify the inclusion of chronotype on the nutritional approach to individuals.

Keywords: Breakfast. Food intake. Chronotype. Sleep.

OBESITY IN A GROUP OF HIV-INFECTED PEOPLE FROM BUENOS AIRES, ARGENTINA

[1]Stambullian, Marcela; [2]Girimonte, Patricia; [3]Slobodianik, Nora H.

[1]PhD. Nutritionist. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Argentina.; [2]BSc. Mathematics. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica y Facultad de Ciencias Económicas. Argentina.; [3]PhD. University of Buenos Aires, School of Pharmacy & Biochemistry. Dept. Nutrition & Food Science. Argentina.

Background and objectives: Since the introduction of highly active antiretroviral therapy (HAART), a significantly reduction in AIDS-related deaths was observed. Despite, metabolic diseases are increasing and are one of the major problems that suffer HIV-infected patients. Obesity is affecting people with HIV infection who starts HAART and in some countries, its prevalence is similar to that in the general population. The aim of this study was to learn about the trend in obesity in a group of HIV-infected people under HAART treatment in Buenos Aires.

Methods: It was performed a descriptive, retrospective, cross-sectional study at 3 different years: 2005, 2010 and 2015. Inclusion criteria were asymptomatic adults under HAART, without any nutritional support. Data of age, sex, CD4 count, viral load, time since used of HAART, height and weight were collected from medical records. BMI was calculated and nutritional status was categorized as WHO classification. Obesity was defined as BMI ≥30 kg/m2. Descriptive statistical analysis was applied.

Results: 106 (69.8% men), 100 (70% men) and 110 (66.4% men) HIV-infected patients were included for the years 2005, 2010, 2015 respectively. CD4 cell count media (SD) were 461 (235), 622 (366.5) and 691 (292) cell/mm3 for the different years. Obese people increased along the years. Obesity prevalence was 5.8% (95% CI: 0.9%, 10.8%) for 2005, 11% (95% CI: 4.9%, 17.1%) for 2010 and 21.8% (95% CI: 14.1%, 29.5%) for 2015. The same tendency was observed by sex. For women, 8% (95% CI: 0%, 18.6%), 6.7% (95% CI: 0%, 15.9%) and 24.3% (95% CI: 10.5%, 38.1%) and for men, 4.9% (95% CI: 0%, 10.3%), 12.9% (95% CI: 5.0%, 20.7%) and

20.5% (95% CI: 11.3%, 29.8%) for years 2005, 2010 and 2015, respectively.

Conclusions: Obesity should be considered en HIV-infected people, preferably those under HAART therapy. In this group of Argentinean people with HIV, prevalence of obesity was the same as the prevalence for the general population (20.1%) for the year 2013.

Keywords: HIV infection, obesity, nutritional status, adults, HAART

VITAMIN D MODULATE THE HUMAN NEUTROPHILS RESPONSE AGAINST CANDIDA ALBICANS

[1]Mejía de los Ríos, Susana Pamela; [2]Rendon Marín, Juan Pablo; [3]Restrepo Moreno, Angela; [4]Cano Restrepo, Luz Elena.

[1]Msc. Biologist. Medical Mycology Group and Experimental Corporation for Biological Research (CIB). Colombia.; [2]BSc. Microbiologist. Medical Mycology and Experimental Group. Corporación para Investigaciones Biológicas (CIB). Colombia.; [3]PhD. Microbiologist. Medical Mycology and Experimental Group. Corporación para Investigaciones Biológicas (CIB). Colombia; [4]PhD, Microbiologist. Medical Mycology and Experimental Group. Corporación para Investigaciones Biológicas (CIB). School of Microbiology, University of Antioquia, Colombia.

Background and objectives: Beyond its classical role in calcium and bone metabolism, vitamin D (Vit-D) is known to exert a protean influence on the immune system. The main source of Vit-D is through the action of UVB rays on the skin and from the diet in a much lesser extent. The prevalence of Vit-D deficiency is higher, even in tropical countries like Colombia, where sun exposure is higher. Several studies have shown that Vit-D plays an immunomodulatory role and its deficiency has been associated with higher risk to developing infectious diseases. Candidemia is the 4th most common bloodstream infection with mortality rates of up to 40%, and one of the main causes is Candida albicans. Neutrophils are the first immune response against Candida infections; however, there are no reports about the direct activity of Vit-D3 on the neutrophil response. The objective for this study was to evaluate the Vit-D effect on the human neutrophil response against C.albicans.

Methods: The effect was evaluated on two group of healthy individuals: 1) Vit-D deficient, and 2) Vit-D normal. The serum levels of 25-OH-D3 were measured by HPLC-UV. Neutrophils of each individual were obtained from peripheral blood. Co-cultures with C.albicans were performed and treated with different concentrations of 25-OH-D3 (25, 100, 200 ng/mL). The efficiency to eliminate C. albicans in each treatment was determined through colony forming units (CFU) counts. Additionally, the immunomodulatory effect of neutrophils was assessed through the burst response of cytochrome C assay.

Results: Significant differences between groups were observed in both, CFU and cytochrome C assay. Individuals from normal

---

group showed a higher elimination of CFU with respect to deficient group. Individuals with normal level of Vit-D had a low response in contrast to deficient individuals. The tested concentrations of 25-OH-D3 did not caused differential effect between groups.

Conclusions: Neutrophils from individuals with normal levels of Vit-D showed an immunomodulatory response against C.albicans. The immunomodulatory effect in cytochrome C was negative; however, the neutrophil from normal individuals could eliminate the fungus more efficiently. The fungicidal effect against C.albicans could be due to production of antimicrobial peptide LL-37 as previously reported.

Financial support: Grant Number FP44842-374-2014

Keywords: Vitamin D, Candida albicans, Neutrophil, Normal Vitamin D level and Deficient Vitamin D level.

INCIDENCE OF ENTERAL NUTRITION THERAPY COMPLICATIONS IN CRITICALLY ILL PATIENTS

[1]Villa, Roberto; [2]Clochiatti, Natalia.

[1]MD. PhD. Professor of Medicine. Intensive Care Unit. Obra Social para la Actividad Docente. Argentina; [2]MD. Physician. Intensive Care Medicine. Obra Social para la Actividad Docente. Argentina.

Background and objectives: Human beings need nutrients in adequate quality and amount in order to satisfy their needs. Sometimes this offer can not be achieved by oral intake and should be done by enteral route. The aims of this study were to evaluate the frequency of tube feeding related complications in critically ill patients and evaluate the relation between complications frequency and enteral feeding nutrition regarding nutrients sources and type of container (open or closed system).

Methods: 364 cases from one single centre in one intensive care unit were reviewed. 166 cases meet the study criteria. Data were analyzed in two separated groups, depending on nutrition solution used. Nutrition solutions were similar in all characteristics except type of container and nutrients sources. The following complications had been analyzed: diarrhea, aspiration, regurgitation, vomits, constipation and abdominal distention.

Results: The incidence of complications was different between groups (22.8% and 38.5%, p< 0.05), being diarrhea the only complication that occurred with different incidence (13.8% and 45.8%, p< 0.05). Tube feeding had an incidence of complications of 27.7% and this may compromises the caloric intake of patients.

Conclusions: Container system does not seem to influence the incidence of complications; however the use of only one or two sources of macronutrients (100% of proteins from casein and 100% carbohydrates from maltodextrin) can be an important factor to predispose diarrhea.

Keywords: Enteral nutrition. Critical ill patients. Complications.

PROLIFERATIVE EFFECT OF VITAMIN D ON CANDIDA ALBICANS

[1]Mejía de los Ríos, Susana Pamela; [2]Díaz Buenaños, Beyfan; [3]Rendon Marín, Juan Pablo; [4]Restrepo Moreno, Angela; [5]Cano Restrepo, Luz Elena.

[1]MSc Biology, Medical and Experimental Mycology Group, Corporación para Investigaciones Biológicas (CIB).; [2]Student of Microbiology and Bioanalise Program, Microbiology School. Universidad de Antioquia. Colombia; [3]BsC. Microbiologist. Medical and Experimental Mycology Group, Corporación para Investigaciones Biológicas (CIB). Colombia; [4]PhD. Microbiologist. Medical and Experimental Mycology Group, Corporación para Investigaciones Biológicas (CIB). Colombia; [5]PhD. Microbiologist. Medical and Experimental Mycology Group, Corporación para Investigaciones Biológicas (CIB). Microbiology School. Universidad de Antioquia (UdeA). Colombia.

Background and objectives: Candidiasis is one of the most frequent nosocomial infections affecting humans. It is caused by one of the fungus in the genus Candida with C. albicans being the most prevalent species. This yeast is considered as a commensal organism for the human being and one that, under certain altered conditions such as changes in the host immune system, behaves as an opportunistic pathogen. Such altered circumstances can be multifaceted with some being related to the nutritional status of the individual and in particular, with deficiencies in vitamin D, molecule that plays an important role. In this sense, it has been demonstrated that vitamin D contributes to the control of infections and is converted into an essential nutrient for the invading microorganism. Up to this moment, studies related to the role of vitamin D in Candida infections reveal no conclusive findings concerning the direct effect of this vitamin on the invading microorganism.

Objective: To determine vitamin D direct effects on C. albicans growth.

Methods: The effect of the 25-OH-D3 (25-Hidroxy-vitamin D3) on C. albicans growth was measured through: a) determination of the Colony Forming Units (CFU) after 2 hours incubation of the fungus in the presence of three different concentrations of 25-OH-D3 (25, 100 and 200ng/ml), and b) the plaque microdilution test with a yeast suspension placed in front of different vitamin D concentrations (25, 100, 200, 400, 600, 800, y 1000ng/ml) with a 22 hours kinetics run.

Results: The CFU values revealed that the treatment with 200ng/ml of vitamin D, induced a significant proliferative effect by doubling (2,16X) the number of CFU in comparison with the control with no vitamin. According to the growth kinetics obtained through the microplate technique, an important increase in growth was noticed starting at 14h post-incubation in the presence of concentrations of 25-OH-D3 ≥ 200ng/ml

Conclusions: Vitamin D induces a direct and dose-depending proliferative effect on C. albicans possibly due to the fungus capacity to develop metabolic pathways related to the P450 enzymatic complex that allows to process the 25-OH-D3.

PERCEPTION OF BODY IMAGE AND DIETARY INTAKE OF MOTHERS OF PATIENTS WITH EATING DISORDERS

[1]*Manochio Pina, Marina Garcia;* [2]*Pilot Pessa, Rosane;* [3]*Cristina Marques Costa, Lauane;* [4]*Meneghetti Miguel, Raphaela;* [4]*Lara Garcia, Caroline.*

[1]Dr. Nutricionista. Universidade de Franca. Brasil.; [2]Dr. Nutricionista. Pontifícia Universidade Católica de Campinas. Escola de Enfermagem de Ribeirão Preto USP. Brasil.; [3]Graduanda em Nutrição. Universidade de Franca. Brasil.; [4]Nutricionista. Universidade de Franca. Brasil.

Background and objectives: Eating disorders are psychosomatic diseases resulting from a conflicting relationship of the individual with the food and the primary symptoms are concern about body weight and shape. Generally mothers are very present since the childhood of the children and can be great allies in the treatment of their daughters with feeding disorder. The objective of the study is to investigate the eating behavior and to evaluate the perception and satisfaction of the body image of mothers of patients with eating disorders.

Methods: A quantitative research,performed in a public and specialized service in the interior of São Paulo, currently serving 18 patients. The methods used were a 24-hours Recall, test "How Is Your Feeding ?" EAT- 26 and Scale of Figures of Silhouettes. Data collection was done in individual and reserved rooms, and the mothers' identity was kept confidential. All the tests were answered by the mothers themselves and the collection lasted about 30 minutes for each participant.

Results: Thirteen mothers of the 18 patients participated during the study. EAT-26 showed a negative result, with an average of 17.23 points, the "How is Your Feeding" test showed an average of 38.85 points, showing that the mothers' diet is practically within what is considered healthy. Regarding body image, mothers were dissatisfied.

Conclusions: The study concludes that mothers present body image dissatisfaction, although they do not present eating behaviors similar to the habits of patients with eating disorders, however, this group should be considered, since it may be a group of risk. It is necessary to include mothers in support groups and further studies with them so that more information about the family's eating behavior can be obtained and other forms of treatment for the disorder can be sought.

Keywords: Eating disorders, food behavior, mother, mother-child relationships, eating habits.

LOW MANGANESE MAY INCREASE THE RISK OF DIABETES IN CHINESE ADULTS

[1]*Du, Shufa;* [2]*Liu, Liping;* [3]*Wang, Huijun;* [1]*Mendez, Michelle A;* [4]*Popkin, Barry M.*

[1]PhD. Department of Nutrition and Carolina Population Center, The University of North Carolina at Chapel Hill; [2]Beijing Municipal Center for Disease Control and Prevention; [3]MD. National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention; [4]Phd. Nutrition. Department of Nutrition. University of North Carolina. United States.

Background and objectives: Diabetes has rapidly increased in past two decades in China. Recent studies reported that manganese may help regulate glucose metabolism, while little is known about the relationship between manganese concentrations and the risk of diabetes.

Methods: We used a subsample (n=5,587 adults aged 18 – 65 years) who provided blood and toenail samples in 2009 from the China Health and Nutrition Survey, a study covering 9 provinces varying in environment and urbanization in China. We measured manganese on toenail samples with inductively coupled plasma mass spectroscopy (ICP-MS), hemoglobin A1c (HbA1c) on fresh whole blood samples with high performance liquid chromatography, insulin on serum samples with radioimmunology method, and glucose on serum samples with Hitachi 7600 Auto-analyzer. We estimated the association between manganese concentrations and diabetes by using logistic regression models in which we controlled for age, gender, body mass index, education, social-economic status, residential region (urban/rural), and urbanization index.

Results: The median manganese concentration was 3.86 mg/kg with a range of 0 – 60.58 mg/kg. The prevalence of diabetes defined as HbA1c ≥ 6.5% was 8.15%, 6.88%, 6.20%, and 4.36% from the 1st to 4th quartile of manganese concentration (p trend <0.001), respectively, and the average prevalence was 6.38%. Compared to the 1st quartile, the odds ratio of diabetes from 2nd to 4th quartile was 0.81 (95% CI: 0.59 – 1.11), 0.83 (95% CI: 0.60 – 1.17), and 0.58 (95% CI: 0.40 – 0.84), respectively. The average serum glucose was 95.87 mg/dL. Serum glucose decreased with increased manganese, but it was significantly lower in the 4th quartile only, compared to the 1st quartile (94.06 vs. 97.68 mg/dL, p trend =0.01).

Conclusions: Manganese is an important element for human health. Our findings suggest that low manganese may increase the risk of diabetes. Manganese may play an important role in preventing the development diabetes.

Keywords: Diabetes, manganese, toenail, hemoglobin A1c, China

RISK FACTORS FOR THE DEVELOPMENT OF CVD BY USING OF FRAMINGHAM RISK SCORE IN ELDERLY

(1)Sanches, Fabiana; (2)Falcäo, Ana Celia; (2)Sanches, Fabiana.

(1)Ms. Nutritionist. University Católica de Santos, Brazil; (2)Nutritionist. University Catholic of Santos, Brazil.

Background and objectives: Various methods are used to measure the risk of CVD in elderly population, being the Framingham Risk Score (FRS) a sensible tool to measure the risk in 10 years. In the elderly, the CVD can affect the nutritional state either by necessity of food restriction, by alteration of energetic needs or by metabolism processes of digestion, absorption and excretion of nutrients. AIM: measure the risk factors for the development of CVD by using of FRS in elderly in the city of Santos-SP

Methods: Cross-sectional study kind, where were measured 54 elderly of both gender, that regularly attend an extension course of an university of the 3rd age, with age over 60 years old. It was used to collect data a questionnaire previously validated, based on Framingham Risk Score and the biochemical values inherent to the questionnaire of Framingham were collected by means of exams done in the last six months.

Results: From the sample of 54 individuals, 35 (64,8%) presented highly increased waist circumference, but 32 participants (64,8%) were diagnosed with BMI of eutrophy. In relation to the lipid profile, it was obtained 20 researched (37,0%) with the total cholesterol >200 mg/dL and 21 with HDL-c 21 (38,9%) <35 mg/Dl. When the group was divided from the classification of FRS, the prevalence of low/moderated risk appeared in 32 (59,25%) participants, while the high risk of developing coronarian events in 10 years was demonstrated in 22 (40,75%) pacients.

Conclusions: Despite the higher prevalence of individuals with low/moderated risk for developing CDV in 10 years, BMI indicative of eutrophy, low index of tabagism and low incidence of DM, the biggest part of the sample presented the CC highly increased, low level of HDL-c and totally elevated cholesterol. Despite the divergences found, the FRS is a very practical parameter to measure the possible deploy of CDV. Thereby it is worth pointing that the better way to quantify cardiovascular risk is to consider all the factors involved.

Keywords: elderly, FRS, CVD, Nutritional Risk.

DIETARY INFLAMMATORY INDEX AND DIABETES MELLITUS IN MEXICAN ADULT POPULATION: THE DIABETES MELLITUS SURVEY OF MEXICO CITY

(1)Denova-Gutiérrez, Edgar; (2)Muñoz-Aguirre, Paloma; (3)Shivappa, Nitin; (4)Hebert, James R.; (5)Tolentino Mayo, María Lizbeth; (5)Batis, Carolina; (5)Barquera, Simon.

(1)Clinical Epidemiology Research Unit, Hospital Infantil de México Federico Gómez.; (2)National Institute of Public Health, Cuernavaca, México; (3)Cancer Prevention and Control Program, University of South Carolina. Columbia, USA. and Department of Epidemiology and Biostatistics, Arnold School of Public Health, University of South Carolina. Columbia, USA.; (4)Cancer Prevention and Control Program, University of South Carolina. Columbia, USA. and Biostatistics, Arnold School of Public Health, University of South Carolina. Columbia, USA.; (5)Centro de Investigación en Nutrición y Salud, Instituto Nacional de Salud Pública. Cuernavaca, México.

Background and objectives: Diet and inflammation have been reported as important risk factors for type 2 diabetes (DM2). In the present study, we aimed to assess the relationship between the dietary inflammatory index (DII) and the presence of DM2 in Mexican adults participating in the Diabetes Mellitus Survey of Mexico City (DMS-MC).

Methods: The study included 1305 subjects (37.6% men and 62.4% women) between 20-69 years. A validated semi-quantitative food frequency questionnaire was employed to evaluate dietary intake and to compute the DII. The DII is based on scientific evidence about the association between dietary compounds and some inflammatory biomarkers. Logistic regression models were used to estimated the odds ratios (ORs) and 95% confidence intervals (95% CIs) adjusted for sex, age, education, physical activity (low vs. moderate/intense); hours of television watching; hours sitting down; tobacco use (current, past, and never); socioeconomic status (low, medium, and high); education (elementary, secondary and high school, and Bachelor's degree or higher); family history of diabetes mellitus (yes vs. no); personal history of hypertension (yes vs. no), medication use (yes vs. no), body mass index (<25.0 vs. ≥ 25.0 kg/m2), and energy intake (kcal/day).

Results: Our data suggest that subjects in the highest quintile of the DII (i.e. with a more pro-inflammatory diet) had higher odds of DM2 (OR = 2.08; 95% CI: 1.27, 3.40; P for trend = 0.007) compared to subjects in the lowest quintile of the DII (i.e. with a more anti-inflammatory diet).

Conclusions: These results propose that a pro-inflammatory diet is associated with significantly higher odds of DM2 in Mexican adult population.

LOW PROTEIN INTAKE OR KILOCALORIE? WHICH, ACTUALLY, CAN INTERFERE IN HAND-GRIP STRENGTH AND IN BODY COMPOSITION IN PATIENTS ON HEMODIALYSIS?

[1]Sanches, Fabiana; [2]Pereira, Leticia; [2]Francotti, Julia; [2]Lopes, Natalia; [3]Ali, Mohamed.

[1]Ms. Nutritionist. University Católica de Santos; [2]Nutritionist. University Catholic of Santos; [3]Md. Santa Casa da Misericordia de Santos.

Background and objectives: The ideal recommendation of proteins for patients on hemodialysis (HD) to promote neutral or positive nitrogen balance must be between 1,1 to 1,2 g/kg/day. This recommendation allied with an average intake of 35 kcal/kg/day, seems to avoid the PEM, which is a frequent condition associated with increase of morbidity and mortality. So, the purpose of this study is to measure the impact of protein and energy intakes on the hand-grip strength (HGS) and on the body composition of the patients with chronic renal diseases subjected to HD.

Methods: the body composition of the patients with chronic renal diseases subjected to HD. Cross-sectional study. 104 patients were measured, from both gender, over 18 years of age and on a regular program of HD. It was gauged after HD session: weight, stature, AC, DCT, HGS and the adductor muscle thickness. The BMI and the AMC were calculated. Protein and energy intakes were calculated from the food register of three days.

Results: were calculated from the food register of three days. The groups were divided by protein and energy intake adequated or not (0,78 vs 1,56 g/kg/day; p<0,01) and (32,4 vs 23,7 kcal/kg/day, p<0,001); respectively. The group that consumed less protein demonstrated lower HGS (21,6 vs 17,1 kg; p=0,02), BMI (24,3 vs 19,9 kg/m²; p<0,01), AC (28,5 vs 24,5 cm; p<0,01), AMC (23,5 vs 20,7 cm; p<0,01) and DCT (16 vs 11 mm; p<0,01). However, the group that consumed less kcal presented just lower BMI (20,4 vs 25,8 kg/m²; p<0,05) and APMT (10,1 vs 13,5 mm; p<0,02).

Conclusions: These results suggest that protein intake is determinative to changes in the body composition and overlaps to energy intake for patient with chronic renal disease in HD.

Nutritionist. Private medical practice. Coordinator Posgrade Obesity Favaloro University.

Background and objectives: BACKGROUND: Evidence shows that distortion of body weight perception is more prevalent in people with a lower educational level, particularly in men and racial minorities. As a result, people may be less likely to demand medical care and this could limit the effectiveness of public health campaigns.

OBJECTIVES: To analyze the ability to self-perceive corpulence in an adult population according to their referred BMI, gender, age and educational level.

Methods: MATERIAL AND METHODS: Cross-sectional, descriptive and analytical observational study. An anonymous questionnaire was provided to individuals belonging to private institutions not related to health. Data obtained included: gender, age, weight and height; perception of body weight (low, normal, overweight, obese); level of education (primary or elementary school, secondary or high school, tertiary-university or college/university). Data were analyzed using the STATA statistical software program.

Results: RESULTS: Respondents surveyed were 1617 individuals aged 18 to 70; female 66.6% and male 33.4%. According to weight and height: underweight 2.2%; normal 49.1%; overweight 30.2% and obese 18.6%.

According to age groups: from ages 18 to 29: 28.4%, 30 to 49 48.3% and 50 to 70 23.3%. According level ef education: primary 22.5%, secondary 40.4% and tertiary / university 37.1%.

There was no evidence of a significant relationship between age and corpulence perception discordance.

While 27.3% of women underestimate their weight, 47.7% of men do. (P <0.001).

9.7% of normal weight individuals, 47.8% of overweight and 80.7% of obese perceive themselves to as thinner than they actually are and in all paired-comparisons the differences were significant

(P <0.001). Obese respondents had the lowest levels of correct weight perception (2 out of 10).

The highest percentage of underestimation of body weight occurs among respondents with primary education (47.8%) and diminishes as the educational level increases: 36.5% for the secondary level and 23.0% for the tertiary / university level (P <0.001).

Conclusions: CONCLUSIONS: In the population surveyed, conditions of lower educational level, higher BMI and male gender, were related to underestimation of body weight.

Keywords: Key words: weight perception, BMI, level of education, gender, obesity.

EVALUATION OF AN INTUITIVE EATING WEIGHT MANAGEMENT PROGRAMME TO SUPPORT WEIGHT MANAGEMENT PATIENTS

(1)Kruger, Rozanne; (2)Yovich, Franica; (3)Haarhoff, Beverley.

(1)PhD. Dietitian. School of Food and Nutrition. Massey University. New Zealand.; (2)PG Dip Diet. Dietitian. Waitemata District Health Board. New Zealand.; (3)PhD. Psychologist. School of Psychology. Massey University. New Zealand.

Background and objectives: Overweight and obesity rates are increasing exponentially worldwide, resulting in high rates of chronic diseases. Maintaining weight-loss can reduce associated risks, however, many dietary restriction weight-loss interventions have poor sustainability. The impact of psychological factors on managing weight and supporting related changes is critical. This study explored whether an intuitive eating weight management programme is an effective intervention for people classified as obese within the hospital system.

Methods: Participants (n=49) were enrolled in a 28-week evaluation study: 4-week usual diet run-in; 4-week intervention; 24-week follow-up. Of these participants, 14 failed to start, four withdrew during the study, and 18 failed to complete all components. Data were collected at baseline and end of periods for anthropometry (height, weight, circumferences), behavioural and cognitive approaches to food (Intuitive Eating Scale (IES-2), Dutch Eating Behaviour Questionnaire (DEBQ), Quality of Life Questionnaire (QoL), dietary intake (24h-Recall)).

Results: Changes in reasons for eating (mean±SD) occurred after attending group sessions, improving significantly from baseline to 6-month follow-up: 'eating for physical rather than emotional reasons' (2.87±.80 to 3.44±.72, P=0.002), 'reliance on hunger/satiety cues' (2.80±.95 to 3.38±.83, P=0.004), and total IES-2score (2.93±.54 to 3.31±.41, P=0.000). Positive changes was observed in the DEBQ emotional and external trigger eating style scores, decreasing from 2.67±1.04 and 3.06±.67 respectively from baseline to 1.98±.86 (P<0.002) and 2.56±.63 (P<0.001) at 6-month follow-up. Participants' reported mean (±SD) intuitive eating level (percentage of total eating times) increased from

baseline to end of intervention, and further increased at 6-month follow-up (35.9±22.0 to 60.0±23.5 (P<0.000) to 67.50±26.356, P<0.001, respectively). Participant's median [95%CI] confidence levels increased significantly after completing the group sessions, from 6.0 [5, 7.5] to 8.0 [7, 9] (P<0.001, r=0.8) and remained higher (7.5 [5,8]), at 6-month follow-up. Weight (mean±SD) did not change significantly from baseline (112.33±26.67 kg) to follow-up (112.04±28.52 kg). However, 32% of participants lost >3% of their initial body weight and 74% either lost or maintained weight.

Conclusions: Group-based intuitive eating weight management programmes can improve psychological factors associated with weight management, and support weight maintenance long term. It further initiates the process of making changes to improve food-related behaviour and lifestyle.

Keywords: Weight management, Intuitive eating, Obesity, Eating behavior, Cognitive approaches.

CENINH (Centro de Investigación en Nutrición Humana. Escuela de Nutrición. Facultad de Ciencias Médicas. Universidad Nacional de Córdoba. Argentina. INICSA-CONICET. Argentina.

Background and objectives: The interrelationship between physical activity (PA) levels and sedentary behavior could promote health or increase the incidence of risk factors to develop cardiometabolic diseases. The aim of this study was to assess the association between auto-reported physical activity levels, sedentary behavior and the incidence of cardiometabolic risk factors.

Methods: To analyze the aforementioned associations, an observational and correlational design was used. Participants (n = 117, mean ± SD for age = 61±1.43 years) were recruited from the non-invasive cardiology division at HNC of Cordoba city during the period between 2014-2016. Physical activity was recorded by

means of the Spanish version of the International Physical Activity Questionnaire (IPAQ) and analyzed using a spreadsheet that allow to estimate three weekly levels of PA (low, moderate and high), the energy expenditure of PA (EEPA) and the sedentary behavior. Incidence of cardiometabolic risk factors was assessed by exploring the patient's medical history. The selected risk factors were: body mass index (BMI), waist circumference (WC), systolic (SBP) and diastolic (DBP) blood pressure and serum lipid profile. Comparisons between men and women were made using independent samples T tests. All analyses were carried out using the Stata v.11.

Results: Average PA levels for the total sample was 240.00 ± 116.44 METs·min/week; representing an EEPA of 1388.31 ± 600.26 Kcal/week. Further analysis showed that 25.63% of women and 18.80% of men reported to be engaged in PA of moderate intensity while only 5% of women and 11% of men were engaged in vigorous PA. Sedentary behavior was reported to be 360 ± 37.82 min/day. Significant associations were observed between BMI and sex (p<0.05), were women tended to have less weight than men. A very high risk regarding WC was found in 82% of the total sample, being the risk higher in women than in man (p<0.05). Moreover, an inverse relationship was found between both SBP (r = 0.51, p<0.01) and DBP (r = 0.35, p = 0.04) and moderate intensity PA levels.

Conclusions: Physical activity was related to an increased risk for metabolic diseases, being this risk higher in women compared to men.

CITIES CHANGING DIABETES MELLITUS: A REPRESENTATIVE SURVEY OF MEXICO CITY

[1]Barquera, Simon; [2]Tolentino Mayo, María Lizbeth; [3]Hernández, César; [3]Mendoza, Kenny; [4]López-Ridaura, Ruy.

[1]PhD. Instituto Nacional de Salud Pública; [2]MSc. Nutritionist. Instituto Nacional de Salud Publica. México.; [3]MSc. Instituto Nacional de Salud Publica. México.; [4]PhD. Instituto Nacional de Salud Publica. México.

Background and objectives: Currently in Mexico, diabetes mellitus type 2 represents a serious public health problem and a challenge for the health system. Diabetes is the second cause of death in the adult population and the main cause of hospitalization related to complications.

A representative survey of adults between 20 to 69 years was performed in Mexico City to know the risk factors and other health indicators of non-communicable diseases to describe aspects in the attention process, quality of services and vulnerability of people who lives with diabetes, hence to obtain information about their socio-economic conditions.

Methods: We applied a questionnaire of seven sections that identified the socio-demographic characteristics of people that integrated the household, the health situation, the usage of health services, general aspects of the household, goods and expenses of the household, and other section that explores aspects about health and usage of medical services. Blood samples and serum were obtained from a sub-sample of participants to obtain the prevalence of diabetes Mellitus in Mexico City, and to compare the results with data shown in the ENSANUT 2012. Different risk biomarkers were used to define metabolic syndrome such as: cholesterol, triglycerides, HDL, LDL, and glycosylated hemoglobin.

Results: The prevalence of diabetes mellitus was 13.9% (9.9% for known diagnosis (KD) and 4.0% known by the survey (Sv). From the total of people with KD, 29% had an adequate control of their disease. In people with KD, the determination of HbA1c was more frequent in people who were not controlled in their disease (67%), than in those people that were controlled (52.7%) (p<0.05). From the total of people that received treatment, only 25.6% had an adequate control of their disease.

Conclusions: A high proportion of the sample presented high levels of glucose, and they are not aware of it. The absence of prevention measures for non-communicable diseases in the adult population are reflected in the results.

Keywords: Diabetes, Non-Communicable-Diseases, Survey, Mexico-City, Changing

ASSOCIATION OF VITAMIN B12 AND HOMOCYSTEINE WITH COGNITIVE DECLINE IN ELDERLY PATIENTS WITH CARDIOVASCULAR DISEASES

[1]Peçanha, Daniela; [2]dos Santos, Elisa Maia; [3]de Paula, Laís Silva; [3]Marotto, Deborah; [3]Costa, Mariana Ribeiro; [3]Souza, Paula; [4]Huguenin, Grazielle Vilas Bôas; [2]Moreira, Annie Seixas Bello.

[1]Msc. Nutricionist. Institute of Nutrition. University of the State of Rio de Janeiro. Brazil; [2]National Institute of Cardiolog. Statue University of Rio de Janeiro. Brazil; [3]Statue University of Rio de Janeiro; [4]National Institute of Cardiolog. Brazil

Background and objectives: Dementia and Cognitive Dysfunction are common in elderly and lower intake of B-vitamins may contribute to the development of neurological diseases, since they participate in the metabolism of homocysteine that, in altered levels, is associated with cognitive disorders. The objective of this study was associate serum homocysteine, dietary intake of B-vitamins and their markers with cognitive impairment in elderly patients with cardiovascular disease.

Methods: A cross sectional study with 194 elderly patients with a mean age of 70,7±7,0 years of both sexes, participants of a multicenter randomized clinical trial that studies the effects of a Brazilian Cardio protective Food Program on reduction of events and risk factors in prevention of CVD. Anthropometric evaluation and blood collection were performed. Dietary assessment (by food frequency questionnaire) was made using Food Processor program. The evaluation of cognitive function were performed

through the Mini Mental Health Examination (MMME). Data was expressed in frequency and medians (P25-75), analyzed in SPSS 21.0, considering a significance level of 5%.

Results: The majority of the population had a clinical suspicion of mild cognitive decline (CDL), 40,2%, male 65,4%. The median score obtained in MMME was 24 (22 - 25) for the group with mild cognitive decline and for the group with dementia was 17 (16 - 19) points and 27 (26 - 27) for those who did not Cognitive decline (CD) p <0.05. The serum homocysteine level of the dementia and DCL groups was adequate 10.87 ± 4.28 μmol / L and 10.69 ± 3.46 μmol / L, and was not significantly different from the group without DC 10.19 ± 3 , 11 μmol / L p> 0.05. The group with dementia consumed 3.8mg (2.77 - 7.74) of vitamin B12, 78.4% had consumption according to the recommendation by the EAR and 83.3% with DCL had adequate intake of this nutrient.

Conclusions: We conclude that the consumption of vitamin B12 and its blood marker and serum homocysteine are adequate in the groups that presented clinical suspicion of cognitive disorders such as dementia and mild cognitive decline, not being associated with this pathology in these elderly people.

Keywords: Cognitive decline , cardiovascular disease, dementia, vitamin B12, homocysteine

ASSOCIATIONS OF STRESS MANAGEMENT WITH METABOLIC SYNDROME IN JAPANESE -SAKU COHORT STUDY-

[1]Morita, Akemi; [2]Yasukawa, Jun; [3]Kawashima, Nobuhisa; [4]Aiba, Naomi; [5]Miyachi, Motohiko; [6]Watanabe, Shaw.

[1]PhD. MD. Koshien University. Japan.; [2]Mr. RD. Koshien University. Japan.; [3]PhD. RD. Koshien University. Japan.; [4]PhD. RD. Kanagawa Institute of Technology. Japan.; [5]PhD. National Institutes of Biomedical Innovation, Health and Nutrition. Japan.; [6]PhD. MD. Life Science Promotion Foundation. Japan.

Background and objectives: Background: The Japanese government launched the Stress Check Program as a new occupational health policy. Stress management is considered useful strategies to prevent the metabolic syndrome (MetS). The effective methods to reduce stress on preventing MetS remained unclear.

Objectives: To evaluate the role of stress management in preventing or exacerbating MetS, we examined the associations between their ways to release stress and the risk factors of MetS in the cohort subjects undergone health checkup.

Methods: 4450 Japanese men and women were enrolled at the Saku Central Hospital. They received an anthropometric and clinical examination and were assessed for present illness, lifestyle factors such as physical activity, smoking, drinking, dietary habits and present stress level and stress busters at the enrollment. Eating behavior was analyzed by the Sakatas Eating Behavior Question-

naire. Dietary assessment was made using a brief self administered diet history questionnaire. 2602 men and 1844 women aged more than 20 were analyzed.

Results: The mean age in men and women were 59.2 and 58.4 years old, respectively. The percentages of MetS were 20.6 in men and 6.1 in women. There was no significant difference in prevalence of MetS between with or without perceived stress in men and women. However, there were significantly more men with Mets in people who reduce stress by eating. The scores of all the categories in eating behavior were worse in subjects with perceived stress than those without perceived stress. Furthermore, the scores in eating behavior were bad in subjects with emotional eating regardless of perceived stress.

Conclusions: The influence of the way to stress management, especially for emotional eating, on MetS was suggested in men and women.

Keywords: Metabolic Syndrome. MetS. Stress Management. Eating Behavior.

APPETITE AND SYMPTOMS OF WOMEN WITH GYNECOLOGICAL CANCER ATTENDED AT BARRETOS CANCER HOSPITAL: A PILOT STUDY

[1]Bernardes Spexoto, Maria Cláudia; [2]de Brito, Ligia Zampieri; [2]Silva, Gesieli; [3]dos Reis, Ricardo.

[1]PhD. Faculdade de Ciências da Saúde. Universidade Federal da Grande Dourados. Brazil.; [2]Student of Nutrition. Curso de Nutrição. Centro Unificado de Educação Barretos Ltda. Brazil.; [3]MD. Hospital de Câncer de Barretos. Brazil.

Background and objectives: The decrease or lack of appetite, affected by both the treatment and the disease itself, are inherent characteristics of the patient with cancer, and can promote weight loss, early satiety, gastrointestinal symptoms and others. The objective was to evaluate the Appetite/Symptoms of women with gynecological cancer treated at the outpatient clinic of the Barretos Cancer Hospital (HCB), Brazil.

Methods: This is a pilot study with the participation of 37 women, cross-sectional, prospective, with sample collection for convenience. All women with an initial diagnosis in HCB were included in the study. Sociodemographic and clinical information were collected. The appetite and symptoms were assessed using the global score of Cancer Appetite and Symptom Questionnaire (CASQ) translated and adapted to the Portuguese language, composed of 10 items with answers arranged in a five-point Likert scale, where the score ≤1 represents low impairment of the Appetite/Symptoms, 1 to 3 moderate impairment and a score > 3 severe impairment.

Results: The average age of participants was 50.6±16.0 years, body mass index equal to 28.4±7.4 kg/m2, belonging to economy class C (62.2%) and married (51.4%). For this sample, 70.3% (n=26) presented moderate impairment, 27.0% (n=10) severe impairment and 2.7% (n=1) low impairment of the Appetite/Symptoms.

Conclusions: Most participants find themselves with moderate impairment of Appetite/Symptoms.

Keywords: cancer, appetite, symptoms

CORRELATION BETWEEN ANTHROPOMETRIC AND BODY COMPOSITION INDICATORS OF PEOPLE LIVING WITH HIV/AIDS WITH HIV ASSOCIATED LIPODYSTROPHY CLINIC DIAGNOSES

[1]Sacilotto, Lívia Bertazzo; [2]Pereira, Paulo Câmara Marques; [3]Mendes, Adriana Lúcia; [4]Corrente, José Eduardo; [5]Manechini, João Paulo Vieira; [6]Justina Papini, Silvia.

[1]MD. Nutritionist. Department of Tropical Disease and Imaging Diagnosis. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [2]Adjunct professor. Department of Tropical Disease and Imaging Diagnosis. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [3]PhD professor. São Paulo State University (UNESP). Botucatu Medical School. Brazil.; [4]Adjunct professor. Department of Bioestatisc. São Paulo State University (UNESP). Institute of Biosciences. Botucatu. Brazil.; [5]MD student. University of São Paulo (USP), Ribeirao Preto Medical School, Brazil; [6]PhD. Nutritionist. Department of Nursing. São Paulo State University (UNESP). Botucatu Medical School. Brazil.

Background and objectives: Nowadays, one of the major problems among people living with HIV/Aids (PLHA) is body composition alteration accompanied to the accumulation and/or loss of body fat in specific locations, being this impairment known as lipodystrophy. The fat accumulation in body central area is associated to an increased risk of developing cardiovascular diseases, glucose intolerance, type 2 diabetes mellitus and, still, decreases in bone density. For the early evaluation of these individuals and a nutritional diagnosis establishment, the protocol must be easily accessed in the clinical practice. The present study had the objective to correlate the anthropometric and body composition indicators of PLHA with HIV associated lipodystrophy diagnosis by means of Pearson correlation test.

Methods: The study was observational and transversal, with its sample selected by convenience and performing clinical immunological characterization, anthropometric assessment, nutritional diagnosis, body composition of PLHA during the follow-up of specialized outpatient service in infectiology with a clinical HALS diagnosis from July 2015 to July 2016, in regular antiretroviral therapy use for at least a year, ranging from 18 to 60 years old. Pregnant women, people with chronic kidney failure, nephrotic syndrome, B and C virus chronic infection, uncontrolled hypothyroidism were excluded from the study.

Results: It was possible to identify strong correlation between Body Mass Index (BMI) with abdominal circumference (AC) and fat visceral area (FVA) (R = 0,86 and R = 0,83, respectively), and between AC and FVA (R = 0,78).

Conclusions: These results deserve to be highlighted because the utilization of simple measures as BMI and AC, despite their limitations, is important in facilities where is not possible to perform more specific evaluations on these individuals, once those measures present low cost and easy applicability in clinic routine, making the nutritional follow up of this population simpler. Considering the follow up of PLHA as complex as it is, the usage of parameters which may indicate increased cardiovascular risk or fat accumulation is determinant for the adoption of specific strategies, beyond the inclusion of low cost and easy access evaluations to correctly monitor the nutritional state of these patients.

Keywords: People living with HIV/aids, lipodystrophy, body composition

NUTRITIONAL STATUS OF HOSPITALIZED PATIENTS BY SUBJECTIVE EVALUATION IN PUBLIC HOSPITALS OF ASUNCIÓN AND METROPOLITAN AREA DURING 2017. PRELIMINARIE STUDY

[1]Bordón Riveros, Claudia; [2]Ferreira Heyn, Ana Maria; [3]Figueredo Grijalba, Rafael; [4]Mayor Oxilia, Rosa; [3]Chirife Fernández, Graciela; [5]Argüello, Rocío; [5]Bareiro Arce, Alberto; [5]Romero Ausfeld, María Jose; [6]Joy, Laura; [6]Báez, Alicia.

[1]Nutritionist; [2]Médico. Sociedad Paraguaya de Nutricion. Paraguay; [3]Médico. Instituto Privado de Nutrición Integral. Paraguay; [4]Medico. Sociedad Paraguaya de Nutricion. Paraguay; [5]Nutricionista. Instituto Privado de Nutrición Integral. Paraguay; [6]Nutricionista. Sociedad Paraguaya de Nutricion. Paraguay.

Background and objectives: Hospital malnutrition is highly prevalent in Latin America. Studies done in Paraguay in 2003 showed a prevalence of malnutrition of 50,9%. The aim of this study was to determine the nutrition status by subjective parameters in adult hospitalized patients in Public Hospitals of Asunción and the Metropolitan Area during 2017.

Methods: Cross sectional study enrolled hospitalized patients older than 18 y hospitalized in 8 highly complex Public Hospitals of Asunción and Metropolitan Area during 2017. We used the Subjective Global Assessment tool to assesses malnutrition.

Results: There were 145 patients enrolled whose mean age was 50,3 ± 16,7 years. The 51,7% (n=75) was men, 53% (n=77) had clinic pathologies and 13,9% (n=20) was infected.

The study showed that 51% (n=74) of patients had a BMI between 25 and 29.9 kg/m2. The mean of BMI was 25,6±5,4 kg/m2. We found that 35,2% (n=51) patients had lost more than 10% of their usual weight in the previous 6 months, 73,8% (n=107) had dietary intake change, 21,4% (n=31) had gastrointestinal symptoms and 80,7% (n=117) had functional capacity dysfunction.

Malnutrition was present in 50.3% (n=73) of the patients. Severe malnutrition was present in 19,3% (n=28) of them.

Conclusions: Hospital malnutrition is still highly prevalent. Data related to severe malnutrition increased in relation to previous data.

Keywords: hospital malnutrition, nutritional assessment

EFFICACY OF NUTRITION SUPPORT AMONGST TUBERCULOSIS PATIENTS AT SELECTED REFERRAL HOSPITALS IN MALAWI

[1]Banda, Mtisunge; [2]Kalimbira, Alexander; [3]Kalumizika, Zione; [4]Mbendera, Kuzani.

[1]Student. Department of Human Nutrition and Health.Lilongwe University of Agriculture and Natural Resources. Lilongwe. Malawi; [2]Phd. Nutritionist. Lilongwe University of Agriculture and Natural Resources. Lilongwe. Malawi; [3]Msc. Nutritionist. Lilongwe University of Agriculture and Natural Resources. Malawi; [4]Phd. Medical Doctor. National Tuberculosis Control Programme. Lilongwe. Malawi.

Background and objectives: Tuberculosis (TB) remains one of the world's deadliest communicable diseases. In 2013, an estimated 9.0 million people developed TB and 1.5 million died from the disease.

Objective: To investigate whether high energy and/or multivitamin supplementation will improve the results of TB treatment based on sputum conversion rate, nutritional status, and clinical outcomes.

Methods: Randomized factorial design was used and patients were recruited at Bwaila and Queens referral hospitals. Patients were provided with multivitamin and/or high calorie and compared to the control group.

Results: A total of 81 patients were recruited, with 3.7% drop-out rate. The mean age of was 35.8 ± 8 years and 80% were males. Mean BMI was 18.7 ± 2.3 and 41.6% classified malnourished. They were gradual increase in BMI to 20.9 kg/m2, presenting 11.8% with p= 0.041. The mean weight gain was 5.9kgs ± 4.3. Performance improvement was recorded with (t=-14.717, p <0.001) using Karnofsky index. Our findings show that the treatment success rate was 86%. The sputum conversion for supplemented was also significant for the supplemented over the controls at RR, 0.39 [95% CI, 0.17 to 0.86, p=0.03] at 2 months.

Conclusions: On the basis of the result we found beneficial factors existing of supplements on enhancing sputum conversion rates, treatment success rates, weight gain, improve quality of life, improve dietary adequacy, and reduce mortality.

Nutritional supplements in tuberculosis patients are a feasible and low-cost intervention and have public health importance.

PREVENTISSIMO – HEALTH ASSESSMENT AND COUNSELLING WITH E-HEALTH

[1]Szlanko, Janos Szlanko; [2]Palik, Éva; [3]Schmidt, Judit; [4]Nacsa, Zoltan.

[1]Msc. Computer-Engineer. Kognitos Ltd. Hungary; [2]Phd. Physician. Semmelweis University. Hungary; [3]Msc. Dietitian. Kognitos Ltd. Hungary; [4]Msc. Computer-Engineer. NIS Informatikai Ltd. Hungary.

Background and objectives: The Preventissimo project aimed to develop an evidence-based, preventive and interventive tool for health assessment and counselling, using e-Health methods.

Methods: We have developed an internet-based application that focuses on the prevention of the most common non-infectious chronic diseases. The application uses questionnaires to get a picture of the client's disease risks. This is followed by a personalized counselling, based upon the individual's answers. Currently the project deals with the main non-communicable diseases: cardiovascular diseases; type 2 diabetes; the most common cancers: breast, prostate, colorectal and lung; chronic pulmonary disease (COPD); depression, dementia; glaucoma; cataracts; macular degeneration). The various questionnaires assess diseases running in the family, already existing abnormalities and various lifestyle factors including nutrition, physical activity, mental health and smoking. The counselling algorithm takes into account not only the risk factors, but also personal preferences and existing disorders, allergies. Last year we extended the original algorithm by including a set of cognitive games to get an indication of the person's performances on the relevant cognitive skills. The use of the cognitive games significantly improves the diagnostic and therapeutic power of the doctor for some patients having risk of dementia or depression.

Results: Preventissimo has been developed through the co-operation of medical doctors, dieticians, physiotherapists, psychologists and IT specialists.

The questionnaires contain 286 questions, 308 risk and protective factor descriptions. 14 cognitive games are also included plus a performance reporting framework.

There is an evidence based knowledge base on the site with more than 300 videos and articles with topics in lifestyle, diseases, diet, stress-management, physical activity. There are illustrated questionnaires for the visitors to check the level of understanding of the various illnesses

The system already collected data from, provided advice to more than 60 thousand people of different regions of the country.

Conclusions: When using Preventissimo (filling out the questionnaires, playing games) the user can download the results and health plan and can e-mail them to their doctor or any other healthcare provider for further input if needed. This helps assessing risk in a community, and can help planning preventative strategy.

Nursing Faculty, University of Valladolid. Spain.; [5]MD. PhD. Nursing Faculty, University of Valladolid. Spain. Endocrinology and Clinical Nutrition Research Center (ECNRC), University of Valladolid. Spain.

Background and objectives: To evaluate weight loss during one year of adolescent patients submitted to gastric bypass by the percentage of the excess of body mass index (BMI) lost and to catalog the results according to recommendations.

Methods: Sample: 18 adolescents were operated through gastric bypass from a single laparoscopic anastomosis in the center of excellence for the study and treatment of obesity (CTO) in the period 2008-2010, 9 women (50%) and 9 men (50%) of average age = 16.6 years with a mean BMI of 42.9 ± 6.8 (range 34.6-56.8).

50% were morbidly obese patients: BMI >40. 27.7 % supermorbid: IMC > 50 and 22.2% obese patients: BMI>35<40.

The weight loss efficacy was determined by percentage of the excess of lost BMI (PEIMCP) (Cigaine criteria).

Results: The results after 3 years correspond to 66.6% of the patients since the rest of them have not yet concluded the study.

100% had no surgical complications nor at the time of follow-up postoperative.

The weight loss results expressed as PEIMCP are:
PEIMCP to 3 months = 95,78% ±8,27;
     6   months = 96,04± 4,39
    12   months = 99,92±2,81
    24   months = 99,77 ±1,85
    36   months = 99,79 ± 2,13
Mean PEIMCP was 99,61% ±15,32 at the end of the review period (3 years).

100% of those who have completed the follow-up show excellent results with a PEIMCP>65%.

Conclusions: Bariatric surgery using laparoscopic One-Anastomosis Gastric Bypass Technique is effective for the treatment of morbid obesity in terms of immediate weight loss and maintained in the time.

IMPACT OF PRE-SURGICAL DIETETIC PREPARATION ON THE WEIGHT LOSS

[1]Castro Alija, Mª José; [2]Cao Torija, Mª José; [3]Garcia del Rio, Ana; [4]Lopez Vallecillo, Maria; [4]Frutos Martin, Manuel; [2]JIMENEZ PEREZ, JOSE MARIA.

[1]MD, PhD. Faculty of Nursing. University of Valladolid. Endocrinology and Clinical Nutrition Research Center (ECNRC), University of Valladolid. Spain.; [2]RN. PhD. Nursing Faculty, University of Valladolid. Spain. Endocrinology and Clinical Nutrition Research Center (ECNRC), University of Valladolid. Spain.; [3]MSNc. Nursing Faculty, University of Valladolid. Spain.; [4]RN. PhD. Nursing Faculty, University of Valladolid. Spain.

Background and objectives: Dietary–nutritional preparation to achieve a weight loss prior to bariatric surgery implies benefits in the surgical act and in the postoperative period, since it allows patients adaptation to a healthy and balanced diet, which must be its habitual pattern for life.

To study the weight loss of patients with morbid and extreme obesity prior to surgery.

Methods: Observational, descriptive, longitudinal study with 192 patients, average body mass index (BMI)=42.24 in the first consultation, of which 22 patients present BMI > 50.

The mean time of preoperative preparation in the group with BMI<50 is 85 days and in the group with BMI >50 is 136 days. To the BMI<50 group, a mixed hyperproteic hypocaloric diet was prescribed for 66 days and the remaining 20 days was prescribed center protocol. Group with BMI > 50, pattern in 3 phases, 1st: 60 days hypocaloric-hyperproteic mixed diet; 2nd: 56 days hypocaloric-hyperproteic exclusived diet with substitutes; 3rd: the same pattern as the previous group. Statistical analysis: mean determination, standard deviation, confidence interval and Pearson coefficient.

Results: Regarding to the mean weight loss in the group with BMI < 50, the decrease of the weight loss mean was 14.97 kg, it assumes that the BMI decreases 5.38 and the mean of the group with BMI>50 is 28.15 kg, which it supposes a decrease in BMI = 10.23 in the pre-surgical period.

The mean daily weight loss in the pre-surgery phases in the group with BMI<50 was 175 g/day and in the group with BMI>50 the weight decrease = 200 g/day.

Conclusions: It is effective to perform dietetic-nutritional interventions differentiated according to the BMI both with respect to the time and the pattern, to minimize the surgical risks.

Patients with extreme obesity require more days of dietetic-nutritional preparation before of the surgery to achieve equivalent results to patients with morbid obesity.

WHAT IS THE PERCEPTION OF BODY IMAGE IN A GROUP OF ADULT WOMEN?

[1]Jiménez Pérez, José María; [2]Cao Torija, Mª José; [3]Garcia del Rio, Ana; [4]Lopez Vallecillo, Maria; [4]Frutos Martin, Manuel; [5]Castro Alija, Mª José.

[1]RN, PhD. Faculty of Nursing. University of Valladolid. Endocrinology and Clinical Nutrition Research Center (ECNRC), University of Valladolid. Spain.; [2]RN. PhD. Nursing Faculty, University of Valladolid. Spain. Endocrinology and Clinical Nutrition Research Center (ECNRC), University of Valladolid. Spain.; [3]MSNc. Nursing Faculty, University of Valladolid. Spain.; [4]RN. PhD. Nursing Faculty, University of Valladolid. Spain.; [5]MD. PhD. Nursing Faculty, University of Valladolid. Spain. Endocrinology and Clinical Nutrition Research Center (ECNRC), University of Valladolid. Spain.

Background and objectives: Body image has been defined as a multidimensional structure that differ in two underlying dimensions, the first refers to the perceptual aspects of body size estimation and the second includes the emotions or feelings that the individual has associated with his physical appearance and cognitive assessments that makes of its own body (Cash 1994). Having a negative body image can affect health. When this happens there is a greater predisposition to more disturbances such as anxiety, depression, low self-esteem, anorexia, bulimia, and many others that can have serious consequences. (Salaberria et al 2007)

Women have a greater vulnerability in light of these disorders due to the strong social pressure on their own appearance and socialization processes that emphasize aspects of appearance.

Set the perception of body image in a representative healthy adult women of Valladolid (Spain) collective.

Methods: Cross sectional study; sample of 500 women aged 40 to 60 years, mean age 51.16, and urban area of the city of Valladolid, intermediate between the Spanish cities, which guarantees that the probability of error will not exceed 5%.

We used a self-designed questionnaire formed by questions that assess anthropometric and attitudinal variables. This questionnaire takes as a reference: Body Image Questionnaire Questionnaire by Cooper and Attitude towards food by Gardner.

Results: From estimates of height and weight data we obtain a mean BMI of 24.43, within normal parameters. 87.5% of women are concerned about their body weight, between of them the 78% of the cases are concerned due to a combination of aesthetic and health reasons. The 57.14%, have tried to hide their silhouette with clothes and if we calculate the IAC (Alvarez Rayon) it gives a score of 108.11 listed as moderate over estimation of weight. In the perception of body image, estimated by using models, we find that the 37.49% believe that the model that represent them has overweight or obesity.

Conclusions: The women in our study have a normal mean BMI. They are concerned about their weight, which overestimate moderately. They try to hide their silhouette and consider that their image corresponds to overweight in a high percentage of cases.

Background and objectives: Acne vulgaris is a chronic dermatologic disease that manifests in adolescence. It is characterized by the presence of comedones, papules, pustules and scars on the skin. The disease is caused by hyper-secretion of sebaceous glands. The manifestation of acne is influenced by many factors. The aim of the study was to assess the relationship between diet and the manifestation of acne vulgaris.

Methods: The instrument used for the purposes of the research was a questionnaire prepared by the authors. The study subjects were individuals affected by acne currently or in the past as well as people not affected by acne. The participants of the study were selected by snowball sampling. Respondents were asked about the age of onset of the first symptoms of acne, the occurrence of acne among their relatives, the location of acne on the skin and its severity, methods of treatment and other ways of coping with acne as well as about the frequency of consumption of specific products/dishes and the change in the severity of acne

due to their consumption. In order to compare the results, cross tabulation, Chi-square test of independence, and Mann-Whitney U test (independent samples) were used. The significance level was α=0.05.

Results: 118 people participated in the survey, including 32 (27.12%) men and 86 (72.88%) women. More than half of the men (56.25%) and women (52.33%) in question had acne vulgaris. The average age of onset of the first symptoms of acne was 14 years. Most frequently acne occurred on the face (92.06%). The majority of the participants assessed the severity of acne as medium (51.61%). More women (57.78%) than men (29.41%) responded that a dermatologist treated them. Participants manifesting acne believed that salty food increases the severity of acne (45.76%, p<0.05). Consumption frequencies of certain products/dishes differed significantly between the surveyed groups (p<0.05).

Conclusions: Most of the products/dishes do not influence the severity of acne in respondents. The difference in responses concerning the change in the severity of acne following the intake of candies and cakes was significant between men and women (p<0.05).

PREVALENCE OF CORONARY HEART DISEASE RISK FACTORS IN PATIENTS WITH HIGH LDL CHOLESTEROL LEVELS, WITH OR WITHOUT FAMILIAL HYPERCHOLESTEROLEMIA DIAGNOSES: A CROSS-SECTIONAL STUDY IN RIO DE JANEIRO

[1]Pinto Gapanowicz, Débora; [2]Saraiva Dias Marques, Mariana; [2]Barbosa Merlim Abrantes, Taciane; [3]Almeida Palles Ramos, Caroline; [4]Vieira Assad, Marcelo Heitor; [5]Vilas Bôas Huguenin, Grazielle; [6]Seixas Bello Moreira, Annie.

[1]BSc. Nutritionist. Education and Research Department . Brazilian National Cardiology Institute. Brazil.; [2]Nutrition Student. Nutrition Institute. Rio de Janeiro State University. Rio de Janeiro. Brazil.; [3]BSc. Nutritionist. Master in Food Nutrition and Health. Nutrition Institute. Rio de Janeiro State University. Rio de Janeiro. Brazil.; [4]MSc. Doctor. Education and Research Department. Brazilian National Cardiology Institute. Brazil.; [5]MD. Nutritionist. Education and Research Department. Brazilian National Cardiology Institute. Rio de Janeiro. Brazil.; [6]PhD. Nutritionist. Education and Research Department. Brazilian National Cardiology Institute. Rio de Janeiro. Brazil.

Background and objectives: Familial hypercholesterolemia (FH) is an autosomal dominant disorder, which can be caused by a mutation in low-density lipoprotein receptor (LDLR). This study evaluated the prevalence of coronary heart disease (CHD) risk factors in patients with high low-density lipoprotein cholesterol (LDL-c) levels, with or without confirmed mutation in LDLR (referred to as familial hypercholesterolemia [FH]).

Methods: A cross-sectional study of 63 patients with high index of FH suspicion (patients with elevated LDL-C levels > 190 mg/dL, significant personal or family history of premature cardiovascular disease). A genetic test was done and HF diagnosis was confirmed by mutation in LDLR. A standardized questionnaire was applied by the researchers to assess patient's personal and clinical information. Medical charts were reviewed to collect additional data on CHD risk factors such as diabetes or hypertension and to obtain LDL-c baseline values. The anthropometric measures were done and checked weight (Kg), height (m), waist circumference (cm), BMI (Kg/m2) and waist/height ratio. Statistical analyses were performed using Software IBM® SPSS® Statistics version 21 and P values were associated with a significance level of .05 for all tests.

Results: Of the 63 patients with high LDL-c, 24 (38,1%) had confirmed HF diagnosis while 39 (61,9%) had unexplained hypercholesterolemia. Patients who carries LDLR mutation were mostly women (75%) and significantly younger than the ones without mutation (mean + SD, 49 + 16 vs 58 + 11 years; P = .008). No differences existed in prevalence of traditional CHD risk factors such as diabetes type II (25% vs 23%, P = .682), hypertension (58% vs 77%, P = .118), exposure to tobacco (43% vs 50%, P =.615), sedentarism (75% vs 95%, P= .06) and raised waist circumference (95 +13 vs 97 +11, P = .599), waist/height ratio (68% vs 87%, P = .051) and BMI (58% vs 69%, P =.378).

Conclusions: Our findings suggest that HF patients were younger, however none of the other evaluated risk factors showed significantly different between both groups. Besides, the food consumption of these patients must be assessed, since this is a modifiable risk factor.

LIPID ACCUMULATION PRODUCT: A SIMPLE AND ACCURATE INDEX FOR PREDICTING CHANGES IN SERUM LEVELS OF C REACTIVE PROTEIN

[1]de Carvalho Vidigal, Fernanda; [2]Enriqueta Frandsen Paez de Lima Rosado, Lina.

[1]PhD in Nutrition Science. Professor of Nutrition. Faculty of Nutrition. Universidade Federal de Alfenas. Brazil.; [2]PhD in Nutrition. Nutritionist. Brazil.

Background and objectives: High sensitivity C reactive protein is increasingly associated with cardiovascular risk. There are several studies regarding the use of the lipid accumulation product as a risk marker for the development of cardiovascular disease. The aim of this study was to evaluate the predictive ability of the lipid accumulation product in detecting changes in serum levels of high sensitivity C reactive protein.

Methods: A cross-sectional study was conducted with 130 apparently healthy Brazilian adults men (20-59 years). Waist circumference was determined. Triglycerides were determined by enzymatic colorimetric method. The lipid accumulation product was calculated as (waist circumference [cm] − 65) × (triglycerides concentration [mM]). C reactive protein was measured by the high sensitivity nephelometry method. It was considered as cutoff point for high sensitivity C reactive protein ≥ 0.12 mg/dL. The statistical analysis consisted in construction of ROC curves (Receiver Operating Characteristic Curve). Statistical analysis was carried out using Medcalc version 12.7.

Results: The frequency of high sensitivity C reactive protein levels ≥ 0.12 mg/dL was 30.8%. The lipid accumulation product showed prediction accuracy to detect changes in high sensitivity C reactive protein with an area under the ROC curve (AUC) of 0.642 ± 0.054 ($p < 0.01$). The cutoff point value of 36.6 cm.mmol/L for the lipid accumulation product provided a sensitivity of 47.5% (95% CI: 31.5-63.9%) and specificity of 82.2% (95% CI: 72.7-89.5).

Conclusions: The lipid accumulation product has a reliable predictive ability to detect changes in serum levels of high sensitivity C reactive protein in apparently healthy Brazilian adults men. In other words, the lipid accumulation product was a good marker to detect individuals with higher cardiovascular risk.

RISK OF MALNUTRITION AT ADMISSION OF CANCER PATIENTS. STUDY OF CASES TREATED IN ONE YEAR

[1]Joy, Laura; [1]Báez, Alicia; [1]Estigarribia, Mariela; [1]Ibarrola, Ana; [1]Benitez, Susana; [1]Arriola, Nidia; [2]Gonzalez Cespedes, Laura Elizabeth; [2]Araujo Pino, Silvia Stella; [2]Morínigo Martínez, Macarena.

[1]Departamento de Alimentación y Nutrición. Instituto Nacional de Cáncer (INCAN). Ministerio de Salud Pública y Bienestar Social. Paraguay; [2]Departamento de Nutrición. Dirección de Investigación. Facultad de Ciencias Químicas. Universidad Nacional de Asunción. Paraguay.

Background and objectives: Because of the characteristics of the disease and the treatments to which they are subjected, patients diagnosed with cancer (CA) have a high risk of malnutrition. The risk could vary according to the type of tumor, location and tumor stage. Therefore, we studied all patients admitted to the National Cancer Institute (INCAN) during 2016 and determined the risk of malnutrition at the time of admission based on the location of the cancer.

Methods: We conducted a cross-sectional study with data obtained from January to December 2016 at INCAN. We attended 912 patients with different types of CA. We analyzed demographic and clinical data and the nutritional status was determined by the screening method proposed by Gómez et al (2010). Patients with location of CA abdominal/peritoneal, head/neck, gastric, colon/rectum/anus, digestive organs annex, and lung were considered in risk of malnutrition. Chi Square and Odds Ratios test was used to determine the risk of malnutrition based on the CA location.

Results: The final sample was 877 patients with CA. The average age was 55±14years (95%CI 54-56years), 65.5% were woman. The location most frequent of CA were gynecological (26.9%), head/neck (15.5%) y colon/rectum/anus (15.2%). In woman prevailed CA Gynecological type, breast and head/neck 38.7%, 21.4% y 12.5%, respectively and in man colon/rectum/anus (24.8%), head/neck (21.1%) y male reproductive system (13.2%). According to the nutritional evaluation, 38.9% presented malnutrition and 42.2% of patients have risk of malnutrition according by location of CA. Patients with Gastric, Abdominal/Peritoneal and Pulmonary CA present a higher frequency of malnutrition, while urinal, breast and skin CA patients present malnutrition in less frequent. 52.2% (n = 178) of the malnourished were patients with risk by CA localization, while 64.2% of the non-malnourished did not present risk by CA localization. The patients with head/neck, digestive (liver, pancreas, gastric, colon, rectum, anus), Abdominal/Peritoneal and Pulmonary CA have 1.957 more likely to present malnutrition ($p < 0.05$).

Conclusions: In the patients treated at the INCAN the location of the cancer would predict the risk of malnutrition. However, it is important to continue the investigations considering that malnutrition in these patients is multifactorial

NUTRIGENETICS AND EPIGENETICS AS COADJUVANTS IN THE THYROID CANCER DIET

[1]Aparecido da Silva, Silvano; [2]Renata Conte Lima, Thais.

[1]PhD Student. Pharmacist. Institute of Scientific and Technological Research. Catholic University of Santos. Brazil.; [2]BS. Nutricionist. Institute of Scientific and Technological Research. Catholic University of Santos. Brazil.

Background and objectives: Thyroid cancer is a disease that affects an important endocrine gland. To achieve better treatment and cure efficacy, it is important to consider the polymorphic aspects of patient genetics, such as single nucleotide polymorphisms (SNPs) that may cooperate with therapeutic success in CYP3A4 cytochrome metabolism. Another characteristic of observed SNPs is mainly due to the enzymes Methionine Synthase and Methylenetetrahydrofolate Reductase involved in the maintenance of methyl group supply by S-Adenosylmethionine, in addition to corroborating cofactors for the epigenetic mechanisms. Objectives: To elaborate a therapeutic diet plan that does not compromise the treatment in thyroid cancer in its main cytochromic metabolizers and that can modulate the epigenetic mechanisms pertinent to the genetic characteristics of the tumor.

Methods: The dietary plan was developed using the databases of the International Human Epigenome Consortium (IHEC),

PharmGKB (Pharmacogenomics Knowledgebase), CIPIC (Clinical Pharmacogenetics Implementation Consortium) and USDA (United States Department of Agriculture).

Results: Bioactive compounds such as bergamottin and furanocoumarin inhibit cytochrome CYP3A4, which is the main drug metabolizer Vandetanib, Cabozantinib and Sorafenib. Inhibition of this cytochrome may alter drug plasma concentrations. Grapefruit juice, tomato fruit, St. John's wort and others with the same inhibitory potentials should be avoided. The correct functioning of the epigenetic mechanisms comes from a diet containing folic acid, vitamins B2, B6, B12 and betaine that aid in the altered kinetics in the presence of SNPs. The use of bioactive compounds active in the inhibition of DNA methyltransferases, such as genistein present in soybean or epigallocatechin gallate of green tea, may provide a decrease in growth and induction of apoptosis of cancer cells. Curcumin acts on gene regulation causing hypomethylation of DNA.

Conclusions: Knowledge of the SNPs of people with thyroid cancer, as well as histology, degree of differentiation and tumor genetics, may cooperate with therapeutic success. Allied to this conduct, a diet can provide elements that do not harm the treatment and act in the modulation of important mechanisms in the pathogenesis of the tumor.

Keywords: Thyroid Cancer, Nutrigenetics, Epigenetics.

SPLENIC INTERSTITIAL FLUID PROTEOMIC PROFILE DURING PROTEIN MALNUTRITION AND LEISHMANIA INFANTUM INFECTION

[1]Losada, Monica; [2]Umaña-Perez, Adriana; [2]Cuervo-Escobar, Sergio; [1]Rodriguez, Andres; [3]Berbet, Luiz; [1]Porrozzi, Renato; [3]Mendes-da-Cruz, Daniella; [3]Savino, Wilson; [4]Carvalho, Paulo; [2]Sánchez-Gómez, Myriam.

[1]PhD. Laboratorio de Pesquisa em Leishmaniose, FIOCRUZ, Rio de Janeiro, Brazil; [2]PhD. Laboratorio de Hormonas, Universidad Nacional de Colombia, Bogotá, Colombia; [3]PhD. Laboratorio de Pesquisas sobre o Timo, Instituto Oswaldo Cruz, Fiocruz, Rio de Janeiro, RJ, Brasil; [4]PhD. Laboratorio de Proteômica e Engenharia de Proteínas, FIOCRUZ, Curitiba, Brasil.

Background and objectives: Protein malnutrition (PM), the most deleterious cause of malnutrition in developing countries, has been considered a primary risk factor for the development of clinical visceral leishmaniasis (VL). Protein malnutrition and infection with Leishmania infantum leads to lymphoid tissue disorganization, changes in cellularity and lymphocyte subpopulations in the spleen. A proteomic analysis of the interstitial fluid (IF) of the spleen in protein restricted BALB/c mice infected with L. infantum was undertaken in this study to define the mechanisms that drive splenic response during PM and infection.

Methods: We compared four groups of mixed IF samples: animals fed 14% protein (CP: iTRAQ 114), animals fed 4% protein (LP: iTRAQ 115), animals fed 14% protein and infected (CPi: iTRAQ 116), and animals fed 4% protein and infected (LPi: iTRAQ 117). Samples were analyzed in a LTQ-Orbitrap-XL.

Results: A total of 344 proteins were identified and the fold changes in protein quantification were calculated from the intensities of iTRAQ reporter ions between the CP and CPi, LP, LPi using the PatternLab plataform. A total of 74 proteins presenting a change in abundance were screened in the splenic IF of LPi mice, of which 27 proteins were upregulated and 47 proteins were downregulated. In total, 291 (85%) proteins were identified as secreted proteins. From the remaining proteins 53 were not predicted as secreted, 45 were previously reported as exosomal proteins, and 8 were neither predicted as secreted nor exosomal proteins.

Conclusions: We identify alterations in different points of the metabolism and splenic immune response, such as proteins of the pentoses phosphate pathway and purine biosynthesis, as well as response to oxidative stress, which may affect the proliferation of splenocytes and generate an imbalance of the oxidative state of splenocytes from LPi mice. We detected reduced levels of various proteins involved in the pro-inflammatory response and chemotaxis in the splenic interstitial fluid of LPi mice, such as: MIF, PPBP, ISG15 and ALDH1A1. Our results reinforces the idea that the increased parasitic load in the spleen of malnourished animals is associated with an altered pro-inflammatory response during protein malnutrition involving different molecules and biological processes during the immune response.

McMaster University.Canada.

Background and objectives: Diet plays an important role in IBS and there is evidence that foods with high Fermentable-Oligosaccharides-Disaccharides-Monosaccharides-and-Polyols (FODMAPs) content and gluten may worsen symptoms. IBS patients with positive antigliadin-antibodies (AGA) may preferentially respond to a gluten-free diet (GFD). Differences in dietary patterns were observed in IBS vs healthy volunteers (HV), however, the effect of food consumption on the symptomatic response to gluten withdrawal in IBS patients stratified by the presence of AGA has not been previously studied. We conducted a clinical trial to evaluate the dietary patterns and nutrient intake in IBS patients stratified by their AGA status, before and after one-month of GFD.

Methods: IBS patients (Rome III criteria) were stratified by the presence of AGA (INOVA Inc). A group of HV served as controls. All participants underwent a GFD for one month. Gastrointestinal symptoms were assessed by the IBS-Birmingham score. A food-frequency questionnaire (FDQ-VES2, Australia) was used to assess: 1)dietary patterns, 2)nutrient intake, and 3)FODMAP consumption before and after GFD.

Results: 44 IBS-patients (24 AGA+; 20 AGA-) and 23 HV were recruited. GFD improved symptoms (indigestion, diarrhea and abdominal pain) in IBS AGA+ patients while only pain improved in IBS AGA– patients. At baseline, IBS AGA+ had significantly lower consumption of protein (p<0.05 vs IBS AGA- and HV). Both IBS AGA+ and AGA- had significantly lower fiber intake compared to HV.IBS AGA+ increased the intake of foods with high content

of vitamin-A and C (carrots, lettuce, spinach and capsicum) and decreased the intake of some cereals (porridge). There was no change in amount of food high-in FODMAPs, except for multi-grain bread which was decreased in the three groups.

Conclusions: The type and quality of food differ between subsets of IBS patients, suggesting that patients may have their dietary preferences based on symptoms. GFD improves IBS symptoms in AGA+ patients, and this seems to be independent of overall FODMAPs consumption. The increase in food with high content of vitamin-A & C may play a role in the beneficial effect of the GFD in IBS AGA+ patients, due to their anti-inflammatory properties or by inducing changes in GI motility.

ESTABLISHMENT OF HEMOGULOBIN MEASURING METHOD FOR THE PREVENTION OF SPORTS ANEMIA IN FEMALE ATHLETES

[1]Abe, Hirotoshi; [2]Matsumoto, Megumi; [3]shirai, Anna; [2]KOYAMA, YUUZOU.

[1]MSc; [2]PhD; [3]BSc.

Background and objectives: For a female athlete, iron deficiency and anemia is one of the symptoms which remarkably lowers performance, and could cause health impairment. Athletes frequently undergo anemia due to rigorous training, reducing food intake for weight control and destruction of erythrocyte by repeated sole impulse. In addition, menses make it difficult for females to improve anemia. In this study, we focused on the collegiate female athletes of land jump, volleyball and fencing who often complain anemia, and tried to establish the simple method of measuring the hemoglobin concentration in blood using non-invasive fingertip sensor, in order to monitor the status of iron nutrition easily.

Methods: Subjects were composed of each 27 collegiate female athlete of land jump, volleyball and fencing. The hemoglobin concentration was measured at before training using measuring instrument of non-invasive fingertip sensor (Pront-7). Furthermore hearing investigation was performed to record the physical condition and food intake frequency of one week.

Results: In hearing investigation, the athletes who complained symptom of anemia were70%, 40% and 35% in land jump, volleyball and fencing, respectively. The score of anemia condition negatively correlated with hemoglobin concentration. Hemoglobin concentrations were 12.4±0.2 g/dL, 12.1±0.4 g/dL and 12.9±0.2 g/dL athletes of land jump, volleyball and fencing, respectively. As a result of surveying the meal intake frequency in the athletes of jumping events of athletic competition, there was a positive corre-

lation between the amount of iron, protein or zinc intake per day and hemoglobin level. (iron: r = 0.575, protein: r = 0.630 and zinc: r = 0.661, respectively)

Conclusions: The measurement of hemoglobin using fingertip sensor might be useful option for monitoring the status of iron nutrition to prevent sports anemia.

Keywords: Sports anemia, Fingertip sensor, Hemoglobin, Protein, Iron.

ROLE OF FATTY ACID BINDING PROTEIN 4 AS AN ADIPOKINE TO REGULATION BONE RESORPTION DURING POSTMENOPAUSE OSTEOPOROSIS MICE FED BY HIGH FAT DIET

[1]*Zhu, Cuifeng;* [2]*Pan, Yong;* [2]*Jin, LengGang;* [3]*Liu, Yan;* [4]*Xu, AiMin.*

[1]Postdoctoral fellows. Department of Medicine, University of Hong Kong. China; [2]PhD,Dept of Medicine of HongKong University . HongKong. China; [3]Dept of Nutrition of Southern Medical University ShenZhen Hospital, China; [4]professor ,Dept of Medicine of HongKong University . HongKong. China.

Background and objectives: Adipokines is involved in both onset and progression of postmenopause osteoporosis(PMOP). However, the link between adipokines and PMOP has not been explored. Present study was designed to investigate the role of fatty acid binding protein 4 (FABP 4 /ap 2) as an adipokines with the effects on bone metabolism in the pathogenesis of PMOP mice.

Methods: 12 weeks old FABP -/- and FABP +/+ mice were fed with standart chow diets (SCD) or high fat diet for (HFD) 8 weeks after ovariectomy or sham surgery , then re-function of FABP by implanted a osmos pump fill with FABP protein (1g/kg.BW.day) into FABP -/- mice or fill with FABP 4 inhibitor BMS309403 (200 ng /day) to FABP +/+ mice fed by HFD for 28 days after ovariectomy. followed by micro CT and histological to evaluations the BMD and bone resorption in all mice of the ten groups ,Real-time PCR analysis the expression of TLR4, JNK, c-JUN-AP1 ,FABP 4 ,RANKL, OCs (TRAP**,** MIP-1α) and TNF-α,IL-6 in femur bone tissues and blood were detected.

Results: The BMD and mRNA exoression of TLR4, JNK, c-JUN-AP1 ,FABP 4 ,RANKL, OCs (TRAP**,** MIP-1α) and TNF-α,IL-6 in femur bone tissues and LPS , FABP 4 ,TNF-α,IL-6 in blood were decreased significantly(P<0.01 or P<0.001) in FABP -/- mice compared with FABP +/+ mice afterovariectomy fed by HFD, Although the biomarkers of four groups of FABP -/- and FABP +/+ mice after ovariectomy were different significantly to other mice after sham surgery, but there were no different significantly between FABP -/- and FABP +/+ mice after ovariectomy fed by SCD compared with these biomarkers (P>0.05). When re-function and inhibitor of FABP 4, all biomarkers mentioned above reversed siginificantly in this two groups. Which indicated that there is a positive feedback loop between FABP4 and LPS-JNK- c-Jun-AP1 in the TLR4 pathway, which is involved in the process of bone metabolis in POMP.

Conclusions: The pathogenesis of FABP 4 acceleration bone resorption in PMOP mice fed by HFD was regulation both LPS-TLR4-FABP4 pathway and stimulate the osteoclast cell activity induced by inflamation adipocytokines.

Keywords: Postmenopause osteoporosis, Fatty acid binding protein, LPS-TLR4-FABP4 pathway, Inflamation adipocytokines.

INTRAVENOUS ARGININE ADMINISTRATION PROMOTES ENDOTHELIAL PROGENITOR CELLS MOBILIZATION AND ATTENUATES LUNG INJURY IN MICE WITH POLYMICROBIAL SEPSIS

[1]*Yeh, Chiu-Li;* [2]*Pai, Man-Hui.*

[1]Department of Nutrition and Health Sciences, Chinese Culture University; [2]Department of Anatomy and Cell Biology, School of Medicine, College of Medicine, Taipei Medical University.

Background and objectives: This study investigated the influences of intravenous arginine (Arg) administration on alteration of circulating endothelial progenitor cells (EPCs) and lung injury in polymicrobial sepsis.

Methods: There were 1 normal control group (NC) and 2 sepsis groups. Sepsis was induced by cecal ligation and puncture (CLP). One sepsis group wasinjected with saline (SS), whereas the other group (SA) was administered 300 mg Arg/kg of body weight once via the tail vein 1 h after CLP. Septic mice were sacrificed either 24 or 48 h after CLP.

Results: Results showed that compared to the NC group, septic mice had higher EPC releasing factors and circulating EPC percentage. Also, inflammatory cytokine concentrations and Ang/Tie2 gene expression were upregulated in lung tissues. Arg administration promoted EPCs mobilization, downregulated inflammatory cytokine production and Ang-2 gene expression in the lungs. Histopathological findings showed that the severity of lung alveoli inflammatory lesions was attenuated after CLP when Arg was administered.

Conclusions: Our results suggest that intravenous administration of Arg after the onset of sepsis enhances the mobilization of circulating EPCs and reverses the imbalance of the Ang-Tie2 axis that may improve the vascular function, reduce inflammatory reaction and offer organ protection in polymicrobial sepsis.

Keywords: Arginine, Sepsis, Endothelial progenitor cell, Ang/Tie2, Lung injury.

BECOMING MALNOURISHED CHILDREN, ONE YEAR AFTER NUTRITION EDUCATION IN KAYA (BURKINA FASO)

[1]Garanet, Franck; [2]Bayo, Abou; [3]Ouedraogo, Mohamed.

[1]Research Institute of Health Sciences; [2]Universite Polytechnique de Bobo-Dioulasso.Unite de Formation et de Recherche en Sciences et Techniques; [3]Ministère de la Santé ; District sanitaire de Kaya.

Background and objectives: The objective of this study is to determine the fate of malnourished children one year after nutrition education ain the nutrition éducation center in Kaya.

Methods: This is a cohort study of children who stayed at the Nutrition Education Center in Kaya in the year 2014.

Results: A total of 135 children were included in our study. The results showed a year after the nutrition éducation center release a relapse in 32% of the cases of which 7.69% in severe form. We recorded five deaths and 30 children were not found. Of 105 children recovered one year after discharge from nutrition éducation center, we noted a relapse in malnutrition in 32% of cases, 7.69% in severe cases. Also, 46.39% of the children received food before the age of 6 months and 86.73% of the mothers know that the food introduced is the porridge prepared from fortified flour and water. In addition, 17.35% of mothers evacuate the child's stool in an unhygienic manner and only 77.55% wash their hands with soap after handling the child's stool. Knowledge assessment revealed that 78.8% of mothers know that complementary food should be introduced at 6 months of age, 53.61% know that porridge and Hygiene and thus have the right knowledge in the care, nutrition and hygiene of the child.

Conclusions: The nutritional situation one year after children received at nutrition éducation center is critical and deserves special attention from the various institutions involved in improving the living conditions of households and the survival of children. Also, post-education monitoring is needed to strengthen mothers' knowledge.

CALORIE RESTRICTION IN THE MANAGEMENT OF OBESITY ASSOCIATED OBSTRUCTIVE SLEEP APNEA - A NON-PHARMACOLOGICAL INTERVENTION STUDY

[1]Nemani, Harishankar; [2]Kallamadi, Prathapreddy; [3]Nemani, Shivaram; [4]Putchaa, Udaykumar; [4]Mullapudi Venkata, Surekha; [5]Pothani, Suresh.

[1]Ph.D.National Institute of Nutrition.ICMR.Hyderabad.India.; [2]M.Sc.National Institute of Nutrition.ICMR.Hyderabad.India.; [3]MDS.Orthodontist.Panineeya Institute of Dental Sciences & Research Centre. Dilsukhnagar. Hyderabad. Telangana, India.; [4]MD.Pathology.National Institute of Nutrition.ICMR.Hyderabad. India.; [5]MVSc.Microbiology.National Institute of Nutrition.ICMR. Hyderabad.India.

Background and objectives: Obstructive sleep apnea (OSA) is the result of a partial or complete blockage of upper airway structures and will reduce the oxygen flow to vital organs, resulting in irregular heart rhythms. Obesity is the strongest risk factor for the development of OSA. Our main objective is to see the fat infiltration in to the tongue of calorie restricted rats and its consequences on upper airway obstruction in comparison with lean and ad lib fed obese rats.

Methods: Eighteen Lean (223.33 g ±20.42), obese (584.22 g ± 5.65) and calorie restricted (CR) (303.00 g ± 16.97) obese rats were taken for the study. Body fat and lean body mass (LBM) was determined by total body electrical conductivity (TOBEC), radiographs of upper airway structure were analyzed by digital X-ray. Ex-vivo biochemistry was carried for leptin, lipids in blood/tissues, and fat infiltration by oil red O staining (ORO). The tongue, masseter muscle fat, fibre and taste buds morphology assessed by scanning electron microscope (SEM).

Results: TOBEC analysis showed higher body fat and low LBM, X-ray displayed excess fat in the neck region. Triglyceride levels were high and leptin levels were reduced in CR rats compared to lean and ad lib fed obese rats. ORO staining of tongue showed fat accumulation of varying degree in different groups. SEM analysis of the tongue and masseter muscle demonstrated an increase in fat infiltration with an increase in fat droplets. Tongue muscle fibres showed rugged abnormal folding, with an increase in width in obese rats. The distance and width between the taste buds of CR reduced to levels of lean rats.

Conclusions: There is a different degree of fat infiltration in the tongue of calorie restricted and adlib fed obese compared to lean rats. The calorie restriction in obese rats also increased the lunge volume and haemoglobin levels compared to adlib obese rats. The hypertrophy seen in the calorie restricted obese rat tongue may play a role in altered tongue neuromuscular function. These findings suggest that, future studies on the role of obesity in OSA should focus on tongue fat infiltration and its distribution with calorie restriction.

Keywords: Calorie restriction, Lipids, Masseter muscle, Obesity, Upper airway structures.

ANALYSIS OF THE EVOLUTION OF NUTRITIONAL PARAMETERS IN PATIENTS TREATED IN BARIATRIC SURGERY THE CLINIC-SCHOOL

[1]Auler, Flavia; [2]Derosso, Ariadne Alves; [2]Pereira, Nicole Martins.

[1]PhD. Nutricionist. Pontifical University Catholic of Paraná. Argentina; [2]Nutricionist. Pontifical University Catholic of Paraná. Argentina

Background and objectives: Currently, bariatric surgery is accepted as the most effective tool in the treatment and control of morbid obesity. Several indicators are used to analyze the success of bariatric surgery. The objective of this study was to analyze the evolution of nutritional and clinical parameters in the postoperative period of patients submitted to bariatric surgery by the Roux-en-Y gastric bypass technique attended at a school-clinic.

Methods: Patients were selected from one month to one year after bariatric surgery without distinction of age and gender, and postoperative complications such as the presence of craving, vomiting and weight gain were evaluated, and clinical signs were more evidenced due to the deficiency Were micronutrients, hair loss and dry skin (protein, zinc and biotin). To obtain the results of the anthropometric evolution, we analyzed records of BMI,% PP and% PEP, CC, CA and CB.

Results: In the anthropometric analysis, the BMI and CB indicators in the 6th month already indicated a drastic reduction for classification for overweight, for the% PP and% PEP, the highest losses occurred until the 3rd month and the CC and CA measures were no longer presenting cardiovascular risk In the 9th month. As for food intake, there was an adjustment in relation to the consumption of dairy and cereal groups and reduction in meat consumption. In general, the individuals presented a reduction in the symptoms analyzed in the first trimester.

Conclusions: In the course of the present study, it is verified that the results obtained were already expected, although the patients' adherence was considered as unsatisfactory as of the 6th month. Nutritional monitoring is necessary so that it can achieve expected success in the indicators.

Keywords: Nutritional parameters, Patients, Bariatric surgery, Clinic-school.

RELATIONSHIP BETWEEN NUTRITIONAL STATUS AND CARDIOVASCULAR RISK IN PATIENTS WITH METABOLIC SYNDROME

[1]Dragut, Ramona Maria; [1]Rusu, Emilia; [2]Rusu, Florin; [1]Cursaru, Raluca; [1]Popescu, Horatiu; [3]Gheorghita, Andra; [1]Enache, Georgiana; [1]Radulian, Gabriela.

[1]University of Medicine and Pharmacy Carol Davila; [2]Emergency Military Hospital Carol Davila; [3]National Institute of Diabetes Nutrition and Metabolic Diseases "N Paulescu".

Background and objectives: The objective of this study was to evaluate the relationship between nutritional status and cardiovascular risk in patients with metabolic syndrome (MetS).

Methods: This study is transversal and included 171 patients with MetS. The nutritional status was assessed using body mass index (BMI) score MNA (Mini Nutritional Assessment) and nutritional assessment score instantly - (instant nutritional assessment - INA). We also calculated a combined score of malnutrition: MNA results have merged, INA and BMI in a single combined score. We considered patients with malnutrition rezutatul based on the combined score, so it is considered malnourished individual score indicates if any is present. The diagnosis of MetS was established using a modified IDF definition. Cardiovascular risk was assessed for each patient using software UKPDS-CHD.

Results: MetS was present in 64.9% of patient. The age of patients with malnutrition and MetS was higher than that with MetS without malnutrition (57.75±6.16 years vs. 51.85±9.65 years, p=0.125). Using the combined score of the total number of patients, malnutrition was present in 18 patients (10.5%). Of these, 12 patients (66.7%) belong to the group with MetS. The combination of malnutrition - moderate cardiovascular risk level, was observed in a small number of patients, most of the malnutrition associating with a low cardiovascular risk (n=2). Cardiovascular risk among those with only 6 patients had moderate malnutrition, and among those at high risk, only 4 associated malnutrition. The presence of MetS is associated with a higher frequency of malnutrition in patients with hepatitis C. Obesity was present in 122 patients (71.3%) - 58 women and 64 men. Of these, 8 patients (4.7%) had malnutrition based on the combined score.

Conclusions: Assessment of nutritional status in patients with MetS brings significant benefits by identifying malnutrition risk and to which they are exposed.The prevalence of malnutrition was high in patients with MetS (10.5%). Assessing the relationship of cardiovascular risk - malnutrition, has placed patients with malnutrition among those with low cardiovascular risk (n=2) or moderate (n=6), only a small number of people with malnutrition (n=4) with a high cardiovascular risk .

GENOTYPE AND PHENOTYPE DETERMINATION IN CHILEAN SUBJECTS WITH PHENYLKETONURIA

[1]Hamilton, Valerie; [2]Santa María, Lorena; [3]Pérez, Belen; [2]Fuenzalida, Karen; [4]Morales, Paulina; [5]Cornejo, Veronica.

[1]M.Sc. Nutricionist. Instutition of Nutrition and Food Techonology, Dr. Fernando Monckeberg Barros, University Of Chile.; [2]PhD. Biochemist. Institution of Nutrition and Food Technology, University of Chile.; [3]PhD. Genetist. Centro de Diagnóstico de Enfermedades Moleculares (CEDEM) Universidad Autónoma de Madrid, Spain.; [4]Medical Technology. Institution of Nutrition and Food Technology, University of Chile.; [5]M.Sc. Nutricionist. Institution of Nutrition and Food Technology, University of Chile.

Background and objectives: Phenylketonuria (PKU, OMIM 261600) is an autosomal recessive disease, caused by mutations in Phenylalanine Hydroxylase (PAH) gene situated in chromosome 12q22-q24.2. This gene has 13 exons. The genotype is one of the main factors that determine the phenotype of this disease. Objective: Characterize Chilean PKU genotype and phenotype.

Methods: 71 PKU subjects to study the PAH gene by restriction fragment length polymorphism (RFLP) and sequencing techniques to identify the genotype, previous exon and intron amplification through PCR technique. We classified the phenotype according to Guldberg predicted value.

Results: 26 mutations in 134 of the 142 alleles studied were identified (94.4%), completing the analysis in 88.7% of the subjects, 11.3% had one allele identified. 84.5% of the sample was heterozygous. Exon 7 included the majority of mutations (23%). 50% of mutations were missense. Most frequent mutations were IVS10-11G>A, p.Ex5del and p.Val388Met. According with results 52.3% of the subjects had a predicted classic phenotype.

Conclusions: The most frequent mutations can be identified by RLFP and MLPA, which lowers the costs of genetic analysis. It is possible to predict phenotype by detecting the genotype, with which we can establish the disease prognosis and ease patient's medical and nutritional management.

University of Buenos Aires. Argentina; [2]PhD. Lipids and Atherosclerosis Laboratory. Institute of Pathophysiology and Clinical Biochemistry (INFIBIOC). Department of Clinical Biochemistry. Faculty of Pharmacy and Biochemistry. University of Buenos Aires. Argentina; [3]Bsc. Central Laboratory. Italian Hospital of Buenos Aires. Argentina.; [4]PhD. Lipids and Atherosclerosis Laboratory. Institute of Pathophysiology and Clinical Biochemistry (INFIBIOC). Department of Clinical Biochemistry. Faculty of Pharmacy and Biochemistry. University of Buenos Aires. Argentina.; [5]Bsc. Lipids and Atherosclerosis Laboratory. Institute of Pathophysiology and Clinical Biochemistry (INFIBIOC). Department of Clinical Biochemistry. Faculty of Pharmacy and Biochemistry. University of Buenos Aires. Argentina.; [6]PhD. Genetic Chair. Institute of Immunology, Genetics and Metabolism (INIGEM). National Council for Scientific and Technical Research (CONICET). Faculty of Pharmacy and Biochemistry. University of Buenos Aires. Argentina.; [7]MD. Gastroenterology Service. José de San Martín Clinical Hospital. University of Buenos Aires. Argentina.

Background and objectives: Hereditary hemochromatosis (HH) is commonly associated with mutations in the HFE gene. Nonetheless, the variable penetrance of these mutations suggests that other genetic host factors may influence the development of overt iron overload (IO). There is a single nucleotide polymorphism (SNP) on position -174 G>C of the gene promoter of interleukin 6 (IL-6) which might be associated with primary IO. Carriers of the C allele were described to produce less IL-6. The aim of this study was to evaluate the SNP -174 G>C of the IL-6 gene and its interaction with iron metabolism and with inflammatory markers in male patients with primary IO.

Methods: Patients with primary IO, evidenced by liver histology, were consecutively recruited during a 12-month period (n=37). Patients were divided into two groups, treated (n=24; ferritin = 85 (28-225) ng/ml) and untreated (n=13; ferritin = 722 (558-986) ng/ml). Controls were age-matched male volunteers (n=37). High sensitive C reactive protein (HsCRP) concentration was determined by an immunoturbidimetric assay and IL-6 by enzyme immunoassay. SNP-174 G>C was evaluated by PCR-RFLP. Differences were analyzed by ANOVA. Genotype distribution was compared by the Chi square test.

Results: HsCRP was higher and IL-6 lower in untreated IO patients than in the other groups (p<0.05). The analysis of the SNP-174 G>C showed different genotype frequencies between patients

(43% CC, 43% CG and 14% GG) and controls (10% CC, 41% CG and 49% GG) (OR= 4.094, 95%CI = 2.062 to 8.128, p<0.0001), being in Hardy-Weinberg equilibrium. IO was significantly associated with CC homozygosis in the SNP-174 [OR= 6.3, 95%CI = 1.9-21.4, p<0.005]. Such association remained significant even when the analysis was performed including age and body mass index in the model (p<0.005).

Conclusions: This study describes for the first time that the C allele in the -174 G>C SNP of the IL-6 gene was associated with primary IO. The probable mechanism by which this polymorphism influences the development of IO is through lowering hepcidin synthesis via IL-6 receptor signaling in hepatocytes. Indeed, untreated IO patients showed significantly lower IL-6 levels, which were not related with the inflammatory process or metabolic abnormalities associated with overt IO.

Keywords: Iron overload, Inflammation, IL-6, Polymorphism, Hereditary hemochromatosis.

LEVEL OF HYPERTENSION TREATMENT ADHERENCE FROM TWO POPULATIONS THAT ARE TREATED IN PUBLIC AND PRIVATE AMBIT DURING THE MONTHS OF OCTOBER AND NOVEMBER 2016

[1]Markmann, Carlos Alberto; [2]Perri, Noemi; [2]Scuri, Micaela; [3]Guida, Roxana.

[1]PhD. Centro de Nutrición. Hospital Oncológico Marie Curie. Argentina.; [2]Nutritionist. Centro de Nutrición. Hospital Oncológico Marie Curie. Argentina; [3]Nutritionist. Departamento de Nutrición. Hospital Dr Antonio Cetrángolo. Argentina.

Background and objectives: The prevalence of hypertension in Argentina is 34% with similar values in the world. It has been seen in different investigations that the knowledge, treatment and control in our country are very low and it is due to, among multiple factors, to poor treatment efficiency and low adherence on the part of the patients.

The objective is to describe the adherence level to the integral treatment for arterial hypertension and to compare obtained data from patients diagnosed and treated over 18 years of age, who were treated in outpatient clinics of one private and one public hospital in the city and province of Buenos Aires respectively, during the months of October and November of the year 2016.

Methods: Quantitative, descriptive, correlational research.

Population: hypertensive patients in treatment older than 18 years.

n = 146, not probabilistic.

Variables analyzed: sex, age, educational level, care system, age in treatment, compliance with medical prescription, lifestyle habits, and professional referral.

Technique and tool: survey, structured questionnaire CAT-HTA.

Results: 42% adhered to integral treatment for hypertension. 79% adhered to the pharmacological treatment. 18% adhered to non-pharmacological treatment. The field of care was a modifying variable in adherence. 64% never consulted other professionals. 66% were never referred by their GP to other professionals. 32% consulted the nutritionist as part of non-pharmacological treatment.

Conclusions: It was observed a greater ease to carry out the medical prescription in relation to the pharmacological aspects of the treatment for hypertension, and not with the modifications in the changes of lifestyle.

Keywords: Arterial pressure. Life style. Patient Compliance. Nutritionists. Professional referral.

THE RELATIONSHIP BETWEEN SUCCESS BARIATRIC SURGERY AND WEIGHT REGAIN AFTER AT LEAST FIVE YEARS POST POSTOPERATIVE

[1]Reynoso, Clarisa; [2]Gómez, Juliana Valeria; [3]Rodriguez, Eugenia; [2]Curriá, Marina.

[1]BSc. Nutritionist. Endocrinology Department. Buenos Aires British Hospital. Argentina; [2]PhD. Endocrinology Department. Buenos Aires British Hospital. Argentina; [3]BSc. Nutritionist. Maimonides University. Buenos Aires. Argentina.

Background and objectives: A successful Bariatric Surgery (BS) is defined as Excess Weight Lost (EWL) of at least 50%. If the patient gains less than 15% of his nadir, it is considered weight loss maintenance. To our knowledge there are no reports about relationship between Weight Regain (WR) over 15% and failure of BS, defined by EWL < 50%. Objectives: To analyze the number of patients with WR above 15% after at least 5 years from surgery and to evaluate relationship between WR and BS success.

Methods: Analytical observational study. Between June 2007 and March 2012, 79 patients underwent on BS at Buenos Aires British Hospital. Anthropometric data, sex, age, date and types of surgery were collected from clinical histories. Current anthropometric data were recorded from 43 patients: 25 interviewed by telephone, 5 by e-mail and 13 personal encounters. Successful BS was considered as EWL at least 50% and weight loss maintenance if the patient gained less than 15% of his nadir.

Results: BS was performed in 79 patients: 57 sleeve gastrectomy (LSG) and 22 Roux-en-Y Gastric Bypass (RYGB). Data of 43 patients were recorded: LSG 27 (63%) and RYGB 16 (37%). Mean age was 51,3± 9,7 years; 29 (67%) female, mean baseline body mass index (BMI) 48,32 Kg/m2 (7,2DE). Mean percent of EWL: 71,32%. At least five years after surgery 8 (30%) of LSG were successful and 15 (94%) of RYGB (p 0.013). Successful patients with LSG 7 (87,5%) reported WR <10% and 1 (12.5%) WR 10-15%. In RYGB successful patients group 6 (43%) reported WR < 10%, 5 (36%) WR 10-15%, 1 (7%) WR 15-20% and 3 (21%) above 20%.

Conclusions: In RYGB group patients were more successful than those in the LSG, 5 years after surgery. None of the successful patients with LSG regained weight. Excessive weight gain was experienced by almost one third of patients in RYGB group, these results are consistent with literature. Even with this setback RYGB continued being successful, this would suggest that WR over 15% would not indicate BS failure in this group. Further extensive studies are needed in order to confirm these results.

Keywords: Bariatric Surgery, Regain weight.

TRIGLYCERIDES/HIGH DENSITY LIPOPROTEIN CHOLESTEROL RATIO AS A PREDICTOR IN DETECTION OF INSULIN RESISTANCE IN TYPE 1 DIABETES MELLITUS

[1]*García, Alicia Beatriz;* [2]*García, Alicia Beatriz;* [2]*Ruiz Morosini, María Lidia;* [2]*López González, Eva;* [2]*Milrad, Silvana;* [2]*Luongo, Ángela;* [2]*Houssay, Solange;* [2]*Varela, María Cristina;* [3]*FRADYC-DM1, Group.*

[1]PhD. Servicio de Nutricion. Hospital General de Agudos Enrique Tornu. Buenos Aires. Argentina.; [2]PhD. Hypertension Committee. Argentine Diabetes Society. Argentina.; [3]PhDs. Hypertension Committee. Argentine Diabetes Society. Argentina.

Background and objectives: The Triglycerides/High Density Lipoprotein cholesterol (TG/HDL-C ratio) is considered a clinical indicator of insulin resistance. The aims is to assess the relationship of a high TG/HDL-C ratio in T1DM with parameters of insulin resistance, habits and diabetes complications

Methods: T1DM patients over 18 years old assisted by 26 Argentinian doctors specialized in Diabetes, year 2011. Evaluation: anthropometric measures, laboratory, habits, treatment and chronic complications. Obesity (WHO criteria), physical activity at least 150 min/week, glycemic control A1c<7%, TG/HDL-C ratio>3 , intensive insulin treatment (IIT) three or more daily injections. Statistical analysis: Chi2, Student t, Spearman correlation, Multiple Logistic Regression (CSS/Statistical)

Results: 514 patients were included (age: 40.6± 14.6 years), T1DM duration: 17.4 ±12.0 years, females: 55.1%, BMI 25.1±4.3 kg/m2; A1c 8.0 ± 1.5%, Fasting blood glucose 147.1±69.1 (mg/dl). Waist circumference in men 90.5±11.4 cm, women 80.6±12.2 cm. Physical activity 45% .

Overweight 34.4%, obesity 11.9%. Intensive insulin treatment: 75.1%. Metabolic syndrome (IDF criteria) 34.7%. LDLc 110.3±31.7 mg/dl(>100 mg/dl: 60,8%), TG 107.6+61mg/dl (>150 mg/dl: 18.2%) and HDLc 50.4+13mg/dl in men (>40 mg/dl in 81.7%) and 57.8+15.2mg/dl in women(>50 mg/dl: 68.3%). The TG/HDL ratio was >3 in 20.1% and Coronary Hearth Disease (CHD)4.6%.

It was found association with high TG/HDL-C ratio with glucose fasting elevated (p<0.0009), men (p<0.03), obesity (p<0.00001), high waist circumference (p<0.0001). IIT (p=0.005)

and physical activity (p<0.009) were found as protective factors. No association with A1c and age were found. Despite the low frequency of CHD, TG/HDL ratio correlationed significantly with CHD(p<0.0001)

In multivariate analysis the high TG/HDL ratio was associated with: glucose fasting elevated(OR 1.004, IC 1.001-1.008; p< 0.008) , male(OR 1.82,IC1.12-2.96; p<0.016) , obesity(OR 2.83,IC1.51-5.28; p<0.001) and high waist circumference(OR 2.98, IC 1.74-5.1; p<0.0001) It was found as protective factor the Intensive Insulin treatment(OR 0.55, IC0.02-0.33; p<0.02)

Conclusions: The elevated TG/HDLc ratio had significance correlation with metabolic syndrome as high waist circumference, obesity and fasting blood glucose elevated. This ratio may be a surrogate marker for insulin resistance in T1DM and to identify persons with high risk of cardiovascular disease. Further studies must be made.

Keywords: TG/HDL ratio, Type 1 Diabetes, Insulin-resistance.

MEASUREMENT OF REST ENERGY EXPENDITURE IN PEDIATRIC ONCOLOGICAL PATIENTS: CONCORDANCE BETWEEN INDIRECT CALORIMETRY AND PREDICTIVE EQUATIONS

[1]*Muñoz, Eliana;* [2]*Cordero, Maria Luisa;* [3]*Castro, Magdalena;* [4]*Derado, Macarena.*

[1]MD. Department of Pediatrics. Division of Nutrition. Clinica Las Condes. Santiago.Chile.; [2]MD. Department of Pediatrics. Division of Nutrition. Hospital Dr. Sótero del Río. Santiago.Chile.; [3]MSc.Registered Nurse. Master in epidemiology. Research Unit. Academic Department. Clinica Las Condes. Santiago.Chile.; [4]MD. Pediatrician. Emergency Department. Clinica Las Condes. Santiago.Chile.

Background and objectives: Cancer in pediatric patients impacts resting energy expenditure (REE) in a way that is not estimable by predictive equations.

The aim of this study is to determine the concordance between the measurement of resting energy expenditure (REE) by indirect calorimetry (IC) in pediatric oncological patients versus World Health Organization (WHO) and Schofield predictive equations.

Methods: Cross - sectional study in children, aged 5-15 years old, receiving chemotherapy, in outpatient from Clinica Las Condes and Hospital Dr. Sótero del Rio, between July 2013 to July 2015.

REE measurement was performed by indirect calorimetry and WHO and Schofield equations.

Concordance analysis was performed, with a clinically relevant cut-off point of 90% concordance coefficient of Lin (CCI).

Results: 27 indirect calorimetry in 27 children were performed. 66% (18) were diagnosed with leukemia, 15% (4) brain tumor. 81% (22) in the maintenance stage of their treatment and 33% (9) eutrophic.

There was no significant difference between indirect calorimetry measurement versus WHO (p 0.18) or Schofield (p 0.07), nor when stratifying by nutritional status, age range or type of cancer diagnosis.

Concordance was calculated between IC and Schofield, with a CCI = 79.4% (CI 65.2 -93.6%) and IC and WHO, CCl = 78% (CI 62.9 -93.2%).

Conclusions: Conclusion: This level of agreement, less than 80% in both cases, is insufficient.

With both equations for estimating REE, there is more than 20% of cases who was an overestimation or underestimation of the energy requirements.

There was no agreement between the measurement of REE, measured with indirect calorimetry versus its estimation with Schofield's equations and WHO, so the use of indirect calorimetry for the determination of energy requirements in pediatric patients with oncological pathology should be considered.

ALCOHOL IN ADULTS WITH TYPE 1 DIABETES MELLITUS: IMPACT ON METABOLIC SYNDROME

[1]*Alicia Beatriz, García;* [2]*Alicia Beatriz, García;* [2]*López González, Eva;* [2]*Houssay, Solange;* [2]*Milrad, Silvana;* [2]*Ruiz Morosini, María Lidia;* [2]*Luongo, Ángela;* [2]*Varela, María Cristina;* [2]*FRADYC-DM1, Group;* [2]*González, Claudio D.*

[1]PhD. Servicio de Nutricion. Hospital General de Agudos Enrique Tornu. Buenos Aires. Argentina.; [2]PhD. Hypertension Committe. Diabetes Argentine Society. Argentina.

Background and objectives: The international guidelines give limits in terms of alcohol quantity consume. The amount of alcohol consumed impacts health differently. Risks associated with excessive alcohol consumption in Diabetes include weight gain, hypoglycemia and hiperglycemia.

To assess the frequency of moderate alcohol consumption in Type 1 Diabetes Mellitus (T1DM), its relationship to habits, glycemic control and the presence of metabolic syndrome.

Methods: Patients with T1DM older than 18 years old, assisted by 26 Argentinian doctors specialized in Diabetes, year 2011. Evaluation: anthropometric measures, laboratory, habits, treatment and chronic complications. Obesity (WHO criteria) and metabolic syndrome(IDF criteria), physical activity at least 150 min/week, alcohol consumption: drinking more than 15 standards drinks a week for men or 10 a week for women (Canada: Guidelines for Low-Risk Drinking), Smoking (current smokers), glycemic control A1C<7%, hyper trygliceridemia TG>150 mg/dl, Hypertension: systolic blood pressure (SBP) >140 and/or diastolic blood pressure(DBP) >90 mmHg. Statistical analysis: Chi2, Student t, Spearman correlation, Multiple Logistic Regression (CSS/Statistica).

Results: 514 T1DM patients were included, 40.6±14.6 years old, T1DM duration 17.4±12.0 years, Females 55%, A1C 8.0±1.5%, and Fasting blood glucose 147.1±69.1mg/dl. BMI 25.1±4.3 kg/m2 and waist circumference 90.5±11.4cm in men and 80.6±12.2 cm in women. Obesity 11.9% and overwheight 34.4%. Physical activity 45%, Smoking 20.2%. LDL-C 110.3±31.7mg/dl, HDL-C 50.4+13mg/dl in men, 57.8+15.2mg/dl in women and TG 107.6+61mg/dl. Metabolic syndrome 34.7%. Hypoglycemia was 67% in the last week and 13% had severe hypoglycemia in the last year. SBP118,8±11,9 mmHg and DBP 73,7±8,4 mmHg, hypertension 22,7%.

The 29.9% of patients consumed alcohol in excess.

The excessive alcohol consumption was in association with: male gender(p<0.0001), smoking(p<0.0001), hypertension(p<0.05), being overweight and obesity(p< 0.0001), hyper trygliceridemia(p<0.041) and metabolic syndrome(p<0.046). There was no association with: age(p=0.2), good glycemic control(p=0.09) and hypoglycemia(p<0.9).

The most frequently consumed beverages were beer, wine, and liquor.

Conclusions: In this study, 30% of adults with Type 1 Diabetes consumed alcohol in excess. Has been more frequent in male gender and smoking. They had an increased risk of the metabolic syndrome as overweight, obesity, hyper trygliceridemia and hypertension. Alcohol use still needs to be tackled. The low consume of alcohol supports healthy lifestyles.

Keywords: Alcohol, Type 1 Diabetes, Metabolic syndrome.

Background and objectives: Zinc is an essential nutrient that is naturally available in most foods. Deficiency of this micronutrient in particular can cause a number of health complications. Zinc deficiency during infancy is more troublesome as rapid growth and nutrient relied development takes place in this period. Most severe outcomes of zinc deficiency during infancy are considered to be cerebral damage, impaired immunity and growth retardation. This feasibility study assesses the effectiveness of zinc supplementation during infancy in Iran.

Methods: Randomized double blind controlled trial that compared oral zinc supplementation with placebo in children aged 6 to 24 months. From children contacted by researchers in the beginning of the study (n=839), 580 completed the trial. Subjects were randomly divided in two groups to take 5ml of zinc sulfate suspension containing 5mg elemental zinc or placebo daily for 6 month.

Results: Following the intervention, compared with the placebo, zinc supplementation was associated with significant difference in the average height increment (placebo 5.23 cm ±2.19 vs. intervention 5.79 cm±2.18 p=0.02). No significant difference was observed in serum zinc, ferritin and high-sensitivity C-reactive protein (hs-CRP) following the 6 month intervention. The prevalence of zinc deficiency was significantly lower in the intervention group compared to the placebo. No complications were reported and the compliance was very good.

Conclusions: Zinc supplementation for 6 month among children (6-24 months) had beneficial effects on growth parameters including average height.

Keywords: Zinc supplementation, Serum zinc, Ferritin.

FOOD INTAKE AND BODY MASS INDEX OF PATIENTS WITH TYPE 2 DIABETES MELLITUS FROM AN OUTPATIENT CLINIC IN SÃO PAULO

[1]Barros Pereira Ferreira, Natália; [1]Parise Polo, Gabriela; [1]Silva Gregório, Amanda; [1]Lekevicius Consolin, Brunna; [1]Fonseca Gonçalves, Daniel; [2]Garcia Peloggia de Castro, Adriana.

[1]Nutrition Student. Centro Universitário São Camilo. Brasil.; [2]PhD. Nutritionist. Centro Universitário São Camilo. Brasil.

Background and objectives: The prevalence of type 2 diabetes mellitus is increasing in all populations worldwide. This increase is accompanied by the rising rates of obesity and overweight observed over the past decade. For this reason, the analysis of the body mass index (BMI) may serve as a powerful tool in the assessment of the risk factor for Diabetes. As overweight is directly related to the to lifestyle and eating habits, a better understanding of food intake in patients with type 2 diabetes mellitus is essential in order to correct problems, stimulate healthy habits and foster weight loss of these population. This study objective is to classify the population using the BMI scale and correlate it to food intake.

Methods: This is a cross-sectional, descriptive study with primary data collection, sampling done by convenience, approved by the Ethics and Research Committee of Centro Universitário São Camilo, Brazil. A structured questionnaire to characterize food intake was developed for this research and applied to 82 patients with type 2 diabetes mellitus, both male and female, attending an outpatient clinic in São Paulo. BMI was classified according to the World Health Organization. Weight and height were self-reported. Data analyses were performed using descriptive statistic, the Quisquare test with a level of significance of p<0.05.

Results: Regarding the interviews, the mean age was 63±10.6 years. Mean BMI was 29.6 ± 5 kg/m2 ranging from 28.5 to 30.8 kg/m2 (for a 95% of confidence interval). When BMI was classified as underweight, normal weight and overweight it was possible to find a significant difference (p=0.04) between the groups regarding their eating habits. As for individuals with overweight the most consumed foods were: fruits, vegetables and greens (86%), pasta, breads and biscuits (82%), foods of animal origin (73%) and sweets in general (27%).

Conclusions: Most patients with type 2 diabetes mellitus are overweight and there are significant differences in food choices according to their BMI score. This insight may bring possibilities

for dietary changes and may facilitate the translation of findings to public health recommendations.

IMPORTANCE OF DIETARY COUNSELING TO PATIENTS WITH DIABETES MELLITUS TYPE 2 FROM AN OUTPATIENT CLINIC IN SÃO PAULO

[(1)]Barros Pereira Ferreira, Natália; [(1)]Parise Polo, Gabriela; [(1)]Silva Gregório, Amanda; [(1)]Lekevicius Consolin, Brunna; [(1)]Fonseca Gonçalves, Daniel; [(2)]Garcia Peloggia de Castro, Adriana.

[(1)]Nutrition Student. Centro Universitário São Camilo. Brasil.; [(2)]PhD. Nutritionist. Centro Universitário São Camilo. Brasil.

Background and objectives: A healthful eating pattern and regular physical activity are extremely important components of type 2 diabetes mellitus management. For many individuals with type 2 diabetes mellitus, the most difficult part of the dietetic plan is to decide what to eat. Dietary therapy has been recognized as an essencial strategy for helping patients with type 2 diabetes mellitus, improving self-management, developing nutritional education and providing an eating plan. In this context the purpose of this work is to correlate the eating habits of patients who received professional guidance with those who did not receive any guidance.

Methods: This is a cross-sectional, descriptive study with primary data collection, sampling done by convenience, approved by the Ethics and Research Committee of Centro Universitário São Camilo, Brazil. A structured questionnaire to characterize food intake was developed for this research and applied to 82 patients with type 2 diabetes mellitus, both male and female, attending an outpatient clinic in São Paulo. Data analyses were performed using descriptive statistic, the Qui-square test with a level of significance of $p<0.05$.

Results: Regarding the interviews, the mean age was 63 ± 10.6 years characterizing an elderly population (64.6%). The majority of respondents (80%) received specific dietary guidance for type 2 diabetes mellitus but only 30% admitted to follow the guidance given by the health professional. It is noteworthy that the main health professionals who carried out dietary counseling were nutritionists (50%) and physicians (46%). People who received guidance showed a slightly more varied diet than those who did not receive guidance. Nevertheless, this result was not statistically significant (p=0.26). The most consumed types of food were: fruits, vegetables and greens (74%), pasta, breads and biscuits (66%) and food of animal origin (59%).

Conclusions: Patients who received professional guidance on diet present a more varied food profile in relation to those who did not receive it. Therefore, the professional counseling in this population is extremely important for an adequate management of the disease and quality of life.

INTEGRATION OF PREVENTATIVE AND CURATIVE ASPECTS OF NUTRITION INTO INTEGRATED COMMUNITY CASE MANAGEMENT (ICCM) IN DEMOCRATIC REPUBLIC OF CONGO

[(1)]Kavle, Justine; [(2)]Pacque, Michel; [(3)]Mbombeshayi, Evariste; [(4)]Anzolo, Jimmy; [(5)]Bachunguye, Richard; [(6)]Tosha, Maphie; [(7)]Mirindi, Janvier; [(5)]Safari, Octave.

PATH. Kisangani, Democratic Republic of Congo.; [(4)]MD. Child Health Advisor. Maternal and Child Survival Program. John Snow Inc. (JSI). Kisangani, Democratic Republic of Congo.; [(5)]BS. Independent Qualitative Consultant. Bukavu. Democratic Republic of Congo.; [(6)]MD. Independent Qualitative Consultant. Bukavu. Democratic Republic of Congo.; [(7)]BA. Independent Qualitative Consultant. Bukavu. Democratic Republic of Congo.

Background and objectives: Integration of nutrition into iCCM provides an opportunity to improve and strengthen IYCF and care practices, nutritional status, and reduce rates of child morbidity. Global iCCM guidelines focus on the identification, treatment, and referral of children who are sick with diarrhea, pneumonia, and/or malaria, as well as acute malnutrition. Yet, the implementation of iCCM is often not delivered with the intensity, quality, and coverage needed to achieve improvements in child nutritional status. Globally, a gap in evidence exists for integrating nutrition into the iCCM platform. The objectives of this study are to 1) examine how various aspects of nutrition integration into iCCM are currently delivered within the DRC health system 2) identify possible approaches for behavior change communication for infant and young child feeding, and advising families with sick children and 3) identify gaps and areas for strengthening nutrition within iCCM programming through health services, including linkages for identification and referral of acute malnutrition.

Methods: In-depth interviews were carried out with mothers (n= 48); grandmothers (n= 20) and fathers (n=21) of children under five years of age, 18 health facility providers and 20 traditional healers in 4 sites in Tshopo, DRC. Eight focus group discussions (FGDs) were carried out with community health workers (CHWs). Following transcriptions of recordings for FGDs and IDIs, key emergent themes were identified and sub-themes were coded.

Results: Our findings reveal inadequate infant and young child feeding practices, with minimal counseling by health providers. Cultural beliefs and traditional practices surrounding breast-

milk sufficiency and breastfeeding problems should be addressed by health providers. Complementary feeding practices are suboptimal, in terms of quantity, frequency and diversity. Involvement of traditional healers is key. Addressing care seeking behaviors for child illness, as well as targeting preventative rather than solely curative care for malnutrition within the iCCM platform is needed.

Conclusions: These findings will be translated into practical approaches for strengthening integration of nutrition into iCCM programming in DRC.

Keywords: Integration, Nutrition, Child health, iCCM

SOCIODEMOGRAPHIC ROLE IN DEPRESSION PREVALENCE AMONG MIDDLE-AGED AND ELDERLY IN CHINA: FINDINGS FROM THE CHINA HEALTH AND RETIREMENT LONGITUDINAL STUDY

[1]Ding, Gangqiang; [2]Li, Yaru; [3]Zhang, Ronghua.

[1]PhD.National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China; [2]MA. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China.; [3]MD. Zhejiang Center for Disease Control and Prevention. China.

Background and objectives: Background and objective: Although several studies explored the prevalence of depression in China, few studies have investigated the sociodemographic impact on depression prevalence. Therefore, this study aimed to examine the association between depression prevalence and sociodemographic factors among Chinese middle-aged and elderly.

Methods: Using baseline data of the China Health and Retirement Longitudinal Study (CHARLS), conducted between March 2010 and June 2011, the study performed a cross-sectional analysis about depression prevalence and socioeconomic role among 15,271 middle-aged and elderly participants aged 45 and older. Depression was diagnosed by Center for Epidemiological Studies Depression Scale-10 (CES-D) score. Multivariable logistic regression model was used to analyze the association between sociodemographic factors and depression prevalence by providing odd ratios (ORs) and 95% confidence intervals (CIs).

Results: The prevalence of depression in the middle-aged and elderly was 37.1% (30.2% for men and 43.2% for women, respectively) in 2011. Multivariable logistic regression model showed that odds of depression in the women was 1.82 times that in the men (95% CI: 1.68-1.97), while the odds of depression in the rural area was 1.42 times that in the urban area (95% CI: 1.31-1.55). Moreover, the depression prevalence was positively associated with age, and negatively associated body mass index (BMI), education and household income level (P for trend < 0.001). Compared with participants living in North region, the ORs and 95% CIs of depression among participants who lived in East, South-Central, North-West, South-West, and North-East regions were 0.81 (0.71-0.93), 0.95 (0.83-1.08), 1.36 (1.15-1.62), 1.26 (1.09-1.45), and 0.84 (0.70-1.00), respectively.

Conclusions: there was about one third of Chinese middle-aged and elderly having depression in 2011. Prior measures should be taken among high-risk middle-aged and elderly with lower education and income levels, older women, living in rural area or west China. Further cohort studies are needed to identify the prospective association between sociodemographic factors, diet and lifestyle factors with depression risk among Chinese populations.

Keywords: Depression, Sociodemographic disparity, Middle-aged and elderly, China.

Clinic of Cognitive Neurology. University Hospital Leipzig. Leipzig. Germany.; [10]PhD. Department of Neurology. Max Planck Institute for Human Cognitive and Brain Sciences. Leipzig. Germany. Collaborative Research Centre 1052 "Obesity Mechanisms". Faculty of Medicine. University of Leipzig. Leipzig. Germany.

Background and objectives: Obesity has been associated with increased risk of dementia. Grey and white matter (WM) of the brain are commonly used as biomarkers for early detection of dementia. However, considering WM, available neuroimaging studies had mainly small sample size and yielded less conclusive results (Kullmann et al., 2015). Recently, a positive correlation between obesity and fractional anisotropy (FA) in a middle age group was reported (Birdsill et al. 2017). Furthermore, obesity is related to many medical problems such as diabetes and hypertension. Diabetes and hypertension were found to be correlated with brain structures independently (de Leeuw et al., 2002; Weinstein et al., 2015). Yet, studies rarely investigated non-lesion WM microstructure and its association with diabetes and blood pressure. Therefore we aim to investigate the relation between abdominal obesity, diabetes, blood pressure and WM microstructural variability in a large cohort of community-dwelling healthy adults.

Methods: The sample included dementia-free participants (mean age 55 ± 16 years; 50.7% women) of the LIFE cohort with brain MRI scans (n = 1255). WM microstructure was measured with diffusion tensor imaging (DTI). Mean FA was derived from the individual WM skeleton processed by tract-based-spatial-statistic method. Linear regression models were used to assess the relationships between diabetes, blood pressure, waist to hip ratio (WHR) and DTI parameters. Adjustments were made for age, sex, education and Apoe4.

Results: The preliminary result indicated diabetes, systolic blood pressure and WHR were independently associated with lower FA, and diabetes explained the most variance besides age. Subgroup analysis revealed both systolic blood pressure and WHR were negatively associated with mean FA in the non-diabetes group (n=1101).

Conclusions: The preliminary result of our study indicates that diabetes accelerated brain aging on directional diffusion of WM. Abdominal fat and blood pressure were associated with WM variabilities independently from age, sex and diabetes. With subsequent analysis of additional DTI measures, blood parameters, WM hyperintensity maps and voxel-based microstructural WM "integrity", we aim to further characterize the associations between obesity, diabetes, blood pressure and WM microstructure. This will contribute to the existing literature and help to disentangle the underlying mechanism.

Keywords: Abdominal fat, Waist to hip ratio, DTI, Fractional anisotropy.

University of Iceland and Landspitali – University Hospital. Iceland.; [7]PhD. Physician. Department of Immunology, Landspitali-University Hospital. Iceland.

Background and objectives: The potential effect of food on Attention deficit hyperactivity disorder (ADHD) symptoms has long been debated. The aim of this pilot study was primarily to investigate compliance to two diets of interest, the healthy diet and the temporary few foods diet (few allergens) and secondary evaluate their effects on ADHD symptoms.

Methods: Participants were children who had been diagnosed with ADHD at the two main psychiatric centers for children in Reykjavik, with 29 children randomized into three groups: healthy diet (n=10), few foods diet (n=10) and a control group (n=9). A three-day food diary and questionnaires for both parents and teachers gave background information and symptoms. The same questionnaires were answered five weeks later as well as questions regarding the participation. A blinded physician interviewed the children and parents before and after the intervention. Compliance checklists were designed for the intervention period. Full participation rate was 68%.

Results: Baseline diet was not in line with dietary recommendations. Compliance to the diets was generally good (70-80%), although most children found it hard to follow the few foods diet and four dropped out. Using ADHD rating scale (ARS) the parents' total score decreased similarly on both diets (median from 35 to 27) or by 25% (p<0.05). Teachers found no change on ARS nor on Achenbach's Teacher Rating Form after the healthy diet, but significant improvement of symptoms were observed after the few foods diet (p=.027). No change was seen in the control group. The psychiatrist also found differences between groups (p<0.05).

Conclusions: With good support, compliance was generally good. Parents reported a decrease in symptoms on both diets, while teachers only reported improvements for children on the few foods diet. Diet of children with ADHD can be substantially improved and nutritional status and food sensitivity should be examined at diagnosis. However, further studies are needed.

Keywords: ADHD, Healthy Diet, Few foods diet, Compliance, Symptoms.

POSTPARTUM ABNORMALITIES OF CARBOHYDRATE METABOLISM IN PATIENTS WITH GESTATIONAL DIABETES AND RISK FACTORS INVOLVED

[1]Baran, Jesica Dana; [1]Aranguren, Marcela; [2]Gentile, Maria Belen; [2]Olmedo Sosa, Maria Victoria; [2]Tapper, Maria Ximena; [2]Anselmi, Maria Eugenia; [2]Schwartz, Nadia; [3]Castro, Maria Jose; [4]Calcagno, Maria Lujan; [1]Boquete, Hugo Ruben.

[1]MD. Endocrinology. Endocrinology Unit. Hospital Agudos Doctor Teodoro Alvarez. Argentina.; [2]MD. Endocrinology Unit. Hospital Agudos Doctor Teodoro Alvarez. Argentina.; [3]BSc. Catedra de Matemática. Facultad de Farmacia y Bioquímica de la Universidad de Buenos Aires. Aregentina; [4]Bioch. Catedra de Matemática. Facultad de Farmacia y Bioquímica de la Universidad de Buenos Aires. Aregentina.

Background and objectives: Gestational Diabetes Mellitus (GDM) is a highly prevalent clinical entity that identifies a population of young women with a high risk of developing type 2 Diabetes Mellitus (T2D) in the future. The rate of persistent metabolic abnormalities after delivery is highly variable and there are no consistent statistics about risk factors. Objectives: 1) To describe the prevalence of carbohydrate metabolism abnormalities in postpartum reclassification 2) To classify risk factors that predict persistence of such abnormalities

Methods: Seventy-eight patients with a diagnosis of GDM within the past 3 years were evaluated and reclassified. Patients with pregestational diabetes, those diagnosed before gestational week 20 and/or with blood glucose levels ≥ 126mg% were excluded. Diagnostic criteria were: fasting plasma glucose (FPG) and blood glucose in OGTT at 120 minutes after a 75-g of glucose, based on the American Diabetes Association and the Sociedad Argentina de Diabetes criteria.

Results: Sixty-four patients had normal OGTT (82.1%), while 14 (17.9%) showed blood glucose abnormalities: IGT in 9 patients, IFG in 2, two cases with both abnormalities and 1 patient developed T2D. In patients with abnormal reclassification, 57% were diagnosed based on FPG and only 25% in the group with normal reclassification (p= 0.03). In patients with pathologic reevaluation, 69.23% had a family history of T2D compare to 36.5% in the other group (p=0.03). There was a tendency towards an age ≥ 30 yr, higher BMI, personal history of GDM and macrosomia in the group that persisted with abnormalities of the carbohydrate metabolism.

Conclusions: In our analysis, we found a high prevalence of carbohydrate metabolism abnormalities following GDM. We found a higher risk for persistent abnormalities in patients who had been diagnosed with GDM based on FGP and in those with a family history of T2D. We consider it is highly important to classify risk factors in order to institute preventive therapeutic actions, particularly in the population with greater vulnerability.

Keywords: Gestational diabetes postpartum reclassification factors.

KETOGENIC DIET COMPLICATIONS IN CHILDREN WITH REFRACTORY EPILEPSY

[1]Armeno, Marisa; [2]Vierini, Antonella; [2]Araujo, Cecilia; [3]Soto Montesano, Betiana; [4]Caraballo, Roberto Horacio.

[1]MD. Clinical Nutrition. Department of Pediatric Nutrition. Garrahan Hospital. Buenos Aires. Argentina; [2]MD, Clinical Nutrition. Nutrition Department. National Pediatric Hospital J.P.Garrahan. Argentina; [3]MSc, Nutritionist. Food Services Department. National Pediatric Hospital J.P.Garrahan. Argentina; [4]MD, Pediatric Neurologist. Neurology Department. National Pediatric Hospital J.P.Garrahan. Argentina.

Background and objectives: The ketogenic diet (KD) is a non-pharmacological treatment used as an alternative in the management of difficult-to-treat epilepsy since 1921. It is a high-fat, low-carbohydrate diet effective in around 50% of the patients. The KD is an unbalanced diet lacking micronutrients leading to possible deficits in energy, proteins, minerals, and vitamins and excess of lipids with a risk of unwanted early as well as late adverse effects (AE). Our aim is to describe the early and late AE of KD treatment in a prospective cohort of 51 children with difficult-to-treat epilepsy seen at a single center.

Methods: We performed a prospective study of children with intractable epilepsy admitted for ketogenic diet initiation at our institution from 2014 to 2016. We studied adverse effects at one and six months after diet initiation.

Results: Before starting the diet, constipation and Vitamin D deficiency were the most common nutritional conditions seen in this cohort, and at one month after the most common acute AE were metabolic acidosis (n=20), constipation (n=13), food intolerance (vomits, food refusal) (n=13), hipoglycemia (n=8), hipercholesterolemia (n=7) and hipertrigliceridemia (n=5). Long-term adverse effects were metabolic acidosis (n=7) hypercholesterolemia (n=6), neutropenia (n=1), selenium deficiency (n=10), and growth impairment (n=4). In only two patients the AE were severe enough to discontinue the diet.

Conclusions: Some AE are difficult to interpret as they may be manifestations of underlying disorders instead of the diet. It is important to follow the protocol regarding frequency of lab tests to detect and prevent these AE. If managed by an experienced multidisciplinary team, all AE are treatable or preventable.

Keywords: Ketogenic diet, Adverse effects, Intractable epilepsy.

ASSOCIATION BETWEEN BLOOD VITAMIN D LEVELS AND METABOLIC SYNDROME BIOMARKERS IN POST MENOPAUSE WOMEN

[1]Netto, Claudia; [2]Maria do Amaral dos Santos, Marta; [3]Figueiredo Marinheiro, Lizanka Paola.

[1]PhD. Nutritionist. Department of Biochemistry. University of Rio de Janeiro. Rio de Janeiro. Brazil.; [2]MSc. Nutritionist. Department of Biochemistry. University of Rio de Janeiro. Rio de Janeiro. Brazil.; [3]PhD. Doctor. Department of Endocrinology. Instituto Nacional de Saúde da Mulher, da Criança e do Adolescente - Fernandes Figueira. Fundação Oswaldo Cruz. Rio de Janeiro. Brazil.

Background and objectives: Vitamin D may act in several vital cellular processes, as well as biochemical and physiological disorders in obesity, cardiovascular disease and diabetes mellitus. This study aims evaluate the association between blood levels of vitamin D and indicators and your relation to metabolic syndrome in postmenopausal women.

Methods: A retrospective cross-sectional study was carried with postmenopausal women living the city of Rio de Janeiro - RJ. The women were interviewed between August 2013 and August 2014 (n=177 volunteers) and Clinical and demographic data were obtained by individual oral interview using a structured questionnaire. The metabolites were measured 25(OH)D3: insulin, C-reactive protein, follicle stimulating hormone (FSH), estradiol, progesterone, and parathyroid hormone (PTH) glucose, triglycerides, total cholesterol, HDL-cholesterol and LDL-cholesterol. cut off for vitamin D was 25(OH)D3 ≥ 30 ng/mL (75 nmol/L) = normal, 25(OH)D3 <30 ng/mL (75 nmol/L) = hypovitaminosis (WHO). In the anthropometry was analyzed: weight, height, body mass index (BMI) and waist circumference (WC). Statistical analyzes were performed using Student's t test, Wilcoxon test and Chi-square test for. The significance level was 5%.

Results: Of the 177 women evaluated, 87 (49,15%) had vitamin D deficiency, and 90 (50,85%) had normal levels of this vitamin; 88 (49,7%) had metabolic syndrome and 89 (50,3%) had no such syndrome. The average weight, body mass index (BMI), waist circumference, blood pressure, insulin, follicle stimulating hormone (FSH), parathyroid hormone (PTH), C-reactive protein (CRP), fasting glucose and triglycerides were higher (p< 0,05) in patients with the metabolic syndrome, while the HDL-cholesterol average was greater (p<0,05) in the group without metabolic syndrome. In the group with metabolic syndrome, the mean diastolic blood calcium and blood pressure were higher (p<0.05) in the group of women with normal levels of vitamin D. In the group without metabolic syndrome, only blood calcium showed a possible relationship with the level of vitamin D in the blood, but the blood calcium was higher (p<0.05) in the group with hypovitaminosis D. There was no statistical difference (p>0.05) between the groups in relation to ethnicity.

Conclusions: The vitamin D showed a possible interference in diastolic blood pressure and blood calcium in metabolic syndrome women.

ANALYSIS AND DESCRIPTION OF AUDITS PERFORMED ON PATIENTS WHO ATTENDED FOR REFERRAL TO BARIATRIC SURGERY IN GALENO GROUP OFFICES

(1)Garcia, Stella Maris; (2)Perri, Noemi; (3)Leal, Marcela; (2)Rodriguez Fanlo, Eugenia.

(1)PhD. Nutritionist. Service of Nutrition. Sanatorio de la Trinidad. Argentina.; (2)BSc. Nutritionist. Maimonides University. Argentina.; (3)MSc. Faculty of Health Sciences. Maimonides University. Argentina.

Background and objectives: Obesity is a chronic, complex, heterogeneous health problem of a growth and epidemic behavior that shortens life expectancy, generates great morbidity and increases socio-health costs. Obesity surgery is safe, presenting low morbidity and mortality, and effective for weight loss and improvement of comorbidities. However, it necessarily implies a change in people's eating habits, it is not curative, nor is it the solution for everyone.

To analyze, describe and interpret a database audits carried out on patients who attended a referral for Bariatric Surgery as a treatment for obesity in the Galeno group Palermo and Barrio Norte clinics from September 2014 to September 2016.

Methods: Quantitative, descriptive, observational, transversal, retrospective research. The sample was non-probabilistic, conformed by 1544 patients who attended the consultation for referral to Bariatric Surgery, analyzing the variables Age, Sex, Family History, Weight, Height, BMI, Derivation and Performing Bariatric Surgery. It was used Excel 2016® to analyze database of audits and medical histories.

Results: The mean age of the sample was 42 years (DS ± 11), 64% were female, 71.5% had an obese family history of at least one relative, 70% had a BMI ≥40, 26% did not meet the requirements for Bariatric Surgery and did not accept another treatment, 1% was placed intragastric balloon, 37.24% was referred to the Comprehensive Center for the Treatment of Severe Obesity (CITOS) and 35.47% that were authorized to perform the surgery, 72% were performed.

Conclusions: Many patients who consult for Bariatric Surgery as a treatment for obesity do not meet the inclusion requirements for it and do not accept another treatment for their disease. Prior audits of referral to appropriate treatment for obesity, personalized according to the history and needs of each patient, can reduce the percentage of failures in the treatment chosen and the economic cost that it represents for health systems.

Keywords: Obesity, Bariatric surgery, Treatments, Medical referral.

EFFECTS OF VITAMIN D SUPPLEMENTATION IN DIABETICS RATS METABOLISM

(1)Netto, Claudia; (2)Lourdes Pereira Tavares de Souza, Laise; (3)Finelli Vanço, Kátia; (3)Helena Trigo da Paz, Jéssica; (3)Garcia Rocha, Isabella; (4)Rodrigues Júnior, Luiz Fernando.

(1)PhD. Nutritionist. Department of Biochemistry. University of Rio de Janeiro. Rio de Janeiro. Brazil.; (2)MSc. Nutritionist. Department of Biochemistry. University of Rio de Janeiro. Rio de Janeiro. Brasil.; (3)Biomedical. Department of Biochemistry. University of Rio de Janeiro. Rio de Janeiro. Brazil.; (4)PhD. Physiotherapist. Department of Physiology. University of Rio de Janeiro. Rio de Janeiro. Brazil.

Background and objectives: Diabetes mellitus affects about 422 million people worldwide and it is considered one of the major global epidemics of the 21st century. However, vitamin D can act in several vital cellular processes, including the pathology of diabetes mellitus. This study evaluated the effects of vitamin D supplementation in diabetic rats metabolism.

Methods: Thirty-two recently weaned rats (21 days of life) were distributed randomly in four groups (n=8 per group): 1- control non-diabetic (C); 2- diabetics control (DC); 3- diabetics treated with 400 IU of vitamin D / day (VD400); 4- diabetics treated with 520 IU of vitamin D / day (VD520), for twenty days. The induction of diabetes was performed by applying streptozotocin intraperitoneally diluted in citrate buffer. The analysis performed were glucose, total cholesterol, HDL-cholesterol, triglycerides, insulin, vitamin D, total protein, albumin and calcium serum.

Results: The control non-diabetic group had a lower consumption (p<0.05) compared to the diabetic groups, while the body weight did not present variation (p>0.05). Fasting blood glucose decreased (p<0.05) in the treated animals compared to diabetic control animals. Total cholesterol, HDLc, vitamin D and calcium did not show significant differences (p>0.05) with the supplementation, while triglycerides showed statistical difference (p<0.05) between the groups applying ANOVA, but with the Newman-Keuls test was not possible to observe difference between them. The total protein and albumin presented an increase (p<0.05) in the groups supplemented with vitamin D.

Conclusions: Vitamin D supplementation may improve glucose control in diabetic rats and total proteins (albumin and globulin) but did not show a significant beneficial change in lipid and insulin profile, suggesting that it may be acting in an alternative way of independent insulin blood glucose control. Thus, the relationship between vitamin D status, fasting blood glucose and insulin action requires a more depth investigation.

PERCEPTION OF BODY IMAGE, KEY FACTOR IN THE CARE OF NUTRITIONAL STATUS

[1]Riccetto, Paula; [2]Calvo, Soledad; [3]Gambogi, Rosana; [4]Nigro, Sonia.

[1]Nutritionist. National Resources Fund. Uruguay; [2]MSc. Nitritionist. National Resources Fund. Uruguay; [3]MD. National Resources Fund. Uruguay; [4]MSc. Nutritionist. National Resources Fund.

Background and objectives: Obesity, particularly abdominal obesity, is considered a very important risk factor for the metabolic syndrome, a situation with a high risk of diabetes and cardiovascular disease. Knowing how overweight and obese people perceive their body image (BI) will help define new strategies that strengthen the need to have a healthy weight.

Objective: To study the perception of the nutritional status of patients attending the Secondary Cardiovascular Prevention Program of the National Resources Fund (NRF) of the city of Montevideo, during the period of May-December 2015.

Methods: The study is descriptive of an exploratory, cross-sectional type. 203 patients were studied, who were given a semi-structured form that contained the Stunkard and Stellard BI test. The nutritional status was assessed through the body mass index.

Results: Two-thirds of the population were men; Six out of ten patients were older adults, and almost nine out of ten had overnutrition, of which almost half were obese. However, more than half were observed with normal weight, of which 65% were male. However, more than half were observed with normal weight, of which 65% were male. Almost half of the obese were perceived as overweight, 8 out of 10 overweight patients were found normal, of those with normal weight, almost half were observed as thinned and those who were underweight were reflected as they are.

Conclusions: Most patients had a severe underestimation of their BI. It was men who underestimated more. Identify the perception of the BI is a key factor in weight control and modification of individual behaviors to improve nutritional status.

Keywords: Obesity, Patients, Body image, Perception, Underestimation.

Conflict of Interest Disclosure: Authors Paula Riccetto, Soledad Calvo, Rosana Gambogi and Sonia Nigro declare to be part of one of the technical teams of the evaluated program, as well as the institution that sends this summary (NRF).

EATING BEHAVIOR AND STRESS PERCEPTION IN ADULT WOMEN FROM BUENOS AIRES PROVINCE, BUENOS AIRES CITY AND CHACO, ARGENTINA

[1]Oliva, María Laura; [2]Janjetic, Mariana; [2]Motta Moreno, Encarnación; [2]Pujol, Mariana; [2]Goldfinger, Mariana; [3]Español, Silvina; [2]Fino, Gabriela; [2]Somoza, María Inés; [2]Grasini, Daniela; [2]Torresani, María Elena.

[1]Especialidad de Nutrición Clínica - Escuela de Nutrición, UBA; [2]Especialidad Nutrición Clinica- UBA; [3]Espacialidad de Nutrición Clinica UBA.

Background and objectives: Stress is considered a disease of the XXI century, and can influence eating behavior and consequently body weight. The aim of this study was to evaluate the relationship between stress perception and eating behavior in Argentinean adult women.

Methods: An observational, transversal and analytical study was carried out on adult women (30-65 years) attending to nutritional appointment in clinics from Buenos Aires Province, Buenos Aires, Buenos Aires City and Resistencia, Chaco. A sociodemographic and lifestyle survey was carried out (physical activity, smoking). The stress perception was assessed by the Preceived Stress Scale (PSS10) with maximum of 40 points and the eating behaviors were evaluated using the Three-Factor Eating Questionnaire (TFEQ-R18), classified as: emotional eating (EE), uncontrolled eating (UE) and cognitive restraint eating (CRE). Nutritional status was assessed by body mass index (BMI) and abdomial fat by waist circumference (WC). Physical activity was defined considering at least 150 minutes of exercise per week. Statistical analysis was performed with SPSS 19.0 using X2, Mann-Whitney Test and Spearman correlation (statistical significance at $p < 0.05$).

Results: A total of 251 women aged 43.3 ± 9.8 years were included. The median values of EE, UE and CRE were: 5.0 (3.0-8.0), 16.0 (12.0-21.0) and 15.0 (10.0-18.0), respectively. The mean values of perceived stress were 15.5 ± 6.0. The stress perception positively correlated with the EE ($r = 0.23$, $p = 0.0003$) and the UE ($r = 0.24$, $p = 0.0001$); however, it did not correlate with CRE ($r=0,08$, $p=0,19$). Meanwhile EE, UE and CRE scores were significantly higher in overweight or obese women, the perception of stress was not associated with BMI.

Conclusions: The stress perception correlated with higher EE and UE scores, however, it was not associated to nutritional status. On the other hand, the three eating behaviors evaluated were associated to nutritional status.

Keywords: Adult woman, Stress, Eating behaviors.

ASSOCIATION BETWEEN DEPRESSIVE SYMPTOMS, NUTRITIONAL AND CLINICAL ASPECTS OF ELDERLY RESIDENTS OF A CITY OF SÃO PAULO: A POPULATION-BASED STUDY

[1]Wendeborn, Gisele; [2]Bassoli, Lucas; [3]Alexandrino, Clóvis; [4]Bottino, Cássio; [5]Ribeiro, Sandra.

[1]Nutricionista; Programa de Interunidades em Nutrição Humana Aplicada; Universidade de São Paulo; [2]Nutritionist. University of São Paulo; [3]Doctor. University of São Paulo; [4]PhD. Doctor. University of São Paulo; [5]Phd. Nutritionist. University of São Paulo.

Background and objectives: Depression, or depressive morbidity, is a complex mental disease that includes different phenotypes and symptoms. It has association with different negative results. There are many questions about the association between diet and eating habits with different brain disorders, including depressive symptoms. Eat now is not examined. To investigate the association between depressive symptoms, nutritional and clinical aspects of elderly residents of a city of São Paulo.

Methods: The present study is part of a larger thematic project: "Study on the Prevention and Treatment of Depression in the Elderly: A Population-Based Study." A cross-sectional, community-based epidemiological study of 2,643 elderly individuals aged 60 years and over. Considering the following variables: Depressive Symptoms: Center for Epidemiologic Studies Depression Scale (CES-D); Nutritional status: BMI and waist circumference; Habit to consume certain food groups and habit to make meals (Brazil, 2006). Presence of chronic diseases: hypertension, diabetes and hypercholesterolemia; Socio-demographic and economic characteristics: Brazil's Economic Classification Criterion (CCEB) (ABEP, 2011). The variables were analyzed by binary logistic regression. All variables investigated as significant values of $p < 0.05$ (SPSS 22.0 software).

Results: We found a high rate of depressive symptoms (38%); Depressive symptoms are associated with the habit of consuming milks and derivatives less than 1 serving per day, olive oil less than 2 times a week, do not consume wine every day, do not often carry out lunch and dinner, possess HAS, be female and be divorced or separated.

Conclusions: This study showed that negative association between depressive symptoms and the consumption of some foods. The results remained positive, even after adjustment for socioeconomic, demographic and clinical variables.

EFFICACY OF A MODIFIED CARBOHYDRATE DIET IN OBESE WOMEN

[1]Chávez Palencia, Clío; [2]Larrosa Haro, Alfredo; [3]Romero Velarde, Enrique; [4]López-Uriarte, Patricia Josefina.

[1]PhD. Nutritionist. Human Nutrition Institute. University of Guadalajara. Mexico.; [2]PhD. Gastroenterologist. Human Nutrition Institute. University of Guadalajara. Mexico.; [3]PhD. Pediatrician. Human Nutrition Institute. University of Guadalajara. Mexico.; [4]PhD. Nutritionist. Center for Research in Food Behavior and Nutrition. University of Guadalajara. Mexico.

Background and objectives: The dietary management of obesity may consider both: energy intake and macronutrient distribution. The most effective dietary treatment for reducing adiposity seems to be a low carbohydrates (CH) and low glycemic index (GI). Fructose and high fructose corn syrup (HFCS) seems to be related to obesity too. The objective was to compare the efficacy of a modified CH diet vs. a diet with a standard proportion of macronutrients within a program of reduced adiposity in obese women.

Methods: A randomized clinical trial was performed. Women in reproductive age diagnosed with obesity (BMI ≥ 30) were included. Dietary intervention was performed for six months. The dietary modification of the intervention group consisted of a hypocaloric diet, with a macronutrient distribution of 45-55% CH, 15-20% proteins and 30% lipids, foods with low or medium GI were recommended and to reduce the intake of industrialized foods with HFCS. In the control group, a hypocaloric diet was also recommended, with a distribution of macronutrients of 60-65% CH, 10-15% proteins and 25% lipids, without restriction of any kind of food. Physical activity recommendations were made equally in both study groups and monthly workshops were implemented to improve adherence to treatment. Measurements of anthropometric (body weight, BMI, fat percentage, arm anthropometry), dietetic (24-hour recalls, food frequency questionnaires), physical activity and adherence to treatment variables were taken at baseline and monthly.

Results: Changes in body composition were observed in both study groups. The greatest differences were mainly intra-group variables shown in adiposity. BMI, fat percentage measured by bioelectrical impedance as well as skinfolds, arm fat area (AGB) triceps skinfold thickness (PCT) and subscapularis (PCSE) showed major differences in the intervention group. The arm muscle area (UMA) increased in the intervention group and only significant statistically differences were detected ($p=0.032$ intervention group vs. $p=0.305$ control group).

Conclusions: The effectiveness of the modified diet in amount and type of CH to reduce adiposity was higher in the intervention group compared with the control group, although both groups were decreased adiposity.

Keywords: Low-carbohydrate diet, Low-glycemic index diet, High fructose corn syrup, Adiposity, Obesity.

LONG-TERM MAGNESIUM RESTRICTION MODIFIED THE BODY IRON STORES IN RATS FED A HIGH-FAT DIET

(1)Fragal, Beatriz; (2)Batista da Rocha Romero, Amanda; (3)De Carli, Eduardo; (4)Rodrigues Lobo, Alexandre; (3)Colli, Celia.

(1)Undergraduate student. Department of Food and Experimental Nutrition. University of São Paulo. Brazil; (2)MSc. Department of Food and Experimental Nutrition. University of São Paulo. Brazil.; (3)PhD. Department of Food and Experimental Nutrition. University of São Paulo. Brazil.; (4)PhD. Department of Food and Experimental Nutrition. University of São Paulo, São Paulo. Brazil. Municipal Secretary of Education. Pirai do Sul. Parana. Brazil.

Background and objectives: Poor iron status described in obese individuals has been attributed either to dietary inadequacies, to increments in body iron requirements or more often to inflammation-induced iron decompartmentalization. Here, we tested the hypothesis that a long-term dietary Mg restriction modifies body iron stores (liver and spleen) in rats fed a high-fat (HF) diet.

Methods: Male Wistar rats (n = 24; initial body weight 97-123 g) were fed ad libitum semipurified AIN-93-based control (CT) or high-fat (HF) diets (adequate or Mg-restricted; 500 [Mg500] and 50 [Mg50] mg Mg/kg diet, respectively) for 24 weeks. Diet consumption and body weights were recorded twice a week. At the end of experiment, liver and spleen iron concentrations were analyzed by atomic absorption spectrophotometry (AAS). Moreover, liver total protein homogenates were employed in analysis of ferroportin (Fpn1) abundance by immunoblotting.

Results: Compared to CT, HF feeding promoted reduced diet consumption (p <0.05) and enhanced body weight gain (p <0.05), irrespective of Mg restriction. Liver iron concentrations did not differ among groups. However, HF fed animals with Mg restriction (HF[Mg50]), but not those with Mg adequate diet (HF[Mg500]), had lower spleen iron concentrations in comparison to controls (CT[Mg500] and CT[Mg50]) (p <0.05). In this context, ferroportin abundance in the liver was significantly lowered in both HF groups (p <0.05), suggesting that Mg restriction did not modified the efficiency of liver iron exportation in response to the dietary lipid overload.

Conclusions: Long-term Mg restriction did not affect weight gain, but modified body iron distribution in rats fed HF diets. Further analysis of serum cytokines and hepcidin concentrations and ferroportin (Fpn1) abundance in duodenum and spleen samples will help to clarify whether these findings are accompanied by changes in the inflammation response, in the intestinal iron absorption or in the mobilization of splenic iron stores for erythropoiesis.

ENTERAL NUTRITIONAL THERAPY IN HOSPITALIZED PATIENTS: EFFECTIVENESS IN DIET ADMINISTRATION?

(1)Teixeira da Silva Chagas Monteiro, Rafaella; (1)Nunes Novais Calisto, Ariane; (2)Resende de Aguiar, Livia; (3)de Lucena Ferretti, Roberta.

(1)Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil; (2)Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil.; (3)PhD Student. MSc. Nutritionist. Federal University of Sao Paulo. University of Taubate. Sao Paulo. Brazil.

Background and objectives: Hospital malnutrition is very prevalent, especially in patients receiving Enteral Nutritional Therapy (ENT), due to several factors such as inadequate and ineffective diet administration, lack of monitoring by the team, among others, which may complicate the Clinical picture of the patient, increasing the hospitalization time. The objectives of this study were to evaluate the nutritional status and the effectiveness in the administration of enteral diets in hospitalized patients.

Methods: A cross-sectional study with adults and elderly individuals over 20 years old in a hospital in Taubate, Sao Paulo, between August 2015 and April 2016. All patients under ENT were selected. It was considered as effective dietary administration when the prescribed diet was completely infused, reaching 100% of the nutritional needs of the patient. To evaluate the effectiveness of diet administration, the dietary prescription, the volume of diet programmed in the infusion pump as a function of time, as well as information obtained by the patient's chart, nursing professionals, physicians and the multidisciplinary team for nutritional therapy. The mean time attributed to interrupting the diet was also verified. For nutritional status assessment, arm circumference was measured, and compared to the reference values demonstrated by Frisancho (1990), and adequate according to Blackburn and Thomton (1979). Descriptive statistics were performed for data analysis.

Results: Among the 135 patients evaluated, 56.3% (n = 76) were males, while the median age for this sex was 76.5 ± 12.3 years and for females 68.5 ± 10.2 years old. Regarding the nutritional status, 72% of the evaluated patients presented some degree of malnutrition. Regarding the diet administration, it was effective in 78% of the sample. Regarding the 22% of the patients who did not receive the prescribed diet, it was observed that there was interruption of diet for at least 2 hours. Among the patients who did not receive the diet effectively, 80% were malnourished.

Conclusions: It is concluded that the majority of the sample was found to be malnourished, and the enteral diet infusion was not effective for all patients. Therefore intervention measures should be adopted and implemented, helping to prevent hospital malnutrition.

FOLLOW UP OF CHILDREN WITH CLASSIC PKU DIAGNOSED BY NEWBORN SCREENING PROGRAM IN CHILE: 24 YEARS OF EXPERIENCE

[1]Castro, Gabriela; [2]Arias, Carolina; [2]Cabello, Juan Francisco; [3]Hamilton, Valerie; [4]Valiente, Alf; [5]Betta, Katerina; [6]De la Parra, Alicia; [2]Colombo, Marta; [3]Cornejo, Veronica.

[1]Nutricionist. Institution of Nutrition and Food Technology. University of Chile; [2]Pediatric Neurologist. Institution of Nutrition and Food Technology. University of Chile; [3]M.Sc. Nutricionist. Institution of Nutrition and Food Technology. University of Chile; [4]Biochemist. Institution of Nutrition and Food Technology. University of Chile; [5]Medical Technologist. Institution of Nutrition and Food Technology. University of Chile; [6]Psycologist. Institution of Nutrition and Food Technology. University of Chile.

Background and objectives: Phenylketonuria (PKU) is a metabolic disease characterized by increased plasma levels of phenylalanine (Phe) which causes mental retardation. Through the National Neonatal Screening Programme for PKU; 248 cases are diagnosed with classical PKU, 46% of the patients are older than 10 years old, which poses important challenges regarding adherence to treatment and PKU Maternal Syndrome prevention.

Methods: The treatment consists in restricting Phe intake, providing Phe-free formula, medical and nutritional assessments, psychometric (Weschsler Bayley Scale) and biochemical evaluations (MS/MS).

Results: Average age of diagnosis: 17.6 ± 9.5 days, with initial values of Phe: 18.5 ± 8.9 mg / dl and Tyrosine: 1.2 ± 0.7 mg/dl. Current age range (1 month to 24 years). The average diet provides 15.5 ± 10 mg Phe/kg/day, 2.1 ± 0.7 g protein/kg/day (80% of the formula), 1330 ± 441 kcals/ ay. 71% of the PKU patients maintains blood FA values under 6 mg/dl (good metabolic control), there was a significant correlation (p <0.01) with IQ. The 89% of PKU have normal IQ, 9% borderline and 2% boundary slight delay. The 61% have normal nutritional status, 19% are overweight, 15% are obese and 5% is underweight.

Conclusions: The PKU population may show normal growth and development because of neonatal diagnosis and strict long-term follow-up.

Keywords: Phenylketonuria, Metabolic control, Treatment.

Department of Biotechnology and Chemical Technology. Institute of Chemistry. São Paulo State University (UNESP). Brazil.; [7]PhD. Department of Physiology. Bioscience Institute. São Paulo State University (UNESP). Brazil.

Background and objectives: The passion fruit (Passiflora edulis f. flavicarpa Degener) has been studied and several researches works the pharmacological and therapeutic properties both for its calming action and its action in hyperlipidemias. Thus, this work verified the possible relation of passion fruit to a caloric diet and the cholesterol level in rabbits with induced hypercholesterolemia.

Methods: The experiment was carried out in rabbits divided into three groups: G1 (without treatment), G2 (commercial passion fruit treatment) and G3 (remedy treatment - simvastatin). The experimental protocol was divided in three phases: 1) was offered normal ration to evaluate the basal level of cholesterol; 2) was offered supplemented ration with egg yolk to obtain hypercholesterolemia; and 3) continued with supplemented feed and daily G2 and G3 rabbits were treated with pulp and passion fruit seed (30g) and medicine (10g), respectively.

Results: The data indicate a decrease in the average feed intake in the animals of the 3 groups, analyzed during the experiment: G1 was 35.77%, G2 was 38.25% and G3 was 31.01%, but without altering the growth and weight of animals. The results of analyzes of total cholesterol level of the animals showed that in phase 1 it was approximately 80.00mg.dL-1; a significant increase in phase 2 (for 151.2mg.dL-1 in G1, 105,9mg.dL-1 in G2 and 116,1mg.dL-1 in G3); and in stage 3 a reduction to 84.5mg.dL-1 in G2 and to 82.2mg.dL-1 in G3 with treatment, while G1 continued with elevation to 182.7mg.dL-1. The increase in cholesterol level in phase 2 proves that the egg yolk diet was efficient in developing hypercholesterolemia and in phase 3 (in G2 and G3 animals), it is clear that the treatment with passion fruit and with the allopathic medicine reduced plasma cholesterol (21% and 29%, respectively).

Conclusions: Passion fruit intake did not change the weight of the animals as it increased progressively and in the same proportion throughout the experimental phases and may be an alternative in the treatment of high cholesterol compared to conventional treatment.

SALT AS MICRONUTRIENT CARRIER FOR SAVING LIVES AT BIRTH

[1]Di´øsady, Levente László; [2]Mannar, M.G. Venkatesh.

[1]University of Toronto. Canada; [2]Honourary Doctor of Science, Adjunct Professor. Department of Chemical Engineering and Applied Chemistry. University of Toronto. Canada

Background and objectives: Deficiency of micronutrients in the diet is a major contributor to maternal and infant mortality, birth defects and development problems . These widespread deficiencies can be readily addressed through food fortification. Unfortunately a very large proportion of rural poor do not participate in the purchase of processed foods, and are not reached by basic fortification programs for flour, bread etc. Salt is an ideal carrier for micronutrients as it is universally consumed in predictable, uniform quantities. Unfortunately salt cannot be directly fortified with combinations of micronutrients. We developed appropriate technologies for multiple fortification of salt,

Methods: Salt has been fortified with different combinations of iodine, iron, zinc, folic acid, and B vitamins. To prevent interactions among the micronutrients, especially iron and iodine, we developed technologies for microencapsulating iron alone and in combination with zinc and vitamin B12 to form a solid premix that can be admixed to salt. We have developed stable spray solutions that contain iodine, folic acid and other B vitamins that can be sprayed onto salt using currently installed iodization equipment.

Premixes and spray solutions as well as salt prepared with them were stored at elevated temperatures for up to a year.

Results: Stable solid premixes were prepared by extruding ferrous fumarate, colour masking it with titanium dioxide, alone or in combination with zinc oxide, and overcoated with a moisture resistant edible coating . The premix was blended with salt at a ratio of 1:200, and sprayed with the combined spray solutions that were pH adjusted and stabilized

The salts retained <80% of the added iodine and vitamins for at least six months at 45°C, <60% RH.

Conclusions: Salt multiple fortified with stable agglomerated and coated premixes and stable spray solutions can provide 30-100% of critical micronutrients at a cost of ≤25US¢ per person per annum, and can reach populations that do not purchase manufactured food products. Salt is a versatile, simple and inexpensive carrier for micronutrients, when combined with appropriate technologies for maintaining organoleptic qualities of food and stability of micronutrients.

Keywords: Salt, Micronutrients, Deficiencies, Fortification, Premixes.

ASSOCIATION BETWEEN FAT INTAKE AND THE RISK OF BREAST CANCER: A CASE-CONTROL STUDY

[1]Belbraouet, Slimane; [2]Gagnon, Charline; [3]Ouellette, Rodney.

[1]Uiversité de Moncton; [2]MS. Dietitician. Université de Moncton. Canada; [3]PhD. MD. IARC. Moncton. Canada.

Background and objectives: This case-control study aims to evaluate the association between dietary fat intake and the risk of breast cancer (BC).

Methods: The dietary intake assessed using "Food Processor" in 31 women newly diagnosed with BC and 39 healthy women. A descriptive approach collected relevant data such as nutritional status, sociodemographic and anthropometric characteristics, and lifestyle of subjects. Comparisons between cases and controls carried out by simple t-tests and statistical correlations conducted between lipid intake and dietary parameters.

Results: The calorie intake is significantly lower (1699±527 vs. 2221± 799 kcal; $p<0.05$) in the subject group vs the control group. The same results are observed with the averages in the protein intake (75± 30 vs 99±36 g; $p<0.05$), carbohydrates (230±73 vs 294±123 g; $p<0.05$), and dietary fibre (21±11 vs 31±14 g; $p<0.05$). No significant association between dietary fat intake and the risk of breast cancer is observed: total fatty acids (68 ± 31 vs 77±36 g), saturated fatty acids (19±12 vs 21±11 g), monounsaturated fatty acids (23±13 vs 27±17 g), polyunsaturated fatty acids (12±8 vs 14± 9 g), or cholesterol (213±177 vs 225±130 mg).

Conclusions: Our results do not support a positive relationship between fat intake and BC.

Keywords: Lipid intake, Dietary assessment, Breast cancer.

IS THE TIME SPENT FETCHING WATER ASSOCIATED WITH CHILDREN'S ANTHROPOMETRIC INDICATORS STATUS? A COMPARATIVE STUDY OF ETHIOPIAN, MALAWIAN AND ZAMBIAN MOTHERS WITH CHILDREN UNDER 5

Ahmadi, Davod; Sinclair, Kate; Cortbaoui, Patrick; Melgar-Quiñonez, Hugo.

McGill University.

Background and objectives: Women's access to water and the time they spent carrying water have implications for maternal and child health status; however, little is known about the association between mothers' time fetching water and children anthropometric indicator status. This study aims to fill the existing knowledge gap.

Methods: The main objective of this paper is to study the association between the amount of time mothers spent carrying water and children anthropometric indicators such as, wasting, stunting, underweight and BMI for age.

Data from three surveys carried out in Ethiopia on 2016, Malawi and Zambia on 2017 were used in this article.

Different statistical analyses such as, descriptive, bivariate and linear regression analyses were used to examine the association between the time mothers spent fetching water and each of anthropomeric indicator status by adjusting children's sex, age, community water supply and mothers' decision making.

Results: Findings of unadjusted linear regression analyses showed negative associations between the time spent fetching water and wasting, stunting, and underweight. But, results of adjusted model revealed that time spent of carrying water is not the final determinant of anthropometric indicators, and children's sex, age, and mothers' decision making were significantly associated with stunting, wasting, and underweight.

Conclusions: Overall, our study found that children's characteristics and maternal decision making influence the anthropometric indicators.

Keywords: Water access, Time fetching water, Children's anthropometric indicators, Ethiopia, Malawi, and Zambia.

ASSOCIATION OF SALT AND POTASSIUM INTAKE ASSESSED BY URINARY EXCRETION OVER 24-HOUR AND BLOOD PRESSURE: A CROSS-SECTIONAL ANALYSIS FROM A POPULATION COHORT

[1]Moliterno, Paula; [2]Boggia, José; [3]Olascoaga, Alicia; [4]Luzardo, Leonella; [5]Marino Donangelo, Carmen; [6]Noboa, Oscar.

[1]MSc. Nutritionist. Escuela de Nutrición. Universidad de la República. Uruguay.; [2]PhD. MD. Departamento de Fisiopatología. Hospital de Clínicas. Universidad de la República. Uruguay.; [3]MD. Laboratorio de Patología Clínica. Hospital de Clínicas. Universidad de la República. Uruguay.; [4]MSc. MD. Departamento de Fisiopatología. Hospital de Clínicas. Universidad de la República. Uruguay.; [5]PhD. Escuela de Nutrición. Universidad de la República. Uruguay.; [6]MD. Centro de Nefrología. Hospital de Clínicas. Universidad de la República. Uruguay.

Background and objectives: Globally, a positive association between sodium consumption and blood pressure has been pointed out. Therefore salt reduction has been recommended as a strategy to reduce population BP levels. Twenty four hour urinary sodium analysis is considered the "gold standard" to estimate sodium consumption, although collection is difficult and cumbersome. In Uruguay, consumption of salt is estimated from national dietary surveys, without considering potassium. The aim of this study is to assess sodium and potassium urinary excretion as surrogate of salt and potassium intake and its main dietary sources in a local population sample, and its relationship with blood pressure.

Methods: Participants form GEFA (Genotype Phenotype and Environment of Hypertension in Uruguay) Study recruited until September 2016 were included. Electrolytes excretion was measured from 24-hour urinary collection, and creatinine excretion (mg/Kg/day) used to validate completeness of urine collection (>13 in women, >15 in men). Blood pressure was considered average of 5 consecutive conventional measurements. Dietary sources of electrolytes were assessed using a food frequency questionnaire.

Results: Form 394 recruited participants, 350(89%) complete urinary collection. From these, only 176(50%) completed valid urine collection. Table shows principal characteristics.

Sodium intake >2g/day was present in 92% of participants (men: 97%; women: 87%). Main dietary sources of sodium were processed meats (21%), sausages (12%) and bread (24%). Most of participants (93%) had potassium intake below 3.5 g/day, being major sources: mate (ilex paraguariensis) drink (29%), milk (13%) and meats (10%). Multivariable analysis in participants without hypertension treatment (n=137), showed a positive association between sodium intake (adjusted by age, sex) and systolic (r=0.18, P=0.033) or diastolic (r=0.21,P=0.011). Linear regression showed per each gram of sodium intake, an increase in systolic and diastolic blood pressure by 1.6 (R2= 0.22, P=0.032) and 1.2 mmHg (R2= 0.15,P=0.011) respectively. Potassium intake and systolic blood pressure were not associated (r=0.11,P=0.17): a trend was observed for diastolic blood pressure (r=0.17, P=0.05).

Conclusions: Less than 50% of participants completed valid urinary collection. Mean salt intake (9.2 g/day) was lower than world estimates (~9.9g/day). Nevertheless, mean sodium intake was over and potassium intake below WHO recommendations. A positive association was found between sodium intake and blood pressure.

Keywords: Urinary sodium, Urinary potassium, Intake, Blood pressure.

DEFINITION AND INDICATORS OF ADHERENCE TO NUTRITIONAL TREATMENT IN PATIENTS WITH METABOLIC SYNDROME

[1]Saravia, Luisa; [2]Ibáñez, Ana.

[1]Nutritionist. MSc. School of Nutrition. University of La Republica. Montevideo. Uruguay; [2]Psychologist. MSc. School of Nutrition. University of La República. Montevideo. Uruguay.

Background and objectives: Backgrounds and objectives: In recent years, diseases related to lifestyle, especially obesity and associated non-communicable diseases (NCDs), have reached global epidemic levels. Adherence to nutritional treatment, as well as other preventive actions, may help modifications of lifestyle-dependent risk factors that could control these diseases. The aim of the study is to define the adherence to nutritional treatment in patients with metabolic syndrome identifying the indicators that measure adherence to treatment.

Methods: Delphi´s Method was the investigation technique use for the study. 24 experts in non-chronicle diseases nutritionists begin the process, 16 finish it. Four consultation instances were held. The first one required a definition of the experts of what is nutritional treatment adherence in patients with metabolic syndrome. Based on the answers, the researchers elaborated three definitions and a list of contributions to the topic that were, in a second query, put into experts consideration. In the third query, a consensual definition was created. In addition, a list of indicators was requested. In the fourth query, agreement or suggestions of the indicators list were requested.

Results: An adherence to nutritional treatment definition was obtained, including the patient's perspective, the personalized treatment performed by the professional and the indicators that allow adherence to be measured.

Conclusions: The obtained definition and the indicators allowing adherence assessment will enable an instrument that facilitate patience adherence to nutritional treatment.

Keywords: Nutritional treatment adherence, Metabolic syndrome patients, Delphi´s Method.

HOSPITAL MENU: ASSESSMENT OF NUTRIENT COMPOSITION AND PATIENT SATISFACTION

[1]Garcia, Alicia C; [2]Greig, Susan; [3]Hekmat, Sharareh.

[1]PhD. Registered Dietitian. School of Food and Nutritional Sciences. Bresica University College. Western University. Ontario. Canada; [2]MScFN. HBSc. MBA. RD. School of Food and Nutritional Sciences. Brescia University College. Western University. Ontario. Canada.; [3]PhD. Food Scientist. School of Food and Nutritional Sciences. Brescia University College. Western University. Ontario. Canada.

Background and objectives: At best, menus fail to be noticed by administrators and ministries when determining overall satisfaction of a patient's hospital experience. Patient satisfaction with hospital food enhances consumption to facilitate adequate intake of nutrients required for recovery. The nutrient content of the menu must balance patient preferences. This study of Ontario hospital foodservice departments determined the prevalence/frequency and methods of menu analysis, nutrients assessed and criteria to determine and provide amounts required for health or foster recovery from illness/injury, methods and frequency of assessing patient satisfaction.

Methods: A review of manuscripts, government documents on hospital services, hospital resources and popular media identified current practices and focused on legislation/standards for menu planning. Survey questions were then developed based on perceived gaps and the researchers' work experiences. Foodservice managers and directors from 57 Ontario hospitals were included in a cross-sectional in-depth telephone survey. Respondents were asked close- and open-ended questions to explore barriers, issues and priorities. Responses to open-ended questions were captured in an Excel spreadsheet and deductive analysis was done to supplement quantitative data.

Results: Of the 140 hospital corporations, 45 foodservice managers from academic hospitals, hospitals with <100 beds and hospitals with ≥100 beds participated in the survey together with 12 managers working in hospitals governing long-term care facilities. Findings indicate that more than or almost half of the hospitals assessed regular, therapeutic and texture modified menus for nutritional adequacy. This differed from hospitals governing long term care facilities where 75 % of regular menus were assessed. Most departments obtained patient satisfaction feedback at departmental and corporate levels.

Conclusions: Inconsistency in practice disables foodservice leaders to identify trends or compare their results to similar facilities. They are challenged to provide high quality regular, therapeutic and texture modified menus for patient satisfaction and quality nutritional care within available resources and nutritional standards. The study suggests the importance of establishing evidence-based standards for assessing nutritional adequacy and patient preferences in Ontario hospitals to assist foodservice leaders in creating or modifying hospital menus.

Keywords: Hospital foodservice, Patient satisfaction, Hospital menu analysis, Long-term care menus, Nutritional adequacy.

PREDICTIVE EQUATIONS FOR INDIAN WOMEN TO CALCULATE BODY FAT PERCENT (BF%)

[1]Sinha, Srishti; [2]Verma, Lalita; [2]Nigam, Shailly.

[1]MSc. Nutritionist. Department of Food and Nutrition. Lady Irwin College. University of Delhi. India; [2]PhD. Assistant Professor. Department of Food and Nutrition. Lady Irwin College. University of Delhi. India.

Background and objectives: Obesity is defined as a condition with an excess accumulation of fat in the body. There are various tools and techniques to assess body fat i.e. laboratory methods and anthropometric indices. The latter has benefit over laboratory techniques as they are simple to use in field setting. However, the accuracy of the same in estimating BF% is debatable. Therefore, the objective of present study was to develop predictive equations using anthropometric measurements to calculate BF%.

Methods: A cross-sectional study was conducted in South Delhi area on 320 subjects (through purposive sampling). The women who were pregnant, habitual smoker, morbidly obese, suffering from thyroid disorder or any other persistent health problem and having irregular menstrual cycle were excluded from the study. The data was collected on basic descriptives, height, weight, waist circumference (WC), hip circumference (HC) and BF% (assessed using Bioelectrical Impedance Analysis method – BIA) of the subjects. The multiple linear regression analysis was done on 261 subjects using SPSS 23.0 version.

Results: The results from Kolmogorov-Smirnov Test showed that the data was normally distributed under the study. The predictive equations were formulated from multiple regression analysis using anthropometric measurements which are highly correlated with BF% (p-value < 0.05). These are:

BF% = (0.444*WC) + (0.065*Age) – 5.204
BF% = (0.506*HC) + (0.149*Age) – 20.970
BF% = (0.584*Height) + (-0.478*Weight) + 74.299

From the regression analysis it was evident that 90.8% variation in BF% was attributed by height and weight of an individual.

Conclusions: The study developed predictive equations for Indian women using anthropometric measurements that can provide an estimate of BF% more effectively than anthropometric indices like BMI, FMI etc. The combination of anthropometric measurements and age provides good combinations that are not only easy to measure but also these can be used in clinical and anthropometric studies.

Keywords: Body Fat Percent (BF%), Predictive equations

IMPLEMENTATION OF NUTRITION-SENSITIVE AGRICULTURE IN THE CENTRAL PROVINCE OF ZAMBIA

[1]Chipili, Given; [2]Msuya, John.

[1]Mukuba University,Department of Nutrition Sciences. Kitwe. Zambia.; [2]Morogoro.

Background and objectives: The Central Province of Zambia contains the majority of the nation's malnourished children, despite being the most productive province in terms of Agriculture. Most studies in the province have not paid attention to the linkages between agriculture performance and nutrition outcomes of the population. In light of this knowledge gap, this study focused on the linkage between nutrition and agriculture. In 2010 the Ministry of Agriculture in the Central Province while working with Non-Governmental Organizations (NGOs), the Ministry of Health and the Ministry of Education started a pilot project in Kapiri-Mponshi on Orange fleshed Sweet Potatoes and Orange Maize and educating farmers on the importance of crop diversity.

Methods: The study assessed the extent to which the small scale farmers are implementing the best practices of nutrition-sensitive agriculture in the Central Province. This study sought to determine the association of crop diversity and nutritional status of children aged 6-59 months in Kapiri-Mposhi district in the Central Province of Zambia. A cross-sectional descriptive study was conducted using a structured questionnaire. A total of 365 households were randomly sampled and the nutritional status of one child from each household assessed using anthropometric measurements. A total of 100 children were included in the study.

Results: Up to 21% of the children were stunted; 2% were wasted; and 9% underweight. There was a significant relationship between crops grown in households (ground nuts, mangoes and orange-fleshed sweet potatoes) and Z-scores for stunting (HAZ) and underweight (WAZ) (p<0.05).

Conclusions: This study has established that farmers may not diversify if they have high market demands on the staple.

Keywords: Agriculture, Crop diversity, Children, Nutrition.

CAUSAL ANALYSIS OF UNDER-NUTRITION IN JEJU AND MELKA BELO DISTRICTS OF OROMIA REGION OF ETHIOPIA

[1]Asamo, Feleke Milikias; [2]Kassa, Yohannes Chanyalew; [3]Boltana, Sisay Sinamo; [4]Teshale, Alemshet Aschalew; [5]Dibaba, Asrat.

[1]BSc.MPH.Nutrition specialist.World vision Ethiopia; [2]MSc. MD.Health and Nutrition Manager. World vision Ethiopia; [3]MPH. MD.Health and Nutrition Senior Technical Advisor. World vision East Africa regional office; [4]BSc.MPH. Nutrition specialist. World vision Ethiopia; [5]MPH.MD.Director of Health. World vision International East Africa region.

Background and objectives: Under-nutrition has been one of the main health problems in Ethiopia. The poor nutritional status in children and women is a consequence of multiple factors. Mainly, inadequate nutrient intake and illness and some underlying conditions being compounded by factors related to socioeconomic conditions. World Vision Ethiopia has been supporting both districts with various emergency relief and development projects. However, the districts faced concurrent malnutrition problems and often classified as hot spot 1 and 2. The current study was, therefore, to assess the magnitude of under nutrition in children 6–59 months and to identify key factors and generate evidence-based responses to address the determinants.

Methods: Both quantitative and qualitative data collection methods were applied. For quantitative data, household questionnaire was used in selected 640 households and for qualitative, 20 key informant interviews and 13 Focused Group discussions (FGD) along with secondary data review were carried out. ENA and SPSS softwares were used for cluster selection, data entry and analysis.

Results: The result of SMART study showed that the assessed areas had a high prevalence of malnutrition. The prevalence of Global Acute Malnutrition (GAM) was estimated at 16.4%, with Severe Acute Malnutrition (SAM) 4.1 % and stunting, 33.2 %.

It was found that, 55% of mothers expressed and disposed colostrum thinking that it is not good and over 77% of children were introduced complementary foods late. The mean dietary diversity score was 4.9 and 94% of children never consumed meat and and only 30% consumed vegetables and 24% fruits. More than 35% drink water from unprotected sources and 62.5% of them do not treat. About 56% reported that they had less than 1 hectare farmland.

Conclusions: Under nutrition is one of the most important public health problem in the study area. Despite the long years intervention, GAM and SAM rate was still at serious stage. The factors significantly related with wasting and stunting include high maternal illiteracy rate, shortage of farmland, poor child care practices, insufficient agricultural production, poor diet diversity, poor hygiene and sanitation practices, which all need to be given due attention to define priorities for action.

Keywords: Wasting, Stunting, Complementary feeding, Diet diversity, Severe Acute Malnutrition, Breastfeeding.

ASSOCIATION BETWEEN MANGANESE INTAKE AND BODY MASS INDEX IN A POPULATION BASED SURVEY IN SÃO PAULO, BRAZIL

[1]Marchioni, Dirce; [2]Macedo Silva, Alexsandro; [3]Gorgulho, Bartira; [4]Fisberg, Regina.

[1]Professor. Nutritionist. Department of Nutrition. University of São Paulo. Brazil; [2]PhD Student. Pharmacist. Department of Nutrition. University of São Paulo. Brazil; [3]PhD. Nutritionist. Department of Nutrition. University of São Paulo. Brazil.; [4]Professor. Nutritionist. Department of Nutrition. University of São Paulo. Brazil.

Background and objectives: Manganese plays an essential role in metabolism, activating mitochondrial enzymes, especially those involved in β-oxidation. The functional impairments of this pathway may lead to incomplete catabolism of amino acids, and promote triglycerides synthesis, consequently, increasing adipose tissue. The aim of this work was to investigate the association between manganese intake and obesity in a population-based study.

Methods: The dietary intake data, a 24hR of 832 adolescents and adults, were obtained from the "Health Survey of São Paulo" (ISA-Capital 2008), a population based cross-sectional survey in Brazil. Linear regression was used to verify the relationship between manganese intake and Body Mass Index (BMI), adjusting by energy intake, age, sex, race, and physical activity. In this model, the energy adjusted manganese intake (independent variable) was log-transformed. It was considered the p-value ≤ 0.05 for statistical significance. The multicollinearity between the predictors variables were verified by the variation inflation factor (VIF).

Results: Manganese intake was negatively associated with BMI (β= -1.30; p=0.031, VIF=1.46), suggesting a BMI decrease of 0.013 units for every one percent increase in manganese intake.

Conclusions: In conclusion, considering the relationship with manganese and mitochondrial metabolism, the low manganese intake could make changes in the metabolism of carbohydrate, cholesterol, and amino acids, by impairing the manganese metalloenzyme activity. These metabolism changes could reflect the metabolism alteration related to the obesity.

Keywords: Manganese intake. Body Mass Index. Obesity. Metabolism.

SUBJECTIVE GLOBAL ASSESSMENT FOR THE DIAGNOSIS OF PROTEIN–ENERGY WASTING IN PERITONEAL DIALYSIS PATIENTS

[1]Hung-Lien, Wu; [2]Ming-Cheng, Wang; [3]Yu-Wei, Wang; [4]Chin-Chung, Tseng; [2]Junne-Ming, Sung.

[1]PhD. Nutritionist. Department of Nutrition. National Cheng Kung University Hospital. College of Medicine. National Cheng Kung University. Tainan. Taiwan.; [2]MD. Divison of Nephrology. Department of Internal Medicine. National Cheng Kung University Hospital. College of Medicine. National Cheng Kung University. Tainan. Taiwan.; [3]BSc. Nurse. Divison of Nephrology. Department of Internal Medicine. National Cheng Kung University Hospital. College of Medicine. National Cheng Kung University. Tainan. Taiwan.; [4]PhD.MD. Divison of Nephrology. Department of Internal Medicine. National Cheng Kung University Hospital. College of Medicine. National Cheng Kung University. Tainan. Taiwan.

Background and objectives: Subjective global assessment (SGA) has been demonstrated to be a reliable method for protein–energy wasting (PEW) in CKD patients. Few data are available on PEW evaluation in chronic peritoneal dialysis (CPD) patients. This study has two purposes, (1) the prevalence of PEW by 7 point SGA; (2) the correlation between SGA and PEW.

Methods: This study enrolled 146 patients (71 males and 75 females) from the PD unit of National Cheng Kung University Hospital, Tainan, Taiwan. Patients were divided into a PEW and non-PEW groups. We measured anthropometric, 7-points SGA, biochemical parameters, body composition.

Results: PEW was present in 57 (39%) patients, Among the SGA components, the most frequent abnormality in patients with PEW were appetite, GI function, activity, stress, muscle score, and total SGA score (P< 0.0001). Hb, HCT%, serum albumin, potassium, uric acid were lower in PEW (P< 0.05). In body composition, lower fat% and higher water % of total body and lean mass in PEW patients (P< 0.05). 32 patients with severe and mild malnutrition (SGA 2~4 score) had 24 (75%) patients with PEW, 46 patients with SGA 5 score had 21(46%) patients with PEW, 68 patients with SGA 6~7 score had12 (18%) with PEW.

Conclusions: The prevalence of PEW was 39% in our CPD patients, malnutrition from SGA score can reflect the status of PEW in CPD patients.

Keywords: Subjective global assessment, Protein–energy wasting, Chronic peritoneal dialysis.

Conflict of Interest Disclosure: Subjective global assessment is a very practical method in assessing overall nutrition and protein-energy wasting. it can be fast and easy diagnosis for protein-energy wasting in diialysis patients. Subjective global assessment is promoted and practical method in peritoneal dialysis patients.

HOW DIFFERENT IS THE DIET OF OBESE PATIENTS COMPARED TO THE NORMAL WEIGHT PEOPLE?

[1]Posea, Mihaela-Cameia; [2]Dragomir, Andreea Diana; [3]Radulian, Gabriela.

[1]Md. Phd. . Diabetes Nutrition and Metabolic Diseases. Smart Nutrition Clinic. Bucharest. Romania; [2]MD. 2- MD. Diabetes Nutrition and Metabolic Diseases. University of Medicine and Pharmacy "Carol Davila ". Bucharest. Romania; [3]3- MD. PhD. Diabetes Nutrition and Metabolic Diseases. National Institute of Diabetes, Nutrition and Metabolic Diseases "N. C. Paulescu", Bucharest, Romania.

Background and objectives: According to World Obesity Federation, in 2025 there will be 2.7 billion adults suffering from overweight and obesity, up from 2 billion in 2014. We need to see how different is the diet of obese patients compared to normal weight subjects in order to make adequate nutritional advises to obtain or to maintain a healthy weight and diet.

Methods: A sample of 199 subjects, 54 normal weight patients and 145 obese people were investigated. Anthropometric and paraclinic data, biological samples and nutritional assessment were made. Using a 7-day food self-recorded questionnaire, we evaluated the nutritional content of food intake: carbohydrates, proteins, lipids, vitamins A, B1, B2, B3, B5, B6, B12, C, D, E, folic acid, and minerals like calcium, iron, magnesium, phosphorus, zinc, copper, manganese, selenium, and sodium. We measured resting metabolic rate using the indirect calorimetry.

Results: As we expected, the differences between the two samples were regarding the weight, body mass index, body fat, percent of body fat, the resting metabolic rate, abdominal circumference and blood pressure.

We found plasma HDL cholesterol in normal ranges more frequently in patients with normal body weight compared to obese subjects (78.79% vs 58.47%, p = 0.03). In 3.81 % of obese patients we found a small, significant, negative correlation between the HDL cholesterol plasma levels and the intake of iron from diet.

All the patients had a high fat, high protein, low carb diet, without significant differences between the two groups.

Regarding the vitamins, the only significant differences were about the mean intake of B1 (thiamine) and B3 (niacin) vitamins.

Obese subjects consumed higher amounts of phosphorus, iron, copper and selenium.

Conclusions: None of the patients, neither normal-weight nor obese, had a balanced diet regarding the intake of macro-nutrients, vitamins and minerals. There are some significant differences between the groups regarding micro-nutrients but not regarding macro-nutrients.

We need to pay more attention to nutritional recommendation in both normal weight and obese people in order to not exceed the recommended daily doses.

Keywords: Obese, Diet, Vitamins, Minerals, Normalweight.

ASSOCIATION BETWEEN DIETARY SERINE IN- TAKES AND TYPE 2 DIABETES AMONG CHINESE ADULTS IN HARBIN, CHINA

[1]Okekunle, Akinkunmi Paul; [2]Hao, Ma; [3]Liu, Liyan; [4]Wu, Xiaoyan; [3]Li, Yanchuan; [3]Na, Lixin; [3]Li, Songtao; [5]Feng, Rennan; [6]Li, Ying; [7]Sun, Chang Hao.

[1]Doctoral Student. Department of Nutrition and Food Hygiene. Harbin Medical University. China.; [2]Doctoral Student. Department of Nutrition and Food Hygiene. College of Public Health. Harbin Medical University. PRC; [3]PhD. Nutritionist. Department of Nutrition and Food Hygiene. College of Public Health. Harbin Medical University. PRC; [4]PhD. Statistician and Epidemiologist. Department of Nutrition and Food Hygiene. College of Public Health. Harbin Medical University. PRC; [5]PhD. Senior Scientist. National Key Discipline. Department of Nutrition and Food Hygiene. College of Public Health. Harbin Medical University. PRC; [6]Professor/Head. Department of Nutrition and Food Hygiene. College of Public Health. Harbin Medical University. PRC; [7]Professor/Dean College of Public Health. Harbin Medical University. PRC.

Background and objectives: Serine (Ser) is a non-essential amino acid associated with metabolic disorders. For example, significantly lower levels of serum Ser has been reported among Type 2 diabetes (T2D) subjects. However, the relationship between dietary Ser intakes (DSI) and risk of T2D is scarcely known. In this study, we evaluated DSI and risk of T2D among normal weight Chinese adults.

Methods: 3006 adults (BMI<24.00kg/m2 and WC<85cm (men)/< 80cm (women)) from the Harbin Cohort Study on Diet, Nutrition and Chronic Non-Communicable Diseases Study (HDN-NCDS) initiated 2010 in Harbin, China participated after duly informed consent. Socio-demographic and lifestyle characteristics (SLCs), anthropometry, habitual dietary intake in the last 12 months preceding the study and fasting blood samples were assessed using standard methods. Ser and nutrient intakes of food item consumed were evaluated by multiplying the mean daily consumption of each food by Ser content of a specified amount according to the Chinese food composition table and adjusted for total energy intake using the residual method. T2D was defined as respondents self-reporting diagnosis of T2D (or on glucose lowering medications) and/or FBG ≥ 7.0mmol/L or 2h-PG ≥ 11.1mmol/L (ADA criteria). SLCs were compared across quartiles of DSI, odds ratio (OR) and 95% confidence interval (CI) of T2D status by quartiles of DSI was assessed using logistic regression at P<0.05.

Results: Prevalence of T2D among men (13.0%) was significantly higher ($\chi 2$=14.8, P=0.000) compared to women (8.0%). Mean age was insignificantly different (F=1.68, p=0.168) across quartiles of DSI. Mean±SD of DSI among men (3.43±1.54g/day) was significantly higher (t=6.04, P=0.000) compared to women (3.01±1.43g/day). With adjustment for potential dietary (energy and protein intakes) and non-dietary (age, education, smoking, alcohol intake, physical activity, and family history of T2D) confounders, OR (95% CI) of T2D status among subjects in the 4th quartile of DSI (1st quartile as reference) were 1.060(0.358–3.135);

P=0.916 and 2.220 (1.117–4.413); P=0.023 among men and women respectively.

Conclusions: Our data suggests higher DSI appears associated with higher prevalence of T2D, especially among women. Further studies are necessary to explore the role DSI in T2D.

Keywords: Dietary Serine Intakes, Type 2 Diabetes, Logistic regression, China.

TEST-RETEST REPRODUCIBILITY OF DIETARY PATTERNS ASSESSED WITH A FOOD FREQUEN- CY QUESTIONNAIRE (KOMPAN): STUDY IN POL- ISH ADOLESCENTS AND ADULTS

[1]Kowalkowska, Joanna; [2]Wadolowska, Lidia; [3]Czarnocinska, Jolanta; [4]Czlapka-Matyasik, Magdalena; [4]Galinski, Grzegorz; [5]Jezewska-Zychowicz, Marzena; [6]Bronkowska, Monika; [7]Dlugosz, Anna; [7]Loboda, Dorota; [6]Wyka, Joanna.

[1]MSc. Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland.; [2]Prof. Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland.; [3]Assoc. Prof. Faculty of Food Science and Nutrition. Poznan University of Life Sciences. Poland.; [4]PhD. Faculty of Food Science and Nutrition. Poznan University of Life Sciences. Poland.; [5]Prof. Faculty of Human Nutrition and Consumer Sciences. Warsaw University of Life Sciences. Poland.; [6]Prof. Faculty of Food Science. Wrocław University of Environmental and Life Sciences. Poland.; [7]PhD. Faculty of Studies Applied. University of Economy. Poland.

Background and objectives: Deriving and interpreting dietary patterns (DPs) is a common approach to assess the diet-disease relationship[1,2]. Estimation of the reproducibility of each newly developed questionnaire is necessary. The aim of the study was an assessment of the test-retest reproducibility of dietary patterns assessed with a food frequency questionnaire (KomPAN).

Methods: The study involved 517 subjects aged 15-64 years. The self-administered KomPAN was used. The interview was repeated after two weeks. The consumption frequency of 33 food groups was analysed. Dietary patterns (DPs) were derived by PCA.

Results: Two major DPs were identified and were similar in both FFQs (test-retest). The Prudent DP was characterized by high frequency of consumption: fermented milk drinks, cottage cheese, vegetables, fruit, cereals, fish, legumes, wholemeal bread, milk, refined grains, water; while the Westernised-Polish DP was characterized by high frequency of consumption: sweetened beverages, instant soups, fried foods, potatoes, energy drinks, cheese, red meat, white bread. Agreement of tertile categorization in test-retest responses was 73.1% for Prudent, 72.0% for Westernised-Polish. Misclassification to the extreme tertile categories for both DPs was 2.1% and 3.5%.

Conclusions: We found good test-retest reproducibility of both DPs derived from the FFQ data. The KomPAN questionnaire is an adequate tool to use in nutritional epidemiologic studies among Poles.

ANTHROPOMETRIC INDICES AND THE EFFECT OF EXERCISE ON SOME URINARY ANALYSIS AMONG ADOLESCENTS IN SECONDARY SCHOOLS IN NSUKKA LOCAL GOVERNMENT AREA, ENUGU STATE, NIGERIA

[1]*Mbah, Obioma;* [2]*Eme, Paul;* [3]*Ozoemena, Eyiuche Chinenye.*

[1]PhD. Lecturer. Department of Nutrition and Dietetics. University of Nigeria, Nsukka. Nigeria; [2]MSc. School of Public Health. Massey University. New Zealand; [3]B.Sc. Department of Nutrition and Dietetics. University of Nigeria, Nsukka. Nigeria.

Background and objectives: Anthropometrics can be a sensitive indicator of health, growth and development in infants and children. Exercise physiology is concerned with the description and explanation of the changes that occur in human body during single or repeated bouts of muscular exercise.This study was aimed at assessing the anthropometric indices and the effect of exercise on some urinary analysis among adolescents in secondary schools in Nsukka Local Government Area.

Methods: A cross-sectional survey design was employed. A multistage sampling technique was used to select 200 adolescents aged 10-19 years from 8 (3 boys and 5 girls) secondary schools. They were randomly selected without replacement. Questionnaire was used to obtain information on the socio-economic status, food consumption pattern and physical activity level (PAL) of the subjects. Anthropometric measurements (weight, height, waist and hip circumferences) of the adolescents were obtained using standard procedures. Body Mass Index and waist-hip ratio were used as an indicator of obesity in terms of over fatness. The measurements were calculated and compared with WHO (2007) reference standard. Data obtained were coded and entered into the computer and analyzed using the Statistical Product for Service Solution (SPSS), version 21. Descriptive statistics (frequencies, percentages, means and standard deviation) were used to examine the anthropometric indices.

Results: About 13% of the respondents were overweight, 5% was severely underweight and 1% was obese. More than a quarter (28.5%) of respondents was at risk of abdominal obesity. All of the boys and 96% of girls were hypervolemic before exercise and after exercise. All the respondents had hypernatremia. Only 8% and 4% of girls showed the presence of impairment of renal function and were hypoalbuminemic before and after exercise. Eight percent of boys and 28% of girls were microalbuminemic before exercise while 78% boys and 20% girls were microalbuminemic after exercise.

Conclusions: Malnutrition prevalence exists amongst the adolescents. Urinalysis results of the adolescents showed some abnormality in the urine before and after the excercise.

Keywords: Urinalysis, Adolescents, Anthropometry, Exercise, Effect.

MEASURING ADIPOSITY AMONG WOMEN IN NAROK COUNTY, KENYA: COMPARISON BETWEEN BODY MASS INDEX, WAIST-HIP RATIO, WAIST CIRCUMFERENCE, FAT MASS INDEX AND PERCENTAGE FAT MASS

[1]*Keino, Susan;* [2]*Plasqui, Guy;* [3]*van den Borne, Bart.*

[1]PhD, Nutritionist. Moi University, College of Health Sciences, School of Public Health, Department of Human Nutrition, Eldoret, Kenya; [2]PhD, Human Biologist, School for Nutrition, Toxicology & Metabolism. Maastricht University. Maastricht. The Netherlands.; [3]Professor, Health Promotion, Department of Health Education & Promotion. Faculty of Medicine & Life Sciences. Maastricht University. Maastricht. The Netherlands.

Background and objectives: There is an increase in the prevalence of overweight and obesity among women in sub-Saharan Africa and there is need for a reliable and validated measure to provide the policy makers with data for timely intervention. Body mass index (BMI), waist circumference (WC), waist-hip ratio (WHR), percentage fat mass (%FM) and fat mass index (FMI) are some of the measures of adiposity. Objective: The aim of this study was to assess overweight using the different measures and to evaluate the association between these measures of adiposity to guide measurements among women in Kenya.

Methods: Our study sample was selected randomly among women aged 15-45 years. Anthropometric measurements were taken to assess BMI, WC, WHR and deterium oxide dilution solution was used to measure total body water and to assess body composition (% FM and FMI).

Results: Using WC as a measure of adiposity, the numbers of overweight women was high (46.4%) compared to BMI (21.4%) and WHR and FMI which had the same results (28.6%). Overweight was high among married and older women in all measures. Post primary education indicated significantly higher overweight than those with less education using BMI (p<0.05), FM (p<0.01) and FMI (p<0.005). FMI and FM correlated significantly with all the other measures (p<0.001) except WHR. Regression coefficients indicated a stronger association between BMI and all other measures (p< 0.001) except WHR (r2 = .15, p<0.05).

Conclusions: More than one measure is needed to assess overweight among women where proper cut-off points are not available.

Keywords: Body mass index, Fat mass, Adiposity, Sub-Saharan Africa, Women.

Universidade Federal do Rio Grande do Sul . Brasil.

Background and objectives: Assessment of basal metabolic rate (BMR) is a fundamental activity in clinical dietetic practice. The aim of this study was to investigate the predictive equations which BMR are the best alternatives to the indirect calorimetry (IC) in patients with Diabetes Mellitus (DM) type 2.

Methods: Diagnostic test study in 21 patients with type 2 diabetes [age 62 (48-70) years; diabetes duration 8 (2-36) years; 52.4% of females]. Patients underwent clinical and laboratory evaluations. The body composition was measured by absorptiometry dual X-ray emission and BMR by IC. BMR was also tested by seven equations based on the age, weight, height, fat mass and glycemic control. Statistical analysis included paired t tests, correlation coefficients and Bland–Altman plots.

Results: Our results demonstrated a wide variation in the accuracy of BMR predictive equations and the CI. The equations reported by Harris-Benedict, Oxford and FAO / WHO / UNO were the ones with the lowest significant differences in relation to IC and presented a bias <8%. However, the equation that most closely approached the real BMR measured by CI was that proposed by FAO / WHO / UNO, underestimating -5.4% Kcal / day.

Conclusions: In patients with type 2 diabetes, the present study indicates that the equation of the FAO / WHO / UNO which includes gender, age and weight in the equation was the one closest to the BMR values measured by CI.

Keywords: Indirect Calorimetry; Basal Metabolic Rate; Type 2 Diabetes Mellitus.

NUTRITIONAL STATUS AND FUNCTIONAL CAPACITY IN HOSPITALIZED ONCOLOGICAL PATIENTS

[1]Steemburgo, Thais; [2]Averbuch, Natalia; [3]Hannah Belin, Christy; [4]Beatriz Behling, Estela.

[1]PhD. Profesor. Department of Nutrition. Universidade Federal do Rio Grande do Sul. Hospital de Clínicas de Porto Alegre. Brasil.; [2]Nutritionist. Department of Nutrition. Universidade Federal do Rio Grande do Sul. Brasil; [3]Nutrition student. Department of Nutrition. Universidade Federal do Rio Grande do Sul. Brasil; [4]Profesor. Department of Nutrition. Universidade Federal do Rio Grande do Sul. Hospital de Clínicas de Porto Alegre. Brasil.

Background and objectives: Malnutrition is an important and prevalent dysfunction in cancer patients. Methods of nutritional assessment and functional capacity can identify the nutritional status by collaborating for a more adequate and early nutritional therapy in these patients. The aim of study was to evaluate the nutritional status and functional capacity of adults hospitalized oncological patients.

Methods: Cross-sectional study in 54 hospitalized patients. Patients were evaluated according to the presence of Solid Tumors (ST) and Hematologic Tumors (HT). The nutritional status was identified by Subjective Global (SGA) and Patient-Generated Subjective Global Assessment (PG-SGA) and functional capacity by the Handgrip Strength (HGS) and the Performance Status of the Eastern Cooperative Oncology Group (PS-ECOG). Kappa concordance and Sperman correlation tests were performed to evaluate the results.

Results: Patients had 52.3 ± 17 years old and 35.2% female. SGA showed that patients with HT had a higher prevalence of malnutrition when compared to ST patients (71.4 vs. 16.7%, respectively; p = 0.001). On the other hand, PG-SGA identified a high prevalence of malnutrition in both ST patients (51.4%) and HT patients (44.0%). Functional capacity instruments demonstrated that 35.2% of the patients had reduced HGS and that 33.3% had significant functional limitation (PS-ECOG ≥2). The agreement analysis identified a strong and significant agreement between the SGA and PG-SGA nutritional assessment methods (Kappa = 0.634, p <0.001). However, it did not observe agreement of the methods of nutritional evaluation with the HGS. Among the instruments for assessing functional capacity, HGS and PS-ECOG, a statistically significant correlation was found (r = 0,136; p = 0.028).

Conclusions: In hospitalized oncological patients, regardless of tumor type, nutritional assessment methods, SGA and PG-SGA, showed strong and significant agreement, demonstrating that the use of any of these instruments can identify nutritional status. The HGS is an efficient tool for evaluating functional capacity and can be complementary in the identification of nutritional status in this group of patients.

Keywords: Nutritional status, Functional capacity, Cancer, Hospitalized patients.

CONTRIBUTION OF SELECTED TRADITIONAL GREEN LEAFY VEGETABLES TO MICRONUTRIENT INTAKE OF WOMEN AND CHILDREN 2-5 YEARS IN ELERUWA FARMING COMMUNITY, OYO STATE NIGERIA

(1)Ejoh, Shirley Isibhakhomen; (2)Adepoju, Oladejo Thomas.

(1)PhD. Lecturer. Department of Human Nutrition. Faculty of Public Health. College of Medicine. University of Ibadan. Nigeria; (2)PhD. Senior Lecturer. Department of Human Nutrition. Faculty of Public Health. College of Medicine. University of Ibadan. Ibadan. Nigeria.

Background and objectives: Traditional green leafy vegetables (TGLVs) are often not considered as sustainable food-based strategy for addressing existing micronutrient malnutrition especially among vulnerable groups in resource poor settings. Their contribution to micronutrient intake is rarely accounted for during dietary surveys and nutrient intake analysis in rural communities. This study investigated the contribution of TGLVs to micronutrient intake of women of reproductive age and children 2-5 years during the pre-planting, planting and harvest seasons in a rural farming community in Oyo State, Nigeria.

Methods: A purposively selected population of women of reproductive age (n=43) and children 2-5 years (n=34) who had lived in the community for ≥1year participated in the study. Socio-demographic characteristics and repeated household dietary assessment in pre-planting, planting and harvest seasons was done using food frequency questionnaire and two non-consecutive 24-hour dietary recalls. Adapted Total Dietary Assessment software was used to determine respondents' micronutrient intake. Data were analysed using descriptive statistics, and repeated measures ANOVA at $p<0.05$.

Results: Age of women and children were 32.5±8.8 and 3.5±0.9 years respectively, 36.4% of women had no formal education and 63.6% were farmers. Intake of TGLVs in the three seasons (pre-planting: 45.8±29.8 g; planting: 49.9±35.7 g; harvest: 43.4±28.2 g) showed no significant difference for women, but was significantly different for children (pre-planting: 25.2±10.1 g; planting: 31.2±24.1 g; harvest: 26.4±21.2 g, ($p<0.05$)). Contribution of TGLVs to women's micronutrient intake was higher in pre-planting season for folate (13.1%), iron (8.8%) and calcium (20.4%); planting season for vitamin C (55.1%) and vitamin A (RAE) (3.7%). Contribution of TGLVs to children's micronutrient intake was highest in planting season for vitamin C (45%), folate (10.1%) and iron (13.1%); harvest season for calcium (19.4%) and vitamin A (RAE) (3.5%).

Conclusions: Traditional green leafy vegetables contributed the most to micronutrient intakes when overall daily intakes were low: for women, in pre-planting, and planting seasons and for children in planting and harvest seasons.

Adequate consumption of these vegetables should be promoted among the people to meet their essential micronutrients needs through all seasons.

BEVERAGE CONSUMPTION AND BODY MASS INDEX OF ADOLESCENTS IN ODEDA LOCAL GOVERNMENT AREA, OGUN STATE, NIGERIA

(1)Oladoyinbo, Catherine; (2)Bolajoko, Opeyemi; (3)Akinbule, Oluwafunke; (4)Abiodun, Mercy.

(1)PhD. Nutritionist. Deparment of Nutrition and Dietetics. Federal University of Agriculture. Abeokuta.; (2)MSc. Dietetian. Department of Nutrition and Dietetics. Federal University of Agriculture Abeokuta. Nigeria; (3)MSc. Nutritionist. Department of Nutrition and Dietetics. Federal University of Agriculture Abeokuta. Nigeria; (4)BSc. Nutritionist. Department of Nutrition and Dietetics. Federal University of Agriculture Abeokuta. Nigeria.

Background and objectives: The consumption of fructose, a component of table sugar and high fructose syrup has been associated with overweight and obesity with hazardous effect on health. Therefore, this study aimed to assess the relationship between beverage consumption and Body Mass Index of adolescents.

Methods: A structured questionnaire was administered to 400 adolescents from eight randomly selected secondary schools to assess their bio-data. Height and weight were measured using standard procedures and body mass index (BMI) for age was determined using WHO anthro plus. Dietary pattern, portion sizes of food consumed and nutrition knowledge were assessed using the semi-quantitative food frequency questionnaire and validated nutrition knowledge questionnaire respectively. Respondents physical activity was measured using the WHO global-activity questionnaire. Data was analyzed using the Statistical Package for Social Sciences (SPSS). Descriptive statistics was used to generate frequencies and percentages while Chi-square tests was used to determine association between variables.

Results: About half (51%) of the respondents were males, 52.8% were within the age range of 15-19years and 56% were in the junior secondary school. The prevalence of underweight, overweight and obesity were 18.5%, 6.8% and 2.2% respectively. Carbonated and flavored drinks were the most frequently consumed beverage with an average intake of 500ml per portion. However, milk consumption was rather low (28ml per portion). Only 4.3% had poor nutrition knowledge while 47.3% had moderate nutrition knowledge. Most of the respondents (56.2%) were moderately active while 10% had low physical activity level. Respondents in senior classes had significantly higher nutrition knowledge than those in junior classes ($p= 0.001$). The male adolescents were more physically active than their female counterpart ($p=0.012$). In addition, consumption of carbonated and flavored drinks contributed significantly to BMI-for-age ($p=0.001$) however, no association was found between nutrition knowledge and BMI-for-age

(p=0.331). Activity levels was also not found to have significant impact on BMI-for-age of respondents (p=0.390).

Conclusions: High consumption of empty calorie carbonated and flavoured drinks of respondents affected to their body mass index-for-age and this may be responsible for the high prevalence of underweight among the respondents.

VALIDITY OF REPORTED NIGHT BLINDNESS AS AN INDICATOR OF VITAMIN A DEFICIENCY STATUS DURING PREGNANCY

Gebremicael, Gebremedhin.

Epidemiologist. School of Public and Environmental Health. Hawassa University. Ethiopia.

Background and objectives: Night blindness is considered as a simple and reliable population based indicator of Vitamin A Deficiency (VAD). Nonetheless, empirical evidence regarding its correlation with bio-markers of vitamin A is scarce. The purpose of the study was to assess the sensitivity and specificity of reported night blindness as an indicator of VAD during pregnancy.

Methods: The analysis was done based on secondary data collected for assessing the prevalence of VAD among pregnant women in rural Sidama, Southern Ethiopia. Night blindness – inability to see normally after dusk or at night during pregnancy – was determined based on self reporting. Sensitivity and specificity of night blindness were determined by taking serum retinol as the gold standard measure of vitamin A status. Serum retinol was determined using high-performance liquid chromatography (HPLC).

Results: The data of 700 pregnant women included in the analysis. About 37.9% of the women had VAD (serum retinol <0.7 µmol/l) and 39.7% reported night blindness. The mean (±SD) serum retinol among women with reported night blindness (0.77 ± 0.42 µmol/l) was significantly lower than their counterparts (0.88 ± 0.41 µmol/l) (t =3.704, p<0.000). Night blindness was significantly association with VAD (x2 =19.541, p<0.000). Nevertheless, its sensitivity and specificity to correctly classify the deficiency status were low, 50.2% and 66.7% respectively. Based on Kappa agreement analysis, significant but weak concord observed between the two indices (k= 0.047, p<0.000).

Conclusions: Reported night blindness, does not correlate strongly with serum vitamin A level.

Keywords: Night blindness, Vitamin A, Serum retinol

STANDARDIZATION, PROXIMATE AND MINERAL CONTENTS OF SELECTED INDIGENOUS SOUPS IN SOUTH WEST, NIGERIA

[1]*Akinbule, Oluwafunke;* [2]*Oladoyinbo, Catherine;* [3]*Onaneye, Ibrahim;* [3]*Oloyede, Abibat;* [3]*Sulaiman, Raji.*

[1]M.Sc. Nutritionist. Nutrition and Dietetics Department. Federal University of Agriculture Abeokuta. Nigeria; [2]Ph.D. Nutritionist. Nutrition and Dietetics Department. Federal University of Agriculture Abeokuta. Nigeria; [3]B.Sc. Nutritionist. Nutrition and Dietetics Department. Federal University of Agriculture Abeokuta. Nigeria.

Background and objectives: Indigenous soups contribute significantly to the nutrient intake of the population. This study standardized and determined the proximate and mineral contents of indigenous soups commonly consumed in Southwestern Nigeria.

Methods: A multi-stage sampling technique was used to select 250 housewives in major cities of Lagos, Ogun and Oyo states. Data on the recipe of fifteen selected indigenous soups were obtained from the housewives using a structured questionnaire. The soups were standardized, prepared, homogenized, dried and analyzed for proximate and mineral contents using standard methods of AOAC.

Results: The moisture contents of the soups ranged from 16.83 g/100g (ekuku with plain soup) to 64.01 g/100g (cocoyam leaf soup), ash contents of the soups ranged from 3.44 g/100g (gbanunu soup) to 7.99 g/100g (igbo soup), crude fibre ranged from 4.10 g/100g (igbo soup) to 8.65 g/100g (egusi with bitter leaf soup), fat ranged from 6.49 g/100g (cassava leaf soup) to 44.73 g/100g (orunla with plain soup), protein ranged from 4.22 g/100g (efinrin soup) to 6.82 g/100g (cottonseed soup) while carbohydrate content ranged from 9.29g/100g (cottonseed soup) to 52.11g/100g (cassava leaf soup). Also, the calcium contents of the soups ranged from 1.80mg/100g (erimonu soup) to 240.00mg/100g (ekuku with plain soup), sodium ranged from 10.80mg/100g (efinrin soup) to 339.00mg/100g (ilasa with plain soup), potassium ranged from 6.20 mg/100g (gbanunu soup) to 775.00mg/100g (marugbo with plain soup), phosphorus ranged from 1.51mg/100g (ekuku with plain soup) to 97.01mg/100g (igbo soup), iron ranged from 0.11 mg/100g (cassava leaf soup) to 22.15 mg/100g (efinrin soup) while zinc ranged from 0.02 mg/100g (cocoyam leaf soup) to 4.39 mg/100g (marugbo with plain soup).

Conclusions: High moisture of these indigenous soups suggest that the soups had low nutrient contents. However, high consumption of some of these indigenous soups may contribute significantly to the micronutrient intake of consumers.

Keywords: Indigenous soups, Standardization, Nutrient contents.

SOCIOECONOMIC DISPARITIES AND NUTRITIONAL QUALITY OF FOOD PURCHASES IN FRANCE: 40 YEARS OF HOUSEHOLD PURCHASES 1969-2010

[1]Caillavet, Françoise; [2]Darmon, Nicole; [3]Létoile, Flavie; [1]Nichèle, Véronique.

[1]PhD. Economist. Alimentation et Sciences Sociales. National Institute for Agronomic Research. France; [2]PhD. Nutritionist. MOISA. National Institute for Agronomic Research. France; [3]MSc. Statistician. Alimentation et Sciences Sociales. National Institute for Agronomic Research. France.

Background and objectives: The evidence of a social gradient in health and food-related diseases shows the crucial role of nutritional quality of diets. However socioeconomic disparities in diet quality have seldom been studied on the long-term. The aim of this study was to analyse the evolution of the nutritional quality of food purchases of French households from 1969 to 2010 and to assess the disparities in nutritional quality according to income and education.

Methods: Time series of food purchases for food-at-home were built based on two representative household surveys: INSEE and Kantar. The average quantities purchased per capita each year were calculated for each food item and aggregated into 80 groups. Food quantities were converted in energy and nutrients using CIQUAL food composition database. The nutritional quality of purchases was estimated by the Mean Adequacy Ratio (MAR), i.e. the mean percentage of daily recommended intakes for 15 key nutrients calculated on a 2000kcal basis. Socioeconomic disparities were measured by disaggregating the above computations according to the household income quartiles from 1969, and to four educational levels of the household head from 1978. We also computed the MAR by income and education level.

Results: All income quartiles showed a similar trend of improvement of the MAR from purchases between 1969 and 2010. However the MAR remains higher for the richest income quartile (75.3 to 86.0) than for the lowest one (66.4 to 80.1) throughout the whole period. By education levels from 1978, we found a higher MAR for higher education level than for lower one (82.5 vs 71.9) but with closer values at the end of the period (83.5 vs 81.5).

Conclusions: During the last four decades, households with higher income or higher education have food purchases of better nutritional quality. Disparities of nutritional quality have decreased according to education but not according to income.

Keywords: Socioeconomic disparities, Food purchases, Nutritional quality.

MIXED GREEN LEAFY VEGETABLES POWDER CONSUMPTION IMPROVES ANAEMIA STATUS OF GHANAIAN SCHOOL CHILDREN

[1]Zotor, Francis; [2]Egbi, Godfred; [3]Gbogbo, Samuel; [4]Ofosu, Winfred; [5]Agbozo, Faith; [6]Harrison, Eric.

[1]PhD. Nutritionist. School of Public Health. University of Health and Allied Sciences. Ho. Ghana; [2]PHD. Nutritionist. Noguchi Memorial Institute for Medical Research. College of Health Sciences. University of Ghana. P.O. Box LG 581. Legon. Accra. Ghana.; [3]MPhil. Nutritionist. Department of Nutrition and Food Science. College of Applied and Basic Sciences. University of Ghana. P.O. Box LG 134. Legon. Accra. Ghana.; [4]MD. MPH. Public Health. Regional Health Directorate. Ghana Health Services. P.O. Box 298. Wa. Upper Region. Ghana.; [5]MPhil. Nutritionist. University of Health and Allied Sciences. School of Public Health. PMB 31. Ho. Volta Region. Ghana.; [6]MPhil. Nutritionist. Noguchi Memorial Institute for Medical Research. College of Health Sciences. University of Ghana. P.O. Box LG 581. Legon. Accra. Ghana.

Background and objectives: Anaemia is a public health problem among Ghanaian school children. Green Leafy Vegetables are the cheapest and most readily available sources of micronutrients and can potentially contribute to reduction of deficiencies and improve human health. This study assessed the effect of Mixed Green Leafy Vegetables Powder (MGLVP) on anaemia status of School Children in Adaklu District in Volta Region.

Methods: The study was cross-sectional at baseline and a three month intervention phase. Study participants; school children 4 - 9 years of age were randomised into intervention group (given MGLVP soup or stew) + school lunch) and Control group (school lunch only). Participants were fed five consecutive week days for three months. Data collected at baseline and end-line involved the use of appropriate standard procedures for the following: height and weight measurements; dietary data collected by 24-hour recall and haemoglobin concentrations, by HemoCue Haemoglobinometer. Participants' blood samples were examined for malaria parasitemia and stools for helminthes using Giemsa stain and Kato-Katz techniques. Changes in baseline and end-line within and between groups were compared using paired and independent sample t-tests. Binary logistic regression was used to identify predictors of anaemia.

Results: At the end of the study, although the mean haemoglobin concentration increased in both groups, the between group difference (0.3g/dl) was significant, p = 0.021. The prevalence of anaemia at baseline was 41.5 % in the intervention group and 37.3 % in the control group. By the end of the study the intervention group registered 28.3% compared to 36.1% in the control group; p = 0.011. Malaria prevalence increased among both study groups by the close of the study; 35.7% at baseline and 40 % at end-line. The mean prevalence of stunting was 12.3% and 14.7 % in the intervention and control respectively. The control group who consumed no MGLVP were 2.8 times at higher risk of being anaemic than the intervention group (p = 0.036).

Conclusions: Mixed Green Leafy Vegetables Powder (stew or soup) improved haemoglobin concentration and minimized the prevalence of anaemia among study participants.

Keywords: Anaemia, Mixed green leafy vegetable powder, Micronutrients, Malaria.

EFFECT OF RED PALM OIL BEANS STEW ON SERUM VITAMIN A AND HAEMOGLOBIN CONCENTRATIONS OF SCHOOL CHILDREN IN GHANA

[1]Zotor, Francis; [2]Egbi, Godfred; [3]Alatiah, Gabriel; [4]Steiner-Asiedu, Matilda.

[1]PhD. Nutritionist. School of Public Health. University of Health and Allied Sciences. Ho. Ghana; [2]PHD. Nutritionist. Noguchi Memorial Institute for Medical Research. College of Health Sciences. University of Ghana. P.O. Box LG 581. Legon. Accra. Ghana.; [3]MPhil. Nutritionist. Department of Nutrition and Food Science. College of Applied and Basic Sciences. University of Ghana. P.O. Box LG 134. Legon. Accra. Ghana.; [4]PhD. Nutritionist. Department of Nutrition and Food Science. College of Applied and Basic Sciences. University of Ghana. P.O. Box LG 134. Legon. Accra. Ghana..

Background and objectives: Vitamin A deficiency, anaemia and parasitic infections are among the major nutritional and health problems confronting Ghanaian school children. The study assessed the impact of red palm oil beans stew consumption on the serum retinol and haemoglobin levels of Ghanaian school children in a malaria endemic setting.

Methods: This was a pre-post nutrition intervention study. It involved 142 children, six to 12 years old. Participants were selected by simple random sampling. Data was collected at baseline after which participants consumed red palm oil beans stew three times a week for a period of six months and data collection repeated. Dietary data was collected using Food Frequency Questionnaires and 24 hour recall. Serum retinol and haemoglobin were measured with High Performance Liquid Chromatography and Haemocue Haemoglobinomter respectively. Malaria parasitaemia and hookworms were examined by microscopy from blood films and stool samples using the Giemsa-staining and Kato-Katz techniques. Data was analyzed with Statistical Package for Social Sciences version-23. Mean values for outcome variables were compared between baseline and endline using paired t-test.

Results: Majority of the participants (82.4%) consumed cereals. Many of them also (98.6%) never consumed dairy or dairy products. Mean serum retinol concentration at baseline and endline were 12.1 ± 6.6µg/dl and 16.2 ± 6.4µg/dl, respectively. The mean change in retinol concentration within intervention periods at baseline and endline (4.1 µg/dl) was significant at p<0.05. The mean haemoglobin concentration at baseline was 119.4 ± 10.6 g/l and 126.0 ± 9.3 g/l at endline, significant at p<0.05. A reduction of prevalence between baseline and endline with significance of p<0.05 were as follows: vitamin A deficiency (VAD) from 93.6% to 76.2% and anaemia from 30.3% to 11.3% whilst malaria parasitaemia was from 67.6% to 62.7%. The prevalence of anaemia among VAD participants was 36.2 % at baseline and 12.1 % at endline.

Conclusions: Red palm oil beans stew consumption increased the haemoglobin and serum retinol concentrations and minimized prevalence of anaemia and vitamin A deficiency (especially severe vitamin A deficiency) among the study participants.

Keywords: Vitamin A deficiency, Anaemia, parasitic infections, School children, Malaria.

VITAMIN D INSUFFICIENCY AND RISK OF METABOLIC SYNDROME IN ELDERLY ADULTS WITH TYPE 2 DIABETES MELLITUS

[1]Ferro, Leticia; [2]Yamaguchi, Analía Verónica; [2]Pieniazek, Diana; [2]Lerner, Mirta; [2]Stolarza, Zulema.

[1]PhD. Nutritionist.; [2]PhD. Nutritionist. Cesar Milstein Hospital. Buenos Aires' University.

Background and objectives: An increase in the prevalence of vitamin D deficiency (VD) in the elderly adults (AM) has recently been observed. Various risk factors have been described such as inadequate sun exposure and insufficient calcium intake. This deficiency causes secondary hyperparathyroidism, accelerated bone turnover, bone loss, osteoporosis, and osteomalacia if it is a long-term and severe shortage. Recent studies have demonstrated the importance of VD in neuromuscular function, and its deficiency has been related to functional alterations and risk of falls in the elderly.

Objective: to determine the prevalence of deficiency (ID) of VD in the elderly population of the Hospital and its relationship with the Metabolic Syndrome (MS).

Methods: We included patients who attended the nutrition service of César Milstein Hospital between March and May of 2016, with Diabetes Mellitus (DM) who were not known their VD value. VD deficiency was defined as values ranging from 20.1 to 29.9 ng/ml, mild deficiency 20 to 10.1 ng/ml, severe deficiency at <10 ng/ml. Overweight was defined as a body mass index (BMI) ≥ 28 kg/m2 and obesity ≥ 32 kg/m2. P <0.05 statistically significant.

Results: The sample size was 175 patients, 56% women, the median age was 71 years. The prevalence of VD deficit was 80%, of these 38.6% (N=54) had insufficiency, 47.85% (N=67) mild deficiency and 13.33% (N=19) severe deficit. The sample was divided into 2 subgroups: normal weight and overweight-obesity. Among patients with BMI <27.9, the ID was 32.85% (N=46) and 67.15% (N=94) in the subgroup with BMI> 28 (p of 0.014). No significant differences were found associated with age, sex, or glycosylated hemoglobin.

Conclusions: The results suggest that ID of VD would be a prevalent factor in AM, even more in those with overweight and obesity. It would be of fundamental importance the opportune diagnosis and the supplementation of VD, thus we would be pre-

venting the risk of falls and all the complications that this deficit brings for AM.

Keywords: Vitamin D, Metabolic Syndrome, Elderly Adults, Type 2 Diabetes Mellitus.

VITAMIN D DEFICIENCY IN CHILDREN (6-18 YEARS) RESIDING AT HIGH ALTITUDE REGIONS OF HIMACHAL PRADESH, INDIA

Kapil, Umesh.

Professor, Public Health Nutrition, Department of Human Nutrition, All India Institute of Medical Sciences, New Delhi, India.

Background and objectives: High prevalence of Vitamin D Deficiency (VDD) has been documented from different plain regions of India. Limited data is available on VDD amongst children residing at high altitude region of country. Hence, the present study was undertaken with an objective to assess the prevalence of VDD and associated risk factors amongst children in the age group of 6-18 years residing at an altitude of 1000mts and above.

Methods: A community based cross-sectional study was conducted in the year 2015-2016. Three districts (namely: Kangra, Kullu and Shimla) of Himachal Pradesh state, India was selected for the present study. In each district thirty clusters/schools were identified using Population Proportionate to Size (PPS) sampling methodology. In the identified school, all the children in schools were enlisted. Twenty children per school were selected by using random number tables. A total of 1848 children (Kangra: 610; Kullu: 612; Shimla: 626) in the age group of 6-18 years were enrolled. The data on socio economic status, physical activity, sunlight exposure was collected. The blood samples were undertaken and serum 25-hydroxyvitamin D, intact parathyroid hormone, serum calcium, phosphorous, albumin and alkaline phosphate were assessed using standard procedures.

Results: Eighty one percent (Kangra), 80.0% (Kullu) and 93.0% (Shimla) of school age children were found vitamin D deficient as per serum 25(OH) D levels (less than 20ng/ml).

Conclusions: A high prevalence of VDD was also found in children residing in high altitude regions of Himachal Pradesh, India.

Keywords: Vitamin D deficiency, Parathyroid hormone, Children, India.

SODIUM BENZOATE IN SOFT DRINKS, A HEALTH THREAT FOR CHILDREN

[1]*Posadas, Marta;* [2]*Elías, Héctor;* [3]*Rigalli, Alfredo;* [4]*Olguin, María Catalina.*

[1]PhD. Biochemist. Cátedra de Biología. Facultad de Ciencias Médicas. Universidad Nacional de Rosario. Argentina.; [2]BSc. Biochemist. Área Bromatología y Nutrición. Facultad de Ciencias Bioquímicas. Universidad Nacional de Rosario. Argentina; [3]PhD. Laboratorio de Biología Ósea. Facultad de Ciencias Médicas. Universidad Nacional de Rosario. Argentina.; [4]MSc. Biochemist. Área Bromatología y Nutrición. Facultad de Ciencias Bioquímicas. Universidad Nacional de Rosario. Argentina.

Background and objectives: The association between dietary habits –including sugary soft drinks intake- and the increasing obesity epidemics and its co-morbidities has been established worldwide. Argentina has been among the top ten countries with the largest daily intake of both regular and low calorie soft drinks in the last 10 years. The scenario completes with the data that nearly 60% of the adult argentine population is overweight or obese; 11% presents T2DM and the number of overweight and obese children is constantly growing. The aim of this study was to evaluate the presence and level of preservatives employed in these beverages since sodium benzoate –present in most of them- has a very low Adequate Daily Intake (ADI), thus representing a serious health risk, particularly for those children who habitually replace water by these products.

Methods: The levels of sodium benzoate (INS 211) and potassium sorbate (INS 202) by high performance liquid chromatography and pH (Methrom E 632) were determined in the most frequently regular and low/zero calories consumed drinks (n=30).

Results: The concentration of sodium benzoate and potassium sorbate ranked from 120 to 450 mg/l and 80 to 460 mg/l respectively and the rank of pH from 2.29 to 3.93. The preservatives were not detected in the two regular cola drinks in which the values of pH were the lowest neither in the pasteurized fruit juices.

Conclusions: Beverages with sodium benzoate as preservative present the risk that children (20-30 kg body weight) may exceed the ADI for sodium benzoate (0-5mg/kg bw) with a daily intake of only two portions (200ml/portion) of the drink.

We conclude that a habitual consumption of soft drinks represents a serious health menace, not only due to the high sugar concentration in the regular ones, the very low acidic pH determined in all of them, but also due to the frequent or daily intake of sodium benzoate present in most of them.

Keywords: Sodium benzoate. Soft drinks. ADI.

ANEMIA PREVALENCE ESTIMATES IN CAMBODIAN WOMEN VARY WIDELY BY METHOD OF HEMOGLOBIN MEASUREMENT AND TYPE OF BLOOD SAMPLE COLLECTED

[1]*Karakochuk, Crystal;* [2]*Rappaport, Aviva;* [3]*Barr, Susan I;* [4]*Green, Tim.*

[1]PhD. RD. Assistant Professor. Food, Nutrition, and Health. University of British Columbia. Canada.; [2]MSc. Food, Nutrition and Health. University of British Columbia. Canada.; [3]PhD. Food, Nutrition and Health. University of British Columbia. Canada.; [4]PhD. South Australian Health and Medical Research Institute. Australia.

Background and objectives: Hemoglobin (Hb) concentration is often measured in field settings using a portable hemoglobinometer, or in laboratories using a hematology analyzer. Discrepancies in measurement between these methods have been reported, which may be the result of the sample collection method typically employed (capillary vs. venous blood, respectively). Our aims were to compare Hb concentrations in fasting venous blood of Cambodian women using a hemoglobinometer and a hematology analyzer, and further, to non-fasting capillary blood from the same women using the same hemoglobinometer.

Methods: Blood was collected in July 2015 from n=28 Cambodian women (18-45 years) in Kampong Chhnang province who were recruited to an iron supplementation trial. Enrolled women had a Hb ≤117 g/L based on a HemoCue® 301. Hb was measured in fasting venous blood using a HemoCue® 301 and a Sysmex XN-1000 hematology analyzer, and in non-fasting capillary blood using the same HemoCue®.

Results: Mean Hb concentrations in fasting venous blood were significantly higher with the HemoCue® as compared to the Sysmex analyzer (123 vs. 118 g/L, respectively, P<0.05); and both were higher than mean Hb concentrations in non-fasting capillary blood from the same women using the same HemoCue® (110 g/L, P<0.05, repeated measures ANOVA). Anemia prevalence estimates (Hb <120 g/L) varied widely across methods: 39%, 64%, and 100%, respectively.

Conclusions: The 5 g/L bias in Hb concentration in fasting venous blood resulted in a substantial and clinically relevant difference in anemia prevalence (39% vs. 64%). Further, mean Hb concentrations in non-fasting capillary blood from the same women using the same HemoCue® were significantly lower as compared to fasting venous blood (using both methods). Overall, there are three sources of potential variability (capillary vs. venous, hemoglobinometer vs. hematology analyzer, and fasting vs. non-fasting); all may have contributed the observed discrepancy in Hb concentrations in our study. These findings are important for the determination of appropriate recommendations of blood collection procedures for Hb measurement. More research is warranted to investigate the possible discrepancies between hemoglobinometers and automated analyzers, and to examine the extent to which a fasting or non-fasting state can influence Hb concentrations.

NUTRITIONAL HEALTH OF UNIVERSITY ADMINISTRATIVE STAFF: RISKS AND OPPORTUNITIES

[1]*Swart, Elizabeth Catherina;* [2]*Kunneke, Ernesta.*

[1]PhD. Dietitian. Nutritionist. Department of Dietetics and Nutrition. University of the Western Cape. South Africa; [2]PhD. Dietitian. Department of Dietetics and Nutrition. University of the Western Cape.

Background and objectives: Health is a complex state influenced by dynamic individual, social and organizational systems. Non-communicable diseases are leading causes of death among adults and have been increasing in the adult population since 1999 but no information is currently available on the nutritional health status of university employees in South Africa.

The aim of this research was to describe the nutritional health status of university administrative staff.

Methods: A descriptive study conducted among all permanent administrative staff of UWC. Participants were recruited via email invitation. Following approval from the Senate Research Ethics Committee, informed written consent was obtained from participants with assurance of anonymity, safe clinical practice and strict confidentiality. Feedback on measurements was given to individual participants and referrals for treatment made were necessary. All interviews and anthropometric assessments were conducted by dietitians trained as fieldworkers. Clinical assessments were obtained by a nurse practitioner with phlebotomist training following standardised operating procedures. SPSS was used for data analysis.

Results: Seventy eight staff members participated during the two week period of data collection (52% response rate). Eighty five percent of men and 80% of women were overweight or obese with 28% of men and 67% of women presenting with a waist circumference indicative of a high risk for chronic diseases of lifestyle. Twenty-eight percent men and 15% had a blood pressure greater than 140/90. Only two of the men have been previously diagnosed with hypertension. Thirty-four percent of men and 22% of women reported daily cigarette smoking whilst more than 40% reported that they never do moderate intensity exercise whilst 83% of men and 59% of women watched between 1-3hours television daily. Not surprisingly only 40% of men and women regarded themselves as having optimum health.

Conclusions: Risk factors for chronic diseases of lifestyle are highly prevalent. Investment in comprehensive health promotion could be beneficial to individual staff members and the university at large.

Keywords: Administrative staff, Obesity, Chronic diseases of lifestyle, Hypertension, Health promotion.

HYPOCALORIC DIET- A GOOD THING OR A BAD THING?

[1]*Mihaela Camelia, Posea;* [2]*Dragomir, Andreea Diana;* [3]*Radulian, Gabriela.*

[1]1- MD. PhD. Diabetes Nutrition and Metabolic Diseases. Smart Nutrition Clinic. Bucharest. Romania; [2]MD. Diabetes Nutrition and Metabolic Diseases. University of Medicine and Pharmacy "Carol Davila ". Bucharest. Romania; [3]MD. PhD. Diabetes Nutrition and Metabolic Diseases. National Institute of Diabetes, Nutrition and Metabolic Diseases "N. C. Paulescu". Bucharest. Romania.

Background and objectives: Obesity is associated with highly elevated risks of adverse health outcomes. We evaluated obese patients during a hypocaloric diet to see the nutritional impact assessment regarding macro and micro nutrients and the impact on the health.

Methods: A sample of 126 overweight and obese subjects were investigated. Using a 7-day food self-recorded questionnaire, we evaluated the nutritional content of food intake before and after the program: total kilocalories, carbohydrates, proteins, lipids, cholesterol, vitamins A, B1, B2, B3, B5, B6, B12, C, D, E, folic acid, and minerals like calcium, iron, magnesium, phosphorus, zinc, copper, manganese, selenium, and sodium. We assessed anthropometric data, laboratory data and resting metabolic rate.

Results: Data analysis at the end of nutritional intervention program showed significant changes in all parameters except for metabolic rate estimated. 91.18% of men and 85.87% of women recorded overall improved weight while fat percentage decreased. The prevalence of normal intake of protein and carbohydrates decreased significantly after the intervention: 67.95% and 15.38% of patients had adequate protein intake (p <0.001) and, respectively, carbohydrates (p = 0.006).

At the end, only 12 to 30% of patients had recommended nutritional intake, depending on the vitamin evaluated.

80% of patients consumed excessive vitamins B12, B2, B3 and B6. More than 80% of patients had deficient intake of vitamin D and E.

At the end of the intervention we observed to be significantly fewer patients covering the recommended daily allowance for calcium and magnesium.

Although there have been deficient intake of minerals, laboratory parameters such as magnesium, calcium and plasma iron were not significant changed at the end of nutritional intervention.

Conclusions: Because of the results regarding anthropometric data which get improved, we can say that hypocaloric diet is a good thing. Considering that the participants in this study were compliant in terms of nutritional recommendations, it can be said that, due to the inefficiency to correct the deficiency and excessive intake of vitamins and minerals, we need to pay more attention to the nutritional recommendations during an interventional program.

EVALUATION OF THE MENUS OFFERED TO PRESCHOOL CHILDREN IN THE CITY OF BOTUCATU. SP

[1]*Aranha, Flávia;* [2]*Carvalho, Sandra;* [3]*Gêa, Meire.*

[1]PhD. Department of Education. Institute of Biosciences. UNESP - Univ Estadual Paulista. Câmpus Botucatu. Brazil.; [2]BSc. Graduation Course in Nutrition. Institute of Biosciences. UNESP. Univ Estadual Paulista. Brazil.; [3]Nutritionist responsible for the Pilot Kitchen. City Hall of Botucatu.SP. Brazil.

Background and objectives: In infancy, children need to receive adequate amounts of nutrients for proper development. The National School Feeding Program (PNAE) aims to collaborate for the development, biopsychosocial growth, income, learning and formation of healthy eating practices of the school. The present study aims to evaluate the supply of nutrients to preschool children, comparing with the parameters established by the PNAE (2009).

Methods: Micronutrients and macronutrients were evaluated for 29 days and compared to the values recommended by PNAE, for preschoolers between 4 and 5 years of age who receive two or more meals per day. To evaluate the composition of the meals, each item present in the cooking in kilos and the quantity in kilos of prepared vegetables, already considering the correction factor, was noted. The calculation of calories, macronutrients and micronutrients of the menu was done with the help of the Microsoft Office Excel 2007 program, following the nutritional composition of the Food Composition Chart (UNICAMP, 2011), the Food Composition Chart (UNIFESP, 2016) and the nutritional label of foods used in the preparations.

Results: The average results were: 450.9 Kcal; Carbohydrate 68.9g; 19.9g proteins; Lipids 10.0g; Fibers 15.2mg; Ca 774.9mg; Fe 10.0mg; Mg 195.3mg; Zn 5.9mg; Vit A 405.2μg and vitamin C 34.4mg. With respect to macro or micronutrients, all have met the needs proposed by the PNAE. This is due to compliance with the regular supply of fruits and vegetables, milk sources and variation of the menu.

Conclusions: It was concluded in this evaluation that the supply of nutrients to preschool children, provided by the Pilucatu Pilot Kitchen, meets the parameters established by the PNAE.

Health and Nutrition Research Team of the Mother Child Couple. Faculty of Medicine and Pharmacy. Mohammed V University of Rabat. Morocco.

Background and objectives: Worldwide, deficiency in calcium increases the risk of developing diseases like osteoporosis and fracture risk at the later life. Depending on the World health organization reports, calcium deficiency is one of the most important deficiencies compared to other micronutrients deficiencies. In Morocco, data on calcium deficiency is limited because there are no specific studies in National level that identified the risks associated to this deficiency Thus; the aim of this study is to evaluate the nutritional profile of calcium in a representative sample of Moroccan children and adolescents.

Methods: 131 children and adolescents aged between 6 and 18 years were recruited from public schools at Rabat and its regions in the framework of descriptive cross-sectional study. For each participant, socio-economic and morbidity status were assessed, and anthropometric parameters were measured. Calcium assessment was estimated through 24 hour urine measurements by ICP-MS.

Results: The findings of this study showed that the mean of urinary calcium was 72.48mg/day. About 73% of children and adolescents present a urinary calcium deficiency. There were no significant differences related to sex towards calcium excretion and its correlation with nutritional status was shown negative.

Conclusions: The present study show that children and adolescents in Rabat and regions present serious calcium deficiency.That leads us to reflect on the various tools needed to remedy this deficit and to response to objectives of the national strategy to combat micronutrient deficiencies.

Keywords: Calcium deficiency. Children. Adolescents. urinary calcium excretion. Morocco

PREDICTING STANDING HEIGHT FROM HEIGHT PROXIES FOR THE DETERMINATION OF BODY MASS INDEX (BMI) OF OLDER PERSONS IN ABIA STATE, NIGERIA

[1]Nzeagwu, Ogechi; [2]Eluwa, Austin; [3]Nkwoala, Chiaka Charles.

[1]PhD. Community and Applied Nutrition. Department of Human Nutrition and Dietetics. Michael Okpara University of Agricultuere. Abia State. Nigeria; [2]PGD. Human Nutrition and Dietetics. Department of Human Nutrition and Dietetics. Michael Okpara University of Agriculture Umudike. Abia State. Nigeria; [3]MSc. Community Nutrition. Department of Human Nutrition and Dietetics. Michael Okpara University of Agriculture Umudike. Abia State. Nigeria.

Background and objectives: Use of BMI to determine nutritional status is limited by height (Ht) measurement, which is often unreliable because of spinal deformities. The study aimed at predicting standing height of older persons using height proxies of arm span, knee and sitting heights and comparing the BMI calculated from the actual standing and predicted standing heights.

Methods: This cross sectional study used multi-stage random technique to select 200 older persons aged $\geq$ 60years living in two Local Government Areas of Abia state, Nigeria. Persons with spinal deformities and osteoporosis were excluded. Weight (kg), standing height, arm span, knee and sitting heights (m) were measured using standard procedures. Linear regression analysis was used to obtain regression equation for predicting standing Ht from each of the Ht proxies. BMI (kg/m2) was calculated using actual standing Ht and the predicted heights. Pearson correlation was used to compare actual standing Ht and BMI from actual standing Ht with predicted standing Hts. Results were expressed as mean and standard deviations. Statistical analyses were done using IBM SPSS Statistics (version 20) and significance judged at P<0.05.

Results: Regression equations were obtained for men: standing Ht = 1.23±0.25(arm span); 1.36±0.52(knee Ht); 1.47±0.23(sitting Ht) and for women: standing Ht = 1.35±0.14(arm span); 1.43±0.29(knee Ht); 1.48±0.15(sitting Ht); revealing that in predicting standing height from arm span for men, the expected value of the standing height when the arm span is zero is 1.23 and for every additional meter in arm span, standing height is expected to increase by 0.25m. Standing Ht estimated from arm span in men had the highest correlation value (r= 0.296). Significant relationship (p<0.05) existed between actual standing Ht and the predicted Hts. BMI from actual standing Ht correlated significantly (P<0.05) with those predicted from height proxies in both men and women.

Conclusions: Standing heights predicted from height proxies using the regression equation obtained in this study can be used to estimate actual standing height of older persons who may have problem standing for height assessment. BMI calculated from actual standing height significantly and positively correlated with those obtained from predicted heights proxies.

Keywords: Height, BMI, Older persons, Prediction, height proxies

DIETARY INTAKE AND NUTRITION KNOWLEDGE OF COMPETITIVE TABLE TENNIS PLAYERS

[1]Nascimento, Marcus; [2]Argôlo, Dayane; [2]Borges, Josefa; [2]Cavalcante, Andressa; [2]Silva, Gilvana; [2]Souza, Matheus.

[1]Tiradentes University; [2]BSc in Nutrition. Department of Nutrition. Tiradentes University. Brazil.

Background and objectives: A proper diet is important for improving sports performance and health. Athletes may have poor nutrition knowledge, which may negatively impact food behavior. The analysis of athlete´s dietary intake may help in the elaboration of nutrition interventions. The objective of the present study was to evaluate and compare the dietary intake and nutrition knowledge between adult and adolescent table tennis players. To our knowledge, this is the first study that assessed the food behavior and nutrition knowledge of table tennis players.

Methods: Forty two competitive athletes responded a three-day food diary and a validated nutrition knowledge questionnaire. Body weight and height were also measured. Nutrient and food portions were adjusted for misreporting using the residual method and compared to athletic guidelines. Pearson correlations were performed between nutrition knowledge and dietary intake for each nutrient.

Results: Athletes of both groups showed a high prevalence of inadequacy in the ingestion of cereals, vegetables, dairy and sweets and more than a half of the adolescents were inadequate in fruits and legumes. Adolescents showed a lower ingestion of vitamins A, C, B5, B6, calcium, zinc and phosphorus. Both groups showed a high prevalence of inadequacy in the ingestion of nutrients, however, adolescents showed a higher inadequacy in vitamin C, B6, B9 and phosphorus. Between group analysis showed that adults had higher nutrition knowledge than adolescents. Statistical analysis in adults showed significantly negative correlations between basic nutrition knowledge and the ingestion of cereals (r= -577), legumes (r= -796) and vitamin b2 (r= -770). Negative correlations were also found between total nutrition knowledge and sodium intake (r= -485). In adolescents, there was a positive moderate correlation between sports nutrition knowledge and the ingestion of vitamin B5 (r= 0,436).

Conclusions: Adolescents showed a higher prevalence of nutrient inadequacies and a lower nutrition knowledge than adults.

Keywords: Table tennis, nutrition knowledge, sports nutrition

ANALYSIS OF DIETARY COMPONENTS OF PREGNANT WOMEN WITH UNCOMPLICATED GESTATIONAL HYPERTENSION AND GESTATIONAL HYPERTENSION COMPLICATED BY HYPOTHYROIDISM

[1]Bobiński, Rafał; [2]Pollok-Waksmańska, Wioletta; [3]Ulman-Włodarz, Izabela; [4]Turbiarz, Agnieszka.

[1]Prof. University of Bielsko-Biała, Faculty of Health Sciences, Poland; [2]PhD. University of Bielsko-Biała, Facultyof Health Sciences, Poland.; [3]Prof. MD. University of Bielsko-Biała, Faculty of Health Sciences, Poland.; [4]PhD, University of Bielsko-Biała, Faculty of Health Sciences, Poland.

Background and objectives: A woman's diet is said to be the most important factor in determining intrauterine growth. In the case of improper diet the hormonal and/or circulation disorders may lead to intrauterine growth restriction. The aim of the study was to determine differences in average daily intake of selected nutrients in women diagnosed with hypertension during pregnancy and women who, in addition to being diagnosed with hypertension, had also been diagnosed with hypothyroidism before pregnancy.

Methods: The test subjects were divided into two groups. Group I – women diagnosed with hypertension in the first trimester of pregnancy. Group II - women diagnosed with hypertension in the first tri-mester of pregnancy and diagnosed with hypothyroidism before pregnancy. The women's eating habits and dietary composition were analyzed based on a dietary questionnaire. Portion sizes were verified using "The Album of Photographs of Food Products and Dishes. The questionnaire allowed the researchers to determine daily consumption of each particular dietary component over a one-week period. The DIETA FAO program was used to estimate the quantity of the aforementioned components.

Results: Hypertensive women have been observed to have higher BMI values both before pregnancy and during pregnancy, as well as higher daily intake of mono- and polyunsaturated fatty acids. There was also a significantly higher intake of vitamin A and nearly twice as high intake of tyrosine in the group of women with hypertension. In both groups folate, iodine and vitamin D intake below daily demand was observed.

Conclusions: The pregnant women's intake of the dietary components which are important for the fetus was higher in mothers with gestational hypertension without complicated pre-existing hypothyroidism. Women with uncomplicated hypertension or complicated pre-existing hypothy-roidism were characterized by lower iodine and vitamin D intake compared to daily requirements. Women with pre-existing hypothyroidism were characterized by lower intake of essential fatty ac-ids which are also important for the nervous system during development of fetus and also in many other metabolic and energy processes. In the group of women with pre-existing hypothyroidism, lower intake of tyrosine, the fatty acid necessary as a substrate in thyroid hormone biosynthesis, was observed.

Keywords: pregnancy, hypertension, hypothyroidism

COMPARISON OF DIETARY DIVERSITY SCORE (DDS) ACCORDING TO THE SOCIO-ECONOMIC STATUS AMONG RURAL MIDDLE SCHOOL CHILDREN IN THE NORTHWEST OF MOROCCO

[1]Sbaibi, Rachid; [2]Aboussaleh, Youssef; [2]Zeghari, Lotfi; [2]Agoutim, Naima.

[1]PhD.Laboratory of Nutrition Health and Environment. Department of Biology. Faculty of Sciences. University Ibn Tofail. Kénitra. Morocco; [2]PhD. Nutritionist. Laboratory of Nutrition Health and Environment. Department of Biology. Faculty of Sciences. University Ibn Tofail.Kénitra. Morocco.

Background and objectives: Diversity score (DDS) is not associated with the staturo-ponderal status or gender among the rural middle school children (12.3 to 19.74 years), in the northwest of Morocco. The purpose of the present study was to compare the dietary diversity score (DDS) according to the Socio-economic status among these adolescents.

Methods: The DDS represents the number of the 11 most frequented food groups (grains, sweet tea, fatty substances, dairy products, vegetables, sweets, poultry, fruits, legumes, red meat, fish) consumed during the preceding 7 days by 300 middle school children (15.45 years± 1.64) of the only middle school in the rural commune of Sidi El Kamel in northwestern Morocco. The general survey was used to record demographic and socio-economic characteristics of subject (age, gender, sibling rank, household size, function of parents, their educational level). The comparison of averages of DDS by socio-economic status, is done by the Mann-Whitney test and the Kruskal-Wallis test at 5% error.

Results: 9% of students haven't a diversified feeding (with DDS less than or equal to 7 of 11 food groups), against 91% had DDS strictly greater than 7 of 11 food groups, in average (9.3; ± 1.33) food groups on 11 groups consumed during the preceding 7 days. the diversification of food is only related to the paternal function. (χ2 = 2.25; df = 5; P = 0.033 <0.05). The children whose parents are farmers or workers, have a high rate of food diversification of 60% and 13% respectively.

Conclusions: The good dietary diversity among adolescents in rural areas is linked to easy access to cereals, vegetables, dairy products via agricultural function of the father.

Keywords: Dietary Diversity Scores , socio-economic status, rural middle school children, Morocco.

COMPLEMENTARY FEEDING PRACTICES AND STUNTING AMONG INFANTS AND YOUNG CHILDREN IN THE NORTHERN PROVINCE OF RWANDA

[1]Uwiringiyimana, Vestine; [2]Veldkamp, Antonie; [3]C. Ocké, Marga; [4]Amer, Sherif.

[1]1MSc. PhD Candidate. Faculty of Geo-Information Science and Earth Observation (ITC). University of Twente. The Netherlands/ 2MSc. Assistant Lecturer. School of Food Science and Technology. College of Agriculture Animal Science and Veterinary Medicine. U; [2]PhD. Dean. Faculty of Geo-Information Science and Earth Observation (ITC). University of Twente. The Netherlands.; [3]PhD. Senior Nutritionist. National Institute for Public Health and the Environment (RIVM). The Netherlands.; [4]PhD. Assistant Professor. Faculty of Geo-Information Science and Earth Observation (ITC). University of Twente. The Netherlands.

Background and objectives: Stunting remains a serious challenge in Rwanda despite the success achieved at reducing acute malnutrition. The aim of this research was to study the factors associated with stunting in Musanze District in the Northern Province of Rwanda, with particular focus on assessing anthropometric, dietary intake and the overall complementary feeding practices.

Methods: A cross-sectional survey was conducted in 2015 with 138 children aged 5 to 30 months. Anthropometric status of children and mothers was assessed using z-scores for height-for-age (HAZ) and body mass index (BMI) respectively. Dietary intakes were estimated using a 24hr recall questionnaire. Multiple linear and logistic regression models were performed to study the predictors and risk factors of stunting respectively.

Results: The stunting prevalence in children was 42%. Among children, only half had been exclusively breastfed. Most of the children fell into the low dietary diversity score group (62%) with the majority of children consuming plant-based diet with little to no animal source foods. Overall the nutrient intake was below the dietary recommendations for breastfeeding children. Higher BMI of caregivers and higher intake of dietary zinc positively predicted height-for-age. Age increased the risk of stunting while exclusive breastfeeding and the use of deworming tablets were protective.

Conclusions: Encouraging exclusive breastfeeding, the use of deworming tablets and timely introduction of complementary foods rich in bioavailable nutrients can contribute in reducing the risk of stunting in children in the Northern Province of Rwanda. Dietary diversification by including locally available and nutritious products can greatly contribute in increasing the micronutrient intakes in children.

Keywords: stunting, dietary intake, complementary feeding practices, exclusive breastfeeding, Rwanda

PREVALENCE OF ANAEMIA AND ITS ASSOCIATED FACTORS AMONG ADOLESCENT FEMALES IN OKRIKA, RIVERS STATE, NIGERIA

[1]Aderibigbe, Olaide R.; [2]Ukegbu, Patricia.

[1]PhD Nutrition. Product Development Programme. National Horticultural Research Institute Ibadan. Nigeria.; [2]PhD Experimental Nutrition. Department of Human Nutrition and Dietetics. Michael Okpara University of Agriculture Umudike. Nigeria.

Background and objectives: Unlike children and women of reproductive age, adolescents have not been the focus of anaemia research in sub-Saharan Africa. Adolescence is a vulnerable period in the human life cycle for the development of nutritional anaemia. Girls are more likely to be victims due to added burden of menstrual loss. The study examined the prevalence of anaemia and its associated factors among adolescent females in Okrika, Rivers State, Nigeria.

Methods: In a cross-sectional design, 400 adolescent females in secondary schools were recruited using a multistage sampling technique. Validated questionnaires were used to collect data on sociodemographic characteristics and other factors associated with anaemia (malaria occurrence, use of mosquito nets, sources of helminthic infection such as unsafe drinking water and poor toilet facilities and menstrual history). A food frequency questionnaire was used collect data on food intake. Haemoglobin and packed cell volume were analysed in blood samples of the girls using standard procedures.

Results: Mild-moderate anaemia (Hb=7-11.9 g/dl) and severe anaemia (Hb<7g/dl) was found in 77.5% and 1.3% of the girls, respectively. Malaria was reported by 59.3%, 44.8% do not use mosquito nets, 42.2% drink unsafe/untreated water and 67.5% do not have good toilet facility. About 20% of the girls were experiencing irregular menses. More than half of the girls consumed at least one animal source of iron foods daily (meat-67.5%, fish-62.5%, periwinkle-51.5%). Family size correlated negatively (r=-0.336, P<0.05) and mother's occupation correlated positively (r=0.606, P<0.01) with haemoglobin levels of the girls.

Conclusions: Anaemia and its associated factors are prevalent among adolescent females in Okrika. Though, the adolescent females consumed adequate representation of iron rich foods, other risk factors of anaemia such as malaria and irregular menses were prevalent. The significant association of family size and mother's occupation with haemoglobin levels suggest a significant effect of these factors on the risk of anaemia in the girls. The results indicate that adolescent females are as vulnerable as under-five children. Therefore, special attention is needed to meet the iron requirement of this group. A holistic intervention is necessary to address these risk factors.

Keywords: Anaemia, adolescent females, risk factors, haemoglobin

Taguig City, Philippines; [5]PhD, Department of Statistics, Iowa State University, Ames, United States.

Background and objectives: The prevalence of stunting, underweight and micronutrient deficiencies are persistently high among Filipino children. Up to now, age-specific assessments of micronutrient intakes in this population are scarce. The objective of this study was to evaluate usual intakes of selected micronutrients of young children from the 2013 National Nutrition Survey in the Philippines.

Methods: Trained interviewers collected 24-hour dietary recalls from caregivers of a nationally representative sample of 2427 children aged 3 to 5 years. A second 24-hour recall was collected from 50% of the sample. Micronutrient intakes were estimated using data from the food composition tables developed by Food and Nutrition Research Institute and usual intake distributions of micronutrients were calculated using the PC-side program from Iowa State University (version 1.0). The distributions were compared with estimated average requirements (EAR) recommended by the Philippine Dietary Reference Intakes 2015. Usual intakes from the following nutrients were estimated: vitamin A, thiamine, riboflavin, niacin, vitamin C, iron, calcium and phosphorus.

Results: High prevalence of inadequate micronutrient intakes defined as the percentage of children with intakes less than EARs were found for all the vitamins and minerals except for niacin. In an ascending order, the prevalence of inadequate nutrient intakes were 11.3% for niacin, 38.2% for phosphorus, 43.9% for vitamin A, 45.2% for riboflavin, 45.2% for thiamine, 56.7% for vitamin C, 76.7% for iron and 82.8% for calcium.

Conclusions: This study demonstrated that usual micronutrient intakes of young children aged 3-5 years in the Philippines were severely inadequate. To gain insights behind the inadequate nutrient intakes and form effective measures to combat the inadequacies, further studies understanding the food sources of nutrients and the regional and socioeconomic disparities in this Filipino population are underway.

Keywords: Usual intake, micronutrients, infants, young children, the Philippines

Department of Physical Education. Tiradentes University. Brazil; [4]MSc in Physical Education. Department of Nutrition. Tiradentes University. Brazil.

Background and objectives: A proper diet is important for improving sports performance. However, athletes may have nutritional inadequacies related to the adoption of erroneous feeding strategies. The analysis of athlete´s dietary intake may help on the elaboration of nutrition interventions. The objective of the present study was to evaluate the dietary intake of adolescent soccer players.

Methods: Fifty-four teenage athletes from three professional clubs answered to a three-day food record. The nutrient intake was estimated and compared with the recommendations for athletes. Body composition was obtained by skin folds.

Results: The athletes presented a percentage of fat of 14.5 (5) percent. The analysis of energy and macronutrients showed that athletes had a low intake of calories, carbohydrate, fiber, monounsaturated fat and poly-unsaturated. About vitamins, vitamin A, C, E and B6 had the highest percentage of inadequacy. Among the minerals, who stood out on the nutritional inadequacy were calcium, folate and magnesium.

Conclusions: The athletes presented a proper body composition, however showed inadequacies both in intake of macronutrients as well as vitamins and minerals.

Keywords: Dietary intake, adolescents, soccer

ONE YEAR ADMINISTRATION OF OMEGA-3 SUPPLEMENTS REDUCES ATHEROSCLEROSIS PROGRESSION AND OXIDATIVE STRESS IN OBESE PATIENTS

[1]Dragomir, Andreea Diana; [2]Rusu, Emilia; [3]Pietrisi, Nicoleta; [4]Alexescu, Alexandra; [5]Radulian, Gabriela.

[1]MD Nutrition and Diabetes. PhD Student Nutrition. University of Medicine Bucharest. Romania. Nutrislim Nutrition Clinic Bucharest. Romania; [2]MD Nutrition and Diabetes. PhD. University of Medicine Bucharest. Romania; [3]MD Nutrition and Diabetes. Nutrislim Nutrition Clinic Bucharest. Romania; [4]MD Nutrition and Diabetes. PhD student. University of Medicine Bucharest. Romania. Nutrislim Nutrition Clinic Bucharest. Romania; [5]MD. PhD. Professor of Nutrition and Diabetes. University of Medicine Bucharest. Romania.

Background and objectives: According to studies, obesity and inflammation are related to important cardiovascular and metabolic complications. The objective of this study was to asses the impact of omega-3 supplements on the progression of atherosclerosis and oxidative stress.

Methods: 290 obese patients, without clinical evidence of atherosclerosis, aged 65 ± 8.4 years, were assigned to 2 groups: group A (140 patients) received only diet according to American Heart Association recommendations; group B (150 patients) received the same diet plus omega-3 fatty acids supplements (1 g eicosapentanoic acid, 1 g docosahexanoic acid, 0,1 g α-tocopherol acetate). BMI > 30 kg/m2 was used as criteria for obesity. Body fat mass (BFM) and body fat percent (%BF) were measured using bioimpedance analysis (BIA). Oxidative stress was determined using FormOx monitor tests on a blood drop. Intima-media thickness (IMT) was measured for atherosclerosis progression. Patients were evaluated at baseline, after 6 and 12 months.

Results: After 12 months, all parameters were significantly improved in group B (diet plus omega-3 supplements) than in group A: LDL-cholesterol was 158 ± 17.4 mg/dl versus 172 ± 18.9 mg/dl (p<0.002), HDL-cholesterol was 59 ± 11 mg/dl versus 50 ± 12 (p<0.05), triglycerides were 121 ± 46 mg/dl versus 136 ± 56 mg/dl (p=0.002) and fasting plasma glucose was 104 ± 12 mg/dl versus 112 ± 14 mg/ dl (p<0.0001). FormOx monitor registered decreased Fort units in group B patients 248 ± 48 Fort units versus 270 ± 78 Fort units in group A (p<0.0001).

Progression of atherosclerosis was more delayed in group B, comparative with group A: IMT on left commune carotid artery was 0.608 ± 0.04 versus 0.622 ± 0.068 mm (p=0.001) and IMT on right commune carotid artery was 0.590 ± 0.048 vs. 0.611 ± 0.056 mm (p<0.0001). IMT was also correlated with %BF (p<0.001), waist-to-hip ratio (WHR) (p=0.002), leptin levels (p<0.001), adiponectin levels (p<0.05), leptin to adiponectin ratio (p<0.001) and oxidative stress (p<0.001).

Conclusions: One year administration of omega-3 fatty acids supplements improves cardiovascular and metabolic parameters, decreases oxidative stress and delays progression of atherosclerosis.

FOOD-TO-FOOD FORTIFICATION OF PEARL MILLET INSTANT PORRIDGE TO INCREASE IRON AND ZINC NUTRITIVE VALUES

[1]van der Merwe, Renee; [2]Taylor, John R.N.; [3]Kruger, Johanita.

[1]MSc. Nutrition. University of Pretoria. South Africa; [2]Professor. Department of Food Science. University of Pretoria. Pretoria. South Africa; [3]PhD. Nutrition. Department of Food Science. University of Pretoria. Pretoria. South Africa.

Background and objectives: The most prevalent micronutrient deficiencies in Sub-Saharan Africa are iron, zinc and vitamin A. Information on food sources rich in provitamin A is readily available, however the efficacy of specific plant foods, used to complement cereal-based diets, to address iron and zinc deficiencies is seriously lacking. The objective was to evaluate the effect of plant foods high in iron and zinc, combined with provitamin A, on the mineral nutritive value of pearl millet instant porridge.

Methods: Dried plant crops (moringa leaves, baobab fruit pulp, hibiscus calyces, mango fruit pulp, and carrots) were analysed for mineral, total phenolics, condensed tannin and phytate contents. The effects of adding 30% provitamin A source (49% carrot and 51% mango blend) and 5% & 15% moringa, hibiscus or baobab to whole pearl millet instant porridges on iron and zinc bioaccessibilities (in vitro dialysability) was determined. The iron and zinc contents and bioaccessibilities were compared to the RDA and absolute (physiological) requirements (AR) of children aged 2-5 years, respectively.

Results: Instant pearl millet porridge fortified with 15% moringa had the highest iron content and could provide approximately 33% and 15% of the iron and zinc RDA, respectively of 2-5 year old children. However, all plant crops had phytate:iron and phytate:zinc molar ratios above the critical levels (1:1 and 15:1, respectively). Despite the high iron contents of moringa (58.4 ± 4.5 mg/100 g, db), 15% addition to pearl millet decreased the percentage bioaccessible iron. Compared to pearl millet porridge alone, moringa addition (5%) roughly doubled the iron and zinc AR, whereas moringa (15%) had the same contribution to iron and zinc AR of 2-5 year olds. Addition of 15% baobab resulted in the greatest significant ($p \leq 0.05$) increase in percentages and amounts of bioaccessible iron (129% and 225%, respectively) and zinc (154% and 181%, respectively), despite the substantial amounts of condensed tannins (228 ± 270 mg CE/100 g). The addition of baobab increased the contribution towards iron and zinc AR approximately 3 fold, probably due to the high organic acid content.

Conclusions: Including baobab in a cereal based diet, shows potential to increase the iron and zinc nutritive values.

BREAST MILK INTAKE IN A GROUP OF EXCLUSIVE OR PARTIAL BREASTFED INFANTS FROM ARGENTINA: PRELIMINARY STUDY

[1]Nápoli, Cristián; [2]Possidoni, Cristina; [3]Tarducci, Gabriel; [4]Giordanengo, Sergio; [5]Vidueiros, Silvina Mariela; [5]Pallaro, Anabel N.

[1]Pharmacist and biochemical. Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Cátedra de Nutrición. Argentina.; [2]Nutritionist. Hospital Sagrado Corazón de Jesús de Basavilbaso. Provincia de Entre Ríos. Argentina.; [3]PhD. Universidad Nacional de La Plata. Facultad de Humanidades y Ciencias de la Educación. Cátedra de Actividad Física para la Salud. IdHICS CONICET. Argentina.; [4]Doctor. Hospital Sagrado Corazón de Jesús de Basavilbaso. Provincia de Entre Ríos. Argentina.; [5]PhD. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Nutrición. Argentina.

Background and objectives: Exclusive breastfeeding is recommended during the first six months of an infant´s life. There is evidence that the early introduction of formula or complementary foods reduce levels of breast milk (BM) intake. The aims of this study were to determine the intake of BM and water from non-breast milk sources (W non-BM) in exclusive breastfed (EBF) and partial breastfed (PBF) infants, and to estimate macronutrient intake in these groups.

Methods: This study was performed in 18 mother-infant pairs at 4 months to birth from Entre Ríos and Buenos Aires provinces. Dose- to the mother deuterium-oxide turnover technique (DMDOT) was used to measure breast milk intake. Mothers received an oral dose of deuterated water and 6 samples of saliva were collected from mother and baby during a period of 15 days. Deuterium enrichment was determined in a Shimadzu FTIR-spectrometer-Affinity to obtain the intake of BM (mL/d) and W non-BM (mL/d). Infants were classified into EBF (n = 11) or PBF (n = 7) categories based on a 24-hour recall to the mother. Macronutrient intake from BM was calculated using WHO data on breast milk composition. We considered that the volume of W non-BM, obtained from the DMDOT technique, was from formula so intake of energy (kcal/day), protein (g/day), fat (g/day), and carbohydrates (g/day) was estimated using the nutritional composition of the commercial infant formula that mothers referred. Energy and protein requirements were calculated according FAO recommendations.

Results: Results are expressed as Mean (IC95%). BM intake was significantly different between groups (EBF: 950.2 (818.2-1082.2) vs PBF: 710.0 (570.6-849.4), p<0.05). W non-BM was significantly higher in PBF compare to EBF (170.0 (-17.0-357.0) vs 15.2 (3.1-27.3), p<0.001). Taking into account only BM intake, all EBF infants met their energy and protein requirements as well as 57% of PBF infants.

Conclusions: Knowing breast milk intake, obtained by DMDOT as the reference method, is relevant to investigate the extent to which the breast milk is being replaced by the consumption of other foods and for evaluating infant feeding pattern and nutritional adequacy. Supported by PB04 and OIEA RLA 6071.

ASSOCIATIONS BETWEEN FAT FREE MASS AND MUSCLE STRENGTH AND PHYSICAL PERFORMANCE IN A GROUP OF OLDER WOMEN FROM ARGENTINA

[1]Zarza, Laura; [2]Nápoli, Cristián; [3]Tarducci, Gabriel; [4]Paganini, Amalia; [4]Gargano, Sofía; [4]Gandini, Agustina; [5]Fernandez, Inés; [5]Vidueiros, Silvina Mariela; [5]Pallaro, Anabel N.

[1]Pharmacist. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Nutrición. Argentina.; [2]Pharmacist and biochemical. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Nutrición. Argentina.; [3]PhD. Universidad Nacional de La Plata. Facultad de Humanidades y Ciencias de la Educación. Cátedra de Actividad Física para la Salud. IdHICS CONICET. Argentina.; [4]Lic. Universidad Nacional de La Plata. Facultad de Humanidades y Ciencias de la Educación. Cátedra de Actividad Física para la Salud. IdHICS CONICET. Argentina.; [5]PhD. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Nutrición. Argentina.

Background and objectives: Low muscle mass and physical performances occur with advancing age. The aim of this study was to analyze the association between the fat free mass (FFM) and muscle strength and physical performance in older individuals.

Methods: 23 older women (60 - 84 years old), who attended recreational centers for elderly in Buenos Aires province, Argentina, were assessed. Body weight (kg) and height (m) were determined and body mass index (BMI) was calculated (kg/m2). %FFM and %Fat mass (FM) were evaluated by deuterium dilution technique. Handgrip strength (HS, kg) was measured using a Jamar ® Hydraulic Hand Dynamometer. Physical performance was evaluated by Gait speed (GS, m/s) and Timed get up and go test (TGUG, s).

Results: 30% overweight and 50% obesity were observed with %FM = 43.1 ± 4.7 (IC95% = 41.1-45.1). BMI and %FM were associated (r=0.87; p<0.0001). HS, GS and TGUG (mean ± DS (IC95%)) were 20.07 ± 3.50 (18.56-21.59); 1.42 ± 0.33 (1.23-1.57) and 8.73 ± 2.16 (8.01-9.38), respectively. HS significantly decreased with age (p<0.0279) but no significant differences were found neither in GS (p<0.8052) nor TGUG (p< 0.7332); however, TGUG tended to increase in older women. %FFM was associated to GS (r=0.58, p<0.0046) and it was inversely associated to TUGT (r=-0.51, p<0.0163).

Conclusions: In this preliminary report, it was found a high obesity degree and associations between FFM and muscle strength and physical performance tests in older women who participate in recreational activities. At present, adult women with greater physical deterioration are being evaluated as these associations could be important risk factors for adverse events like falls, fractures, daily living disabilities and independence loss. Supported by PB04 and IAEA RLA 6073.

EFFECT OF MILK ADDED WITH COCOA POWDER ON APPARENT CALCIUM ABSORPTION IN AN EXPERIMENTAL MODEL IN RATS

[1]Weisstaub, Adriana Ruth; [1]Vidueiros, Silvina Mariela; [2]Fleischman, Silvana; [1]PERRIS, PAULA; [1]Langini, Silvia; [1]Pallaro, Anabel N.

[1]PhD. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Nutrición. Argentina.; [2]Pharmacist. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Nutrición. Argentina.

Background and objectives: Calcium (Ca) absorption from foods varies between 30-40%, and is conditioned by the presence of components that stimulate or inhibit it. Low intakes of Ca during childhood and adolescence could condition the subsequent loss of bone mass in adulthood, resulting in a high incidence of osteoporosis. Therefore, Ca bioavailability becomes a key factor to reach or maintain a critical peak bone mass. The addition of chocolate or cocoa powder to milk is a popular nutrition habit. Cocoa powder contains oxalic acid (450-480 mg/100g), an inhibitor of calcium absorption. However, calcium bioavailability studies regarding oxalate impaired effect are contradictory. Therefore, the effect of milk added with cocoa powder on the apparent calcium absorption (ACaA%) was studied in an animal model including young and adult rats.

Methods: Thirty-six Wistar rats at weaning (6/group) were fed:1)a control diet prepared according to the American Institute of Nutrition (C); 2) a semisynthetic diet prepared with whole milk powder reduced in lactose (77 mg lactose/g milk) (M), and 3) the milk diet added with cocoa powder (MC).The three diets were isocaloric (4.1 kcal/100g diet) and supplied the same amount of Ca (0.5 g/100g diet). Three groups of rats received control or experimental diet from weaning (age=23 days) up to 33 days old (T1); other three groups of young adult rats (age=49 days) were fed the same diets up to 66 days old (T2). At T1 and T2, food intake was recorded and feces were collected during the last three experimental days to determinate ACaA% = [(CaI - CaF)/CaI] x100. Ca intake (CaI) (mg/d) was calculated from Ca concentration in diets. Microwave acid digestion for Ca diets and Ca feces (CaF, mg/d) was done in Parr Bombs (Parr Instrument Company). Ca concentration was determined by atomic absorption spectrometry (Perkin Elmer AA400).

Results: At T1, MC had lower ACaA% than M and C: 45.0±3.9 vs 82.9±6.4 vs 69.0±3.3, respectively; at T2 ACaA% was: 21.1±5.5 vs 54.5±9.1 vs 71.1±3.0, respectively (p<0.0001).

Conclusions: These results suggest that the addition of cocoa powder to milk may result in a decrease apparent calcium absorption in rats, either earlier or later in life.

Keywords: Calcium absorption, milk, cocoa powder, rats.

DIETARY SUPPLEMENT INTAKES AMONG HIGH SCHOOL MALE ATHLETES

[1]*Kanbe, Kinuyo;* [2]*Muto, Shimako;* [3]*Koyama, Yuzou;* [4]*Musha, Yoshiyuki.*

(1) PhD. Nihon University; (2) PhD. Kagawa Nutrition University; (3) PhD. Nihon University; (4) Director at track and field club.

Background and objectives: Dietary supplements are intended to make up for nutrient deficiency in daily life and to improve sports performances. We clarified the status of supplement usage, comprehension, and nutrient intakes for high school male athletes from the questionnaires.

Methods: In total, we surveyed 239 people with a football club (64 members), a tennis club (75), a baseball club (45) and track-and-field club (55) belonging to the male athletic clubs of N University Highschool. The self-administered questionnaires on supplements and nutrient intakes (food frequency questionnaire) were distributed and collected later.

Results: The rate of supplement intake was 35% overall. The track-and-field club was significantly higher with 65.5% than the others and were the same level as top athletes. The main purpose of intake for 60% of all subjects was "increasing muscle and weight", and 40% for "fatigue recovery". 80% of baseball members took supplements for "increasing muscle and weight", and 70% of track-and-field for "fatigue recovery" which was significantly high. The breakdown of "no reason" was 30% for "enough in the usual diet", 20% for "seems to be bad for health" and "bothers to use", and 10% for "expensive", 50% for "not interested in". As for the nutrients, protein intake was 70%, carbohydrates 30%, both amino acids and vitamins were 10%. The track-and-field was significantly high in 30% of amino acids. The timing of intake was "before going to bed" "after exercise" and "during exercise" which were high. 80% of subjects answered "read" or "read and understand" of nutritional labeling of supplements and 50% were careful with "usage quantity" or "intake time". The sources of information are "at a sports store"40%, "from the Internet" and "from friends or parents" were 30%.

Conclusions: In contrast to team play, individual competitive edge is directly connected with the high intake rate of the track-and-field club. Some members took supplements despite the fact that they didn't understand the suitable amount of nutrient intake. Since supplement intake is ultimately based on athletes' self-control, supervisors, and coaches must understand the need of athletes and cooperate with registered dietitians, including correct knowledge for legally prohibited additives or doping substances.

Keywords: dietary supplements ,high school male athletes,sports performances,nutrient intakes

DETERMINATION OF NIACIN ACTIVITY IN WHEAT GERM USING QUINOLINATE PHOSPHORIBOSYLTRANSFERASE DEFICIENT MICE

[1]*Fukuwatari, Tsutomu;* [2]*Ohara, Chihiro;* [2]*Miyoshi, Asami.*

[1]PhD. Department of Nutrition. The University of Shiga Prefecture. Japan.; [2]Department of Nutrition. The University of Shiga Prefecture. Japan.

Background and objectives: Taking enough niacin and tryptophan is important to prevent pellagra and maintain niacin nutrition. Although wheat germ contains tryptophan and high amount of niacin, matured cereal grains generally show low bioavailability of niacin. This is because several factors such as food matrix, chemical structure and presence of bound form affect bioavailability of B-group vitamins in foods. In the present study, we investigated niacin activity including bioavailability of niacin and conversion of tryptophan to nicotinamide in wheat germ using quinolinate phosphoribosyltransferase deficient (QPRT-KO) mice, which lack tryptophan-nicotinamide pathway.

Methods: Wild type (WT) and QPRT-KO mice were fed a control diet containing 0–30 mg/kg nicotinic acid or 60% wheat germ diet for 28 days. Urine nicotinamide metabolites, and blood and liver NAD and total nicotinamide were measured. These biomarkers were compared between mice fed control diets and wheat germ diets, and niacin activity in wheat germ was determined.

Results: Urinary nicotinamide metabolites strongly correlated with nicotinic acid intake in both WT and QPRT-KO mice fed control diets, and the linear regression equation was determined. Bioavailability of niacin in wheat germ was calculated to be 79 ± 10% using the equation and urinary nicotinamide metabolites in QPRT-KO mice fed wheat germ diet. Conversion ratio of tryptophan to nicotinamide was also determined in mice fed wheat germ diet, and was 1.3 ± 0.2%, same ratio as mice fed 20% casein diet. NAD and total nicotinamide in the liver and blood were same in mice fed control diets and 60% wheat germ diet.

Conclusions: Wheat germ shows high niacin activity both in bioavailability of niacin and conversion ratio of tryptophan to nicotinamide. When present results apply to human, wheat germ may contain 8 mgNE/100 g of bioavailable niacin which corresponds to 50% of RDA for adult men. Wheat germ can be a good niacin source to prevent pellagra and maintain niacin nutrition.

Institute of biomedical researcher in Málaga (IBIMA). Regional University Hospital of Málaga. Spain.

Background and objectives: Obesity is thought to be an important contributing factor to the development of elevated blood pressure (BP) in children, and intra-abdominal fat (IAF) has been identified as the main determinant of several metabolic disorders. Changes in central adiposity and BP can occur in response to physical activity (PA) and a balanced diet. The aim of this study was to examine the associations among PA, fat distribution, mainly abdominal fat, nutrition and BP in obese children.

Methods: Seventy-eight obese children (n = 43 boys, age = 7.8±1.3 years, weight = 46.9±10.3 kg, FMP = 40.8%, BMI = 25.1±3.4 kg/m2) participated. Total body fat and IAF were assessed by dual energy x-ray absorptiometry (DXA). The abdominal region was delineated by an upper horizontal border located at half of the distance between acromion and external end of iliac crests, a lower border determined by the external end of iliac crests and laterally to any trunk soft tissue. PA was objectively assessed on 7 consecutive days by accelerometry (Actigraph TM GT3X). BP was measured using an automated BP monitor. Adherence to a Mediterranean diet was estimated by a modified version of the Trichopoulou questionnaire (removing item 8). Spearman rank correlation coefficient were used to explore associations between variables.

Results: No child met PA recommendations (≥60 minutes daily of moderate-to-vigorous PA). The prevalence of elevated systolic BP and diastolic BP was 1.3% and 13.2%, respectively. There were significant associations between systolic BP and IAF (rho = 0.324, p<0.01); MVPA and %IAF (rho = -0.526, p<0.001); and the nutrition questionnaire score and %IAF (rho = -0.298, p<0.01). There was no association between PA and BP.

Conclusions: There is a positive relationship between IAF and blood pressure, and a strong negative relationship among PA, diet and IAF in obese children. Adherence to a Mediterranean diet and the performance of MVPA could help to reduce visceral abdominal fat in obese children.

Keywords: obesity, childhood, DXA, exercise, nutrition.

ANTHROPOMETRIC STUDY BY SOCIOECONOMIC STATUS IN SEMI-URBAN SCHOOLCHILDREN IN KENITRA CITY IN NORTH-WEST MOROCCO

[1]Agoutim, Naima; [2]Aboussaleh, Youssef; [3]Ahami, Ahmed Ot; [4]Sbaibi, Rachid.

[1]Phd Nutrition ,Health and environement . University IBN TOFAIL KENITRA/MOROCCO; [2]Pr.Phd Nutrition, Laboratory of Nutrition. Health and Environment. Department of Biology. Faculty of Sciences. University Ibn Tofail. BPa; [3]Pr.Phd Neurosciences, Behavioral and Cognitive . Laboratory of Neurosciences, Behavioral and Cognitive. University Ibn Tofail, Kénitra, Morocco; [4]Phd Nutrition, Laboratory of Nutrition. Health and Environment. Department of Biology. Faculty of Sciences. University Ibn Tofail. BPa.

Background and objectives: The nutritional problem among schoolchildren, in rural and urban areas has been the subject of several studies, while the semi-urban environment remains to be unveiled. The present study aims to evaluate the nutritional status according to the socio-economic status of schoolchildren aged from 6 to 16 years, from Imam Boukhari school in the Kenitra city in northern Morocco.

Methods: The anthropometric survey was conducted among 239 schoolchildren of average age (10.22 ± 2.10), weight and height were measured according to the procedure recommended by WHO (World Health Organization), The anthropometric indices adopted are: weight-for-age, and height-for-age and body mass index (BMI), determined by the Z score calculated according to the WHO growth references 2007 (5-19 years). The socio-economic status of schoolchildren was assessed by a questionnaire that refers to age, gender, household size, parental education, and the job of the parents.

Results: The finding showed an underweight of 4.3% (<10 years), stunting (6.3%), thinness (3.8%), a low rate of risk of overweight (4.3%) and obesity (0.9%). The socio-economic status of parents is quite low: The size of the household is 5 persons (42.7% of households have more or equal to 5 persons). The illiteracy

among parents is high 31.5% (25.1% of fathers, 38% of mothers), 58% of fathers have a low monthly income, as well as 79.1% of mothers are not engage in any paid occupation. In addition, a CH2 test of independence at 5% error revealed an independence between the socio-economic factors and the various anthropometric indicators.

Conclusions: The sample studied suffers from moderate malnutrition, with no socio-economic effect on nutritional status. The semi-urban environment showed a slight regressive effect on the prevalence of malnutrition in relation to the rural environment.

Keywords: schoolchildren, semi-urban, nutritional status, socio-economic status

DIETARY PATTERNS DESCRIBED BY PRINCIPAL COMPONENT ANALYSIS AND SODIUM INTAKE IN HEALTHY ADULTS

[1]Benítez, Alejandra; [2]Becerril Alarcón, Yizel; [2]Neri Sánchez, Marisol; [3]Valdes-Ramos, Roxana; [3]Martinez-Carrillo, Beatriz Elina; [3]Vargas Hernández, Joel Alberto.

[1]PhD. Professor researcher. Medicine School. Universidad Autónoma del Estado de México. México.; [2]Master in Health Science. Universidad Autónoma del Estado de México. México.; [3]Dr. in Science. Professor researcher. Universidad Autónoma del Estado de México. México.

Background and objectives: Dietary patterns (DP) are widely used to assess nutrients intake. High sodium intake has been described as a modifiable risk factor for hypertension and cardiovascular disease. Identification of risk factors in healthy populations, makes it possible to propose preventive interventions. The propose of this research was to identify dietary patterns in healthy adults describing its relationship with sodium intake.

Methods: Longitudinal study in 130 healthy men and women. DP were identified by principal component analysis (PCA); dietary sodium derived from multiple 24 hour recalls and quantified according to the content of sodium in food.

Results: Five DP were identified: DP-I characterized by consumption of cereals and sugars, DP-II by meat and canned food; DP-III by fruits, vegetables, oils-fats, and the lowest amount of sodium (prudent), DP-IV by meat; and DP-V by dairy products. In this healthy subjects, consumption of fruits, vegetables, cereals and legumes explains 69% of the variance, and men exceed daily sodium intake recommendations.

Conclusions: Prudent DP is practiced only by 20% of participants. Healthy men in this study consume very high amounts of sodium in their diet. Interventions in DP are necessary in disease prevention and health promotion strategies.

Keywords: dietary patterns, principal component analysis, sodium.

IRON INTAKE AND STATUS: HOW ARE THE RESIDENTS OF SÃO PAULO, BRAZIL

[1]Hermes Sales, Cristiane; [2]dos Santos Vieira, Diva Aliete; [3]de Mello Fontanelli, Mariane; [4]Fisberg, Regina.

[1]PhD. Postdoctoral researcher. Department of Nutrition. School of Public Health. University of Sao Paulo.; [2]PhD. Department of Nutrition. School of Public Health. University of Sao Paulo. Brazil.; [3]MSc. PhD Student. Department of Nutrition. School of Public Health. University of Sao Paulo. Brazil.; [4]PhD. Assistant Professor. Department of Nutrition. School of Public Health. University of Sao Paulo. Brazil.

Background and objectives: Worldwide, iron has been a target of studies, because of the functional consequences related to its deficiency. In Brazil, since 2004 was introduced the policy to fortify wheat and corn flours with iron for all population, which reinforcing the importance of nutritional iron status monitoring. This study aimed to estimate the prevalence of dietary iron inadequacy and its blood status.

Methods: Data were obtained from the 2015 Health Survey of Sao Paulo (n 880; age range 12 to 93 years), a cross-sectional population-based study developed among residents from urban area of São Paulo, Brazil. Dietary iron intake was measured using two 24-h dietary recalls, and it was assessed in Nutrition Data System for Research programme. The dietary iron content of foods was checked and when necessary corrected using data from Brazilian food composition tables. Usual iron intake was estimated using the Multiple Source Method programme. Probabilistic approach was used to estimate the prevalence of inadequate intake. Haemoglobin and serum ferritin concentrations were assessed in fasting blood samples. The presence of anaemia was established by haemoglobin concentrations < 120 g/dL (male adolescents with 12 to 14 years); < 130 g/dL (men with 15 years and older), and < 120 g/dL (all non-pregnant women); and low serum ferritin was defined as serum ferritin concentrations < 15 μg/L.

Results: The prevalence of iron inadequacies varied from 1.6% to 13.8% in men, and from 7.3% to 40.5% in women. Otherwise, the prevalence of anaemia was from 0.0% to 10.5% in men, and 0.0% to 13.8% in women, and low serum ferritin varied from 0.0% to 3.0% in men and 1.7% to 18.4% in women.

Conclusions: Women showed to be more vulnerable to nutritional iron deficiency. Prevalence of iron inadequacy assessed by dietary intake overestimate iron deficiency when compared to blood status.

Keywords: Dietary iron. Iron deficiency. Nutrition survey. Nutritional status.

NUTRITION KNOWLEDGE AND FOOD PORTIONS INGESTION OF ADOLESCENT SOCCER PLAYERS

[1]Sobral, Camille; [2]Santos, Monique; [2]Brito, Layla; [2]Barreto, Anna; [2]Noronha, Danilo; [2]Fernandes, Rúbia; [3]Gomes, Luis; [4]Nascimento, Marcus.

[1]Bsc.Nutritionist.Department of Nutrition.Tiradentes University. Brazil.; [2]BSc in Nutrition. Department of Nutrition. Tiradentes University. Brazil; [3]MSc in Nutrition. Department of Physical Education. Tiradentes University. Brazil; [4]MSc in Physical Education. Department of Nutrition. Tiradentes University. Brazil.

Background and objectives: Athlete´s Nutrition knowledge may improve food choice and dietary ingestion, however, studies have shown that athletes have poor nutrition knowledge. The analysis of athlete´s nutrition knowledge and dietary intake may help in the development of specific nutrition intervention strategies. The objective of the present study was to evaluate the nutrition knowledge and food portions intake of adolescent soccer players.

Methods: Fifty-four athletes from three professional clubs responded to a three day food record and a validated questionnaire about nutritional knowledge and sources of information on nutrition. The ingestion of food portions was estimated and compared with the recommendations for the Brazilian population.

Results: The athletes had a hit percentage of 44.7 (25.6) percent in the test of knowledge in nutrition. The most commonly used source of nutrition information for athletes was the coach, followed by the internet and friends. The athletes presented a low consumption of vegetables, fruits and a high intake of oils and fats. The main difficulties reported by athletes for the adoption of healthy eating were the and the lack of time and willpower. There was no correlation between knowledge in nutrition and the ingestion of food portions.

Conclusions: The athletes presented low knowledge in nutrition and reported using sources of nutrition information of low reliability. In addition, they presented an inadequate food intake.

Keywords: Nutrition knowledge, teenagers, soccer

IRON, VITAMIN B12, AND FOLATE BIOMARKERS AND ANEMIA IN WOMEN PARTICIPATING IN A RANDOMIZED TRIAL OF DOUBLE-FORTIFIED SALT IN DARJEELING, INDIA

[1]Fothergill, Amy; [2]Haas, Jere D.; [2]Venkatramanan, Sudha; [3]Finkelstein, Julia.

[1]MPH. Department of Nutritional Sciences. Cornell University. USA.; [2]PhD. Division of Nutritional Sciences. Cornell University. USA; [3]ScD. Division of Nutritional Sciences. Cornell University. USA.

Background and objectives: The objective of this analysis was to examine the associations between iron, vitamin B12, and folate biomarkers and anemia among women of reproductive age participating in a randomized efficacy trial of double-fortified salt in India.

Methods: Participants were 244 women (18-55 y) enrolled in a randomized efficacy trial of double-fortified salt in Darjeeling, India. Iron status [hemoglobin (Hb), serum ferritin (SF), soluble transferrin receptor (sTfR), and total body iron (TBI)], inflammatory biomarkers [C-reactive protein (CRP) and -1 acid glycoprotein (AGP)], serum vitamin B12, and serum folate were evaluated at enrollment. Anemia was defined as hemoglobin <120 g/L; iron deficiency was defined as serum ferritin <15.0 μg/L (TBI<0.0 mg/kg, sTfR>8.3 mg/L); and inflammation was defined as CRP >5 mg/L or AGP >1 g/L. Vitamin B12 deficiency and insufficiency were defined as <148 pmol/L and <221 pmol/L; and folate deficiency defined as serum folate <6.8 nmol/L. Linear and binomial regression models were used to examine the associations between micronutrient biomarkers and hemoglobin concentrations and anemia, respectively.

Results: At baseline, 52.9% of women were anemic (Hb<120 g/L), 44.3% were iron deficient (SF<15.0 μg/L), and 42.6% had iron deficiency anemia (Hb<120 g/L and SF<15.0 μg/L); 25.0% had elevated CRP or AGP (CRP>5 mg/L or AGP>1 g/L). B-vitamin deficiencies were also common at enrollment: 30.3% of women were vitamin B12 deficient (<148 pmol/L), 63.5% were vitamin B12 insufficient (<221 pmol/L), and 83.2% had folate deficiency (<6.8 nmol/L). Increased serum ferritin, sTfR, and TBI levels were associated with significantly higher hemoglobin concentrations at baseline. Higher total body iron was associated with lower risk of anemia at baseline, while iron deficiency (SF<15.0 μg/L) and inflammation (CRP>5.0 mg/L) were associated with increased risk of anemia; B-vitamin deficiencies were not significantly associated with risk of anemia. The risk of anemia at baseline was 1.6 times higher among women with iron deficiency (SF<15.0 μg/L), compared to women with replete iron status (RR: 1.61; 95% CI: 1.29, 2.01; p<0.0001).

Conclusions: The prevalence of iron, vitamin B12, and folate deficiencies and anemia were high in this population. Iron deficiency and inflammation were associated with significantly increased risk of anemia.

Keywords: Anemia, micronutrient, iron, B-vitamin, fortification

ASSESSMENT OF NUTRITIONAL STATUS, EATING HABITS AND THEIR DETERMINANTS AMONG MAKERERE UNIVERSITY STUDENTS, UGANDA

[1]Ainomugisha, Prudence; [2]Ssenyondo, Muzafaru; [3]Murungi, Solomon; [2]Nyakake, Lynn; [2]Ahumuza, Gracious; [4]Opolot, Phillip.

[1]Bsc.Nutritionist. Food Technology And Nutrition. Makerere University. Uganda; [2]BSc.Nutritionist. Food Technology and Nutrition. Makerere University. Uganda.; [3]BSc. information Specialist. Information Technology. Makerere University. Makerere; [4]BSc. Statistician.Statistic and Applied Economics.

Background and objectives: Back ground: Eating habits determine the health status of individuals (Walter and willet, 2003). A healthy eating habit involves having at least three main meals a day and healthy snacks in between. WHO recognizes the importance of improving diet and lifestyle for prevention of chronic diseases like diabetes and hypertension. However, increased industrialization, technology and changing lifestyles have led to change in eating habits of students, tending to much lower consumption of vegetables, fruits and whole grains with high consumption of foods high in fats, free sugars or salt that lead to chronic development of diseases. Eating habits and their determinants vary across cultures, while information about these nutrition-related factors would help in the development and implementation of effective nutritional programs in the universities that may act as a deterrent against unhealthy eating habits since universities provide an ideal means for reaching out to a large number of young adults. Objective: To identify the eating habits, their determinants and assess the nutritional status among Makerere university students.

Methods: A self-administered questionnaire was filled by 393 students (47.8%) females and (52.2%) males. Eating habits and demographics were recorded while blood pressure, height, weight were measured and BMI calculated. Data analysis was performed using SPSS version 16.

Results: Most of the respondents had unhealthy eating habits like unhealthy snacking (85% of students) with 42.1% snacking on cookies and very few (1.0%) on vegetables. Their eating habits were mainly influenced by availability of time, accessibility of eating places, availability of food stuffs, tastes and preferences. Most of the students (96.1% and 76.9%) had good nutritional status basing on waist circumference and BMI respectively. According to BMI, 15% of the students were overweight and 8.1% underweight. Basing on WC, 3.9 % of the respondents were obese. Most of the students had high blood pressure (46%). Nutritional status (based on waist circumference) was significantly (p<0.005) associated with eating habits.

Conclusions: Most University students had unhealthy eating habits. There is a need of nutrition intervention programs that can improve the eating habits of University students.

Keywords: Eating habits, health status, snacking, and nutrition intervention.

PREDICTORS OF SUB-CLINICAL VITAMIN A DEFICIENCY IN SENEGALESE 6 MONTHS LACTATING WOMEN

[1]Idohou-Dossou, Nicole; [2]Agne-Djigo, Anta; [3]Diouf, Adama; [4]Wade, Salimata.

[1]PhD. Nutritionist. Laboratoire de Nutrition. Faculté des sciences et techniques. Université Cheikh Anta Diop de Dakar. Senegal. BP 5005, Dakar-Fann, Sénégal; [2]PhD. Nutritionnist. Laboratoire de Nutrition. Faculté des Sciences et Techniques. Université Cheikh Anta Diop de Dakar. Sénégal.; [3]PhD. Nutritionnist. Laboratoire de Nutrition. Faculté des Sciences et Techniques. Universisté Cheikh Anta Diop de Dakar. Sénégal.; [4]PhD. Nutritionist. Laboratoire de Nutrition. Faculté des Sciences et Techniques. Université Cheikh Anta Diop de Dakar. Sénégal.

Background and objectives: Plasma retinol (PR) and breast milk retinol (BMR) were indicators recommended by WHO for assessing vitamin A status of lactating women at subclinical level. PR is homeostatically controlled, and was usually affected by infections/inflammation. BMR may reflect recent dietary intake but it is currently unknown if the level was influenced by systemic infections. Thus, this study aimed to evaluate the performance of BMR and PR to detect vitamin A deficiency (VAD) among the Senegalese lactating women, and the relationship between BMR and their inflammatory status.

Methods: An experimental study was undertaken in 184 non-pregnant lactating women at 6 months post-partum, randomly selected in suburbs of Dakar (Senegal). The indicators measured were: plasma, casual and full breast milk retinol concentrations by HPLC, fat content of fresh milk by creamatocrit, plasma C-reactive protein (CRP) and alpha 1-acid-glycoprotein (AGP) by immuno-turbidimetry. Receiver operating characteristics (ROC) analysis was used to compare the performance of BMR (expressed as μmol/L and μg/g fat) and PR to predict VAD among the Senegalese lactating women.

Results: PR detected 3.3% of VAD among the women. BMR, expressed by μmol/L (≤1.05 μmol/L) in casual and full milk, detected 22.7% and 21.6% of VAD, respectively. When expressed by μg/g fat, the prevalence of VAD (BMR<8.8 μg/g fat) were 10.3% and 8.2% using casual and full milk, respectively. ROC-analysis showed that the area under the curve of BMR μg/g fat in full milk (AUC=0.949; 95% CI: 0.917-0.981) was higher than the others indicators to predict VAD. No significant relationship was found between CRP/AGP and BMR.

Conclusions: PR detected the lowest prevalence of VAD among the women. However, according to WHO, BMR μmol/L indicated moderate VAD while PR as well as BMR μg/g fat suggested that VAD was not a major concern among the Senegalese 6 months lactating's women living in Dakar. None of the predictors was related to systemic inflammation.

Keywords: Vitamin A deficiency, breast milk retinol, plasma retinol, lactating women, Senegal.

RISK OF ABDOMINAL ADIPOSITY AMONG BRA-ZILIAN SCHOOLCHILDREN, 2002, 2007 AND 2012/13

[1]Soar, Claudia; [2]Altenburg de Assis, Maria Alice; [3]Biazzi Leal, Danielle; [2]Faria Di Pietro, Patrícia; [4]Engel, Raquel.

[1]PhD - Graduate Program in Nutrition, Health Sciences Center. Federal University of Santa Catarina.; [2]PhD - Graduate and Postgraduate Program in Nutrition, Health Sciences Center. Postgraduate Program in Physical Education. Sports Center. Federal University of Santa Catarina.; [3]PhD - Postgraduate Program in Physical Education. Sports Center. Federal University of Santa Catarina.; [4]Postgraduate Program in Nutrition, Health Sciences Center. Federal University of Santa Catarina.

Background and objectives: Waist circumference (WC) is a sensitive marker for abdominal obesity in the pediatric age group. It has emerged as an index of pediatric adiposity that predicts fat mass as well as or better than body mass index (BMI). The purpose this study was to describe trends of the abdominal adiposity among 7–10-year-old children by investigating changes in the prevalence of the risk of abdominal adiposity.

Methods: A school-based sample of 7–10-year-old children participated in three cross-sectional studies in 2002 (n=2,936), 2007 (n=1,232) and 2012/13 (n=1,531) in Florianopolis, southern Brazil. The prevalence of the risk of abdominal adiposity was assessed using the 91st centile of the British reference as cut-off points.

Results: In 2012/13, 26,3% of the students were identified in risk of abdominal adiposity, with a substantial increase since 2002 (22,1%) and 2007 (24,6%) (p trends=0,001).

In girls, the prevalence of abdominal adiposity was 21% (2002), 21,8% (2007) and 25,9% (2012/13) (p trends=0,001). In boys the prevalence of abdominal adiposity was 23,2% (2002), 27,3% (2007) and 26,8% (2012/2013) (p=0,056).

Conclusions: Over the period studied (2002-2012/13) an increase of the risk of abdominal adiposity among schoolchildren was identified. This finding is a concern because of its association with disease risk including clustering of metabolic and cardiovascular disease risk factors. The prevalence of risk of abdominal obesity among children has become a public health problem, which would arouse special attention and an urgent need for school intervention programs.

Keywords: abdominal obesity; children; trends

PERFORMANCE OF THE GLOBODIET-BRAZIL-IAN VERSION SOFTWARE FOR DIETARY INTAKE ASSESSMENT

[1]Marchetti, Beatriz S.; [2]Steluti, Josiane; [3]Castilho, Ana C.; [4]Crispim, Sandra; [5]Araujo, Marina C.; [6]Pereira, Rosangela A.; [7]Sichieri, Rosely; [8]Yokoo, Edna; [9]Slimani, Nadia; [2]Marchioni, Dirce.

[1]Department of Nutrition. School of Public Health. University of São Paulo; [2]PhD. Department of Nutrition. School of Public Health. University of São Paulo. SP. Brazil.; [3]Department of Nutrition. School of Public Health. University of São Paulo. SP. Brazil.; [4]PhD. Departament of Nutrition. Federal Universidade University of Federal do Paraná. Curitiba. PR. Brazil; [5]PhD. Sergio Arouca National School of Public Health. Oswaldo Cruz Foundation. Ministry of Health. Rio de Janeiro. RJ. Brazil; [6]PhD. Department of Social and Applied Nutrition. Federal University of Rio de Janeiro. Rio de Janeiro. RJ. Brazil; [7]PhD. Department of Epidemiology. Institute of Social Medicine. State University of Rio de Janeiro. Rio de Janeiro. RJ. Brazil; [8]PhD. Department of Epidemiology and Biostatistics. Fluminense Federal University. Niterói. RJ. Brazil; [9]Independent researcher. France.

Background and objectives: GloboDiet is a software that conduct the interview of the 24-hour dietary recall (R24h) guided by a standardized routine. The successful experience of adapting this software in different cultural contexts in Europe led to the extension of the project to Latin American countries. Brazil was one of the selected countries to start the LA-DIETA project in collaboration with IARC, and a Brazilian version of the GloboDiet software was developed. Actually. there is a need to evaluate the performance of the Brazilian version of the GloboDiet compared to others software that have being used to estimate the dietary intake in Brazilian studies. The aims of the study were to estimate food consumption using the GloboDiet Brazilian version software and verify the agreement between the estimated intake of energy, carbohydrates, protein. and lipids on the GloboDiet versus Nutrition Data System for Research – NDSR software.

Methods: A sub-sample of 100 adult individuals was drawn from a representative sample of the resident population in the urban area of São Paulo - ISA-Capital 2008. A R24h was collected in pencil and paper for all participants and the data obtained was entered using both NDSR and GloboDiet Brazilian version. Bland and Altman analysis and Kappa statistic were used to evaluate the agreement between the software, considering the tertiles of energy and macronutrients.

Results: The mean (SD) obtained for energy, protein, carbohydrate and lipids in the NDSR were 2386.47(444.25)kcal, 100.08 (35.33)g, 286.75 (84.02)g, and 87.34(28.32)g, respectively. In comparison, the mean(SD) obtained to GloboDiet of those same variables were 2279.67(655.50)kcal, 92.94(38.35)g, 277.62(93.86)g, and 83.12(33.69)g, respectively. The mean (95%CI) of the differences between two measurements for energy, protein, carbohydrate and lipids were 106.8 (-961.3; 1174.9)kcal, 7.142 (-58.6;72.9)g, 9.1(-128.9;147.2)g and 4.2(-64.0;72.4)g, respectively. From the Kappa

statistic, it is possible to notice a slight and significant agreement(p <0.05) between the data of the software; the obtained values of Kappa were 0.28 for energy and lipids and 0.35 for carbohydrate and protein.

Conclusions: The GloboDiet Brazilian version estimated similar dietary intake (energy and macronutrients) compared to NDSR. However, further research is needed to validate the dietary intake assessment obtained using GloboDiet.

Keywords: GloboDiet, NDSR, software validation, R24h dietary recall, dietary intake assessment.

Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Nutrición. Argentina.

Background and objectives: Elevated sodium intake has been associated with a number of NCDs. To evaluate sodium intake, 24-h urinary sodium excretion (24-h UNa) was estimated using predictive equations from measured sodium concentrations in a spot urine sample.

Methods: 470 students (361 women and 109 men), aged 25.5±3.5 years, from Universidad de Buenos Aires, Argentina, were studied. Anthropometric measurements and supine blood pressure were determined. A spot urine collection was obtained to determine sodium, potassium and creatinine excretion. To estimate 24-h UNa, the INTERSALT equation was used.

Results: The mean estimated 24-h UNa (mg/d) was 2596 (95%CI: 2534 – 2658) and, as expected, was significantly higher in men than in women (3028.5±862 vs. 2465.4± 568; p< 0.0001). The 24-h UNa (mg/d) of overweight/obese students was significantly higher than in the normal weight students (2997±660 vs. 2512±662; p< 0.001). The 24-h UNa (mg/d) of pre/hypertensive students was significantly higher than in the normotensive students (2751±811 vs. 2473±545; p = 0.0003).

Conclusions: The highest estimated sodium intake was related to overweight/obesity and hypertension. The estimated 24-h UNa pointed out a sodium dietary intake increased in 81% of women and 85% of men, exceeding the current World Health Organization (WHO) recommendation of 2 g sodium per day.

USE OF NUTRITIONAL SUPPLEMENTS IN NORMAL ADULTS. NEIGHBORHOOD NEW CITY-ASUNCIÓN-PARAGUAY

[1]*Chirife Fernández, Graciela;* [2]*Amarilla, Maria Rosa.*

[1]Md. nutritionist; [2]msc.

Background and objectives: When analyzing the diet of the population, nutritional supplements (SN) should be taken into account. Its great free supply, in the market, favors its consumption without Prescription medical, representing risks for the health.
There are Evidence that contraindicates its use in normal adults, such as the Preventive Services Task Force, United States, February 24, 2014 (Health Day News); Research by Dr. R. Redondo, Regional Sports Medicine Center, Castilla-León Regional Government.
Few scientific studies on the use of NS make it difficult to orientate the problem of its use, misuse and abuse. Paraguay, does not present studies in this regard.
Objectives: To know the consumption of nutritional supplements, in adults, Ciudad Nueva-Asunción-Paraguay neighborhood.
Knowing age, reason for consumption SN in adults and who indicates.

Methods: Method: Observational, descriptive study, transverse cut. Non-probabilistic sampling of consecutive cases, in normal adults, 18 to 70 years, healthy.
Research carried out in October, 2016.
Data were collected by self-completed survey, with informed consent of the respondent.

Results: Result: Interviews with 220 adults, men and women. 80% of respondents consume SN. Men 40% to increase muscle mass, the elderly to improve quality of life-sexual vitality.
Women, 60% to decrease body fat, vitality, rejuvenate, prevent cancer, cholesterol, diabetes.
L-carnitine (10%), protein (15%), amino acids (25%), vitamins-minerals (34%), food substitutes (6%), natural leaf products . They consume NS more than 40 to 60 years, followed by young adults from 18 to 30 years.
60% consume without medical indication; Recommended by friends, coach, media, internet.
Older adults prefer SN in milks, powders, infusions of herbs-seeds or fruits, and the active compounds or their utilities can not be determined.

Conclusions:
- The consumption of NS must indicate and supervise a health professional.
- It is not prudent to use them freely, since they are not safe for health.
- People should be educated to get nutrients from a healthy diet, rather than using SN.

Keywords: SN :nutritional supplements

AMINO ACID PROFILE OF DIFFERENT PRODUCTIVE LINES OF CHICKEN, TURKEY AND PORK MEAT

[1]Figueroa, Constanza; [2]Bas, Fernando; [2]Larrain, Rafael; [3]Matilla, Eugenio; [4]Dorta, Eva.

[1]MSc. Nutritionist. Associate Teaching Unit. Faculty of Medicine. Pontifical Catholic University of Chile. Chile.; [2]PhD. Agricultural Engineer. Animals Science Department. Faculty of Agronomy and Forest Engineering. Pontifical Catholic University of Chile. Chile.; [3]Agricultural Engineer. Animals Science Department. Faculty of Agronomy and Forest Engineering. Pontifical Catholic University of Chile. Chile.; [4]Biology. Chemistry-Physics Department. Faculty of Chemistry. Pontifical Catholic University of Chile. Chile.

Background and objectives: The nutritional composition of meat has varied through time due to industrialization of production systems, genetic improvement and lean carcasses design experienced by domestic animals.

Objective: Compare the amino acid (AA) composition of cuts of chicken, turkey and pork meat with standards utilized for the evaluation of AA of the Chilean diet.

Methods: The samples of chicken cuts (wings, breast, thigh, leg, liver and gizzard), turkey (whole, breast, thigh and leg) and pork (veiled chop, ribs, fillet, leg, shoulder, bacon-loin and heart), were given by the company Agrosuper and selected by the investigators. The samples where homogenized and freezed at -20°C before the analysis. A T-Test was performed to estimate the difference between AA analysis and AA composition referred by the FAO 1981.

Results: Chicken thigh had less concentration for all AA (p<0,05) according to the standard, meanwhile, fillet and shoulder had higher amount of almost all AA (p=0,05), except for isoleucine, which had lower concentration (p<0,05). All turkey cuts presented a smaller amount in relation to the standard for phenylalanine (p<0,05). The whole turkey presented higher concentration of threonine, leucine, and lysine (p=0,02, 0,01 and <0,0001 respectively); the breast had higher concentration of leucine and lysine (p=0,03 and 0,002) and lower in valine (p=0,03); the thigh had less amount for all AA except for arginine, leucine and lysine (p=0,41, 0,08 and 0,86 respectively); turkey leg had higher concentration of leucine and lysine (p=0,006 and 0,006), and less of proline, valine, methionine, phenylalanine (p=0,02, 0,04, 0,03 and 0,01).

Conclusions: There is a difference between the AA composition of some cuts of chicken, turkey and pork meat and the standard. An explanation for this situation could be the genetic and nutrition improvement of these animals that modified their nutritional composition.

Keywords: AA: Amino acids

NUTRITIONAL EVALUATION OF AUTISTIC CHILDREN

[1]Bagatini Saud Ferro, Élen Lúcia; [2]Manochio Pina, Marina Garcia; [3]Marçal, Daniela Cristina de Sousa; [1]Haddad Caleiro Pereira, Cláudia; [3]Silva, Maísa Ferreira; [4]Rossi, Camila Manfredi dos Santos.

[1]MD. Nutritionist. Curso de Nutrição. Universidade de Franca. Brasil.; [2]PhD. Nutritionist. Curso de Nutrição. Universidade de Franca. Brasil.; [3]Bel. Nutricionist. Curso de Nutrição. Universidade de Franca. Brasil.; [4]MD. Nutricionist. Curso de Nutrição. Universidade de Franca. Brasil.

Background and objectives: Autism is nowadays described by some authors as Autism Spectrum Disorders, a type of neurodevelopmental disorder with different degrees of severity. It is commonly characterized by communication, social interaction and imagination deviances. Regarding nourishment, it is commonly observed food refusal, indiscipline and hyper-selectivity among these children, which may lead to cases of malnutrition. This research aimed to assess the nutritional status of autistic children aged five to fourteen years, who attend a unit of the Association of Parents and Friends of Exceptional Children (APAE), through the Body Mass Index, and verify their dietary characteristics.

Methods: It was evaluated 14 children of both sexes, aged between five and fourteen years, who attend a unit of the Association of Parents and Friends of Exceptional Children (APAE). It was applied a survey about children's eating habits and preferences to the parents. By calculating the BMI/age it was measured the nutritional condition of each child. The data obtained from anthropometric measurements were related to the results of the survey about children's eating habits applied.

Results: It was observed that 50% of the children had difficulty accepting hard and dry food and in extreme temperatures (hot or cold). Only 50% of them showed a good acceptance of new food. 66.6% of the children who needed assistance to feed themselves were overweight or obese. Concerning the nutritional status, it was observed that the rate of overweight children was very high (57%), which is not common in children with autism spectrum disorders. Parents did not have a correct perception of the nutritional status of their children, since most of the mothers (64.28%) underestimated the children's weight, which may be a factor that causes overweight..

Conclusions: The rate of autistic and obese children is very high, following what has been happening with children through out the country. The use of restrictive diets should be weighed and always accompanied by specialized professionals. Most parents did not have an adequate perception of the nutritional status of their offspring, which could result in late diagnosis and intervention and consequently nutritional problems that could be avoided if detected previously.

Keywords: autism, eating habits, nutritional status

Graduate School of Sagami Women's University. Japan.; [3]PhD. Epidemiology and Prevention Group. Center for Public Health Sciences. National Cancer Center. Japan.; [4]PhD. Cancer Prevention and Control Program. University of South Carolina. USA.; [5]PhD. Graduate School of Medicine. The University of Tokyo. Japan.

Background and objectives: Inflammation is related to the development of many cancers and diet plays a central role in the regulation of inflammation. The dietary inflammatory index (DII TM) is a literature-derived dietary index designed to assess the impact of diet on people's inflammation status. All studies validating the DII have been conducted exclusively in Western populations, heretofore not in Eastern populations whose dietary habits are very different from those in the West. Therefore, the aim of this study is to validate, in a Japanese population, DII scores derived from a food frequency questionnaire (FFQ) with DII scores calculated from 28-day dietary records (DR) in the Japan Public Health Center-based prospective study (JPHC Study).

Methods: Validation studies were conducted in 1994 (Cohort I, n=215) and in 1996 (Cohort II, n=350). In each study the DRs were collected over one year. The FFQ was distributed before and after DR collection. DII scores calculated from both dietary assessment tools were compared. Spearman's rank correlation and weighted kappa coefficients were calculated from energy-adjusted DII. Density method was used for energy adjustment.

Results: Median (min, max) energy-adjusted DII for men and women from DR were -1.00 (-4.47, 2.02) and -2.15 (-5.43, 1.16) in Cohort I and -1.61 (-4.86, 2.29) and -2.70 (-5.49, 1.62) in Cohort II, respectively. Correlation coefficients for validation analysis for men and women were 0.35 and 0.39 in Cohort I, and 0.48 and 0.47 in Cohort II, respectively. Weighted kappa coefficients in men and women were 0.82 and 0.85 (Cohort I), and 0.86 and 0.86 (Cohort II), respectively. Correlation coefficients for reproducibility analysis for men and women was 0.63 and 0.59 in cohort I, and 0.63 and 0.62 in cohort II, respectively.

Conclusions: DII assessed by FFQ was valid when compared to the DII derived from DRs.

Keywords: Validation study; FFQ; DII; inflammation

NUTRITIONAL ASSESSMENT AND THE INFLUENCE OF BREASTFEEDING IN PATIENTS WITH DOWN SYNDROME

[1]Bagatini Saud Ferro, Élen Lúcia; [2]Manochio Pina, Marina Garcia; [3]Furlan, Ester Cristina; [1]Haddad Caleiro Pereira, Cláudia.

[1]MD. Nutritionist. Curso de Nutrição. Universidade de Franca. Brasil.; [2]PhD. Nutritionist. Curso de Nutrição. Universidade de Franca. Brasil.; [3]Bel. Nutricionist. Curso de Nutrição. Universidade de Franca. Brasil.

Background and objectives: Studies indicate that most of the children and adolescents with Down Syndrome present overweight or obesity due to genetic, environmental and physiologic aspects. Since the nutritional factors can help the improvement in these individuals' quality of life and prevent pathologies related to the bad feeding, the adaptation of the Down Syndrome bearers to a healthy feeding is fundamental, starting from the breast feeding period. Thus, these are the aims of this research: evaluate the difficulties of the breastfeeding and the occurrence of early weaning in children bearers of Down Syndrome and also verify the influence of the breastfeeding on its nutritional state.

Methods: The nutritional evaluation was accomplished in APAE children of a municipal district in the countryside of São Paulo and a questionnaire was the period of breastfeeding. The sample was composed by 16 children with age varying from 3 to 6 years old and the anthropometric evaluation was accomplished through weight/age and height/age which were analyzed through the specific growth curves for the population with Down Syndrome by Mustacchie e Cronk.

Results: The classification of the nutritional state showed that all the participants turned eutrophic. In agreement with the obtained results, 83,3% of the mothers who received formal orientations were breastfeeding, as recommended by the World Health Organization (WHO -OMS), superior result to those mothers who did not receive that orientation type. Factors such as work, age and primiparous mothers have not influenced the breastfeeding time. The main difficulty relate was getting the baby to breast which is a responsible factor for 71,4% of the breast feeding desertion among the mothers who could not breastfeed for six months or over.

Conclusions: Qualified professionals' attendance becomes necessary so that the difficulties are resolved, making exclusive mothers' breast feeding desertion a practice less common in this population.

Keywords: Down Syndrome, mother breastfeeding, nutritional state

SELF-ADMINISTERED STRUCTURED FOOD RE-CORD FOR MEASURING INDIVIDUAL ENERGY AND NUTRIENT INTAKE IN LARGE COHORTS: DESIGN AND VALIDATION

[1]Gagliardino, Juan José; [2]García, Silvia; [3]González, Claudio D.; [4]Rucci, Enzo; [5]Ambrosino, Cintia; [6]Vidal, Julia; [7]Fantuzzi, Gabriel; [8]Prestes, Mariana; [9]Kronsbein, Peter.

Faculty of Nutrition, Food and Hospitality Sciences, Niederrhein University of Applied Sciences; Mönchengladbach, Germany.

Background and objectives: Introduction: Several instruments were developed to assess group or population dietary intake, but all have strengths and weaknesses that affect their specific application. Additionally, there is no self-administered close-ended dietary record previously employed in Argentina to assess current food and nutrient intake by recording food intake on a daily basis.

Objective: We designed and validated a self-administered structured food record (NutriQuid, NQ) representative of Argentine population food consumption pattern to measure individual energy and nutrient intakes in adults.

Methods: Materials and methods: Records were loaded onto a database using software that checks a regional nutrition information system (SARA program), quantifying automatically energy and nutrient intake. NQ validation included two verification phases: 1) NQ construct validity comparing records simultaneously kept by healthy volunteers (45-75 years) and a nutritionist who provided the meals offered (reference), and 2) whether NQ reflected our target population consumption (calories and nutrients), weekday consumption differences, respondent acceptability and ease of data entry/analysis. Data analyses included descriptive statistics, repeated measures ANOVA, intra-class correlation coefficient, nonparametric regression and cross-classification into quintiles.

Results: The first validation (study group vs. reference) showed a slight underestimation (10%) of carbohydrate, fat and energy intake. In the second one, 109 volunteers (91% response) completed the NQ for seven consecutive days. Record-keeping took about 9 min/day and data entry 3-6 min. Mean caloric intake was 2240±119 kcal/day (42% carbohydrates, 17% protein, 41% fat). Intake significantly increased over the weekend.

Conclusions: Conclusion: NQ is an easy and efficient tool to assess dietary intakes in large samples.

Keywords: close-ended food record,nutrition evaluation,validation,self-administered food record.

ASSOCIATION OF BODY IMAGE DISSATISFACTION AND BODY MASS INDEX TRAJECTORY OF STUDENTS FROM RIO DE JANEIRO: ADOLESCENT NUTRITIONAL ASSESSMENT LONGITUDINAL STUDY - ELANA

[1]da Veiga, Gloria Valeria; [2]Dias Santana, Danilo; [3]Barbosa Cunha, Diana; [3]Sichieri, Rosely.

[1]Instituto de Nutrição Josué de Castro - Universidade Federal do Rio de Janeiro; [2]Nutricionist. Instituto de Nutrição Josué de Castro. Universidade Federal do Rio de Janeiro. Brasil; [3]PhD. Instituto de Medicina Social. Universidade do Estado do Rio de Janeiro. Brasil.

Background and objectives: Adolescents have concerns related to body and appearance, which makes them more vulnerable to body image dissatisfaction (BID) that is defined as the negative evaluation that the individual has in relation to your body, i.e. the difference between the body realized and desired by the individual. The aim of this study was to examine the effect of BID on the Body Mass Index (BMI) trajectory among students from public and private schools from Rio de Janeiro, Brazil.

Methods: Prospective cohort study entitled "Adolescent Nutritional Assessment Longitudinal Study " was composed of two cohorts of students. Data regarding of 809 adolescents from middle school (2010 until 2013) and 1131 students from high school (2010 until 2012) were analyzed. BID data was performed using the body silhouettes scale composed by 9 silhouettes ranging from the corresponding extreme thinness to obesity. The BID was considered by the difference between the image that the adolescents judged to be their current and the one they would like to have. BMI (weight/height2) was calculated. Linear mixed effects models were used to assess the BMI trajectory according to the levels of BID (-1, -2: desire to have larger silhouettes; +1, +2, +3: desire to have smaller silhouettes).

Results: In the middle school, girls from private schools who wanted to have smaller and bigger silhouettes gain less BMI units (BID levels: -1: 1.7 kg/m²; 1:1.9 kg/m²; 2: 1.4 kg/m²) than girls who were satisfied with their body image (2.8 kg/m², $p < 0.05$). In high school, girls from private schools who wished to have smaller (BID levels: -2: 1.2 kg/m²) and bigger silhouettes (BID levels: 1: 1.1 kg/m²; 2: 1.4 kg/m²; 3: 1.4 kg/m²) experienced greater BMI in-

crease compared to girls who were satisfied with their body image (0.5 kg/m², p < 0.05). There was no association between BID and BMI trajectory for girls from public schools and boys from private or public schools.

Conclusions: The findings suggest that BID may be related to BMI trajectory in girls from high socioeconomic status and contribute to comprehend the relation of BMI trajectories and BID during adolescence

Keywords: body dissatisfaction, body mass index, adolescents, longitudinal study

ASSESSMENT OF FASTING BLOOD GLUCOSE LEVEL OF UNDERGRADUATES IN ABEOKUTA OGUN STATE NIGERIA

[1]*Olunusi, Abosede;* [2]*Sunday, Nupo.*

[1]PhD. Senior Lecturer at Department of Home Economics and Hotel Management.Tai Solarin University of Education. Nigeria; [2]PhD.Lecturer.Department of Nutrition and Dietetics. MoshoodAbiola Polytechnic.Ojere.Abeokuta.Nigeria.

Background and objectives: Impaired Fasting Glucose (IFG) is a condition where Fasting Blood Glucose (FBG) is above normal but not high enough to be considered diabetic. Impaired fasting glucose is linked with many co-morbid diseases such as obesity, the prevalence of impaired fasting glucose concentration among undergraduates in Ogun state South-West Nigeria.

Methods: A purposive sampling technique was used to select three hundred undergraduate students willing and ready participant. A pretested structured questionnaire was used to obtain the socio-economic information of the undergraduates. Fasting blood glucose, weight, height and blood pressure were determined using glucometer, weighing scale, heightometer and sphygmomanometer respectively.

Results: The result of the study showed that the prevalence of IFG among undergraduate in South West Nigeria was 11.0% (n=33) of total participants. A higher prevalence of impaired fasting glucose (IFG) was found with females than males. Body mass index of the subject reviewed that (11.0%, n=33) were underweight, (61.0%, n=183) had normal weight, (27.3%, n=82) were overweight and (0.7%, n=2) were obese.

Conclusions: In conclusion, some of the participants had abnormal FBG (11%, n=33). Nutritional program/workshop should be organized by the institutions to enable undergraduates make a healthy, responsible lifestyle choices and consume a well-balanced diet.

A BODY SHAPE INDEX (ABSI) AS AN ADIPOSITY MEASURE AND DIET QUALITY IN MEN: A CROSS-SECTIONAL STUDY (MEDISH PROJECT)

[1]*Lonnie, Marta;* [2]*Kowalkowska, Joanna;* [3]*Wadolowska, Lidia;* [4]*Bandurska-Stankiewicz, Elzbieta.*

[1]MSc; [2]MSc. Department of Human Nutrition. Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland.; [3]Full Professor. Department of Human Nutrition. Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland.; [4]Full Professor. Department of Internal Medicine. Faculty of Medical Sciences. University of Warmia and Mazury in Olsztyn. Poland.

Background and objectives: Accurate and simple adiposity measures have been in the forefront of research since the controversies around measures utilising only one or two parameters arose. We hypothesised that a new, combined adiposity measure – a body shape index (ABSI) [1] – may be a superior indicator of a diet quality comparing to others. Objective: to assess an association of ABSI and other commonly used adiposity measures with a diet quality in men.

Methods: In all, 246 men 19-50 years old participated in the study. Diet quality was assessed using food frequency questionnaire (KomPAN). Two diet quality scores were created: prohealthy (pHDI) and non-healthy (nHDI) based on KomPAN procedure [2]. Five measures were investigated: ABSI (ABSI=WC/BMI^2/3 multiplied by Height^1/2), body fat percentage (%BF), body mass index (BMI), waist-to-height ratio (WHtR) and waist circumference (WC). The associations between adiposity measures and diet quality scores were evaluated by multivariate logistic regression, adjusted for age and physical activity.

Results: Very high risk (ABSI z-score≥0,798) was found in 18.7% men; obesity (%BF≥25% or BMI>30kg/m^2) in 33.3% or 9.8%, respectively; central obesity (WHtR>0.5 or WC>102cm) in 41.9% or 11.4%, respectively. Men in the upper tertile of pHDI were less likely to be in the top (very high risk) category of ABSI (odds ratio, OR=0.24, 95%CI confidence interval, 95%CI:0.08;0.75; adjusted OR=0.19, 95%CI:0.04;0.90). Men from the upper tertile of nHDI were more likely to be in the obese category of %BF (OR=2.60, 95%CI:1.20;5.62; adjusted OR=3.31, 95%CI:1.32;8.30). No significant associations with diet quality were found in terms of BMI, WHtR and WC.

Conclusions: Among all adiposity measures studied, only ABSI and body fat percentage were associated with diet quality, regardless of adjustment for age and physical activity. In the obesity context ABSI can be considered as a good indicator of higher quality diet and body fat percentage as an indicator of a low diet quality in men.

DEUTERIUM COMPARED TO 15N-LABELING TO DETERMINE DIGESTIVE AND METABOLIC FATE OF MILK PROTEINS

[1]Tomé, Daniel; [2]Khodorova, Nadezda; [3]Calvez, Juliane; [4]Tessier, Joseph; [5]Kapel, Romain; [3]Gaudichon, Claire.

[1]Professeur, PhD, AgroParisTech, Paris, France; [2]PhD. Chemist, UMR PNCA, INRA-AgroParisTech-Université Paris Saclay, Paris, France; [3]PhD. Nutritionist, UMR PNCA, INRA-AgroParisTech-Université Paris Saclay, Paris, France; [4]PhD. Nutritionist, UMR MOSAR, INRA-AgroParisTech-Université Paris Saclay, Paris, France; [5]PhD. Chemist, UMR LRGP, CNRS-Université de Lorraine, Nancy, France.

Background and objectives: The intrinsic labeling of dietary proteins with 15N is convenient to determine their digestive and metabolic fate. The use of 15N ammonium salts and/or nitric oxide allows the uniform labeling of proteins in ruminant products and plants, but this procedure cannot be used for all protein sources. Deuterated water is an alternative but its accuracy has not been assessed. We aimed to compare the performance of 15N and 2H.

Methods: Milk was labelled from 4 goats receiving orally 5g of 15N ammonium sulfate (99 %) for 4 consecutive days. Eighty or 160 mL $2H_2O$ (98%) was given in drinking water for 1 or 3 consecutive days. Milk was collected for 5 days. Proteins were purified from milk and their 15N and 2H enrichments determined. Labelled protein digestibility was assessed in twelve rats receiving a single test meal. Rats were sacrified 4h (n=6) or 6h (n=6) after the meal. Dietary proteins were quantified in gastrointestinal segments (stomach, duodenum, jejunum, ileum, caecum and colon) by elemental analyzer coupled to isotope ratio mass spectrometer.

Results: The 15N enrichment in milk proteins increased during 3 days to a value of 1%. Whatever the dose of $2H_2O$, 3 days administration enabled a better 2H enrichment, reaching 0.032 % and 0.051% with 80 and 160 mL, respectively. In rats, the digesta to meal enrichment ratio was strongly correlated between 15N and 2H in the stomach (R=0.94) and in the ileum (R=0.91) but the correlation was lower in the caecum (R=0.64). In the colon, no 2H enrichment was found in contrast to 15N. The recovery of dietary protein was similar with both tracers in the stomach, and tended to be lower in the caecum with 2H (P=0.08). Orofaecal digestibility was slightly higher using 2H than 15N (98.2 ± 0.3% vs 97.6 ±0.1%, P= 0.001) but orocaecal digestibility was similar.

Conclusions: Deuterium labeling of dietary protein appears as convenient as 15N to follow the digestive fate of protein sources. The discrepancies between 15N and 2H observed in the colon is probably due to the bacterial metabolism. However, the impact on the determination of digestibility was slight.

THE EFFECT OF PROTEIN INTAKE AND PROTEIN DISTRIBUTION ON MUSCLE STRENGTH AND MUSCLE FUNCTION IN PHYSICALLY ACTIVE ELDERLY

[1]Ten Haaf, Dominique; [2]Nuijten, Malou; [3]de Vries, Jan; [4]Bongers, Coen; [5]Eijsvogels, Thijs; [6]Hopman, Maria.

[1]PhD. Nutrition scientist. Department of Physiology. Radboud Institute for Health Sciences. Radboud university medical center Nijmegen. The Netherlands.; [2]BSc. Exercise physiologist. Department of Physiology. Radboud Institute for Health Sciences. Radboud university medical center Nijmegen. The Netherlands.; [3]PhD. Nutrition scientist. Division of Human Nutrition. Wageningen University, Wageningen. The Netherlands.; [4]MSc. Exercise physiologist. Department of Physiology. Radboud Institute for Health Sciences. Radboud university medical center Nijmegen. The Netherlands.; [5]PhD. Exercise physiologist. Department of Physiology. Radboud Institute for Health Sciences. Radboud university medical center Nijmegen. The Netherlands.; [6]Prof. MD. Exercise physiologist. Radboud Institute for Health Sciences. Radboud university medical center Nijmegen. The Netherlands. Division of Human Nutrition. Wageningen University, Wageningen. The Netherlands.

Background and objectives: The effect of protein intake and protein distribution on muscle strength and functionality has mainly been studied in frail elderly, while physically active elderly show age-related declines in muscle strength as well. Therefore, it is of high interest to study the effects of amount and distribution of protein intake on muscle strength and -function in physically active elderly.

Methods: The amount of protein intake and its distribution over the day were assessed using two 24-hr recalls and average values were calculated. Based on protein intake, participants were allocated to a sufficient and non-sufficient protein intake group, based on the cutoff value of ≥1.2 g/kg bw/day or <1.2 g/kg bw/day. Skewness of distribution was calculated as coefficient of variance (CV). Based on the CV participants were divided in tertiles. Muscle strength and function were measured by handgrip strength and the Short Physical Performance Battery (SPPB), respectively.

Results: 82 participants (79% male, 84±2 yrs) with a daily physical activity of 11.8±6.5 METhr/day were enrolled in this study. The average SPPB score was 10.3±1.6 and the handgrip strength was 36±8 kg for males and 25±4 kg for females. A sufficient protein intake was associated with higher SPPB score compared to the non-sufficient protein group (11.1±0.9 versus 9.9±1.7, P=0.001). Handgrip strength showed no significant differences between protein intake groups for both sexes (both P>0.05). Regarding protein distribution pattern, no significant differences were found between tertiles for SPPB score or handgrip strength (all P>0.05).

Conclusions: Higher protein intake in physically active elderly seems to be related to improved muscle function, but this effect

was not found for muscle strength. Distribution of protein intake had no effect on muscle strength and function in active elderly.

Keywords: Protein distribution, physical functionality, muscle mass, sarcopenia.

BODY COMPOSITION OF THE POLISH SKI JUMPERS

[1]Ostachowska-Gasior, Agnieszka; [2]Kwiatkowski, Jacek.

[1]PhD. Nutritionist. Department of Hygiene and Dietetics. Dietary Lab Counseling. Medical College. Jagiellonian University of Krakow. Poland.; [2]MSc. computer programmer. Department of Hygiene and Dietetics, Dietary Lab. Counseling. Medical College. Jagiellonian University of Krakow. Poland.

Background and objectives: The results of the wind tunnel experiments and simulated ski-jumping models suggest that body weight and body composition of ski jumpers have tremendous impact on performing a long ski jump. Lower Body Mass Index (BMI) correlates with longer jump and in a response to this conclusion, controlling body weight and active weight loss have become popular among ski jumpers. Thus, the purpose of this study was to evaluate body composition and body symmetry of Polish elite male ski jumpers and its comparison with non-athletic Polish male of the same age and body height.

Methods: For the research a group of ski jumpers (n=18; mean age: 20.1) and non-athletic male volunteers (n=18; mean age: 20.9) as a control group have been chosen. Body composition was assessed using segmental bioelectrical impedance analyzer InBody S10, Biospace. Differences between control group and ski jumpers were tested with the Student t-test and 95% confidence intervals (CI) were calculated for the inter-group differences. Statistical analysis was performed with Statistica 10 software package.

Results: Ski jumpers were 13.1 kg lighter than controls (95% CI 6.8 to 19.4, P < 0.001). Body Cell Mass and Bone Mineral Content had greater values in a control group but the differences were not significant. Total fat mass and body fat % were 5.2 kg (P < 0.001) and 4.5% units (P < 0.001) lower in ski jumpers. Lean-to-fat mass ratio was 4.5 units greater in ski jumpers (95% CI 2.6 to 6.4, P < 0.001). Ski jumpers' perfect body symmetry (lack of right or left body side domination) appeared to be a feature significantly differentiating - in control group both right arm and right leg turned out to be dominant.

Conclusions: Body composition of polish ski jumpers, despite the lower body weight, indicates healthy proportion between fat tissue and lean tissue. It is very likely that perfect body symmetry observed in ski jumpers is an effect of their training specificity, but the possibility that this symmetry is an individual primary feature, influencing a success rate in this sport discipline cannot be ruled out.

Keywords: ski jumpers, body composition, BMI, body symmetry

Background and objectives: Introduction: The effects of free sugars on health have received worldwide attention in research and public health. Consistent information on sugar content of foods and sugar intake in children is required.

Objective: To report dietary free sugars consumption and their different types and food sources in European children.

Methods: Design: The present research are results from a multicenter study in children, the IDEFICS (Identification and prevention of dietary and lifestyle induced health effects in children and infants) Study. A total of 8308 children (50.9 % males) of eight survey centers aged 2-9 years were studied. The participants were a subset of the original sample (n=16228) with complete data on dietary data obtained using at least one 24-h recall. Sugars intake was assessed as total sugars, free sugars and energy intake.

Results: Mean total energy intake was 1613.1 (SD 452.8) kcal/d for boys and 1489.4 (SD 390.7) kcal/d for girls. The percentage contribution of total sugars to daily energy intake was 23.7%. Free sugars intake provided 15.1% to daily energy intake. Girls had significantly (p < 0.001) lower intakes of energy, carbohydrates, total sugars and free sugars, compared with boys. When examining by age groups, the intake of free sugars was significantly higher in older boys and girls than in younger ones, for all food groups except for coffe, tea, herbal and similars group. The main contributor to free sugars intake was the group of 'Soft drinks' (23 g/d), followed by 'Fruit juices manufactured' (21.1 g/d) and 'Fruit and fruit juices' (13.7 g/d).

The main food contributors to free sugars intake are shown in Figure 1.

The percentage contribution of free sugars to daily energy intake, per countries, is shown in Figure 2.

Conclusions: This study provides important information about the pattern of sugar intake in European children. High intake of sugar remains an important nutritional problem in children of many European countries. Continued and coordinated efforts are required at a national, community and individual level to reduce the intake of total sugars.

Keywords: sugars, children, intake, Europe, IDEFICS

DEVELOPMENT OF A TOOL TO AID CAREGIVERS' RECALL OF SNACKS AMONG CHILDREN 12-23 MONTHS OF AGE IN KATHMANDU VALLEY, NEPAL

[1]*Pries, Alissa;* [2]*Sharma, Nisha;* [3]*Upadhyay, Atul;* [4]*Adhikari, Babita;* [5]*Niraula, Pratik;* [6]*Filteau, Suzanne;* [6]*Ferguson, Elaine.*

[1]MPH. Technical Advisor. Helen Keller International. USA.; [2]MPH. Helen Keller International. Nepal.; [3]PhD. Helen Keller International. Nepal.; [4]MRD. Helen Keller International. Nepal.; [5]BND. Helen Keller International. Nepal.; [6]PhD. London School of Hygiene and Tropical Medicine. UK.

Background and objectives: Twenty-four hour recalls are commonly conducted with caregivers to measure dietary intake of children. However, recall bias can result in under-reporting of certain foods. This research assessed the accuracy of caregivers' recall of their child's food/beverage consumption in order to develop a recall-aid for use in a dietary assessment of young children in Kathmandu Valley, Nepal.

Methods: Ten children 12-23 months of age were observed for 12-hour periods (7am-7pm), with all feeding episodes noted in detail; the following day, a semi-quantitative 24-hour recall was conducted with the primary caregiver. A pictorial recall-aid tool was developed based on these formative research findings, and piloted among caregivers from varying socio-economic backgrounds. A final version was used in a quantitative 24-hour recall of 401 young children.

Results: Comparison of what children consumed during observations and what caregivers reported in subsequent 24-hour recalls found that snacks fed to children between meals were commonly omitted; these included: biscuits, fruits, milk, candy, and porridges. Observations also found that multiple caregivers provided snacks to children. Images of these forgotten foods/beverages were compiled in the recall-aid, which was distributed to survey participants 2-3 days prior to interview. Participants were instructed to keep the aid with their child so that anyone feeding could indicate foods/beverages fed. In the quantitative survey,

82.3% of caregivers used the recall-aid; in 43.6% of these cases, the recall-aid captured at least one food/beverage omitted during recall. The mean number of forgotten foods/beverages captured by the recall-aid was 2, with a range of 1-9. Of caregivers with food/beverage omissions, 47.2% forgot candy/chocolates, 36.8% savory snacks (instant noodles/chips), 36.1% biscuits, 34.7% fruits (apple/banana/grape/ orange/pomegranate), 16.0% milk, and 4.9% porridge.

Conclusions: Because snacks may be fed spontaneously and by multiple caregivers, these foods/beverages may be omitted in 24-hour recalls for young children. Capturing these items in dietary assessments is important, as they cover food categories relevant for certain IYCF indicators, and their omission may result in misrepresentation of diet quality. Use of a context-specific recall-aid may assist in capturing consumption of these otherwise missed foods/beverages and further validation of such tools is needed.

Keywords: diet assessment, IYCF, Nepal, nutrition, 24-hour recall

CORRELATIONS BETWEEN SERUM 25(OH)-VITAMIN D AND FAT MASS, FAT-FREE MASS AND TOTAL BODY WATER IN ADULTS OF BOTH SEXES WITH DIFFERENT BODY MASS INDEX

[1]*Nikolova, Maria;* [2]*Boyanov, Mihail;* [3]*Penkov, Alexandar.*

[1]Medical Doctor. Department of Hygiene, Medical Ecology and Nutrition. Medical University of Sofia. Bulgaria; [2]Professor. MD. Phd. Clinic of Endocrinology. Department Internal Medicine. Alexandrovska University Hospital. Medical University of Sofia. Bulgaria; [3]Assoc.Professor. MD. Phd. Department of Hygiene, Medical Ecology and Nutrition. Medical University of Sofia. Bulgaria.

Background and objectives: We assessed the correlations of serum vitamin D with body composition parameters.

Methods: 109 men and 155 women (20-60 years) participated. Body composition was recorded by bioelectrical impedance (Tanita BC 420 MA, Tanita Inc., Japan): % body fat (% BF); fat mass (FM), fat-free mass (FFM), total body water (TBW). The fat mass index (FMI) and fat-free mass index (FFMI) were calculated. Serum 25(OH)Vitamin D Total was measured by electro-hemi-luminescence on an Elecsys 2010 analyzer (Roche Diagnostics, Switzerland).

Results: 27.2 % of the participants had normal weight, 24.6 % - overweight, 29.2 % - class I obesity, and 18.9 % – class II or III. 33.3 % had vitamin D deficiency, 40.2 % - insufficiency. Vitamin D was weakly and inversely correlated to most of the variables except for age, height, FFM, FFMI and bone mass. The FM and FFM were correlated to vitamin D only in obesity class II and III. In men the FFM, the FFMI, the TBW and the BM were not correlated to vitamin D, while in women they were.

Conclusions: Serum 25(OH)vitamin D is tightly correlated to FM, % FM and %TBW but not to FFM or TBW.

DIETARY PATTERNS OF BRAZILIAN ADOLESCENTS ASSOCIATE WITH ANTHROPOMETRIC AND LIFESTYLE FACTORS

[1]Cominetti, Cristiane; [2]Moraes Lobo, Ana; [3]Cristina de Morais, Carla; [3]Morais Alves Machado, Malaine.

[1]Professor and Researcher. Nutritonal Genomics Research Group. Faculty of Nutrition, Federal University of Goias, Goiania-GO, Brazil; [2]Master student. Nutrition and Health Program, Faculty of Nutrition, Federal University of Goias, Goiania-GO, Brazil; [3]PhD student. Health Science Program, Faculty of Medicine, Federal University of Goias, Goiania-GO, Brazil.

Background and objectives: Dietary and physical activity patterns in Brazil have foment an increase in the prevalence of overweight and obesity, which are beginning in the early stages of life. Therefore, the aim of this study was to identify dietary patterns of Brazilian adolescents and to determine the associated factors.

Methods: It was a cross-sectional study with 446 adolescents aged 10-19 years, enrolled in a public school in Goiânia, Goiás. Brazil. Dietary intake was assessed by a usual food recall. Socioeconomic, anthropometric and lifestyle data were collected through classical protocols. Principal component factor analysis with Varimax rotation was used to identify dietary patterns. Factor scores were calculated and then used in multiple linear regression to evaluate socioeconomic, anthropometric and lifestyle factors associated with the patterns.

Results: Four dietary patterns were identified and together explained 38.8% of the food consumption total variance. These patterns were denominated: 1) traditional Brazilian meal (characterized by cereals and roots, legumes, meats, vegetables and sugar-sweetened beverages), 2) traditional snack (which included farinaceous snacks, butter and margarine, dairy and sweets, and was inversely associated with processed meat consumption), 3) processed snacks (processed meat, yellow cheese and farinaceous snacks), and 4) junk food (composed by candies, fatty snacks, sugar-sweetened beverages and pastas, and inversely associated with intake of fruits). The pattern "traditional Brazilian meal" was inversely associated with BMI and female sex. The pattern "traditional snack" was inversely associated with BMI and positively associated with greater time sitting at the weekend. The pattern "junk food" was associated positively with the greater daily time in front of television. Only this latter pattern did not present an inverse association with commuting to school by car.

Conclusions: Adolescents' dietary patterns were associated with anthropometric and lifestyle variables, so that a diet based on traditional Brazilian foods is recommended because it seems to favor lower BMI values.

Keywords: Factor analysis, Adolescent, Feeding behavior, Food consumption.

PREVALENCE AND FACTORS ASSOCIATED WITH UNDERWEIGHT, OVERWEIGHT AND OBESITY AMONGST ELDERLY POPULATION LIVING AT HIGH ALTITUDE REGIONS OF RURAL UTTARAKHAND, INDIA

[1]Khandelwal, Ritika; [2]Kapil, Umesh.

[1]M Sc. Research Scientist. Department of Human Nutrition Unit, All India Institute of Medical Sciences New Delhi, Delhi.; [2]Professor. Human Nutrition Unit, All India Institute of Medical Sciences.

Background and objectives: Nutrition is an important element of health in the geriatric population. Geriatric has an increased risk of malnutrition due to physiological changes such as reduced metabolic rate, loss of appetite, difficulties in chewing, and various co-morbidities. Objective: To assess the nutritional status and its associated risk factors amongst geriatric population aged ≥ 60 years living in high altitude regions of rural Uttarakhand, India.

Methods: A community-based cross-sectional study was conducted during 2015-2016 in District Nainital. Thirty clusters were identified using population proportionate to size sampling method; 30 geriatric subjects were selected from each cluster. Study population included 981 geriatric aged 60 years and above. Standard procedures were used to determine the height and weight and the BMI was calculated from the results of the measurements of weight (kg) and height (cm) (kg/m2). Data was entered in MS Excel 2007 and analyzed using SPSS version 20.0. Univariate and multivariate analysis was done to identify factors associated with underweight and overweight.

Results: About 26.6% geriatric were underweight, 18.0% were overweight and 4.6% were obese. In univariate analysis male gender, low education, low income, chewing problem, less number of meals was found to be associated with underweight, while overweight/obesity was found to be associated with age, female gender, higher level of education and income.

Conclusions: In rural India prevalence of underweight and overweight was found to be high amongst geriatric. There is a need for geriatric nutritional intervention in rural population.

IN HAITIAN WOMEN AND CHILDREN, IRON AB-SORPTION FROM WHEAT FLOUR FORTIFIED WITH NAFEEDTA IS HIGHER THAN FROM FLOUR FORTIFIED WITH FERROUS FUMARATE AND IS NOT AFFECTED BY H. PYLORI INFECTION

[1]Herter-Aeberli, Isabelle; [2]Eliancy, Kerline; [3]Rathon, Yanick; [4]Loechl, Cornelia; [2]Marhone, Joseline; [5]Zimmermann, Michael Bruce.

[1]Senior Scientist. Human Nutrition Laboratory. ETH Zurich. Switzerland.; [2]Ministère de la Santé Publique et de la Population. Port au Prince. Haiti.; [3]Laboratoire Nationale de la Santé. Port au Prince. Haiti.; [4]International Atomic Energy Agency. Vienna. Austria.; [5]Professor. Human Nutrition Laboratory. ETH Zurich. Switzerland.

Background and objectives: The prevalence of iron deficiency in Haiti is high and a program of iron fortification of wheat flour has been proposed; however, there are no data on iron bioavailability from iron fortificants in Haitian women or children, two key target groups. We aimed to investigate the bioavailability of ferrous fumarate (FeFum), NaFeEDTA and their combination from fortified wheat flour.

Methods: We recruited 22 healthy mother-child pairs in Port au Prince, Haiti for an iron absorption study. We administered stable iron isotopes as FeFum or NaFeEDTA in low-extraction wheat flour bread rolls consumed by all participants in a randomized, cross-over fashion. In a final meal, consumed only by the women, FeFum+NaFeEDTA was administered. The amount of iron used in the test meal was chosen to simulate the fortification level currently discussed by the Haitian government. We measured iron absorption by using erythrocyte incorporation of stable isotopes 14 days after consumption of each meal, and determined iron status, inflammatory markers and H. pylori infection.

Results: Iron absorption (geo mean (95% CI) was 9.24 (6.35,13.44) and 9.26 (7.00,12.31) from FeFum and 13.06 (9.23,19.10) and 12.99 (9.18,18.39) from NaFeEDTA in mothers and children, respectively (p<0.05 between compounds). Iron absorption from FeFum+NaFeEDTA was 11.09 (7.45,17.34) and did not differ from the other two meals. H. pylori infection did not influence iron absorption in either group or meal.

Conclusions: In conclusion, in Haitian women and children consuming low extraction wheat flour, iron absorption from Na-FeEDTA was 40% higher than from FeFum, and the combination FeFum+NaFeEDTA did not significantly increase iron absorption compared to FeFum alone. In the context of Haiti, where the high costs of NaFeEDTA may not be affordable, the use of FeFum at 60 mg Fe/kg flour may be a preferable, cost-effective fortification strategy.

Brazil.; [7]BSc in Nutrition. Nutritionist. Department of Nutrition and Health. Federal University of Viçosa. Brazil.

Background and objectives: Iron deficiency affects more than 2 billion people worldwide, being the most common and serious micronutrient deficiency. Some strategies for preventing iron deficiency anemia include food fortification and iron supplementation. Biofortification has the potential to become a sustainable, inexpensive, and effective solution. The goal was to evaluate the iron bioavailability in rats fed with biofortified beans.

Methods: The Iron biofortified beans were developed by the Brazilian Agricultural Research Corporation (EMBRAPA) and used as flour for preparing experimental diets. Some analyzes such as chemical composition, mineral quantification and antinutritional factors were performed only with the flour; the iron determination with both, flour and prepared experimental diet. Lastly, the depletion-repletion hemoglobin method was used to evaluate in vivo the iron bioavailability, thus the induction of iron deficiency anemia. The test was conducted with 32 anemic wistar rats. The rats were distributed in 4 groups and fed with diets containing 12 mg iron/kg supplied from ferrous sulfate sources, biofortified beans (Pontal and Agreste), except for the fourth group on the iron-free diet. After 14 days of repletion, hematological parameters such as hemoglobin repletion efficiency, hemoglobin gain and relative biological value were analyzed.

Results: At the end of the repletion, parameters such as the iron bioavailability, the hemoglobin gain and the iron gain of hemoglobin of group of biofortified grains did not present significant differences when compared to the group that consumed ferrous sulfate, with respective values of 91%, 2.78 (g/dL) and 1.76 mg. Our biofortified cultivars had iron concentrations 50% higher than the common bean varieties, in which 100 grams of cooked biofortified beans provide between 7.6 to 8.5 mg of bioavailable iron, corresponding to 40% of the Dietary Reference Intake (DRI) recommendation for women of childbearing age and 80% of DRI's for 4-to-8-years-old children.

Conclusions: Our results confirm that biofortification can be considered a promising strategy in the anemia recovery. However, researches involving humans with iron deficiency anemia are necessary to evaluate the efficacy of biofortified beans, since this is a sustainable and low-cost strategy to be implemented in public health programs.

Keywords: biofortified beans; biofortification; iron bioavailability; iron deficiency.

ENTERAL NUTRITION IN THE PUBLIC CHILDREN´S HOSPITAL OF CORRIENTES: EVALUATION OF THE PRESCRIPTION CHARACTERISTICS

[1]Romero Vidomlansky, Patricia Ruth; [2]Colussi, Narella Antonina; [3]Cabral, Agostina Ximena; [4]Aguirre, María Victoria; [5]Gorban de Lapertosa, Silvia.

[1]Food Engineer. Nutrition course. Faculty of Medicine. Northeast University. Argentina; [2]MSc. Nutritionist. Medicine career. Biochemical Research Laboratory. Faculty of Medicine. National Northeastern University. Corrientes. Argentina.; [3]Undergraduate student. Kinesiology and Physiatrics career. Faculty of Medicine. National Northeastern University.Corrientes. Argentina.; [4]PhD. Biochemist. Biochemistry Professor. Medicine career. Biochemical Research Laboratory. Faculty of Medicine. National Northeastern University.Corrientes. Argentina.; [5]MD. Nutrition professor. Kinesiology and Physiatrics career. Nutrition Course. Faculty of Medicine. National Northeastern University. Corrientes. Argentina.

Background and objectives: In order to achieve an adequate nutritional intervention in hospitalized children, a diagnosis and monitoring of the nutritional status must be performed before and during hospitalization, and this diagnosis must be known by all health staff. However, there is no yet an integrated system of the clinical histories (CH) data storage in Corrientes, especially concerning to Nutrition Service. The creation of this system would favor a consensual analysis and the elaboration of a specific regulation for the provision of pediatric nutritional support in the public health of the province. Objective: To know the characteristics of Enteral Nutrition (EN) prescribed in hospitalized patients at the Children's Hospital (Corrientes, Argentina) in order to improve the pediatric EN provision system.

Methods: A descriptive study in patients hospitalized at Children 's Hospital, Corrientes, during September/2016. The EN pre-scription circuit, CH, Lactarium orders and nutrient ingredients purchase worksheets were analyzed. Descriptive statistics were used to evaluate relationships between demographic, clinical and economic variables.

Results: Of a total of 254 hospitalized patients during the study period, were observed 110 childrens with indication of EN (46 females, 64 males), in Interment Room 58%, ICU 28%, Burns 8%, Hemato-oncology 6%. The age was 3.42±4.02 years. The prevalent diagnosis at admission was respiratory disease (24%), while others included: burns, appendicitis, epilepsy, cancer, congenital malformations and accidents, cuts and fractures. During September, the time of internment was: 8.67±7.97 days and consumption of EN: 8.33±7.12 days. Patients received the different formulations from the powder individual ingredients prepared in Lactarium, orally, by nasogastric tube or gastric button. The CH analyses revealed that the attending physicians indicated EN regarding patient weight percentile and basic disease requirements in 80% of the cases, while only 20% of the children had nutritionist indication of an appropriate diet.

Conclusions: The clinical histories failed to reflect the necessary data to decide the nutritional support to be supplied, operating according to daily requirements. This research serves as a basis for the development of a pediatric AE provision Program in the Public Health system of Corrientes.

Escuela Superior Politécnica del Litoral. Ecuador; [5]Nutritionist. Faculty of Medical Sciences. Catholic University of Santiago de Guayaquil. Ecuador.

Background and objectives: Handgrip strength (HGS) reflects both integrity and functionality of skeletal muscle mass (SMM). HSG has been customarily used for detecting loss of active SMM. SMM loss is associated with disability and mortality in elder subjects. Ageing population is rapidly increasing in Ecuador.

A window of opportunity was opened to document HSG values in Ecuadorian elder subjects.

Methods: One-hundred-and-one elder subjects (Females: 74,3%; Average age: 70,5 ± 9,0 years) living in an urban destitute community in the city of Guayaquil (Ecuador). HSG was measured on both hemibodies with a mechanical dynamometer (Lafayette Inc., United Sates). HGS values were distributed according with age. Additional body composition (BC) measurements were performed with a professional bioimpedance machine (BodyStat Inc., United States).

Results: Average BMI was 27,5 ± 5,4 Kg.m-2. BC measurements were influenced by subject´s sex. Males sustained higher HGS values, regardless of dominant arm. HGS values decreased with age.

Conclusions: HGS depends upon sex, dominant arm, and age.

Keywords: Muscle Mass; Hand Grip Strength; Dynamometer; Frailty; Sarcopenia; Geriatric Assessment; Aging.

THE INFLUENCE OF MINERAL STATUS ON THE ACADEMIC PERFORMANCE

Assimiti, Daniela.

MSc. Teacher . California Prep International School . Saraburi . Thailand.

Background and objectives: A balanced nutrition supplying the right amount of minerals is absolutely essential for the development of the brain , a normal cognitive function , and is a major influencing factor of behavior . This fact is even more important in the school-aged children but little has been studied on the actual extent in which mineral deficiencies actually affect the academic performance .

Methods: The study used a very simple non-invasive method observing mineral deficiencies in fingernails in 46 boys and 38 girls age 3-11 from Kindergarten and Elementary, and 33 boys and 21 girls age 12-18 from Middle and High School . Pictures were taken and their GPAs were collected for reference .

Results: In the age group 3-11 , zinc deficiency was found in 26.09% boys and 23.68% girls , while iron deficiency was present in 13.04% boys and 7.89% girls. In the age group 12-18 , 47.62% girls and 36.36% boys were zinc deficient , while 24.24% boys and 9.52% girls showed to be iron deficiency . Selenium and calcium deficiencies were found in isolated cases . Observations of the behavior were found to be concordant with the GPA and some previous ITBS scores addressing particularly the attention spans , concentration and comprehension .

Conclusions: Overall , this easy way of identifying eventual mineral deficiencies as early as possible by observing the fingernails proved to be a valuable method to trigger the students with problems and help improve academic performance while promoting the general health and improved behavior , through nutrition

Keywords: minerals , academic performance , fingernails

NUTRITIONAL STATE AND BODY COMPOSITION OF ELDERLY CONSULTANTS IN OUTPATIENT MEDICINE IN CASABLANCA - MOROCCO

[1]*El Arabi, Fatine;* [2]*NEJJAR, BASMA;* [3]*Bour, Abdellatif.*

[1]Fatine El Arabi. MSc. Dietician. Department of Biology. Faculty of Sciences Kenitra. Morocco.; [2]MSc. Department of Biology. Faculty of Sciences Kenitra. Morocco. And. Department of Clinical chemistry. Faculty of medicine of Liège. Belgium.; [3]PhD. Professor. Department of Biology. Faculty of Sciences Kenitra. Morocco.

Background and objectives: Senescence represents a public health problem and its management is partly conditioned by assessed nutritional profile of the person. Thus, we have found it useful to conduct a study whose objective is to assess the nutritional state and body composition of the elderly Moroccan consulting in geriatric service in Casablanca region.

Methods: This is a cross-sectional survey of 62 elderly subjects: Aged over 60 years, selected from the database of the geriatric service of a Moroccan public hospital, from April to September 2015, in Casablanca. A questionnaire was used to identify socio-demographic characteristics and a grid to identify anthropometric (weight, height, body mass index (BMI), Calf circumference (CC) and brachial (CB)) and body composition indicators (lean mass (LM), fat mass (FM), Total cellular water (TCW), intracellular water (IW) and extracellular water (EW)) for each subject.

Results: The 62 subjects in the study represented a sex ratio of 0.5 and mean age, BMI, LM and FM were respectively 65.5 ± 6.8 years, 26.2 ± 4.8 Kg/m2, 64.3 ± 8.6 kg and 34.9 ±8.7 Kg. 53.2% (n=33) of sample were in overweight (BMI> 18 Kg/m2) affecting women more (p<0.001). Significant differences between male and female subjects were recorded for LM and FM measurements (p <0.001) TCW (p<0.01), and EW (p<0.01). Negatively significant correlations were found between BMI and TCW (r = -0.3, p = 0.003) and EW (r = - 0.3, p = 0.003) and FM (r = -0.6, p<0.001) and positively significant between BMI and CB (r =0.6, p<0.001) and CC (F=0.7, p<0.001) and between TCW and EW (r = 0.7, p <0.001) and LM (r =0.5, p<0.001). The model of the multiple descending linear regression showed that FM is an associated factor with TCW (beta= -0.1, p= 0.05) in the elderly of our study.

Conclusions: At the end of this study, we concluded that the evaluation of the nutritional state of elderly was useful to prevent any risk of late complications and to allow early management.

IRON ABSORPTION FROM BEANS WITH DIFFERENT IRON CONTENTS EVALUATED BY STABLE ISOTOPES

[1]Junqueira-Franco, Márcia Varella Morandi; [2]Nutti, Marilia R; [3]de Carvalho, José Luis V; [4]Pereira, Helton Santos; [5]Abrams, Steven A; [6]Dutra de Oliveira, José Eduardo; [7]Marchini, Júlio Sérgio.

[1]PhD. Pharmacyst. Internal Medicine Department, Ribeirão Preto Medical School, University of São Paulo; [2]Msc. Food Engenner. Brazilian Company of Agricultural Research (EMBRAPA) Brazil; [3]Food Enginner. Brazilian Company of Agricultural Research (EMBRAPA) Brazil; [4]Agronomist Engineer. Brazilian Company of Agricultural Research (EMBRAPA) Brazil; [5]MD. Dell Medical School –University of Texas Austin, USA; [6]PhD. MD Internal Medicine Department, Ribeirão Preto Medical School, University of São Paulo. Ribeirão Preto – SP. Brazil; [7]PhD MD Internal Medicine Department, Ribeirão Preto Medical School, University of São Paulo. Ribeirão Preto – SP. Brazil.

Background and objectives: Introduction: Brazil is a major beans producer and consumer and is part of the basic diet of the population. The introduction of biofortified crops such as beans with higher iron content is a useful tool in preventing iron deficiency diseases, as anemia. Thus, the measurement of the absorption of minerals is essential to evaluate the use of biofortified foods. Objective: This study evaluated the iron bioavailability of common beans cultivars BRS Estilo, with low iron content and BRS Pontal, that present intermediate iron content, in man through reliable techniques, not yet used in Brazil. The beans were produced by EMBRAPA.

Methods: Subjects and Methods: 29 young adult volunteers were divided into 2 groups: Group CB (13 subjects) received 100g of common beans (BRS Estilo) cooked labeled with iron 58 (58Fe) and Group BB (16 patients) received 100g target to biofortification beans (BRS Pontal), cooked and labeled with iron 58 (58Fe). The next day they receive the reference dose of ferrous sulfate enriched iron-57 (57Fe). After consumption was conducted isotopic evaluation of iron, for measurement of iron incorporation into erythrocyte.

Results: The difference between iron absorption from the meal containing common bean and that from the meal containing target to biofortification bean examined by means of a paired t test, were considered significant at $P<0.05$. The groups CB and BB did not differ in hemoglobin or serum ferritin concentrations. Serum ferritin ranged from 41 to 298 μmol/L. Mean isotopic ratio of iron absorption from the meal with common beans was 0.409% (±0.040%) and mean iron incorporation from the meal with biofortified beans was 0.407% (±0.038%).

Conclusions: The iron absorption from the common beans and target to bifortification beans was not significantly different. This study tested a single food; if its results are considered in making programmatic decisions, consideration must be given to the balance between iron absorption enhancers and inhibitors in the whole meal. The multiple meal study is necessary to evaluate the real iron absorption. The challenge for the global health community remains how to tackle this efficacious intervention and implement it in a large scale.

Keywords: Biofortification, iron bioavailability, beans, iron deficiency.

PSYCHOSOCIAL AND FUNCTIONAL STATUS IN HOSPITALIZED GERIATRIC PATIENTS WITH MALNUTRITION

[1]Ouyang, Chung-Mei Ouyang; [2]Lin, Yu-Ru; [2]Fan, Ya-Wen; [3]Lai, Hsu-Yun.

[1]PhD. Dietitian. Department of Dietetics. National Taiwan University Hospital Hsin Chu Branch. Taiwan; [2]MS. Dietitian. Department of Dietetics. National Taiwan University Hospital Hsin Chu Branch. Taiwan; [3]Dr. Department of Family Medicine. National Taiwan University Hospital Hsin Chu Branch. Taiwan.

Background and objectives: Malnutrition has been associated with adverse outcomes such as functional disability, morbidity, mortality, and longer stays in the hospital. It is also a risk factor for frailty, particularly in older people. Physical function and psychological factors apparently contribute to dietary condition. Identification of those related status and treatment of malnutrition earlier can lead to improved clinical outcomes. This study was to investigate psychosocial and functional status of hospitalized geriatric patients with malnutrition screened by Mini Nutritional Assessment (MNA) tool at a regional hospital in Hsinchu, Taiwan.

Methods: We screened all hospitalized patients aged 65 years or older by using MNA from April to November of 2014 and excluded patients with confusion, terminal cancer and non-malnutrition caused by hypoalbuminuria. A total of 374 patients were screened and asked for attending the project if they were malnourished from screening. There were 160 patients included and their demographic characteristics, 3-day 24-hour diet recalls, anthropometric and biochemical data, Geriatric Depression Scale Short Form (GDS-SF) and Activities of Daily Living (ADL) scores were collected and analyzed. Statistical analysis for categorical variables was performed by the Chi-Square and t-tests, and Person's correlation test was used for two continuous variables.

Results: The mean age of 160 subjects (84 men and 76 women) was 77.0±6.8 years old. According to ADL and GDS-SF results, 43.5% of the patients were functionally dependent and 47.5% of them were with mild to severe depression. The results showed that protein intake was significantly related to body mass index (BMI),

mid-arm circumference (MAC), triceps skinfold (TSF), and grip strength. Patients' GDS-SF and ADL scores were correlated to their age and MNA.

Conclusions: About half of the hospitalized geriatric patients had functional and depressive problems and those were related to their nutritional status. Dietary intake especially protein intake was associated with many anthropometric measurements which were positively related to their daily activities.

Keywords: geriatric patients, activities of daily living, geriatric depression

HEAD CIRCUMFERENCES AND BODY MASS INDEX ARE PRESERVED IN THE PRESENCE OF HIGH STUNTING PREVALENCE AMONG 4-7 YEARS OLD CHILDREN FROM WESTERN HIGHLANDS OF GUATEMALA

[1]Liem, Windy Mulia; [2]Shiu, Kimberly; [3]Garcia, Rosario; [4]Melse-Boonstra, Alida; [5]Solomons, Noel W.

[1]MSc.; [2]None; [3]MDS. Center for Studies of Sensory Impairment, Aging and Metabolism, Guatemala.; [4]PhD. Assistant Professor. Division of Human Nutrition. Wageningen University, Netherlands; [5]MD. Executive and Scientific Director. Center for Studies of Sensory Impairment, Aging and Metabolism, Guatemala.

Background and objectives: Stunting is suggested to be associated with suboptimal cognitive development, obesity, and chronic degenerative diseases. Researches on physical brain growth, as reflected in head circumference Z-scores, has been focusing on early childhood. Little is known about the brain growth nor how early is the onset of obesity during later childhood. The purpose of this study was to investigate circumferential measurements in preschool children with an extreme degree of linear growth retardation.

Methods: Body height, clothing-adjusted body weight, and circumferential measurements were obtained from 212 children, aged 4-7 years, 87 boys and 125 girls, from two rural areas with high prevalence of stunting in Western Guatemala. Conventional Z-scores for height, weight and head circumference, as well as body mass index (BMI), were derived; whereas waist circumference (WC) values were further divided by height to obtain waist-to-height ratio (WHtR) and neck circumferences values were compared with findings from other settings.

Results: The stunting prevalence was 63.2%, higher than the national under-five average of 46.5%, and similar to the Maya-indigenous rate of 61.2%, and higher among girls (65.6%) than boys (59.8%). Prevalence of underweight was 33%, with no instance of thinness, defined as < -2 SD in BMI-for-age (BAZ). Despite the highly prevalent stunting, median head circumference Z-scores (HCZ) was within the normal range (-0.65, 95% CI -0.72, -0.55),

with only 1 value (0.5%) below -2 SD. NC was lower than in peers in other countries' reports. HC, NC, and WHtR values were lower in stunting children than non-stunting (p < 0.001). No obesity (BAZ >2 SD) was observed among the sample.

Conclusions: In the presence of linear growth retardation and underweight, head circumference is relatively preserved. At this age, obesity is virtually non-existent in preschoolers with widespread short stature,and neither waist nor neck circumferences appear to be increased.

Keywords: Stunting; cognitive development; head circumference; obesity; Guatemala

MALNUTRITION AND ASSOCIATED FACTORS AMONG HOSPITALIZED GERIATRIC PATIENTS

[1]Ouyang, Chung-Mei Ouyang; [2]Lin, Yu-Ru; [2]Fan, Ya-Wen; [2]Yu, Szu-Chieh; [3]Lee, Ai-Ting; [4]Lai, Hsu-Yun.

[1]PhD. Dietitian. Department of Dietetics. National Taiwan University Hospital Hsin Chu Branch. Taiwan; [2]MS. Dietitian. Department of Dietetics. National Taiwan University Hospital Hsin Chu Branch. Taiwan; [3]Dietitian. Department of Dietetics. National Taiwan University Hospital Hsin Chu Branch. Taiwan; [4]Dr. Department of Family Medicine. National Taiwan University Hospital Hsin Chu Branch. Taiwan.

Background and objectives: Malnutrition negatively impacts on overall health status, morbidity and mortality. It is also a risk factor for frailty, particularly in older people. Nutritional status has been also shown to relate to many factors in the elderly. Identification and treatment of malnutrition earlier can lead to improved clinical outcomes. This study was to investigate nutritional status of hospitalized geriatric patients and its associated factors if they were malnourished or at risk of being malnourished.
