Methods: We screened all hospitalized patients aged 65 years or older by Mini Nutritional Assessment (MNA) and Nutrition Risk Screening 2002 (NRS 2002) from April to November of 2014 and excluded patients with confusion, terminal cancer and non-malnutrition caused by hypoalbuminuria. A total of 374 patients were screened and asked for attending the project if they were malnourished from screening. There were 160 patients included and their demographic characteristics, 3-day 24-hour diet recalls, anthropometric and biochemical data and Activities of Daily Living (ADL) were collected and analyzed.

Results: The mean age of 374 subjects (193 men and 181 women) was 77.1±6.8 years. The NRS 2002 categorized 49.7% of patients as being malnutrition, and MNA categorized 19.5% and 52.4% of patients as being malnourished and at risk of being malnourished respectively. The average body mass index (BMI) of patients was 24.0±8.1 and only 9.2% was under 18.5. Weight status of the patients was significantly related to nutritional status. Age was associated with BMI, MNA, NRS 2002, hemoglobin, and total lymphocyte counts.

Conclusions: Results of this study identify multiple modifiable factors associated with the problem of malnutrition in hospitalized geriatric patients. Anthropometrical malnutrition as well as inadequate dietary intake at hospital were related to functional impairment and clinical outcomes.

Keywords: Malnutrition, geriatric patients, risk factors

RELIABILITY AND VALIDITY OF THE MEDITERRANEAN DIET ADHERENCE SCREENER AMONG THE IRANIAN ADULTS

[1]*Mahdavi-Roshan, Marjan;* [2]*Soltanipour, Soheil Soltanipour;* [3]*Salari, Arsalan.*

[1]Assistant Professor in Nutrition Sciences, School of Medicine, Guilan University of Medical Sciences, Rasht, Iran.; [2]Associate Professor in Community Medicine, Department of Community Medicine, School of Medicine, Guilan University of Medical Sciences, Rasht, Iran; [3]Associate Professor in cardiology, Guilan Interventional Cardiovascular Research Center, Department of Cardiology, Heshmat Hospital, School of Medicine, Guilan University of Medical Sciences, Rasht, Iran.

Background and objectives: Validated dietary assessment methods specific to population and food habits are needed for dietary assessment. Therefore, the aim of study was to assess the reliability and validity of the 14-point Mediterranean Diet Adherence Screener (MEDAS) among the Iranian adults.

Methods: Study was carried out on adults aged ≥ 43 who were admitted to a tertiary hospital in Rasht in the North of Iran, for elective angiography. Study was conducted in a country with a Shiite majority with religious restrictions, for this reason we eliminated some items and modified the MEDAS in the Farsi version by backward -forward method. We applied reliability analysis using model alpha, with SPSS to interpret the effects of each item of MEDAS in its internal consistency.

Results: After correcting the item scores, coefficients of Kuder-Richardson-20 was calculated 0.598. The mean ±SD of 13 items MEDAS was 5.82 ±1.90. None of Corrected Item-Total Correlation coefficients were negative. According to three categories of adherence to the Mediterranean diet, 42.5%, 50% and 7.5% participants had low, medium and high adherence to a Mediterranean diet respectively.

Conclusions: In spite of eliminating and making a few changes in questions due to religious reasons, the coefficients of Kuder-Richardson-20 did not decrease in reliability analysis. The MEDAS was translated and modified for the first time into Farsi. Administering this tool in future researches will help to understand how Iranian adhere to the mediterranean diet, aiming at improving cardiovascular health.

Keywords: Reliability, Validity, Mediterranean Diet Adherence Screener, Iranian adults

ANALYZING PROTEIN OXIDATION PERTURBATIONS AND ITS ROLE IN PROTEIN METABOLISM

[1]*Vonk, Roel;* [2]*Reckman, Gerlof;* [3]*Koehorst, Martijn.*

[1]PhD. Department of Medical Biomics. University of Groningen, University Medical Center Groningen. The Netherlands; [2]MSc, Department of Internal Medicine. University of Groningen, University Medical Center Groningen. The Netherlands; [3]BASc, Department of Pediatrics University of Groningen, University Medical Center Groningen. The Netherlands.

Background and objectives: Protein intake has been suggested to play an important role in development of obesity; on one hand in newborn, where excess protein intake might stimulate development of obesity in later life. On the other hand, protein consumption is promoted for weight management. At present, no formal recommendations for the upper limit of protein intake have been presented. Information about rate-limiting steps in protein catabolism is scarce. We therefore studied the role of protein oxidation in this process.

Methods: To monitor protein oxidation we have developed a noninvasive 13C-protein breath test using naturally enriched 13C-milk protein (fractions). We used this technique to analyze the kinetics of protein oxidation and its interfering factors. Breath samples were collected and analyzed by Isotope Ratio Mass Spectrometry

Results: Whey was oxidized for 28.6% ± 6.8% (mean ± sd) during 240 min, compared to 22.9% ± 6.2% for glucose. Maximal milk protein oxidation was measured at a rate of 0.06 g/min, leading to a maximal oxidation capacity of 1.3 g/kg bw/day. Combining 30 g 13C-whey with 30 g glucose resulted in a 49% increase of whey oxidation. A three day low protein diet and/or exercise preceding the breath test resulted in a decrease in protein oxidation of ~20% and ~40% respectively.

Conclusions: Oxidation of whey protein is quantitatively of high importance and not down regulated by concomitant administration of glucose. Analyzing biological variations in acute protein oxidation in various target groups, in defining the upper limit of intake, might be relevant.

Keywords: protein oxidation, protein metabolism, breath test, naturally enriched 13C-milk proteins,

Conflict of Interest Disclosure: The naturally enriched 13C-milk protein has been made available as an in kind contribution by Hanze Nutrition B.V., which is owned by co-author prof. dr. R.J. Vonk. There are no other conflicts of interest.

DIFFERENCES IN ANEMIA DIAGNOSIS OBTAINED USING VENOUS VERSUS CAPILLARY BLOOD: BIOLOGICAL BASIS AND POLICY IMPLICATIONS

[1]Neufeld, Lynnette M.; [2]Kurpad, Anura; [3]Mburu, Sheila; [4]Larson, Leila; [5]Martorell, Reynaldo; [6]Brown, Ken.

[1]PhD. Director Monitoring, Learning and Research. Global Alliance for Improved Nutrition. Switzerland.; [2]MD, PhD. Professor and Head of the Divison of Physiology and Nutrition. Deparament of Physiology. St John's Medical College. India; [3]MSc. Independent researcher. UK.; [4]MPH. PhD Candidate. Nutrition and Health Sciences Doctoral Program. Emory University. USA.; [5]PhD. Robert W. Woodruff Professor of International Nutrition. The Hubert Department of Global Health and the Nutrition and Health Sciences Program. Emory University. USA.; [6]PhD. Senior Program Officer and Initiative Lead, Nutrition, Global Development. Bill & Melinda Gates Foundation. USA.

Background and objectives: Anemia is recognized as a high priority health issue globally. The World Health Assembly (WHA) has set a target for 50% reduction in the prevalence of anemia in women of reproductive age by 2025, and relevant data will be needed to inform progress. However, factors affecting anemia diagnosis need to be considered to ensure accurate and comparable estimates of hemoglobin concentration and anemia prevalence (across countries and within countries over time). Possible sources of variability include: 1) differences between automated laboratory methods and portable devices, 2) differences between individual devices of a given type (e.g., different automated laboratory equipment or individual field instruments), 3) methodological errors due to sample collection technique, particularly for capillary samples and, 4) normal biological differences between venous and capillary blood, and as modified, for example, by age and sex.

Methods: In this presentation we will provide an in-depth literature review of the biological basis for differences in venous versus capillary blood and on the potential for systematic differences in hemoglobin concentration from diverse analytical platforms that cannot be attributed to sample collection technique. We will then use data from a recently completed survey in the state of Uttar Pradesh, India, (and other data sets if needed) to illustrate the implications that the choice of such method and the consistency of its use across multiple surveys may have on prevalence estimates and ultimately policy making.

Results: Ongoing

Conclusions: Forthcoming

Keywords: anemia, hemoglobin, diagnosis, capillary, venous

CALCIUM SUPPLEMENTATION AMONG TARGETED PREGNANCIES: A LIFE SAVING STRATEGY TO REDUCE THE RISK OF ECLAMPSIA AND MATERNAL AND NEWBORN DEATHS

[1]Aminee, Ahmadwali; [2]Safi, Shir Agha; [3]Anwari, Ehsan.

[1]MD.MPH. Global Alliance for Improved Nutrition. Kabul office. Kabul.Afghanistan; [2]MD.Public Nutrition Department.Ministry of Public Health. Kabul .Afghanistan; [3]PU-AMI .Kabul.Afghanistan.

Background and objectives: Maternal mortality ratio in Afghanistan is 372 deaths per 100,000 live births, which is the highest in the south Asian region. Hypertension during pregnancy increases the risk of eclampsia, newborn and maternal deaths. The World Health Organization (WHO) recommends calcium supplementation for pregnant women after the 20th week of gestation until the end of pregnancy, particularly among those at higher risk of hypertension. The objective of this study was to determine the effect of calcium supplementation to targeted pregnant women reduced the occurrence of eclampsia and related maternal mortality in one province of Afghanistan.

Methods: Quantitative methods were used to collect and analyses the data from health facilities including the provincial hospital in 15 districts of Kunar provinces during the life of the calcium supplementation pilot project, and comparison of reported eclampsia cases with the same period in the last year.

Results: The pilot project was implemented in Kunar province located in west part of Afghanistan. The project targeted pregnant women (N=785) in 15 districts of the province during a six-month period. They received 1.5-gram calcium tablet per day from the 20th week of gestation onwards through all health facilities. The project was funded by Common Humanitarian Fund and implemented by PU-AMI the main health care implementing Non-Governmental Organization (NGO) in the province. The analysis of data from Kunar provincial hospital register books (which is the only health facility for treatment and follow-up of pregnancy revealed complications including eclampsia in the province) revealed that during the life of the project (from Jun-Nov 2015) total of 50% reduction in the number of eclampsia cases admitted in the hospital compared to the same period in 2014.

Conclusions: Calcium supplementation among target pregnant women is associated with a reduction in eclampsia cases, in Kunar province, Afghanistan.

DIETARY INTAKE AND METABOLIC PHENO-TYPES IN A COMMUNITY-DWELLING COLOMBI-AN COHORT

[1]Corrales-Agudelo, Vanessa; [2]de la Cuesta-Zuluaga, Juan Jacobo; [1]Pulgarín-Zapata, Isabel Cristina; [3]Carmona-Valencia, Jenny Andrea; [4]Abad-Echeverry, José Miguel; [5]Escobar Restrepo, Juan Sebastián.

[1]MSc. Nutritionist. Vidarium - Nutrition, Health and Wellness Research Center. Grupo Empresarial Nutresa. Colombia.; [2]MSc. Biologist. Vidarium - Nutrition, Health and Wellness Research Center. Grupo Empresarial Nutresa. Colombia.; [3]Research Coordinator. Dinámica IPS Especialista en Ayudas Diagnósticas. Colombia.; [4]MSc. MD. EPS-SURA. Colombia.; [5]PhD. Biologist. Vidarium - Nutrition, Health and Wellness Research Center. Grupo Empresarial Nutresa. Colombia.

Background and objectives: The analysis of dietary intake includes different components that individually analyzed are insufficient to explain health risks. The aim of this study was to integrate anthropometric and metabolic indicators to the nutritional analysis to identify the risk prevalence in nutrient intake according to metabolic phenotypes.

Methods: Participants were part of an adult community-dwelling cohort, enrolled across five cities of Colombia, South America. Anthropometric and clinical parameters in blood were assessed, as well as blood pressure. Clinical parameters and blood pressure served to classify participants by metabolic status. The metabolic status and the body mass index (BMI) were used to classify participants in six metabolic phenotypes (lean, overweight and obese, crossed by healthy or abnormal metabolic state); dietary intake was assessed in these groups of participants.

Results: Independent of BMI, the healthy metabolic phenotypes had greater contribution of proteins from the diet, while the lean abnormal and overweight abnormal phenotypes had excess intake of carbohydrates and sugars. Importantly, healthy lean participants had the lowest prevalence of nutrient deficiency, while abnormal lean, overweight and obese participants showed greater risk of micronutrient intake deficiency, especially calcium, magnesium and zinc. All metabolic phenotypes had low fiber intakes.

Conclusions: We report a comprehensive way to analyze dietetic intake that integrates nutritional status and health-related parameters. This analysis let us identify important nutrients in intervention or nutritional therapy that would improve metabolic health. Our analysis makes use of clinical parameters routinely assessed and could be applied to individuals or groups with normal weight or overweight; these results can be useful in the clinical practice to detect early risk factors of disease and to guide dietetic interventions.

Keywords: Metabolic phenotype, metabolic status, BMI, nutritional assessment, intake indicators.

DAIRY AND CALCIUM INTAKE BY QUILOMBO-LAS FROM RIO GRANDE DO SUL- BRAZIL

[1]Pacheco, Pauline Müller; [1]Pauli, Sílvia; [2]Neutzling, Marilda Borges; [3]Bairros, Fernanda Souza de; [4]Knauth, Daniela Riva; [5]Drehmer, Michele.

[1]MSc in Epidemiology. Department of Social Medicine. Universidade Federal do Rio Grande do Sul. Brazil.; [2]PhD in Nutrition, Department of Nutrition. Universidade Federal do Rio Grande do Sul. Brazil; [3]PhD in Epidemiology. Department of Social Medicine. Universidade Federal do Rio Grande do Sul. Brasil.; [4]PhD in Ethnology and social anthropology . Departament of Professional Assistance and Guidance. Universidade Federal do Rio Grande do Sul. Brazil.; [5]PhD in Epidemiology. Department of Nutrition. Universidade Federal do Rio Grande do Sul. Brazil.

Background and objectives: Milk and derivatives are the main source of calcium and recent studies have shown benefits in reducing risk for diabetes and metabolic syndrome. Quilombola communities are traditional communities of African origin organized from the slavery process and for which food consumption data are scarce. Thus, the objective of this work was to evaluate the consumption of calcium and its source food in quilombola communities of Rio Grande do Sul (RS)- Brazil.

Methods: Descriptive, cross-sectional population-based study of quilombola communities in RS developed in 2011. A total of 634 families, from 17 quilombola communities in the state, were selected by size-proportional sampling. Altogether, 589 household heads were interviewed. Calcium intake was assessed through a 24-hour food recall referring to the day before the interview. The data were processed in the ADS Nutri software - which uses the Brazilian Food Composition Table - and analyzed in the SPSS 18.0 software. The recommended calcium recommendation was the RDA for adults. The consumption of milk and dairy products (milk, cheese and yogurt) was evaluated as a dichotomous variable, considering the consumption report or not in the previous day. Ethical approval was received from the Research Ethics Committee of Universidade Federal do Rio Grande do Sul.

Results: About 30.0% of the sample reported having consumed milk or dairy products the previous day, being primarily cows'milk, whole and direct from the producer. The prevalence of dairy products consumption in the previous day varied among the 17 communities studied: in some of them, household consumption was not mentioned by anyone and in others by 63.6% of respondents. In relation to calcium, median consumption was 266.4mg (IQ 161.8-429.4). Considering the daily recommendations of 1000mg for adults, only 2.4% consumed the recommended amount.

Conclusions: The quilombolas of RS presented a low consumption of calcium and milk and dairy products, which can be explained by the impoverishment of the communities and consequent limitation for the acquisition of dairy products. These have a high price, besides the difficulty of access to purchase in more isolated rural communities.

THE IMPACT OF IRON SUPPLEMENTATION AND DAILY AEROBIC EXERCISE ON PHYSICAL FITNESS IN NON-ANEMIC CHINESE WOMEN

[1]Pompano, Laura; [2]Haas, Jere D.

[1]Msc. PhD Candidate. Division of Nutritional Sciences. Cornell University. United States of America; [2]PhD. Nancy Meinig Professor Emeritus. Division of Nutritional Sciences. Cornell University. United States of America.

Background and objectives: Background: Iron deficiency without anemia has detrimental effects on physical performance. However, the relationship between iron supplementation, daily aerobic training, and changes in fitness in untrained, non-anemic women remains unclear.

Objective: To determine whether iron supplementation increases fitness, measured as maximal oxygen consumption (VO2max), in trained and untrained women.

Methods: This randomized-control trial included 72 iron depleted, non-anemic women, defined as serum ferritin (sFer) < 25 μg/L and hemoglobin (Hb) >110 g/L. A double-blind study was conducted with a 2x2 design including iron supplements (42mg elemental iron/day) or placebo and daily aerobic training (five 25-minute sessions/week at 75-85% maximum heart rate) or no training. General linear models were used to evaluate the relationship between supplement type, training, and changes in fitness after 8 weeks.

Results: There were no baseline differences in any variable between groups. Additionally, there were no differences in compliance to training or supplementation. At endline, sFer significantly increased in the iron group (23.6 μg/L, p<0.01), but not the placebo group (6.0 μg/L, NS). Similarly, the trained group showed a significant improvement in VO2max (3.8 mL/min/kg, p<0.01), whereas there was no change in the untrained groups (-0.89 mL/min/kg, NS). There was a significant supplement by training-group interaction in models predicting VO2max (p<0.05). Specifically, the iron-untrained group had a greater change in VO2max than the placebo-untrained group (1.9 mL/min/kg, p=0.01), which remained significant when change in Hb was included in the model. No supplement effect was seen between the trained groups.

Conclusions: The data show that iron supplementation alone improves VO2max in untrained women. However, this improvement is masked by changes in fitness gained from regular aerobic exercise. The improvements in VO2max in the iron-untrained group were not affected by Hb concentration, suggesting that this change is independent of oxygen delivery to the muscles. Further analyses could help clarify whether other indicators of fitness such as energetic efficiency or the anaerobic threshold benefit from iron supplementation and whether an interaction exists between training and supplementation in these variables. These findings indicate that fitness in relatively unfit women could improve from daily iron supplementation, even without regular aerobic training.

Keywords: iron deficiency, aerobic exercise, physical performance, VO2max

CHEMICAL, PHYTOCHEMICAL AND ANTINUTRIENT COMPOSITION OF ALOE VERA (ALOE BARBADENSIS) SOURCED FROM THREE STATES OF SOUTH-EAST OF NIGERIA

[1]Mbah, Obioma; [2]Eme, Paul; [3]Iredu, Ifeoma.

[1]PhD. Lecturer. Department of Nutrition and Dietetics. University of Nigeria, Nsukka. Nigeria; [2]MSc. School of Public Health. Massey University. New Zealand; [3]B.Sc. Department of Nutrition and Dietetics. University of Nigeria, Nsukka. Nigeria.

Background and objectives: Aloe vera contains multitudes of potentially active constituents of essential vitamins and minerals, enzymes, sugar, lignin, saponins and wealth of amino acids. The aim was to analyze quantitatively the Aloe barbadensis for proximate, anti-nutrient and phytochemical composition to find out if location affects their nutritional composition.

Methods: The aloe vera was collected from three different eastern regions. The proximate composition involves the moisture content, crude protein, crude fibre, crude fat, ash content and carbohydrate and it was determined using standard methods. The phytochemicals (saponins, alkaloids and flavonoids) and anti-nutrients (oxalate, tannin and phytate) were also obtained using standard methods. Mean, standard deviation and ANOVA was used to separate the means and p<0.05 was set to be a significant.

Results: Protein, fibre, fat and carbohydrates contents 1.57%, 0.15%, 0.04% and 1.72% respectively were highest in aloe vera sourced from Enugu State where protein was lowest in aloe vera sourced from Ebonyi State, and fibre did not differ significantly between aloe vera sourced from Anambra and Ebonyi States. Vitamin A (β-carotene RE), vitamin C (ascorbic acid), and vitamin B12 (Cyanocobalamin) content 51.64 μg RE//100g, 46.41mg/100g and 46.60μg/100g respectively were highest in aloe vera from Enugu State while vitamin A (β-carotene RE), vitamin C (ascorbic acid), and vitamin B12 (Cyanocobalamin) content 31.06 μg RE//100g, 36.46mg/100g, and 20.82μg/100g were lowest in aloe vera sourced from Ebonyi. However, iron content was highest (0.21mg/100g) in aloe vera sourced from Ebonyi State. Alkaloid and flavonoid were highest (1.60%, 2.40%) respectively in aloe vera sourced from Enugu State while alkaloid from aloe vera sourced from Anambra was lowest (0.50%) and flavonoid was lowest (0.97%) in aloe vera sourced from Ebonyi State. Saponin was highest (1.13%) in aloe vera in Anambra State but lowest (0.74%) in aloe vera sourced from Enugu State. Phytate, oxalate and tannin were highest in aloe vera sourced from Enugu, although Phytate of aloe vera sourced from Enugu and Anambra were statistically similar.

Conclusions: Nutrient contents of the Aloe vera varied in the different studied States which might be due to soil and seasonal differences of cultivation

Keywords: Aloe vera; nutrients; phytochemicals; Nigeria

RELATIONSHIP BETWEEN BODY COMPOSITION AND PLAYING LEVEL IN RUGBY UNION PLAYERS

[1]Barale, Adrián; [2]Perovic, Nilda Raquel.

[1]BSc. Nutritionist. School of Nutrition. National University of Córdoba. Argentina.; [2]PhD. Nutritionist. School of Nutrition. National University of Córdoba. Argentina.

Background and objectives: Body composition (BC) is a factor that can influence sport performance. Therefore, its assessment, especially with simple methods such as anthropometric measurements, is essential to optimize performance.

The purpose of this study was to analyze the relationship between playing level (PL) with BC in rugby union players of the Province of Córdoba (Argentina).

Methods: A total of 94 players were grouped according to PL in: a) State Team (ST) (n=24), the highest level, b) 1st Division (D1) (n=52), c) 3rd Division (D3) (n=18), the lowest level of performance. Thirty-three anthropometric variables were measured following the protocol of the International Society for the Advancement of Kinanthropometry (ISAK). Body composition was assessed using the five-way fractionation method, partitioning the body into anatomically defined adipose, muscle, skeletal, residual, and skin tissue masses.

Descriptive (mean ± SD) and comparative statistics were calculated with Stata 14 software. A one-way analysis of variance (ANOVA) with Bonferroni post-hoc test for differences was used for the comparison between PL. The statistical significance was set at $P < 0.05$.

Results: The basic characteristics of the sample were: age 25.1 ± 4.2 years, weight 93.5 ± 12.6 kg and height 180.1 ± 7.3 cm. PL was associated with height (D3 players were shorter than the other 2 groups; p = 0.005) and age (D3 players were older than the other 2 groups; p = 0.001), but not with weight (p = 0.35).

BC in absolute terms (kg) was associated with PL; D3 players had significantly less muscle mass (p < 0.01), bone mass (p < 0.05) and residual mass (p < 0.05) than the other 2 groups. As well, BC relative to body mass (%) was associated with PL; D3 players had significantly more adipose mass (p < 0.05) than the other 2 groups, and less muscle mass (p = 0.015) and bone mass (p = 0.001) than D1 players. The residual mass (%) was significantly different (p < 0.01) among all 3 groups (D1 > ST > D3).

Conclusions: The PL was associated to height, age and BC in rugby union players.

Keywords: Body composition,Anthropometry,Rugby.

ANTHROPOMETRIC PROFILE, SOMATOTYPE AND BODY COMPOSITION OF RUGBY UNION PLAYERS ACCORDING TO PLAYING POSITION

[1]Barale, Adrián; [2]Perovic, Nilda Raquel.

[1]BSc. Nutritionist. School of Nutrition. National University of Córdoba. Argentina.; [2]PhD. Nutritionist. School of Nutrition. National University of Córdoba. Argentina.

Background and objectives: The morphology and body composition (BC) are factors that can influence sport performance. Therefore, their assessment, especially with simple methods, such as anthropometric measurements, is essential to optimize performance.

The purpose of this study was to analyze the relationship between playing position (PP) with somatotype and BC in rugby players of the Province of Córdoba (Argentina).

Methods: The sample were 94 players. Thirty-three anthropometric variables were measured following the protocol of the International Society for the Advancement of Kinanthropometry (ISAK). The somatotype was assessed with Heath-Carter's method. Body composition was assessed using the five-way fractionation method, partitioning the body into anatomically defined adipose, muscle, skeletal, residual, and skin tissue masses. The players were grouped by PP into forwards (F) and backs (B).

Descriptive (mean ± SD) and comparative statistics were calculated with Stata 14 software. A Student's t-test for independent samples was used for the comparison between F (n=55) and B (n=39), with statistical significance set at $P < 0.05$.

Results: The basic characteristics of the sample were: age 25.1 ± 4.2 years, weight 93.5 ± 12.6 kg and height 180.1 ± 7.3 cm. PP was associated with height (F: 181.4 ± 7.3 cm vs. B: 178.1 ± 7 cm; p = 0.03) and weight (F: 100.0 ± 11.6 kg vs. B: 84.5 ± 7.3 kg; p < 0.0001), but not with age (p = 0.30).

The mean somatotype of the overall players was 4.1-6.9-1.0. With respect to somatotype components, endomorphy was greater (p < 0.0001) in F (4.7 ± 1.8) than in B (3.1 ± 1.1); the same relationship was observed in mesomorphy (F: 7.2 ± 1.3 vs. B: 6.5 ± 0.8; p = 0.004); ectomorphy was greater (p = 0.001) in B (1.3 ± 0.6) than in F (0.8 ± 0.8).

Regarding BC in absolute terms (kg), F had greater values (p < 0.0001) for all fractions of tissue masses than B. Relative to body mass (%), F had greater adiposity (p = 0.0001), but B had greater muscle, bone and skin mass (p<0.01).

Conclusions: The PP was associated to physical characteristics, somatotype and BC in rugby union players.

Keywords: Body composition,Somatotyp,Anthropometry,Rugby.

NUTRITIONAL STATUS OF SCHOOL-ADOLESCENTS IN OGUN WEST SENATORIAL DISTRICT, NIGERIA

Olunusi, Abosede.

PhD. Senior Lecturer at Department of Home Economics and Hotel Management.Tai Solarin University of Education.Nigeria.

Background and objectives: Adequate nutrition is the pivot for nutritional development. Promoting good nutrition among school-adolescents will not only enhance excellent academic performances but foster optimal national development. Hence, the thrust of this research was to assess the nutritional status of school- adolescents in Ogun West Senatorial District, Nigeria

Methods: A cross- sectional study on nutritional status of 375 school-adolescents drawn from 3 out of 5 Local Governments (LGs) in the district using multistage random sampling was carried out. Twenty-five participants were chosen from 5 schools(1 private and 4 public schools) in each LGA. Validated questionnaire was used to collect socio- demographic, daily food intake and anthropometric (height and weight) data. Food intake data were obtained through a-24 hour dietary recall and analyzed using WHO total diet assessment software. Height z-score and body mass index (BMI) were used to evaluate subjects' nutritional status. Descriptive statistics were obtained using SPSS (version 17.0) software. Analysis of variance was used to explore differences in nutrient intake and anthropometric indices at 5% significant level.Male/Female participants were 49.9% /50.1% with 51.2% being younger adolescents (10-14 years) and 48.8% being older adolescents (15-19years).

Results: Anthropometric findings revealed 16.3% stunting, 17.4% underweight, 65.6% normal weight, 12.5% overweight and 4.5% obesity. Stunting was significantly (p<0.05) higher in girls and public school-adolescents while underweight was significantly higher (p<0.05) in boys and public school –adolescents. The dietary intake analysis reflected adequacy of energy (77%), protein (85%), though mostly of plant origin), vitamin A (81%), iron (91%) and thiamine (90%). The intake of vitamin C, riboflavin, niacin and calcium were inadequate. Differentials of intake between genders, age-cohorts and school categories were insignificant (p>0.05).

Conclusions: There was prevalence of double burden of malnutrition among the adolescents. Consequently, there is need to implement nutritional intervention program in the district.

Keywords: Nutritional status, Body mass indices, school-adolescents, Ogun West District.

NUTRITIONAL STATUS, FOOD SELECTIVITY AND NUTRITIONAL ADEQUACY OF CHILDREN AND ADOLESCENTS BETWEEN 6 AND 16 YEARS OLD WITH AUTISTIC SPECTRUM CONDITION

[1]*Baquerizo Sedano, Luis;* [2]*Lazo Paúcar, Pabel;* [3]*Mamani Salinas, Juan;* [2]*Santillán Gonzáles, Pamela;* [2]*Simeón Zacarías, Amery;* [4]*Aguilar Mendoza, Luis;* [2]*Baquerizo Sedano, Marilia.*

[1]MSc. Nutritionist Laboratory of Neuroscience and Behavior. Cayetano Heredia Peruvian University. Peru; [2]BSc. Nutritionist. Laboratory of neuroscience and behavior. Cayetano Heredia Peruvian University. Peru; [3]BSc. Nutritionist. Deparment of nutrition. Ramiro Priale Priale National Hospital. Peru; [4]PhD. Biologist. Laboratory of neuroscience and behavior. Cayetano Heredia Peruvian University. Peru.

Background and objectives: A healthy diet is essential for adequate growth and development. The autistic spectrum condition (ASC) presents some special characteristics, like hypersensitivity or altered sensory processing, that can hinder a feeding that meets all the nutritional requirements. The main objective was to analyze the nutritional status of 16 children between 6 and 16 years old with ASC.

Methods: This is an observational, descriptive and cross-sectional study, the nutritional status was assessed by anthropometry, nutritional adequacy through a seven-day prospective registration, and main gastrointestinal disorders and food selectivity by clinical interview.

Results: The results showed that 31% of participants had an adequate height and adequate BMI, 38% had an adequate height but their BMI indicated overweight, 6% had an adequate height but their BMI indicated obesity, 6% had an adequate height but his BMI indicated thinness, 13% had a low height and normal BMI and 6% had a low height and his BMI indicated overweight. About muscle mass, 31% of participants had an arm muscle area above average and 19% below average; according to abdominal perimeter only 1 participant presented metabolic risk. Also, age adjusted nutritional requirements indicated that the mean adequacy was: calories 112.5% (sd= 25.19%), protein 213.25% (sd=100%), calcium 38.25% (sd=22.46%), phosphorus 87.06% (sd = 45.12%), iron 86.81% (sd=28.21%), retinol 40.97% (sd=26.92%), thiamine 19.31% (sd=9.44%), riboflavin 34.68% (sd=15.14%), niacin 34.43% (sd=15.99%) and vitamin C 144.43%(sd=87.89%). The main gastrointestinal disorders were diarrhea in 13% of participants, constipation in 19% and flatulence in 13%, however, no food selectivity in number or type was found. It is highlighted that the percentage of adequacy of iron consumption with p = 0.068 was the one that most approached a significant correlation with the height-for-age index.

Conclusions: The analysis of the nutritional status of children and adolescents shows the existence of a double burden of malnutrition in 69% of participants, with high consumption of calories and proteins, that cause overweight, and at the same time an insufficient micronutrients consumption.

Keywords: autism spectrum condition, nutritional status, food selectivity, nutritional adequacy.

ASSESSMENT OF THE VALIDITY AND RELIABILITY OF THE DIETARY INDEX FOR A CHILD'S EATING (DICE) IN CHILDREN AGED 2 TO 8 YEARS LIVING IN AUCKLAND, NZ

[1]von Hurst, Pamela; [2]Delshad, Maryam; [3]Conlon, Cathryn; [3]Beck, Kathryn; [4]Mugridge, Owen.

[1]PhD.Senior Lecturer in Nutirition. School of Food and Nutrition. Massey University. Auckland. New Zealand; [2]Graduate Student. School of Food and Nutrition. MasseyUniversity. Auckland. New Zealand; [3]PhD. Senior Lecturer. School of Food and Nutrition. Massey University.Auckland.New Zealand; [4]Research Project Manager. School of Food and Nutrition. Massey University. Auckland.New Zealand.

Background and objectives: Background: Completing a four-day estimated food record (4DFR) can be a high burden for parents, but New Zealand has no valid and reliable dietary index to assess the adherence of children to the New Zealand Food and Nutrition Guidelines for Healthy Children and Young People Aged 2 -18 years (NZFNG).

Aim: To examine the validity and reliability of the Dietary Index for a Child's Eating (DICE) in children aged 2 to 8 years living in Auckland, NZ.

Methods: Caregivers of healthy children (2-8 years) living in NZ were recruited by email and print advertising. Caregivers completed both 4DFR for their child, and the DICE online on 2 occasions, eight weeks apart, to assess reliability. The DICE consists of 17 questions that reflect current statements in the NZFNG, with greater adherence indicated by a higher score (maximum 100). Relative validity was assessed by comparing the DICE scores with 4DFR scores using Wilcoxon signed rank test, Spearman correlation coefficients, cross-classification, and weighted kappa (κ) statistic. For evaluating construct validity, the DICE scores were compared with energy and nutrient intake extracted from the 4DFR. Intra-class correlation coefficients (Cronbach's α) were used to assess the reliability of DICE.

Results: From a possible score of 100, the mean ± SD of DICE was 78.2±11.5 (range 47-100) and the 4DFR was 73.8±10.8. Pearson's correlation coefficient showed a high correlation between the total scores for DICE and 4DFR (r=0.72; P<0.001). Results from the weighted κ-statistic also showed that the DICE total score and 4DFR total score had very good agreement (κ=0.94). There were positive relationships between the DICE total score and vitamin C (r=0.53), folate (r=0.45), and calcium (r=0.44) (P<0.001). Those who were categorised in the highest tertile of DICE consumed higher fibre, vitamins A, C, D, folate (P<0.05), and calcium (P<0.001). Almost perfect agreement (0.87) was found through the Intra-class correlation coefficient for reliability test (P<0.001).

Conclusions: Discussion and Conclusion: Results from this study demonstrated that DICE is a valid and reliable tool for the assessment of children's adherence to a health-promoting diet, and could be used in certain circumstances instead of the more burdensome 4FDR.

Keywords: dietary assessment, diet index, validity, reliability

HIDDEN HUNGER IN INDONESIA: WHAT ARE STILL HIDDEN?

[1]Usfar, Avita; [2]Riyanti, Akhir.

[1]Dr. Avita A. Usfar. Nutritionist. Sakanti Consulting. Jakarta. Indonesia.; [2]Akhir Riyanti, MSM. Nutritionist. Sakanti Consulting. Jakarta. Indonesia.

Background and objectives: Indonesia has recognized the importance of addressing stunting (35% children 24-59 months) and obesity (12% age 0-59 months, 11% 13-15 years, 29% adult). However, little is known on the magnitude of the problem of hidden hunger in the country, nor integrating effort to combat them.

Methods: The authors conducted literature search of nationally represented data and interviews with key informants.

Results: . The national prevalence of anemia is available for all age groups, while information on the prevalence of iodine deficiency is only available for children and women, and vitamin A and D for children. The prevalence of anemia in children 6 to 23 months is 57% (2011) and in pregnant women 37% (2013). The prevalence of vitamin D deficiency is 43% in children (2011). Fortification of salt with iodine was mandated in 1975 and wheat flour with iron, zinc, folic acid, vitamin B1 and B2 in 2001. Iron and Folic Acid distribution to pregnant women and vitamin A supplementation to children 6-59 months and to post-partum women are on-going programs. However, less progress is made on fortifying other products. A pilot of multiple micronutrient (MNP) to pregnant women was tried in 2000, but no follow-up thereafter. Trials of home fortification of MNP to children 6 to 59 months started in 2008, which resulted in a decree of mandatory content of the powder in 2013. However, its use is left to the local government and unevaluated. Voluntary fortification of vitamin A in cooking oil started in 2012, but experienced delay on its mandatory implementation. The result of rice fortification pilot in 2016 is yet to be announced. Based on six nationally represented food intake data, inadequacies of calcium, iron, vitamin A and C are found in children. Based on the interviews, the following deficiencies are suspected: calcium, vitamin B12, D, and E.

Conclusions: National data of the following micronutrients need to be updated or made available: vitamin A, B1, D, E, folic acid, iron, zinc, selenium, iodine, and calcium.

THE PILOT KOREAN KEY FOODS BASED ON DIET COMSUMPTION

[1]Chang, Moon Jeong; [2]Shim, Jee Seon; [3]Lee, Jung Sug; [4]Kim, Hye Young; [5]Lee, Hyun Sook; [6]Kim, Ki Nam.

[1]Professor. Department of Food and Nutrition. Kookmin University. South Korea.; [2]PhD. Medical college. Yonsei University. South Korea.; [3]PhD. Department of Food and Nutrition. Kookmin University, South Korea.; [4]PhD. Department of Food and Nutrition, Yongin University. South Korea; [5]PhD. Department of Food and Nutrition. Dongseo University. South Korea.; [6]PhD. Department of Food and Nutrition. Daejeon University. South Korea.

Background and objectives: This study was performed to develop the Key foods approach to select food for nutrient analyses of up-to-date National Food Nutrient Composition database by National Laboratory System(NLS) of the Ministry of Food and Drug Safety in Korea(KFDA), based on the United Stated Department of Agriculture(USDA) Key concept. The primary objective of NSL in Korea is to provide the best database to represent the nutrients consumed by the population of the nutrient profile for each offds identified as important in the food consumption. The key food approach assists NLS to prioritize foods that contribute significant amounts of nutrients of public health interest to the diet.

Methods: The Key Foods approach used 16 nutrients and energy (Key nutrients) of public health significance identified in the intake data from KNHAES 2013-2014. The recipe file from KNHANES containing the list of ingredients and their amounts was used to identify the Key Foods. At first food lists that contributed to the intake of each nutrient were selected using recipe code from raw data in KNANES. Then We determined foods that contributed the most to intakes across all key nutrients. After selecting foods list, Key Foods were identified as those food components that contribute up to 85% of any one nutrient.

Results: From this procedure, 570 primary Key Foods were aggregated, which account for approximately 90.5% of the contribution of the nutrient consumption for the Korean diet. 456 Key Foods were identified after further refinement procedure to insure that we have a representative list of what Koreans eat by considering some foods that are not widely consumed by the Korean population.

Conclusions: This Key Foods list will be used for updating and revising the KFDA Food nutrient composition database from 2017 and allow NLS to concentrate resouces for food composition analysis. We expect the updating database will give representative data for researchers, consumers, and policy makers.

THE RELATIONSHIP AMONG HOUSEHOLD FOOD INSECURITY, DIETARY DIVERSITY, AND MICRONUTRIENT INTAKE BETWEEN FARMING AND NON-FARMING HOUSEHOLDS IN SELECTED RURAL COMMUNITIES ACROSS GHANA

[1]Christian, Aaron; [2]Marquis, Grace; [3]Colecraft, Esi; [4]Lartey, Anna.

[1]Regional Institute for Population Studies, University of Ghana, Legon. Ghana; [2]PhD.Nutritionist.Canadian Research Chair in Social and Environmental Aspects of Nutrition.School of Dietetics and Human Nutrition.McGill University. Ste. Anne-de-Bellevue. Quebec. Canada; [3]DrPH.Nutritionist.Nutrition and Food Science Department.University of Ghana.Legon.Accra; [4]President, IUNS 2013-2017.

Background and objectives: Improving nutrition requires both access to food, higher dietary quality and diversity and the understanding of the relationship among these indicators in different livelihoods. This study examined the relationships among household food insecurity, dietary diversity, and the micronutrient density adequacy of diets of children 2-5 years of age of farming (n=461) and non-farming households (n=147) in Ghana.

Methods: Household food insecurity (HFI) was measured using an adapted version of the USDA Household Food Security Core Module. A household dietary diversity score (HDDS) was calculated based on the number of food groups (12 maximum) from which a household consumed. Children's diet quality were assessed using data from 2-d, 12-hr weighed food records, for a sub-sample of 120 households.The nutrient density adequacy of eight micronutrients -vitamin A, vitaminB6, vitamin B12, vitamin C, calcium, folate, zinc and iron- were calculated by dividing individual nutrient densities by recommended nutrient densities based on age-specific energy requirements. The mean micronutrient density adequacy (MMDA) of children's diets was then calculated as the mean of all eight individual micronutrient density adequacies, capped at 1. Spearman's correlation was used to assess the relationship among HFI, HDDS and MMDA. Predictors of MMDA were examined with linear regression analysis.

Results: Fewer non-farming households were moderately or severely food insecure compared to farming households (63.3% vs.75.7% P=0.003). HDDS of non-farming households was significantly higher than that of farming households (mean ± SD: 10.0 ± 1.8 vs. 9.3 ± 1.9; P=0.0001). MMDA was not significantly different between the non-farming farming and households. There were negative correlations between HFI and HDDS and MMDA (rs = -0.38, p<0.001 and rs = -0.25, p=0.005 respectively). After controlling for wealth, caregiver's education, and the number of children <5 y in the household, HFI was negatively associated with MMDA only in non-farming households.

Conclusions: Non-farming households consume more diverse foods and were less food insecure compare to farming households. This study suggests the utility of HFI to predict adequate intake of micronutrients in the diets of 2-5 yr. olds may be limited to non-farming households and not farming households.

CONSUMPTION OF ULTRA-PROCESSED FOODS AMONG JAPANESE MIDDLE-AGED ADULTS AND THE ASSOCIATIONS WITH DIETARY INTAKES AND BMI

[1]koiwai, kaori; [2]Hayashi, Fumi; [1]Matsumoto, Saika; [3]Takemi, Yukari.

[1]RD. Graduate School of Nutrition Sciences Kagawa Nutrition University. Japan; [2]Ph.D. RD. Faculty of Nutrition. Kagawa Nutrition University. Japan; [3]Ph.D. RD. Graduate School of Nutrition Sciences Kagawa Nutrition University. Japan.

Background and objectives: Japan retained the top spot in terms of average life expectancy, and nutritionally balanced Japanese diet is thought as being an important factor. However, in Japan, consumption of processed foods has continued its upward trend in recent years due to the reason to easy to cook, and to be able to eat at anytime or anywhere. The present study aimed to estimate the consumption of ultra-processed foods(UPF), and determine its association with dietary intakes and body mass index (BMI) among Japanese adults.

Methods: Cross-sectional study data from the Saitama Prefecture Health and Nutrition Survey 2011 was used for analyses. Dietary intake was assessed using two non-continuous day dietary records. Foods were classified based on NOVA system. Sociodemographic factors, lifestyle, height and weight were obtained from self-administered questionnaire. BMI was calculated using self-measured weight and height. 376 (156 men, 220 women) subjects aged 30 to 59 years who completed non- continuous two-day dietary records and self- administered questionnaire were included for the analysis. We divided the subjects into three groups according to tertile of the contribution of UPF in the total energy intakes (% of total energy):Low group (<30.7%) ,Middle group(30.7≤andc48.9%),High group (48.9%≤). ANCOVA adjusted for sex and age, marital status, income, total energy was used for the association with dietary intakes. For the association with BMI, exercise habits, smoking status were additionally adjusted.

Results: The mean ± standard deviation contribution of UPF was 41.0±20.5. High group had a significantly greater intakes of total fat, saturated fat, smaller intakes of potassium, iron, vitamin K, dietary fiber than lower groups. Furthermore, High group had a significantly greater intakes of other cereals (except rice), confectioneries, smaller intakes of rice, vegetables than lower groups. In addition, BMI of High group tended to be higher BMI in women.

Conclusions: UPF consumption were significantly related to dietary intakes. Out findings suggest that higher consumption of UPF among Japanese middle-aged adults was associated with intake of unhealthy diet and greater BMI.)

APPLICATION FOR MEASURING FREQUENCY OF EATING HIGH-FAT FOODS – COMPARISON WITH OTHER METHODS

[1]Chmurzynska, Agata; [2]Mlodzik, Monika; [3]Czarnocinska, Jolanta; [4]Wiebe, Douglas.

[1]PhD. Nutritionist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland. International Society of Nutrigenetics/Nutrigenomics (ISNN).; [2]MSc. Biotechnologist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland; [3]PhD. Nutritionist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland; [4]PhD. Epidemiologist. Department of Biostatistics and Epidemiology. Perelman School of Medicine. University of Pennsylvania. USA.

Background and objectives: Monitoring food intake is a challenge in nutritional studies. Ecological momentary assessment (EMA) may offer a solution, by enabling data collection on study participants' activities and states in real-time by means of a smartphone application (app). The aim of our study was to design and test the feasibility of an application for assessing the frequency of eating high-fat foods.

Methods: 30 subjects (15 men and women) were enrolled in Poznan, Poland for the so called Fat Taste Project. Usual frequency of eating high-fat foods were assessed with the Block Screening Questionnaire for Fat intake (Q1) and a version modified to include products typically consumed in Poland (Q2). We also developed an app that was loaded on a smartphone provided to each participant for use daily over 10 days. The app gave prompts four times per day to report on high-fat foods consumed since the last prompt. The app contained the same list of food items as Q2. Overall food intake was assessed with dietary records.

Results: The average total frequencies of eating high-fat foods per week were 17.1±1.5 (Q1), 32.7±2.2 (Q2), and 34.5±2.1 (the app). There were no significant correlations between % energy from fat and the frequencies of eating high-fat foods, irrespective of the method used. The results from Q1 and Q2 were correlated (r=0.78, p<0.001). There was also a correlation between the results from Q2 and the application (r=0.56, p<0.05) but in women only. The mean difference between Q1 and Q2 was 15.6, while between Q2 and the application 1.73.

Conclusions: Using the application for measuring frequency of eating high-fat foods does not significantly affect assessment of the overall mean frequency of eating those products. However, the detailed data analysis considering time intervals and types of products eaten is needed.

THE LEVEL OF HEMOGLOBIN AND THE MEAN CORPUSCULAR VOLUME (MCV) AMONG PRE-CONCEPTION WOMEN IN BANGGAI REGENCY

[1]Monoarfa, Yustiyanty; [2]Widasari, Lucy; [3]Yekti, Rahayu; [4]Narsi, Ketut; [5]Otoluwa, Anang Samudera; [6]Daeng Mamala, Firman; [7]Retnowati, Endang; [8]Gumilar, Erry; [9]Thaha, Abdul Razak; [10]Wirjatmadi, Bambang.

Background and objectives: Because the most common cause of anemia in pregnancy is iron deficiency, it is important to study the level of hemoglobin and the mean corpuscular volume (MCV) in preconception women.The current study aimed to describe the level of hemoglobin and the MCV, which are iron status parameters in red blood cells, among preconception women in Banggai Regency.

Methods: The research was conducted in threesub-districts of Banggai district, namely, Luwuk, North Luwuk, and South Luwuk, from October 2016 to February 2017. The subjects were newlywed preconception women who were visiting the religious affairs office to register their marriages; who were 18-35 years of age; and who did not have serious diseases, such as tuberculosis, heart disease, or kidney failure. A total of 102 preconception women were recruited. Venous blood samples were extracted, and hemoglobin and the MCV were measured using the SLS-hemoglobin method. The normal values for hemoglobin and the MCV are 12 g/dL and 80-100 fL, respectively.

Results: The results showed that of 102 preconception women, 16 women (15.7%) had a hemoglobin level under 12 g/dL or reported anemia, and 21 women (20.6%) had an MCV below 80fL. Of the 16 women who had anemia, 12 women (57.14%) had an MCV under 80 fL, which indicated that their anemia was correlated with the iron parameters in red blood cells.

Conclusions: The results of study indicated that anemia is frequent in preconception women and that iron plays an important role in this anemia. This study indicates the importance of multi-micronutrient supplementation in preconception women

PHYSICAL CHARACTERISTICS, PROXIMATE COMPOSITION AND ANTI-NUTRIENT FACTORS OF LABLAB BEAN (LABLAB PURPUREUS) VARIETIES GROWN IN KENYA

[1]Kilonzi, Sheila; [2]Makokha, Anselimo; [3]Kenji, Glaston.

[1]Karatina University; [2]PhD. Professor. Department of Food Science. Jomo Kenyatta University of Agriculture and Technology. Kenya..; [3]PhD. Professor. Department of Food Science. Jomo Kenyatta University of Agriculture and Technology. Kenya.

Background and objectives: The lablab bean (lablab purpureus) is an important staple food in Kenya. It is well adapted to the local climatic conditions and plays an important role in food and nutrition security, particularly in the arid and semi-arid parts of the country. However, there is limited information on the nutritional value of the different varieties of the beans. The main objective of this study was to determine the physical characteristics, proximate composition and anti-nutritional factors of three lablab bean varieties.

Methods: The length, width and thickness of the seeds was determined using vernier calipers. Seed density was determined by water displacement. Hydration and swelling coefficients were determined by soaking the seeds in water and determining the water absorbed. Crude protein was determined by Semi-Kjedahl method while crude fat was determined by Soxhlet extraction. Phytic acid was determined using HPLC, while tannin content was determined by the Vanillin Hydrochloric method.

Results: The mean 100 seed weight was significantly different among the three varieties, and ranged from 26.1 g to 29.2 g. The length, thickness and width ranged from 9.7 to 10.7 mm, 5.2 to 5.6 mm and 6.8 to 7.4 mm, respectively. The hydration and swelling coefficients of the beans ranged from 130.7 to 147.2, and 125.1 to 153.3, respectively. The mean protein and energy content varied from 22.5 to 25.4%, and 347.4 to 353.7 Kcal/100g, respectively, and differed significantly among the varieties. There were significant differences in the phytic acid and tannin levels, which ranged from 533.4 to 723.6 mg/100 g, and 0.27 to 232.6% CE, respectively.

Conclusions: There is good potential to select for lablab varieties with good cooking and nutritional characteristics.

HOW WELL DO DIFFERENT NUTRITION ASSESSMENT TOOLS MATCH? INSIGHTS FROM KENYA

[1]Fongar, Andrea; [2]Goedecke, Theda; [3]Qaim, Matin.

[1]Research Associate. University of Goettingen. Department of Agricultural Economics and Rural Development; [2]Dr. University of Goettingen. Department für Agrarökonomie und Rurale Entwicklung; [3]Prof. Dr. University of Goettingen. Department für Agrarökonomie und Rurale Entwicklung.

Background and objectives: Multifaceted indicators, scores and assessment tools exist to measure and depict food insecurity and malnutrition. However, most studies eventually only use one approach. Relatively little is known about how the results of different approaches relate, which is important to evaluate the reliability of the estimates and to better plan nutrition interventions. We contribute to the literature by comparing results from different assessment tools for the same households and individuals.

Methods: The study took place in two counties in Western Kenya in 2015 and included 809 households and 1,775 individuals. A 24-hour dietary recall and a 7-day food consumption recall were administered at individual and household level, respectively. At individual level, children between six and 59 month and male and female adults were targeted. Anthropometric measures were also taken. Pearson's correlation coefficient was used to evaluate the relationship between different measures.

Results: Household dietary diversity (HDD) depicts a usage of nine food groups per week. In contrast, the average individual dietary diversity score (IDDS) for adults and children depicts usage of six food groups. Average individual energy intake is 2237.43 kcal/day (± 961.59) and 1759.21 kcal/day (± 981.31) for adults and children, respectively. Significant correlation is found between energy intake (kcal) and different dietary scores for children and adults (e.g. adult energy intake and HDDS r=0.195***; adult energy intake and IDDS: r=0.258***; child energy intake and HDDS: r=0.244***). However, the magnitude of the correlation coefficients is mostly small. Looking into macro- and micronutrient levels, significant correlation is found only for selected nutrients and score combination and at adult level.

Conclusions: We tentatively conclude that there is a positive and significant relationship between different scores of the same households and individuals. However, further analyses are needed to understand the relationship across households, individuals and nutrient level. Additional research steps will be to look into the relationship between dietary quality indicators/scores and anthropometric measures.

Institut national de la recherche agronomique. France. Division of Human Nutrition. Wageningen University and Research. The Netherlands.; [7]PhD.MD. Physiologist. Division of Human Nutrition. Wageningen University and Research. The Netherlands.

Background and objectives: Dietary protein quality has been recognised as a critical issue by international authorities. It depends on amino acid (AA) composition and bioavailability. We aimed to investigate whether differences in the amount of bioavailable AA can be measured using a dual stable isotope ratio method. The principle is the use of two differently labelled proteins in a single meal; one test protein (e.g. 15N-labelled) given at a normal dietary quantity and one protein (e.g. 13C-labelled) given at trace quantity. The ratio between the two labelled AAs in serum (15N/13C) reflects the relative bioavailable amount of the differently labelled AA in the meal. Here, we have tested the difference in the amount of bioavailable AAs between two meals, hypothesizing that a two-fold difference in the amount of test protein in the meals would proportionally cause different ratio (15N/13C) in the serum.

Methods: In a cross-over study, ten subjects ingested a 500 kilocalorie pudding containing either 50 or 25 gram of intrinsically labelled 15N-milk protein (1.9 atom percent excess (APE)) and 400mg intrinsically labelled 13C-spirulina (97APE), along with 10E% fat and 50 or 70E% carbohydrates. On both days, pudding was divided in nine portions provided every 20 minutes. Isotopic enrichment of total serum free AAs at baseline and in the postprandial period was determined.

Results: The meal containing 50 gram dose of 15N-milk protein compared to 25 gram 15N-milk protein, also resulted in two-

fold higher serum free AAs 15N-enrichment. Both meals contained 400mg 13C-spirulina, resulting in similar serum free AAs 13C-enrichment. The high protein meal resulted in a 15N/13C ratio of 11.04(±1.53 (mean±SEM)) at t=180 minutes and the low protein meal resulted in a 15N/13C ratio of 6.26(±1.27).

Conclusions: A two-fold difference in the ingested amount of bioavailable 15N-milk protein in our test meal resulted in a 1.8 fold difference in serum free AA 15N/13C ratio. We showed that using this dual stable isotope ratio it was possible to detect differences in the amount of bioavailable protein. Thus, the dual stable isotope ratio might be a potential method for the estimation of protein bioavailability and hence protein quality in vivo in humans.

VITAMIN D AND ITS RELATIONSHIP WITH OBESITY, DYSLIPIDEMIA AND DIABETES MELLITUS 2 IN ADULT WOMEN, LIMA - PERU

[1]Bernui, Ivonne; [2]Pajuelo Ramírez, Jaime; [1]Bernui, Ivonne; [3]Sánchez González, José; [3]Arbañil Huamán, Hugo; [3]Gamarra González, Dante; [4]Miranda Cuadros, Marianella; [3]Chucos Ortiz, Rafael; [5]Estrada Acero, Bill; [5]Salas Ramos, Humberto.

[1]MSc. Biologist. Centro de Investigación de Bioquímica y Nutrición. Universidad Nacional Mayor de San Marcos. Perú; [2]MSc. Medical Doctor. Instituto de Investigaciones Clínicas. Universidad Nacional Mayor de San Marcos. Perú; [3]Medical Doctor. Servicio de Endocrinología. Hospital Nacional Dos de Mayo. Perú; [4]MSc. Nutritionist. Centro Nacional de Alimentación y Nutrición. Instituto Nacional de Salud. Perú; [5]Estudiante. Escuela de Nutrición. Universidad Nacional Mayor de San Marcos.

Background and objectives: Vitamin D deficiency is considered a public health problem. The objective was to determine the relationship between vitamin D and obesity, dyslipidemias and type 2 diabetes mellitus in a group of adult women.

Methods: One hundred and ten adult women between 20 to 55 years were weighted and their height measured in order to obtain the BMI to define the nutritional status. Insulin, glucose, lipid profile and vitamin D (25 (OH) -D) were determined. With the first two we calculated the Homeostatic Model of Assessment Index (HOMA-I) and to define insulin resistance (RI) a HOMA-I ≥ 2,7. Holick cutoff points were used to categorize 25-hydroxyvitamin D level: deficient <20 ng/mL, insufficient 21-29 ng/mL and sufficient ≥ 30 ng/mL. We identified dyslipidemia as recommended by the Third Report of the National Cholesterol Education Program. The frequency of consumption was used to measure vitamin D intake. We calculated prevalence, average, SD, 95% CI, correlation of quantitative variables, and association of categorical variables.

Results: Forty nine percent of the respondents were insufficient and 2,7% deficient of 25 (OH) -D. The intake was about 3

ug/d. The lowest averages of 25 (OH)-D were for obese 31, RI women 28 and obese with RI 28,2 ng/mL. The highest prevalence (25 (OH) -D <30 ng/mL) was for the obese women (62.2%), those with RI (72.4%) and for obese with IR (76.5%). HOMA-I and triglycerides had a moderate negative relationship with serum 25 (OH) -D levels. The prevalence of deficiency + insufficiency had a significant association between 25 (OH) -D with IR and hypertriglyceridemia.

Conclusions: The deficiency plus vitamin D insufficiency showed an association with two variables that identify cardiovascular risk, which could explain the possible relationship of this vitamin with cardiovascular diseases

BODY WEIGHT CONTROL, NUTRIENT INTAKE AND RESTRAINED EATING BEHAVIOURS OF HEALTHY ADULTS

[1]Madali, Berna; [2]Dikmen, Derya; [2]Inan-Eroglu, Elif; [1]Ozdemir, Aslihan.

[1]MSc. Nutrition and Dietetics Department, Hacettepe University, Turkey.; [2]PhD. Nutrition and Dietetics Department, Hacettepe University, Turkey.

Background and objectives: Dietary restraint is defined as the intention to restrict food intake in order to control body weight. The Restraint Scale (RS) is the most widely used measure for dieting to achieve or maintain a desired weight. Therefore the aim of this study was to evaluate the nutrient intake and BMI values of participants according to their restrained scale scores.

Methods: In order to determination a relation between nutrient intakes, anthropometric measurements and restrained scale scores of participants a questionnaire that consists restrained scale and some socio-demographic characteristics of healthy participants were administered by the face-to-face method. Participants' 24 hour food recall and anthropometric measurements were also taken by specialized dietitians. The results were evaluated by the statistical program SPSS.

Results: The mean energy value of the individuals was 2038.4 ± 678.34 kkal. According to the participants' 24-hour food recall, the average percentage of energy from carbohydrate, fat and protein intake were 47.9 ± 9.31%, 37.2 ± 8.66% and 14.9 ± 3.50%, respectively. According to RS, 37% of the participants had restricted eating behaviours. The mean energy value of the individuals with restricted eating behavior were 2209.2 ± 716.09 kkal, while the mean energy value of the individuals with restricted eating behavior were 1747.1 ± 503.74 kkal (p = 0.02). Similarly, individuals without restrained eating behaviors were found to have higher carbohydrate (g / day), protein (g / day) and fat (%) values compared to individuals with restricted eating behaviors and the difference was found to be statistically significant (p = 0.01 , 0.04 and 0.01, respectively). The mean BMI of women without restricted eating

behaviors was 23.1 kg/m2, while the BMI of women with restricted eating behaviors was 21.0 kg/m2 (p = 0.03). But there was no significant difference between the mean BMI values of individuals with and without restricted eating behaviors in men (p> 0.05).

Conclusions: The findings of this research suggest that restraint subscales are sensitive to nutrient intake of participants.

Keywords: Nutrient intake, body weight, restrained scale

EFFECTS OF IODISED SALT AND IODINE SUPPLEMENTS ON PRENATAL AND POSTNATAL GROWTH: A SYSTEMATIC REVIEW

[1]Farebrother, Jessica; [2]Naude, Celeste; [2]Nicol, Liesl; [3]Sang, Zhongna; [4]Yang, Zhenyu; [5]Andersson, Maria; [6]Zimmermann, Michael Bruce.

[1]MPharm MPH. Human Nutrition Laboratory. Institute of Food, Nutrition and Health. ETH Zurich. Switzerland.; [2]PhD. Centre for Evidence-Based Healthcare, Faculty of Medicine and Health Sciences. University of Stellenbosch. South Africa.; [3]PhD. Department of Nutrition and Food Hygiene, School of Public Health. Tianjin Medical University. China.; [4]PhD. Key Laboratory of Trace Element Nutrition of the Ministry of Health. Chinese Centre for Disease Control and Prevention. China.; [5]PhD. Human Nutrition Laboratory. Institute of Food, Nutrition and Health. ETH Zurich. Switzerland.; [6]MD. Human Nutrition Laboratory. Institute of Food, Nutrition and Health. ETH Zurich. Switzerland.

Background and objectives: Globally, 161 million children are stunted. Stunted children have an increased risk of mortality and morbidities. Iodine is a key component of thyroid hormone, which influences the growth of skeletal and peripheral tissues. Inadequate dietary iodine intake is associated with stunted growth. We systematically reviewed the evidence for the effectiveness of iodine supplementation or fortification on growth (prenatal to 18 years).

Methods: Following Cochrane methods, we searched ten databases including two Chinese databases (latest search February 2017) for eligible studies. RCTs and non-RCTs controlled before-after studies, interrupted time-series studies and interrupted time series studies with repeated measures conducted in pregnant women and children aged 0-18 years, comparing the effectiveness of iodine (in any form, dose or regimen) to a placebo, non-iodised salt, or no intervention, on pre-and post-natal growth markers were assessed. Analyses were stratified by iodine status. We calculated mean differences (MD) with 95% confidence intervals (95%CI), and performed random-effects meta-analyses. The quality of the evidence was assessed using GRADE.

Results: Nineteen trials with 5733 participants were included in the review. Providing moderately-to-mildly iodine deficient pregnant women with iodine supplements may make little or no difference to offspring birth length (MD 0.01 cm (95% CI -0.39, 0.41cm); I2=0%; 3 RCTs, n=1106; low quality evidence). The impact of iodine supplements to severely iodine deficient pregnant women on offspring birth length is uncertain due to the very low quality of evidence (MD 4.7 cm (95% CI -1.6, 11cm); 1 non-RCT, n=456; very low quality evidence). Similarly, supplementing schoolchildren with iodine may make little or no difference to their height, irrespective of their baseline iodine status (MD -0.03 cm (95% CI -1.45, 1.39 cm); I2=28%; n=890; 4 RCTs; low quality evidence).

Conclusions: Despite the importance of adequate dietary iodine intake for normal growth during infancy, childhood and adolescence, there are few rigorous, adequately powered trials investigating the effectiveness of iodine supplementation or fortification on prenatal and postnatal growth during these life stages. Based on the limited, low quality data available, the impact of iodine supplementation or fortification on prenatal or postnatal growth outcomes remains uncertain.

Keywords: Iodine, iodine deficiency disorders, growth, stunting

NUTRITIONAL STATUS ASSESSMENT OF ELITE MALE CRICKETERS FROM GUJARAT, INDIA

[1]Deota, Prachi; [2]Chandorkar, Suneeta.

[1]MSc. Doctoral Scholar. Department of Foods and Nutrition. The Maharaja Sayajirao University of Baroda. India.; [2]PhD. Assistant Professor. Department of Foods and Nutrition. The Maharaja Sayajirao University of Baroda. India.

Background and objectives: There is lack of data on nutritional status of cricketers and therefore the study was planned to assess the anthropometry, body composition and dietary intake of the male cricketers 19-23 years of age (n=28). The subjects trained for 4 hours a day for 6 days a week at the academy and had an average 9 years of experience.

Methods: Weight, height and Waist- hip circumference were measured using standard procedures. Body mass index (BMI) was classified using Asia Pacific cut offs. Body composition analysis was conducted using Bio-electrical impedance method (Bodystat Quadscan 4000 unit). Dietary intake was assessed using 24-hour dietary recall method (3 days) and food frequency questionnaire was used for Iron and Calcium intake. The data for macronutrient intake were compared with the Recommended Dietary Allowances by National Institute of Nutrition (NIN) for Team event athletes while for micronutrients, RDA by NIN for non-athletic population were used as those for athletes are unavailable.

Results: The measured BMR of subjects was higher (1679±153 kcal/day) than the BMR for reference man (1587 kcal/day) calculated using formula by Indian Council of Medical Research. A typical short fat phenotype was observed even in the elite cricketers as indicated by the waist height ratio which identified 21% to be abdominally obese. Body composition revealed that only 46% subjects had normal body fat while 93% had normal lean mass. Thirty nine percent of cricketers were identified as overweight (28%) and obese (11%) by BMI. Percent energy contributed by Carbohydrate: Fat: Protein (50:35:15) compared well with the rec-

---

ommended values (54:31:15). None of the subjects met the (RDA) for Energy (-48%), Carbohydrates (-52%), Protein (-47%) and Fat (-59%). Daily Iron (19.31mg) and Calcium intake (1572mg) met the RDA of 17mg and 600mg respectively. Iron rich foods consumed daily were whole wheat flour (96.4%), Lentil (7.1%) and Puffed rice (7.1%) while the Calcium rich foods were Milk (100%), Dried dates (42.9%), Curd (39.3%).

Conclusions: Overweight and obesity was prevalent even in elite cricketers along with central obesity. The deficits in Energy and macronutrients if not corrected may lead to impaired performance.

College of Physicians and Surgeons. USA; [5]Bsc. Department of Laboratory Medicine. Translational Metabolic Laboratory. Hepcidinanalysis.com. Radboud University Medical Centre. The Nederlands; [6]PhD. Department of Laboratory Medicine. Translational Metabolic Laboratory. Hepcidinanalysis.com. Radboud University Medical Centre. The Nederlands; [7]MD. Department of Health Science and Technology. Laboratory of Human Nutrition. ETH Zürich. Switzerland.

Background and objectives: Oral iron supplementation (OIS) is a primary approach to treat iron deficiency, but there is no clear consensus on the optimal regimen, and compliance is often poor. Oral iron supplements acutely increase serum hepcidin (SHep); the duration and magnitude of this increase and its dose dependence could be used to optimize OIS to maximize absorption. In short-term studies (1-3) we defined the duration of the SHep increase, compared single day versus two consecutive daily doses and single versus twice a day (b.i.d.) dosing. In long-term studies (4), we compared iron absorption (60mg) from consecutive day dosing for 14 days versus alternate day dosing for 28 days (equal total dose) and (5) from 120mg given in daily doses versus split b.i.d. 60mg over 3 days.

Methods: In studies (1-3: n=54; 4: n=40; 5: n=20) labeled Fe [54Fe]-, [57Fe]- or [58Fe]-FeSO4 was given to fasting iron-depleted women (plasma ferritin <25μg/L). Iron absorption was measured as erythrocyte incorporation of iron stable isotopes 14 days later.

Results: Studies 1-3 showed an increase in SHep at 24h after doses of >60mg (P<.05), but not at 48h. Fractional iron absorption (FIA) decreased by 36% when 60mg was administered on the second day compared with the first day (P<.001). Total iron absorption (TIA) did not improve if 3 doses were administered within 24h (b.i.d.) compared to when only the 2 morning doses were given (P=.79). In study 4, TIA from alternate day dosing was increased compared to consecutive day dosing: geometric mean (-SD,+SD) 175.3 (110.3,278.5) versus 131.0 (71.4,240.5)mg (P=.001). SHep increased over time in both groups, with a time x group interaction (P<.001). In study 5, there was no difference in TIA over 3 days between single dosing and b.i.d: geometric mean (-SD,+SD) 40.7 (40.9,40.6) versus 44.7 (44.8,44.5)mg, respectively; b.i.d. dosing increased SHep over the 3 days compared with single day dosing (P<.05)

Conclusions: In both short- and long-term studies in iron-depleted women: 1) FIA and TIA are higher from 60 mg doses given on alternate days versus consecutive days; and 2) an iron dose (120 mg) split b.i.d. does not increase TIA compared with a single morning dose.

Keywords: oral iron supplementation, iron absorption, hepcidin

Conflict of Interest Disclosure: DWS and AJGM are employees of Radboud University and Medical Centre that offers high quality hepcidin measurements to the scientific, medical and pharmaceutical community, at a fee for service basis. The other authors do not have conflict of interest to disclose.

HARMONIZATION OF DIETARY INTAKE ASSESS-MENT IN BALKAN REGION USING DIET ASSESS & PLAN (DAP) PLATFORM

Capacity Development Network in Nutrition in Central and Eastern Europe, Capnutra, Serb.

Background and objectives: Initiatives in the Capacity Development in Nutrition Research in Balkan region in past decade have been toward creation of contemporary, harmonized Research Infrastructure (RI) compliant to European standards. One of the elements of this RI is an innovative tool, DIET ASSESS & PLAN (DAP), a platform for standardized food consumption collection, comprehensive dietary intake assessment and nutrition planning.

Methods: DAP, advanced dietary assessment application, compliant to EuroFIR(TM) standards, comprises computerized food consumption questionnaires (24-h dietary recalls (24HDR), Food Frequency Questionnaire (FFQ), Food Records (FR), Food Propensity Questionnaire (FPQ)), general and pre-screening information about subjects, anthropometric and biochemical parameters, blood pressure measurements, supplements intake and physical activity, and complementary Food photo atlas. It extracts nutrient data from compatible food composition database (FCDB) (30 national FCDBs from EuroFIR(TM) Food platform), and evaluates results based on sets of international nutrient recommenda-tions. Its structure is based on MySQL database (for FCDB) and Microsoft VisualFoxPro database engine.

Results: DAP enables dietary intake assessment on individual and/or population levels, dietary planning (for public institution procurements and personal dietary advice), foods design/reformulation, food labelling, and assessment of the Minimum Dietary Diversity-Women (MDD-W) as one of the priority indicators forPost-2015 Sustainable Development Goal (SDG) framework. It operates in bilingual options: English (default) and other language. DAP platform has EuroFIR(TM) thesaurus, LanguaL(TM) and EFSA FoodEX2 coding systems integrated in its structure, where food matching is possible on level of foods, recipes and dietary questionnaires. The software has been evaluated within EFSA project: "Dietary monitoring tools for risk assessment", 2014, and presents major platform for two new EFSA projects in Balkan region: National Dietary Surveys in Compliance with the EU Menu methodology (sixth support): "The adults' survey", including subjects from 10 to 74 years old, 2017-2021 (Serbia, Bosnia and Herzegovina and Montenegro) and "The children's survey", including subjects from three months up to 9 years old, 2017-2021 (Serbia and FYROM).

Conclusions: DAP platform with its standardized and harmonized tools for dietary assessment is RI that synchronizes nutrition surveillance in the Balkan region, and with is features could be employed on larger scale nutrition epidemiology studies.

EFFECT OF DIFFERENT AMOUNTS OF ALCOHOL INTAKE ON GUT MICROBIOTA COMPOSITION OF HEALTHY ADULTS

[1]Nova, Esther; [2]Redondo, Noemí; [3]Villavisencio, Brenda; [1]Díaz-Prieto, Ligia E.; [1]Marcos, Ascensión.

[1]PhD. Nutritionist. Institute of Food Science, Technology and Nutrition (ICTAN) - CSIC. Madrid. Spain; [2]MSc. Nutritionist. Institute of Food Science, Technology and Nutrition (ICTAN) - CSIC. Madrid. Spain; [3]BSc. Nutritionist. Institute of Food Science, Technology and Nutrition (ICTAN) - CSIC. Madrid. Spain.

Background and objectives: Knowledge on the effects of alcohol consumption on the gut microbiota composition is scarce and mainly derived from animal studies or from studies on alcoholic subjects with alcohol-liver disease or cirrhosis. However, the effects are bound to be different depending of the amount of alcohol intake, as evidenced with other alcohol effects on health. The objective of the present work was to assess the effect of the amount of alcohol intake in the gut microbiota composition of healthy adults

Methods: A non-representative population sample of 261 healthy adults (25-45 y) of Madrid was studied (51% males, 49% females). Anthropometry was measured and socioeconomic, life-style and medical history data were obtained through a battery of

validated questionnaires. Gut microbiota composition was analyzed in fecal samples through 16S rRNA gene amplicon sequencing (V3+V4 gene regions. MiSeq 2x250 Illumina) and taxonomic analysis. Three groups of alcohol consumption were considered. 1) None-Low (N=124), average consumption <5g alcohol/day; 2) Moderate: ≥ 5 g/d and ≤20g/d (men) or ≤12 g/d (women) (N=99); 3) High: > 20 g/d (men) or > 12 g/d (women) (N=38). After post-processing OTUs data cleaning, general lineal model including alcohol group and sex as independent factors and non-parametric Kruskal-Wallis and Mann-Whitney tests were used for the statistical analysis of normal and non-normal distribution phyla encountered, respectively

Results: Differences between groups of subjects with different amount of alcohol intake were observed specially in the less abundant phyla while the predominant phyla were similar irrespective of alcohol consumption. A higher proportion of Spirochaetes was observed when alcohol consumption is high (Kruskal-Wallis test, P=0.001), and remains significant in a separate sex analysis. Other differences are observed in some minor phyla depending on amount of alcohol consumption but the findings are different in men and women.

Conclusions: Alcohol consumption above the recommended daily intake was associated with an increased proportion of Spirochaetes in gut microbiota of healthy adults compared to moderate, low or no-alcohol intake.

Keywords: Gut microbiota. Alcohol intake. 16S metagenomics. Healthy adults.

DIETARY INTAKE AND SOURCES OF ADDED SUGAR AMONG BRAZILIAN POPULATION: RESULTS FROM ELANS/EBANS STUDY

[1]Fisberg, Mauro; [2]Previdelli, Ágatha Nogueira; [3]Gómez Salas, Georgina; [4]Guajardo, Viviana Beatriz; [5]Zimberg, Ioná; [6]Kovalskys, Irina.

[1]MD. Instituto Pensi. Fundação Jose Luiz Egydio Setubal. Hospital Infantil Sabara. São Paulo. Brazil; [2]PhD. Professor. Faculdade de Ciências Biológicas e da Saúde. Universidade São Judas Tadeu São Paulo. Brazil; [3]MSc. Professor. Departamento de Bioquímica. Escuela de Medicina. Universidad de Costa Rica. Costa Rica; [4]Bcs. International Life Science Institute (ILSI). Buenos Aires. Argentina; [5]PhD. Departamento de Psicobiologia. Universidade Federal de São Paulo. São Paulo. Brazil; [6]MD. International Life Science Institute (ILSI). Buenos Aires. Argentina.

Background and objectives: Added sugar (AS) intake is highly associated with the epidemic of overweight and obesity. This study aimed to identify the dietary intake and sources of AS among Brazilian population.

Methods: Latin American Health and Nutrition Study (ELANS) is a multicenter study developed in urban areas of 8 Latin American countries: Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela. Data were obtained from 2,000 Brazilians (15-65 y.o) participating in EBANS (Brazilian Health and Nutrition Study). Two 24-hour recall were used to identify the intake of AS and the major food items accounting for AS, using the weighed-proportions formula developed by Block (1985) in which the relative contribution (RC) of a given food item/food group is defined as: RC=[(Total AS grams from a food item x 100)/Total AS grams from all food items]. Median intake and sources of AS were performed by age group, gender, socioeconomic level (SES) and nutritional status.

Results: Median AS and AS percentage of energy intake were 52.4g/day and 12.6%, respectively. More than 63% of the subjects had %energy from AS >10%. Comparison of median AS intake (g/day) between age groups, nutritional status and SES showed that the highest intake was found among male adolescents, obese male and high SES. Carbonated soft drinks accounted for the highest contribution of AS intake in the whole sample, providing from 26.8% to 40.1% of total AS intake. Infusions were the second main source, except for adolescents that had cookies and cakes as the second contributor of AS intake. Sugar-sweetened beverages (SSBs) represented 68% of total AS intake among Brazilians, based on gender it was 69.2% for male and 57.5% for female.

Conclusions: Brazilians are consuming AS above the level recommended by the World Health Organization (10%). The main source of AS was SSBs independent of gender, age group, SES and BMI status. These results reinforce the importance of reducing sugar content in manufactured foods. However product reformulation alone may not be enough, public health programs should also focus on strategies that reduce the quantity and frequency of others sources of AS, such as homemade drinks, cakes, cookies and desserts.

Keywords: Food source, Added sugar, Brazilian population, multicenter study.

MONITORING AND EVALUATION OF DIET-RELATED NCD RISK FACTORS UNDER NUTRITION TRANSITION: A SECONDARY ANALYSES OF THE DATA OF NATIONAL FOOD CONSUMPTION SURVEY, LAO PDR

[1]*Miyoshi, Miki;* [2]*Kounnavong, Sengchanh;* [2]*Douangvichit, Daovieng;* [3]*Yoshiike, Nobuo.*

[1]RD. MPhil. PhD. Head, Section of Section of International Nutrition Research and Development, National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition; [2]National Institute of Public Health, Lao PDR; [3]Dean, Graduate School of Health Sciences, Aomori University of Health and Welfare, Japan.

Background and objectives: Recently, the countries where undernutrition and infectious diseases have been the significant public health problems are increasingly facing with the increased disease burden of non-communicable diseases (NCDs) like diabetes and cardiovascular diseases under nutrition transition, hence "double burden of malnutrition". Sustainable development goals (SDGs) were formulated in September 2015 as post-MDGs, thereby promoting global trend to focus on nutrition and NCDs. It is therefore important to develop a framework of policy planning to tackle "double burden of malnutrition" as well as evaluate the diet-related NCD risk factors in the countries undergoing nutrition transition. In our previous study, we developed the database on nutrition/NCDs monitoring systems and the relevant indicators (e.g. definition, criteria). The present study aims to develop a standardized tool (FFQ) for dietary assessment to evaluate the impact of intervention for "double burden of malnutrition" using the dataset of nationwide food consumption survey in Lao PDR.

Methods: National Food Consumption Survey is the first comprehensive nationwide survey on dietary intake in Lao PDR, which has been conducted by the National Institute of Public Health, Lao PDR (NIOPH) since 2014. This survey was undertaken by one day 24-hour recall method using food photo book developed by a pilot study, and INMUCAL-N was applied for calculation of nutrient intake. In addition, a questionnaire on the socio-demographic characteristics and the anthropometric data were collected. For the purpose of this study, the approval for secondary analyses is being sought to the NIOPH and the supporting bodies (e.g. FAO).

Results: Results of data analyses will be presented at the congress.

Conclusions: We expect to apply the newly-developed FFQ for monitoring and evaluation of diet-related NCD risk factors in the country, followed by the dietary surveys in Cambodia and Myanmar for standardization to monitor and evaluate diet-related NCD risk factors in each country.

Keywords: nutrition transition, food consumption data, dietary survey, 24-hour recall, FFQ

EXPLORATORY STUDY ON FATTY ACID PROFILE FROM SEVERAL EDIBLE FISH SPECIES IN CHILE

[1]*Rincón-Cervera, Miguel Ángel;* [2]*González-Barriga, Valeria;* [3]*Romero Ormazábal, Jaime;* [4]*Valenzuela-Báez, Rodrigo;* [3]*Valenzuela-Bonomo, Alfonso.*

[1]PhD. Chemist. Institute of Nutrition and Food Technology (INTA). University of Chile. Chile; [2]Nutritionist. Institute of Nutrition and Food Technology (INTA). University of Chile. Chile.; [3]PhD. Biochemist. Institute of Nutrition and Food Technology (INTA). University of Chile. Chile.; [4]PhD. Nutritionist. Department of Nutrition, Faculty of Medicine. University of Chile. Chile.

Background and objectives: Marine fish is one of the most important current dietary sources of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), two of the most recognized omega-3 long-chain polyunsaturated fatty acids (ω-3 LCPUFA) because of their beneficial effects and physiological roles in human health. In Chile there is a lack of information concerning EPA and DHA content in fish consumed by the population. In this work, we determined the fatty acid amount of seven fishes consumed in Chile with a focus on EPA and DHA, thus providing relevant information for consumers.

Methods: Specimens from seven fish species were collected for this study from local fishermen in Coquimbo (IV Region, Chile): Chilean hake (Merluccius gayi gayi), Peruvian morwong (Cheilodactylus gayi), Southern rays bream (Brama australis), Pacific sandperch (Prolatilus jugularis), Chilean jack mackerel (Trachurus murphyi), chub mackerel (Scomber japonicus) and Chilean flounder (Paralichthys adspersus). Fillets from 3 fishes of each species were put together and minced, and then the lipid fraction was extracted by the Folch method. Fatty acid profiles were obtained by gas chromatography coupled with flame ionization detection (GC-FID) using methyl tricosanoate as internal standard.

Results: Most analyzed fish fillets contained an EPA+DHA amount higher than 250 mg per serving size (100 g fillet), which is the minimum recommended daily intake of both ω-3 LCPUFA. The highest EPA+DHA amount was found in Peruvian morwong (440 mg/100 g fillet) whereas the lowest amount was found in Chilean flounder (202 mg/100 g fillet). It was observed that DHA amount was higher than EPA in all studied species: the highest and lowest DHA levels were found in Chilean jack mackerel (280 mg/100 g fillet) and Chilean hake (149 mg/100 g fillet) respectively, whereas the highest and lowest EPA levels were found in Peruvian morwong (144 mg/100 g fillet) and Southern rays bream (24 mg/100 g fillet) respectively.

Conclusions: This exploratory study provides valuable data to the very scarce literature regarding fatty acid composition of Chilean fishes. It did not include longitudinal data, but it can be used as starting point to design a larger study considering geographical, climate and seasonal conditions.

Keywords: Fish fillet, eicosapentaenoic acid, docosahexaenoic acid, fatty acid profile.

PROTEIN INTAKE, PROTEIN QUALITY, PROTEIN STATUS AND EARLY CHILDHOOD LINEAR GROWTH IN RURAL ETHIOPIA

[1]Tessema Anegago, Masresha; [2]D. Brouwer, Inge; [3]S. Gunaratna, Nilupa; [4]Belachew, Tefera; [5]Belayneh, Demissie; [6]Donato, Katherine; [7]De Groote, Hugo.

[1]PhD Fellow in Wageningen University's, Associate Researcher, Food Science and Nutrition Research Directorate Ethiopian Public Health Institute (EPHI); [2]PhD.Division of Human Nutrition, Wageningen University. Wageningen. The Netherlands.; [3]PhD. Harvard T.H. Chan School of Public Health. Boston.MA, USA; [4]PhD.Human Nutrition Unit, Jimma University. Jimma. Ethiopia; [5]MSC.International Maize and Wheat Improvement Center (CIMMYT). Addis Ababa. Ethiopia.; [6]MSC.Harvard University, Cambridge. MA. USA; [7]PhD. International Maize and Wheat Improvement Center (CIMMYT). Nairobi Kenya.

Background and objectives: Linear growth failure is a major public health concern in developing countries. Poor linear growth of children, manifested as stunting, is associated with higher child mortality and morbidity, poorer motor and cognitive development, and lower educational attainment and economic productivity in adulthood. Protein and essential amino acids play biological roles in bone elongation and necessary for linear growth. The quality of protein in foods consumed by low-income groups in developing countries is often limited, which reduces the availability of protein for use by the human body. However, so far limited evidence is available on the relationship between early childhood linear growth and protein intake, particularly in settings with a high prevalence of inflammation. we therefore examine the associations among protein intake, protein quality, protein status, and linear growth among young children in rural Ethiopia

Methods: We used a cross sectional data set (n=846) collected from July-September 2015 during baseline of an ongoing randomized controlled intervention trial of children aged 6-35 months in a rural area of Ethiopia. Protein intake was assessed using 24 h dietary recall, and protein quality was measured using the PDCAAS method. Determination of protein status (prealbumin), alpha-1-glycoprotein (AGP), and C-reactive protein (CRP) was conducted using immunoturbidimetry. Multivariable linear regression was used to evaluate the associations among protein intake, protein quality, protein status, and early linear growth.

Results: Prevalence of inflammation (elevated AGP > 1 g/L or CRP > 5 g/L) was about 37%. After adjustment for sex and socioeconomic status, we found protein status measured using prealbumin was correlated with height and weight of children. We found that among stunted children in the first one year, median protein intake was below the estimated average requirement (EAR) (P<0.05). After adjusting for potential confounders, we found total protein intake(β=0.32), and protein quality((β=0.45), and intake of the most limiting amino acids(β=0 .53) were positively associated with early childhood linear growth(P<0.005)

Conclusions: High linear growth failure in Ethiopian children likely affected by low protein intake. Nutrition programs that emphasize higher dietary protein intake as well as improving the quality of that protein might improve early child linear growth

Keywords: protein intake; protein status; linear growth; Ethiopia

VALIDATION OF A MOBILE APPLICATION AS A TOOL TO ESTIMATE FOOD INTAKE IN ADULTS

[1]Bittencourt Mescoloto, Samantha; [2]Caivano, Simone; [2]Domene, Semiramis.

[1]Dietitian. Graduate student at Health Sciences Interdisciplinary Program. Federal University of São Paulo. Brazil; [2]PhD. Department of Public Policies and Collective Health. Federal University of São Paulo. Brazil.

Background and objectives: Knowing the dietary patterns of the population includes nutritional assistance actions and can contribute to health care. However, traditional methods of dietary intake analysis have weaknesses that lead to measurement errors. The development of new tools can assist in information quality in dietary surveys while the use of digital technology with mobile devices facilitates recording and analysis of data, as already demonstrated. The objective of this investigation is to verify the validity of Nutrabem application -NApp, as a tool for recording food intake in adults. This study was conducted to determine the optimal sample size by considering dietetic variability.

Methods: A cross-sectional pretest study conducted with NApp users; food intake was also estimated by the application of a 24-hour recall; nutritional composition analysis was performed using Nutrabem Pro software. Student' t-test, Pearson's Correlation Coefficient and Bland Altman's chart will be applied to verify the agreement between methods.

Results: The sample of 40 subjects was composed of 33 women (82,5%); the average age of the respondents was 29.7 years (SD=8.96).

Conclusions: This study indicated that a sample of 280 individuals will able to produce results accurate enough to identify the significant differences in the variables of interest in this study with the power of 0.8.

Keywords: validation studies, dietary surveys, digital technology.

MARKET ASSESSMENT OF OIL BRANDS TO ASSESS THEIR AVAILABILITY AND COMPLIANCE WITH VITAMIN A FORTIFICATION STANDARDS IN PAKISTAN

[1]*Jungjohann, Svenja;* [2]*Rasool, Faiz;* [3]*Anjum, Faqir Muhammad;* [4]*Arshad, Muhammad Umair;* [5]*Ahmad, Nazir;* [5]*Afzaal, Muhammad.*

[1]Global Alliance for Improved Nutrition (GAIN); [2]Public Health (MSc). Global Alliance for Improved Nutrition (GAIN). Islamabad. Pakistan; [3]Food Science (PhD). University of The Gambia. Islamic Republic of The Gambia; [4]Food Science (PhD). Institute of Home and Food Sciences. Government College University Faisalabad. Pakistan; [5]Food Science (MSc). Institute of Home and Food Sciences. Government College University Faisalabad. Pakistan.

Background and objectives: The mandatory fortification of oil with vitamin A has been identified as a key strategy to address prevalent deficiency in the Pakistan population. However, the potential efficacy of fortification can be compromised by sub optimal compliance to standards. Given the need to ascertain compliance, we sought to assess (1) availability of oil brands across provinces and (2) compliance of oil brands and producers with oil standards.

Methods: In Aug 2016, different retail outlets were visited in the 2-4 main urban market hubs (based on high population density) to record available brands in each of the 4 main provinces.

12 oil samples were collected from each oil brand available in Pakistan. Composite samples were prepared by brand and the average vitamin A content was quantified using HPLC. Unweighted averages by producer were calculated across brands.

Results: We were able to identify the number of brands available in Pakistan and the variety of available brands in the main provinces. Punjab province has the highest variety of available oil/ghee brands (70 brands), Sindh (45), KPK (44) and Baluchistan province the lowest (19).

The annual market volumes of the 50 producers included in the compliance assessment represents about 70% of the market volume. 70% of this volume is fortified (by 28 producers), but only 40% according to the national standard (by 11 producers).

The fortified oil is available in all the main 4 provinces.

Conclusions: The majority of the oil in Pakistan is fortified and fortified oil is available in all the main 4 provinces. Two-thirds of the oil is not fortified or does not meet the standard. Therefore, strengthening of the regulatory monitoring by key stakeholders (Regulatory bodies including Pakistan Standards and Quality Control Authority (PSQCA) /Food Authorities etc.) may be required to ensure inspections are carried out at the production sites of producers that do not fortify or do not meet the standard requirements, to understand the bottlenecks in collaboration with industry and to make sure that fortification of oil is initiated and quality assurance and control measures improved.

Market monitoring can identify non-compliant producers and prioritize follow-up for corrective action.

Keywords: market assessment, compliance, availability, food fortification, Pakistan

Further collaborators:
The market assessment was made possible through the support of the Pakistan Vanaspati Manufacturers Association (PVMA), stakeholders from the National and Provincial Governments, PSQCA, Pakistan Council for Scientific Research (PCSIR), Qarshi research Centre, Institute of Home and Food Science of the Government College of the Faisalabad University and GAIN, as well as the financial support from the USAID/GAIN Pakistan Regional Food Fortification Project.

Argentina.; [6]PhD. Professor. Harvard T.H. Chan School of Public Health. Boston. United States.; [7]MD. PhDr. Professor. Department of Nutrition. Harvard T.H. Chan School of Public Health. Boston. United States.

Background and objectives: The need for information on food composition that is up to date, accurate and reliable is critical to assess components of the diet aiming to promote health. The DietSys diet-data processing system allows using customized databases to calculate food components. We aimed to build a comprehensive food and nutrient database to be used in the DietSys system to assess dietary intake in epidemiological research in Brazil, Argentina, and the United States.

Methods: Three nutrient composition tables were unified: the Brazilian food composition table (TACO), the Argentinean food composition table (Argenfoods), and the U.S. Department of Agriculture, Agricultural Research Service (USDA) release 27. We created 21 food groups and used NOVA to classify food items into four food processing categories (FPC): unprocessed or minimally processed foods (UMP), processed culinary ingredients (PCI), processed foods (PF), and ultra-processed foods (UPF). For each FPC and food group, we calculated the number and proportion (%) of food items and the average density of energy (kcal/100 grams) and macronutrients (grams/100 grams).

Results: The DietSys database comprised 9386 food items: 6.1% from TACO, 4.7% from Argenfoods, and 89.2% from the USDA. Of food items classified as UMP, 53% were from Argenfoods and 23% from USDA. The USDA contained 78% of the UMP (N=1987), 83% of the PCI (N=318), 89% of the PF (N=2404), and 96% of the UPF (N=4203). Average density of energy, proteins, lipids, and carbohydrates from PCI was 23%, 4%, 26% and 42% lower in TACO and Argenfoods food items than the three tables' average. Some food groups included more than one FPC (e.g. in TACO, 16.0% of meats and derivatives were UMP, 34.6% were PF, and 3.7% were UPF; whereas in the USDA 39.9% of meats and derivatives were UMP, 50.4% were PF, and 1.1% were UPF).

Conclusions: This food and nutrient database will allow the DietSys user to calculate the intake of foods, food groups, FPCs, and nutrient content for Brazilian, Argentinean, and North-American populations, and to prioritize regional food items or to select alternative items. This dynamic database allows the addition of other foods and nutrients in the future.

SOMATOTIPO AND NUTRITIONAL STATUS OF SCHOOLCHILDREN OF ETNIA MAPUCHE OF THE COMMUNE OF PADRE LAS CASAS-CHILE

Rosas Muñoz, Marcelo Elías.

MSc. Nutritionist. School of Nutrition and Dietetics. Santo Tomás University. Temuco. Chile.

Background and objectives: The Mapuche ethnic group, originally from southern Chile, is suffering from a migration from rural to urban, adapting to changes in current society, developing behaviors and lifestyles typical of urban and industrialized areas where it predominates excess of malnutrition. The objective of this research is to establish the impact of these social changes on the somatotype and nutritional status of Mapuche youth.

Methods: A descriptive, cross-sectional and quantitative study of 127 Mapuches schoolchildren of both sexes with their parents' consent was carried out in three rural schools in the community of Padre Las Casas, Chile. 74 men (58.3%) and 53 women (41 , 7%), between 10 and 14 years of age. Measurements were taken of: weight, height, skin folds and bones diameters; following the ISAK protocol. BMI and nutritional status were determined according to the Chilean standard and somatotype (endomorphy, mesomorphy and ectomorphy) using the anthropometric method described by Heath & Carter. Student's t test and Mann Whitney U test were used to analyze the results (p <0.05).

Results: Men presented a mesoendomorphic somatotype (4.1 - 4.7 - 1.6). Women are endomesomorphic (5.0 - 4.2 - 1.3). Nutritional status showed that 37.8% of the men were obese and 16.2% were overweight. In the ladies, 34.6% were obese and 22.1% were overweight. When comparing by gender, significant differences were found in Endomorphism in favor of women (p = 0.01), but not in Mesomorphy and Ectomorphism, with no differences.

Conclusions: It is evident that in schoolchildren of the Mapuche ethnic group of both sexes a nutritional state of excess predominates. In relation to the somatotype, the women showed a higher relative adiposity than the men. The Obesigenic environment, which highlights the modification of lifestyle, food, and the effect of sedentarism is affecting the Mapuche population as well as the rest of the school population.

Keywords: Somatotype, Nutritional Status, Mapuches Schoolchildren.

EFFECT OF DIETS RICH IN SATURATED FATTY ACIDS ON THYMUS OF GROWING RATS

[1]*Perris, Paula;* [1]*Fernandez, Inés;* [2]*Godoy, Maria Fernanda;* [3]*Mambrin, Maria Cecilia;* [4]*Slobodianik, Nora H.;* [1]*Feliu, Maria Susana.*

[1]PhD. University de Buenos Aires. Faculty of Pharmacy and Biochemistry. Nutrition and Food Science.; [2]Biochemical. University de Buenos Aires. Faculty of Pharmacy and Biochemistry. Nutrition and Food Science.; [3]Technical assistant . University de Buenos Aires. Faculty of Pharmacy and Biochemistry. Nutrition and Food Science.; [4]PhD. University of Buenos Aires, School of Pharmacy & Biochemistry. Dept. Nutrition & Food Science. Argentina.

Background and objectives: The importance of diet in maintaining health is widely accepted and recognized. Dietary lipids play an important role in the regulation of the immune system. Thymus shows important functional changes in response to nutritional disorders.

The aim of this work is to analyze the effect of diets rich in saturated fatty acids in normal and high concentration on thymus' fatty acid profiles of growing rats.

Methods: Weanling Wistar rats were fed during 10 (10D) and 40 (40D) days with 15% and 42% (F%=Kcal lipids/100total Kcal) of dietary fat provided by butter (F15 y F42 groups). Control group received normocaloric diet (soy oil, F%=15) according to AIN´93. Thymus was removed. Thymus fatty acid profiles were determined by gas chromatography (GC). The statistical analysis used analysis of variance (ANOVA) and Dunnett´s post test (*p<0.01).

Results: Thymus fatty acid profile were (% area):

F15-40D=0,57±0,21; F42-40D=0,73±0,19;
CONTROL 40D=0,51±0,15.

Conclusions: All experimental groups showed decrease of linoleic and alfa linolenic acid.

The results observed on thymus lipid profile, demonstrate a decrease on the levels of essential fatty acids when a diet rich in saturated fatty acids is administered, independent of F%.

Thymus, characterized by a high rate of cellular turnover, is severely affected by nutritional imbalances and particularly by distortion in the proportion and type of fat.

Keywords: Thymus- essential fatty acids- diet- rat

EVALUATION OF RISK FACTORS THAT PREDISPOSE TO METABOLIC SYNDROME THE WORKERS OF THE SÃO CAMILO UNIVERSITY CENTER PARTICIPANTS OF THE PROJECT "HEALTH FOR ALL" - SÃO PAULO - BRAZIL

[1]Korukian Freiberg, Clara; [2]Basso, Renata; [3]Bom, Juliana; [3]Corcovado, Fabiana; [3]Silva, Bruna Carina; [3]Parise, Nicole; [3]Camargo, Lais.

[1]MSc. Nutricionist. Nutrition Department. São Camilo University Center. São Paulo. Brazil.; [2]MSc. Farmaceutic. Nutrition Department. São Camilo University Center. São Paulo. Brazil.; [3]Nutritionist. Nutrition Department. São Camilo University Center. São Paulo. Brazil.

Background and objectives: Inserted in the context of obesity and related co-morbidities, the metabolic syndrome (SM) is a complex disorder that encompasses cardiovascular risk factors associated with abdominal obesity and insulin resistance. The metabolic syndrome has become the most frequently diagnosed, proving to be a trend for the next few years. According to the who, about 25% of adult Americans fit the profile that characterizes the syndrome. It is estimated that between 20-25% of the world population report SM.

The main objective of this study was to to evaluate the risk factors that predispose to metabolic syndrome of São Camilo University Center workers, participants of the "HEALTH FOR ALL" project.

Methods: This study was carried out with 107 workers of both genders, aged between 18 to 60 years, with a predominance of younger adults that voluntarily were involved at the research. Were measured height and weight for the calculation of body mass index (BMI), waist circumference (CC), hip circumference and neck circumference as well as percentage of body fat and blood pressure. Others tests carried out: glycated hemoglobin, triglycerides, total cholesterol and his fractions. This work is part of the project presented by the ethics and Research Committee under paragraph 61/2014.

Results: It was found that 64.4% presented excessive weight, being 45.8% overweight, 21.5% with different degrees of obesity and only 31.8% had weight adequate. Of individuals diagnosed with metabolic syndrome (17.8% of the population), they all showed levels of diabetes diagnosed, glycated hemoglobin, abdominal obesity appears in both sexes, prevalent in these individuals with metabolic syndrome, and strongly associated with increase cardiovascular morbidity and mortality. In this same group, found himself high percentage of body fat, total and HDL quite diminished. 19.6% of the studied population showed hypertension. 53.2% of the population were sedentary.

Conclusions: This is a population with numerous risk factors for cardiovascular diseases. The results presented in the study, suggest the need for specific actions that intervene in factors that determine the triggering of the metabolic syndrome and that can contribute to the promotion of health.

AN ASSESSMENT OF THE QUALITY OF DHS ANTHROPOMETRIC DATA, 2005-2014

[1]Kothari, Monica; [2]Kothari, Monica; [3]Pullum, Tom.

[1]PATH; [2]MS, MPH. Deputy MQSUN+/M& E Lead. Washington DC. PATH. USA; [3]PhD. Director of Research. Demographic Health Surveys. Rockville. Maryland. USA.

Background and objectives: Providing reliable estimates of anthropometric indicators among children is important for monitoring global progress toward the World Health Assembly targets, and also for short and long-term nutrition and health interventions. The collection of anthropometric data has been a key component of the Demographic and Health Surveys (DHS) since 1986.

To date, DHS has collected height and weight data for more than three million children and adults in 238 surveys in 77 countries. It is important to assess the quality of the nationally representative data for future improvements.

Methods: This analysis examines the quality of anthropometric data from 52 DHSs conducted between 2005 and 2014. The analysis includes height, weight, and age measurements of children under five years of age as well as three nutritional status indices—height-for-age (HAZ), weight-for-age (WAZ), and weight-for-height (WHZ)—that follow WHO guidelines. The data quality indicators used to investigate the measurements include: standard deviation of z-scores; heaping of measures of height, weight, and age; and the percentage of extreme cases flagged during data processing. In addition, linear regressions of the z-scores were conducted to examine the amount of heterogeneity in z-scores that can be explained by covariates, including cluster-level variation. The analyses identified surveys that have outperformed others in terms of anthropometric data quality along with surveys that have been deficient in data quality.

Results: The countries vary substantially in the data quality indicators examined. Some countries perform poorly on several of the data quality indicators, Albania and Benin, while other countries such as Colombia, Honduras, and Peru were identified as having high quality data. Of particular concern is the higher variability in the SD for children at younger ages, which may be due to the difficulty of measuring very young children lying down in contrast to measuring older children standing up.

Conclusions: Based on the results, the quality of anthropometric data can be improved in nationally representative surveys by including rigorous training on measurement of younger children. It is important to identifying new types of equipments to accurately measure the height/length of children, including digital and lightweight measuring boards.

Keywords: Anthropometry, stunting, nutritional status, z-score, DHS, data quality.

DESIGN OF CLINICAL TRIALS IN ADULTS WITH METABOLIC SYNDROME. SYSTEMATIC REVIEW

[1]*Reig García-Galbis, Manuel;* [2]*Albert Pérez, Enrique;* [3]*Mateu Olivares, Victoria;* [4]*Martínez-Espinosa, Rosa María;* [5]*Molina Vila, Mariola D.*

[1]PhD. Department of Nutrition and Dietetics, Faculty of Health Sciences, University of Atacama.; [2]Department of Nutrition and Dietetics, Faculty of Health Sciences, University of Atacama (Chile).; [3]Department of Nursing, Faculty of Health Sciences, University of Alicante (España).; [4]PhD. Division of Biochemistry and Molecular Biology, Department of Agrochemistry and Biochemistry, Faculty of Sciences. University of Alicante (España).; [5]PhD. Department of Mathematics, Faculty of Sciences, University of Alicante (España).

Background and objectives: Background: Metabolic syndrome (MS) currently affects to more than 20% of the adult population.

Objective: evaluate the variation of the expressions of loss in the ME in ≥ 18 years, through dietary intervention and / or physical exercise.

Methods: Method: four databases, Pubmed, CINAHL, ProQuest and Web of Science were used. Selection criteria: ≥ 18 years; diagnosed with MS; weight loss intervention programs, which use diet and exercise as tools; Interest in loss should be manifested through parameters and units; clinical trials published between 2005 and 2015, in English and Spanish, in peer-reviewed scientific journals. The protocol of the PRISMA method was used to analyse the information.

Results: only 2% of clinical trials were selected (1805). The most frequent characteristics are: ATPIII and FID, as diagnostic criteria; number of patients ≤100; male sex; located in Europe, the United States and Oceania; duration of ≤6 months; waist circumference (cm), BMI (kg/m2), weight (kg and%) and multidisciplinary interventions showed the highest losses.

Conclusions: Discussion: the heterogeneity in the design of clinical trials makes difficult to identify the interventions with the highest losses in the parameter analysed and which techniques are the most advisable to achieve this goal.

Conclusion: there is a great diversity in the diagnoses of MS and disparity in the design of these clinical trials. Therefore, a series of recommendations are presented for the design of future clinical trials and, in addition, the most adequate techniques for loss with the Extrapolation of two clinical guidelines for overweight and obesity (ACE / AACE and European Guidelines).

Keywords: metabolic syndrome, weight loss, fat loss, diet, exercise and lifestyle.

VARIATION OF THE EXPRESSIONS OF LOSS IN THE METABOLIC SYNDROME, IN CHILDREN AND ADOLESCENTS: DIETARY INTERVENTION AND PHYSICAL EXERCISE

[1]Reig García-Galbis, Manuel; [2]Pérez Albert, Enrique; [3]Mateu Olivares, Victoria; [4]Martínez-Espinosa, Rosa María.

[1]PhD. Department of Nutrition and Dietetics, Faculty of Health Sciences, University of Atacama.; [2]Department of Nutrition and Dietetics, Faculty of Health Sciences, University of Atacama (Chile).; [3]Department of Nursing, Faculty of Health Sciences, University of Alicante (Spain).; [4]PhD. Division of Biochemistry and Molecular Biology, Department of Agrochemistry and Biochemistry, Faculty of Sciences. University of Alicante.

Background and objectives: Background: Metabolic syndrome (MS) affects ≥ 10% of the adolescent population worldwide.

Objective: evaluate the variation of the expressions of loss in the MS in ≤18 years, through dietary intervention and / or physical exercise.

Methods: Method: search date, between 2005 and 2015, in English and Spanish, in peer reviewed journals and following the PRISMA method. The selection criteria were: diagnostic for MS, overweight, obesity, type II diabetes, insulin resistance, hyperinsulinemia, hyperinsulinism, hyperglycemia, dyslipidemia, glucose intolerance and / or prediabetes; Randomized clinical trials, ≤18 years of age; Intervention programs that use diet and / or exercise as a tool, with or without metformin (interventions showing an interest in weight loss).

Results: only 1.3% of the clinical trials were selected (924) and the use of the diagnosis of MS was not observed. The most frequent characteristics of the clinical trial selected were: they were carried out in North America; the number of patients ranges from 25 to 120; female sex; duration of 6 months; weight loss (kg), BMI (kg/m2, percentile) and multidisciplinary intervention reported the highest losses.

Conclusions: the design of the clinical trials is heterogeneous and no trials diagnosed as MS have been found. A series of recommendations are presented for the design of future clinical trials; the most adequate techniques for loss with the extrapolation of two clinical guidelines for overweight and obesity (AND and ISCI) are indicated and it is recommended to investigate why the diagnosis of MS is not used.

Keywords: metabolic syndrome, children, teens, diet and exercise.

BETTER MICRONUTRIENT INTAKE COULD BE RELATED TO PHYSICAL FITNESS IN OLDER ADULTS?

[1]Aparicio Ugarriza, Raquel; [1]López Torres, Olga; [2]Maroto Sánchez, Beatriz; [3]Bibiloni, María del Mar; [4]Julibert, Alicia; [2]Palacios, Gonzalo; [3]Tur, Josep Antoni; [2]Gonzalez Gross, Maria Marcela.

[1]MSc. ImFINE Research Group. Department of Health and Human Performance. Universidad Politécnica de Madrid. Spain; [2]PhD. ImFINE Research Group. Department of Health and Human Performance. Universidad Politécnica de Madrid. Spain; [3]PhD. NUCOX Research Group. Fundamental Biology and Health Science. University of the Balearic Islands. Spain.; [4]MSc. NUCOX Research Group. Fundamental Biology and Health Science. University of the Balearic Islands. Spain.

Background and objectives: Diet and physical fitness (PF) have been described as major modifiable behaviours related to poor health. Indeed, diet and PF seem to be strong promoters of healthy ageing. Hence, the main aim of this study was to assess the association between micronutrient intake and PF in Spanish older adults.

Methods: 428 participants (43% males) aged over 55 years were recruited for the study. Dietary intake was assessed using two non-consecutive 24h dietary recalls. Energy intake (EI) and micronutrient intake were calculated through ALIMENTA software. Estimated average requirements (EAR) cut-off point method was applied to estimate the prevalence of nutrient intake adequacy/inadequacy. When EAR was not defined for a specific micronutrient, adequate intake (AI) was chosen. Energy expenditure (EE) was calculated using a validated physical activity questionnaire. Likewise, participants completed a battery of validated PF tests. The total score for each test ranged from 0 (worst) to 3 (best) points. The maximum score was 12 points. Scores of PF tests were added together and participants were divided into 3 groups (low, medium and high) using cluster statistical analyses. Data was analysed using generalized linear model.

Results: Inadequate intake for 11 and 8 micronutrients was observed in 9.8% and 11.4% of the subjects, respectively. More than 50% presented inadequate intakes for potassium, vitamin D, vitamin E, calcium, magnesium, vitamin B6, pantothenic acid and

folates. Only two participants were above EAR or AI for all micronutrients. Higher EI and EE was found in the high PF group compared to in the low PF group (all p<0.05). Subjects from the high PF group had significantly higher intakes for potassium, magnesium, phosphorus, calcium, selenium, zinc, vitamin B6, niacin, vitamin C and folates (p<0.05).

Conclusions: Subjects in the high PF group presented a better micronutrient intake profile than the others. Nevertheless, a considerable number of subjects presented micronutrient intake below the EAR. Therefore, there is a need to improve nutritional education and fitness among older adults and to consider supplementation for micronutrients at risk.

ASSESSMENT OF THE ADEQUACY OF DIETARY INTAKE OF WORKERS FROM AN EDUCATIONAL INSTITUTION LOCATED IN THE CENTRAL REGION OF SÃO PAULO CITY-BRAZIL

[1]*Freiberg, Clara;* [1]*Toscano Ferreira, Rosana;* [2]*Rodrigues, Natalia;* [2]*Monteiro, Taynara.*

[1]MSc. Nutricionist. Nutrition Department. São Camilo University Center. São Paulo. Brazil.; [2]Nutricionist. Nutrition Department. São Camilo University Center. São Paulo. Brazil.

Background and objectives: Food and Nutrition Units, here called UAN, aims to manage the production of meals consumed outside the home adequate nutritionally and hygienic-sanitary proper. The Workers' Food Program (PAT), in Brazil aims to improve the quality of life of workers through adequate food, promoting greater physical capacity, greater resistance to fatigue, greater resistance to disease and lower risk of work accidents.

The objective was to assess the adequacy of dietary intake and the nutritional adequacy in energy and nutrients through the intention of food consumption of the workers of a school according to the recommendations of PAT and FAO/WHO (2003).

Methods: This is a study, developed in UAN that meet the workers of an educational institution. It was rated the average consumption of 95 staff of this school, in four different dates. It had been assessed for each participant, the amount of food served during the meal and the size of the portion that had been offered. It was also calculated the nutritional needs of each one of them, considering sex, age, occupation and their suitability in accordance with the recommendations.

Results: According of the energy of the food offered, found an average of 633, 75Kcal (dp 278.88Kcal), and 23% of the population has consumed a caloric value of proper diet. Noted an inadequate consumption of protein, (high in 54% of the population) and high

fat consumption in 25% of them. Significant reduction in the consumption of carbohydrates (95% of the population consumes below the needs). Low consumption of food sources of calcium and iron and proper consumption of fiber. The Brazilian Food Guide recommends adhering to public nutrition programs that promote the principles of healthy nutrition.

Conclusions: There are lags in the intake of macro and micronutrients by workers, stressing the necessity of implementing nutrition education for employees, so that your choices may be consistent with their needs. The nutritionist job is to worry about disease prevention and health promotion through the choice of food. In addition, it is important to provide proper food in UAN, whereas, for many employees, the food received in the company represents the main meal of the day.

National Institute of Nutrition.

Background and objectives: Vitamin B6 is one of the important water soluble B-vitamins essential for hemoglobin formation and energy metabolism. The Recommended Dietary Allowance (RDA) of vitamin B6 for a health human is 2.0 mg per day. Vitamin B6 is widely available in almost all foods including meat and plant foods. However there is no record on the intake of dietary B6 data in Indian rural population. Therefore this study was aimed to determine the intake of vitamin B6 through diet among Indian rural population.

Methods: The recently released Indian Food Composition Tables (IFCT2017) which contains completely analysed vitamin B6 data from nation-wide sampling plan was used for the calculation. Twenty four hours dietary recall method was used to access the dietary intake in rural population of 9 states which covers 11910 households and 50293 populations. The dietary intake of vitamin B6 was calculated independently for different groups of age, sex and physiological status.

Results: Vitamin B6 content was highest in fish followed by meat and plant foods. Average intake (per Consumption Unit) of vitamin B6 was 1.17 mg per day. Consumption of dietary B6 varied from 0.47 to 1.45 mg per day among different age or sex or physiological status of population. Vitamin B6 intake among children were <1.0 mg while, it was >1.2 mg in both adult male and female. Among the different physiological groups, the pregnant and lactating women intakes were <50% of the RDA.

Conclusions: The IFCT2017 shows that fish is the richest source for dietary B6. The dietary intake results suggest that, intake of vitamin B6 significantly varies among all age and sex groups. The dietary intake of vitamin B6 in the rural Indian population appears to be not adequate to meet the RDA across all age groups.

Keywords: Vitamin B6; Dietary intake; Indian rural population;, RDA; 24 hours dietary survey.

ROLE OF A-TOCOPHEROL TRANSFER PROTEIN ON THE CELLULAR UPTAKE AND INTRACELLULAR LOCALIZATION OF A-TOCOPHEROL AND A-TOCOTRIENOL IN CULTURED LIVER CELLS

[1]Irías Mata, Andrea Paola; [2]Sus, Nadine; [3]Frank, Jan.

[1]MSc. Chemist. Division of Biofunctionality and Safety of Food. Institute of Biological Chemistry and Nutrition. University of Hohenheim. Germany.; [2]BTA. Chemist. Division of Biofunctionality and Safety of Food. Institute of Biological Chemistry and Nutrition. University of Hohenheim. Germany.; [3]PhD. Nutritionist. Division of Biofunctionality and Safety of Food. Institute of Biological Chemistry and Nutrition. University of Hohenheim. Germany.

Background and objectives: Since its discovery, vitamin E and its functions have been deeply studied. However, the mechanism underlying the intracellular localization and preferential retention of α-tocopherol (αT) in the body are still incompletely understood. The liver protein α-tocopherol transfer protein (α-TTP), located in the lysosomes is suggested to be involved in the preferential transport of αT in the liver. Despite the preferred affinity for αT, previous research shows a possible interaction of α-TTP with vitamin E metabolism that protects from metabolization other forms of vitamin E. The α-TTP role in the absorption and intracellular distribution of αT, but also the others forms need to be clarified. This research focuses on αT and it unsaturated isomer α-tocotrienol (αT3).

Methods: Time dependent absorption of αT and αT3 in HepG2, with and without αTTP expression, was investigated. Concentrations were measured inside and outside the cells by HPLC-FD over a time period of 72 hours. Maximum absorption times were selected for the intracellular distribution. This was ascertained using a density gradient centrifugation. Therefore HepG2 cells were separated into their cell compartments, identified by Western Blot, and αT and αT3 amounts were analyzed after 24 and 6 hours incubation with 50 μM of each compound.

Results: A continuous uptake of αT and αT3 in cells was determined, with no significant differences after 24 h. We observed a higher cellular uptake of αT3. αTTP did not reveal a significant enhance in the concentrations of each compound in cells. Intracellular distribution of αT and αT3 showed an accumulation in lysosomes, mitochondria and plasma membrane; being stronger in lysosomes at 6 h. No significant differences were detected for intracellular distribution between cells with and without αTTP expression.

Conclusions: Results suggest that αTTP is not essential for the uptake of the compounds in hepatocytes; its site of action is at a later step in the intracellular processing. The intracellular distribution might be because these organelles presumed to have higher levels of oxidative stress; or because is associated with the sites where αTTP is in the hepatocytes. However, with our results, an involvement of αTTP in specific transport inside cell compartments is still unclear.

Laboratory of Nutrition and Minerals. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Science, University of São Paulo.

Background and objectives: Obesity is associated with important metabolic disorders and enhances the comorbidity of related disorders such as type 2 diabetes, hypertension, and cardiovascular disease. Many micronutrients are involved in reducing the risk of such metabolic disorders. Thus, the aim of this study was to evaluate the intake of selected micronutrients and their relation to body composition and lipoprotein-lipid concentrations among obese women.

Methods: We enrolled 71 obese women recruited in the outpatient clinic of endocrinology from Clinics Hospital of São Paulo, Brazil. To evaluate the habitual consumption of micronutrients, diet assessment was accomplished by using a 3-day nonconsecutive dietary food record and entered into the NutriQuanti Online Computerized System (http://www.nutriquanti.com.br). The nutrients analyzed were calcium, iron, magnesium, zinc, copper,

manganese, potassium, and selenium. Fasting blood samples were collected for analysis of total cholesterol (TC), low-density lipoprotein cholesterol (LDL-c), high-density lipoprotein cholesterol (HDL-c) and triacylglycerol levels (TG). Pearson's correlations were calculated between micronutrients intake and body composition variables [body mass index (BMI) and waist circumference(WC)] and plasma lipoprotein-lipid variables (including the atherogenic indexes TG/HDL-c, TC/HDL-c and LDL-c/HDL-c ratios, which are powerful predictors of cardiovascular disease).

Results: The women aged 40.5±9.0 years and had a BMI of 35.56±5.88 kg/m² and WC of 100.20±9.27 cm. Some minerals were inversely correlated with body composition and atherogenic indexes. Magnesium intake was inversely correlated with BMI (r = −0.35, P = 0.003), WC (r = −0.44, P < 0.001), TC/HDL-c ratio (r = −0.26, P = 0.026), and LDL-c/HDL-c ratio (r = −0.29, P = 0.013). On the other hand, this intake was positively correlated with HDL-c (r = 0.27, P = 0.023). Copper (r = −0.25, P = 0.041) and manganese intake (r = −0.30, P = 0.013) were inversely correlated with WC. Sodium intake was positively correlated with TG levels (r = 0.26, P = 0.030) and TG/HDL-c ratio (r = 0.25, P = 0.037).

Conclusions: These results highlight the importance of healthy eating in body composition and risk of cardiovascular diseases among obese women.

ASSESSMENT OF CONSUMPTION AND CHALLENGE OF FOOD CLASSIFICATION IN GROUPS: EXPERTS' PANEL REPORT

[1]de Andrade Gomes, Adriana; [2]Santos, Débora Martins; [3]Barbosa Brito, Flávia.

[1]Nutritionist. PhD Student in Food, Nutrition and Health Program. Rio de Janeiro State University. Brazil.; [2]PhD. Nutritionist. Adjunct Professor of the Social Nutrition Department. Rio de Janeiro State University. Brazil.; [3]PhD. Statitician. Adjunct Professor of the Social Nutrition Department. Rio de Janeiro State University. Brazil.

Background and objectives: The panel of experts is a research technique employed in social sciences that is also used in investigations that include multi-method conceptions. The proposal is to bring together experts to produce suggestions for solving the doubts and gaps existing in a certain subject. One of the great challenges of assessing food consumption has been the structuring of harmonized food databases. How and where to allocate food in groups requires the structuring of defined parameters, especially when comparing the results within and between studies. The present study reports the use of this technique as a strategy to aid the decision regarding the allocation of food in groups, aiming the structuring of a harmonized food database.

Methods: Six specialists working in the area of clinical/outpatient nutrition and researchers/teachers in the nutrition area participated in the meeting. The guests were previously given a script, containing objectives, justifications and methodology addressing information on the conduction of the "experts' panel" and harmonization of food database. The classification of food in groups proposed by the researcher, based on household food availability data between 2008-2009 Brazilian Household Budget Survey, was sent to the experts for prior appraisal. During the meeting, the questions of harmonization were raised, followed by discussion.

Results: The panel contributed to the reorganization of food groups. The 1121 foods previously distributed in 15 groups and 33 subgroups, now consist in 14 groups and 42 subgroups. Culinary preparations and foods with a higher degree of industrialization, such as tapioca, fruit juice/soft drink, mate tea, couscous and sweetener, were some of the items that presented the greatest difficulty in being classified into groups.

Conclusions: The panel of experts proved to be an adequate tool to find consistent answers taking into account the experience of other professionals/researchers in the field of nutrition. The specialists' participation allowed the articulation of different visions and reduction of possible tendencies coming from the exclusive look of the researcher.

Keywords: Expert's panel. Nutrition. Food classification.

BRAZILIAN FOOD DATABASE HARMONIZATION: WHY FOOD GROUPING IS SO IMPORTANT?

[1]de Andrade Gomes, Adriana; [2]Santos, Débora Martins; [3]Barbosa Brito, Flávia.

[1]Nutritionist. PhD Student in Food, Nutrition and Health Program. Rio de Janeiro State University. Brazil.; [2]PhD. Nutritionist. Adjunct Professor of the Social Nutrition Department. Rio de Janeiro State University. Brazil.; [3]PhD. Statitician. Adjunct Professor of the Social Nutrition Department. Rio de Janeiro State University. Brazil.

Background and objectives: Recent Brazilian population based studies analyzing food intake reports different food grouping, as shown by bibliographic research. This issue may affect the characterization of nutritional profile and restrict comparison between studies, even when they report results from the same dataset. Furthermore, the food identification through its group is almost mandatory when the goal is to develop food based approaches. As discussed by European Food Safety Authority (EFSA), "food classification and description system allow to improve the ability to capture all the useful details of food groups in exposure assessments", a crucial requirement for the risk assessment process for public health nutrition intervention. Additionally, in Brazil, we need to consider our food diversity, which may introduce misunderstandings in the food identification and group allocation, especially when the intention is to compare studies within and between countries.

Methods: This study proposes a standardized and harmonized food classification system using data from the 2008-2009 Brazilian Household Budget Survey. The discussion was based on the Data Food Networking (DAFNE) procedures.

Results: Harmonization procedures were based on food characteristics (nutritional/botanical), criteria used in previous studies, international and national food classification system (Codex Alimentarius and Anvisa food) and expert panel consultation. Therefore, were built 14 main food groups and 42 subgroups.

Conclusions: The proposed harmonization system allowed food grouping in accordance to pre defined criteria. Our results suggests that the use of this system may improve between and within studies (at national and international levels) comparison.

GREATER HEIGHT GROWTH AND OVERWEIGHT IN PRESCHOOL CHILDREN

[1]*Forster Lopes, Amanda;* [2]*Mara Braga Rocha, Elida;* [3]*Bertoli, Ciro;* [3]*Leone, Claudio.*

[1]MSc. Nutritionist. Department of Maternal and Child Health. School of Public Health. University of São Paulo. Brazil.; [2]PhD. Nutritionist. Department of Nutrition. School of Public Health. University of São Paulo. Brazil.; [3]PhD. Pediatrician. Department of Maternal and Child Health. School of Public Health. University of São Paulo. Brazil.

Background and objectives: Not unlike the world population, which experiences an important process of nutritional transition, an important increase in the diagnosis of overweight and obesity in childhood has been observed since the 1990s. Monitoring the nutritional status of children may help identifying patterns that may lead to the development of excess weight, since investigations have considered that differences in growth and body composition during childhood are determinants of nutritional status, in childhood and/or later. The purpose of the study was to verify if there is a relation between the greater growth in height and the excess of weight in children in preschool age.

Methods: An analytical cohort study of a representative sample of preschool children in a city in the countryside of São Paulo - Brazil. Weight and height of the children were collected in two moments: 2014 and 2016. Based on the anthropometric data and the age, the children were evaluated according to the anthropometric indices calculated in z-score with Anthro software v.3.2.215: height for age, and Body Mass Index (BMI) for age. The data analysis was performed using the Stata statistical package, version 9.2. The study was approved by the IRB of the School of Public Health/University of São Paulo.

Results: The final sample consisted of 359 children, 52.9% female, who had a mean age of 2.4 years on the first evaluation, and 4.8 years on the second evaluation. There was a positive and significant correlation (Pearson r = 0.28, 95%CI: 0.18 to 0.37, p<0.001)

between the differences in BMI z-score and in height z-score. Confirming this result, it was observed that children with the highest BMI in 2016 were those that presented the greatest difference in height between the two evaluations (Pearson r = 0.24, 95%CI: 0.14 to 0.34, p<0.001).

Conclusions: The results observed show that there is a correlation between the greater growth in height between 2 and 5 incomplete years of age and the risk of developing overweight.

Keywords: Growth, Body Height, Obesity, Overweight, Preschool.

THE POTENTIAL OF FOODBOOK24 TO COLLECT NATIONALLY REPRESENTATIVE NUTRIENT INTAKE DATA

[1]*Timon, Claire;* [2]*Blain, Richard;* [3]*Pigat, Sadrine;* [4]*Bompola, Foteini;* [5]*Walton, Janette;* [6]*Flynn, Albert;* [7]*Gibney, Eileen.*

[1]Post doctoral researcher. Institute of Food and Health. UCD. Dublin. Ireland.; [2]Research assistant. Institute of Food and Health. UCD. Dublin. Ireland; [3]Head of Food and Nutrition. Creme Global. Dublin. Ireland; [4]Food Safety Scientist. Creme Global. Dublin. Ireland; [5]Research Fellow. School of Food and Nutritional Sciences. UCC. Cork. Ireland; [6]Professor. School of Food and Nutritional Sciences. UCC. Cork. Ireland; [7]Lecturer. Institute of Food and Health. UCD. Dublin. Ireland.

Background and objectives: National food consumption surveys are necessary to estimate dietary intakes of populations from specified regions for the purposes of: (i) evaluating compliance with dietary guidelines (ii) identification of deficiency or excess intakes of particular foods or nutrients and (iii) to investigate food safety risks such as contaminant exposures. However, there are many constraints to conducting large surveys including significant cost, time and participant burden. The aim of this study is to investigate the comparability of data collected from the Foodbook24 (a web based dietary assessment tool developed for the Irish adult population) Proof of Principle (PoP) study to the dietary intake data from most recent Irish national food consumption survey.

Methods: The Foodbook24 PoP study involved the web based, self-administered 24 hour recall tool being made freely available to the Irish adult population. The data collected as part of the PoP study was weighted to represent the population of participants that completed the National Adult and Nutrition Survey (NANS) (2008-2010). The comparison of weighted mean daily nutrient intake data collected from the Foodbook24 PoP study (n= 330 plausible reporters) and the mean daily nutrient intake data collected

from NANS (n=1051 plausible reporters) was conducted using the Wilcoxon-Mann–Whitney U-test in Creme Nutrition® software.

Results: Preliminary results highlight similar mean daily intakes for the majority of nutrients investigated. Percentage difference between mean daily intakes ranged from as little as 0.5% (potassium mg/day) to 35% (vitamin C mg/day). Despite weighting the PoP survey data, there were significant differences for some nutrient intakes however, for others e.g. energy (kcal/day), carbohydrate (g/day), iron (mg/day) and sodium (mg/day), there was no significant difference.

Conclusions: Foodbook24 (and similar validated web based dietary assessment methods) may offer a solution to the current constraints associated with the collection of data from large populations. Although further analysis is required, Foodbook24 has potential to assist in the collection of data in national nutrition surveys and also to facilitate the collection of rolling data intermittently between surveys.

Keywords: Foodbook24, web based, dietary assessment, consumption survey, comparison.

NUTRITION STATUS AND RISK FACTORS ASSOCIATED IN OF HOSPITALIZED CHILDREN AND ADOLESCENTS IN THE PEDIATRIC SERVICE AT HOSPITAL SÃO JOÃO PORTO

[1]Silva, Diana; [2]Silva, Sara; [3]Rola, Marta; [4]Camila, Cláudia; [5]Guerra, António.

[1]PhD. Nutritionist. Faculty of Nutrition and Food Sciences of the University of Porto. Nutrition and dietary unit and Integrated pediatric hospital of São João Hospital Center. Portugal; [2]Dr. Nutritionist. Integrated pediatric hospital of São João Hospital Center. Portugal; [3]MSc. Nutritionist. Nutrition and dietary unit and Integrated pediatric hospital of São João Hospital Center. Portugal; [4]PhD. Stastit. Biostatistics and Medical Informatics Service of Faculty of Medicine of Porto University. Porto; [5]PhD. Pediatrician. Nutrition unit of Integrated pediatric hospital of São João Hospital Center. Faculty of Medicine of Porto University. Porto.

Background and objectives: Identifying malnourished children/adolescents at hospital admission is important for their clinical evolution and growth. It is fundamental to research the risk associated.

The aim is to assess the nutritional status of an inpatient paediatric population at the Paediatric Service/Hospital São João (PSHSJ) and identify the risk factors responsible for their nutrition status impairment.

Methods: We included 813 patients, between the ages of 0-18 years old, who were admitted to the PSHSJ, from 2/19/2016 to 3/30/2017. The Anthropometrics Measure (AM) include weight and length/stature and it was calculated the weight/length index (W/L) for children ≤2 years old, body mass index (BMI) for >2 years old according World Health Organization (WHO), and the

respective z-score. Based on Fenton intrauterine growth curves, the newborn was classified as intrauterine growth restriction (IUGR), adequate for gestational age (AGA) or large for gestational age (LGA). The results are present in the total sample and per age groups: [0-2] years;]2-5] years;]5-10] years and >10 years. Statistic analyses were performed with SPSS® and the protocol was approved by Ethic Committee of Hospital São João.

Results: Of the 813 patients, 54,5% were males and 44,6% females on average 5,7±5,5 years. It was found 17,5% of undernutrition and 23,6% of overweight/obese on the admission. The higher frequency of undernutrition was verified in the first two years of life (25%) but in the other hand 34,8% of overweight/obese was found in school age (]5-10] years) with significant statistically difference between the groups (p=<0,001).

The multivariate analysis for children risk factors associated with child malnutrition we observed that a lower risk of undernutrition in the children/ adolescents was associated with age (]2-5] years: OR =0,320 (p=0,016);]5-10] years: OR=0,140 (p=0,002); >10 years: OR=0,005 (p=0,194)), in comparison with a younger group ([0-2] years) and birth weight (AGA: OR=0,285 (p=0,011)), in comparison with IUGR.

Conclusions: The results seem to indicate a very high prevalence of undernutrition, particularity in the first two years old and overweight/obese among the oldest.

This reinforces the importance of adequate nutritional assessment of the inpatient children/adolescents to prevent this deterioration during the hospitalization stay.

COMPARING THE EFFECTIVENESS AND COST-EFFECTIVENESS OF FACILITY- VERSUS COMMUNITY-BASED DISTRIBUTION OF MICRONUTRIENT POWDERS IN RURAL UGANDA

[1]Namaste, Sorrel; [2]Richardson, Belinda; [3]Ssebiryo, Francis; [4]Katuntu, David.; [5]Vosti, Stephen; [6]D'Agostino, Alexis.

[1]MHS. DrPH. Nutritionist. SPRING Project. Helen Keller International. USA.; [2]MSc. Economist. SPRING Project. John Snow Inc. USA;; [3]MSc. Monitoring and Evaluation. SPRING Project. John Snow Inc. Uganda; [4]MPH. MBA. Nutritonist. SPRING Project. John Snow Inc. Uganda; [5]PhD. Economist. Department of Agricultural and Resource Economics. University of California Davis. USA.; [6]MPP. Monitoring and Evaluation. SPRING. John Snow Inc. USA.

Background and objectives: Micronutrient powders (MNP) are one of the few available nutrition interventions shown to reduce anemia and iron deficiency. While efficacy is well established, regular and sustained use of MNP in program settings has faced challenges. To better understand MNP delivery channels, we compared the effectiveness and cost-effectiveness of facility versus community-based distribution.

Methods: We conducted the randomized intervention study in Namutumba, Uganda. The six sub-counties in Namutumba were randomly allocated to either a health facility (HF) or voluntary health team members [(VHT) (i.e. community health worker)] distribution arm. Individual packets containing 30 MNP sachets, a two-month supply, were available to caregivers from February to November 2016. Cost data were continuously collected, and included total direct and indirect costs to NGO implementers, delivery channel providers, and beneficiaries. A cross-sectional survey was conducted at the end of the intervention to obtain data on the following program outcomes: coverage (consumed MNP in the previous 24 hours), intake adherence (received more than 2 packets of MNP), and appropriate use (no more than one sachet per day, MNP consumed with food, and minimum of 3 sachets consumed in the previous week). Unweighted and unadjusted data were analyzed based on intention to treat using chi-square tests.

Results: Data for analysis were available on 1060 children 8-23 months. Nearly all caregivers had heard of MNP (100% VHT versus 98% HF, p<0.006) and most caregivers had received MNP at least once (98% VHT versus 84% HF, p<0.001). Coverage (54% vs 33%, p<0.001), intake adherence (59% vs 15%, p<0.002), and appropriate use (39% vs 19 %, p<0.001) were higher in the VHT compared to the HF arm. Preliminary data on the incremental cost-effectiveness ratio (taking into account costs, program outcomes, and delivery channel) indicate the VHT arm was more cost-effective.

Conclusions: A community-based MNP delivery channel was more effective and more cost-effective at producing desired program outcomes compared to facility-based distribution. However, the difficulty in maintaining high levels of the desired program outcomes in both the facility and community-based delivery channels, as is often the case with other behavioral change interventions, may compromise sustainability.

ANEMIA, LOW CONSUMPTION OF IRON-CONTAINING FOODS AND ENHANCER OF IRON ABSORPTION IN PRESCHOOL CHILDREN OF THE EASTERN PROVINCES OF CUBA, 2016

[1]Basabe Tuero, Beatriz; [2]Pita-Rodríguez, Gisela María; [3]Puentes Márquez, Ileana; [4]Arocha Oriol, Caridad; [4]Herrera-Javier, Dania.

[1]Phd.Department of Bioquemistry and physiology.National Institute of hygiene, epidemiology and Microbiology.; [2]Msc. Doctor in medicine; [3]Msc; [4]Th.

Background and objectives: Anemia is the main nutritional health problem in preschool children in Cuba in spite of the multiples fortified food and supplemental intervention. Iron deficiency is the principal cause of anemia; other causes are invoked such as deficiency of other micronutrients, infection and inflammation. Eastern provinces remain as the most vulnerable region of the country.

To evaluate the prevalence of anemia in preschool children in two provinces of eastern region of Cuba and the relation to food intake.

Methods: Children of 6 to 59 months living in provinces of Santiago de Cuba (Mella, La Maya and Santiago de Cuba municipalities) and Holguín (Frank País, Sagua de Tánamo, Antilla and Holguín municipalities). Hemoglobin (Hb) was measure by hematological cell counter ABX Micros 60 and anemia was defined as hemoglobin <110g/L in children. Food frequency questionnaire one month previous was used. The foods were classified as meat (red meat, poultry, fish and viscera), vegetables (lettuce, tomato, spinach, chard, carrot, okra, parsley and watercress), fruits (orange, tangerine, grape fruit, guava, papaya, mango, tamarind, banana, watermelon) and legumes (beans, pea, lentils, chickpea. Frequency intake was consider: "Frequently" (over 3 times a week or more), "Few Frequently" (intake below 3 times a week) and Never in this period.

Results: 450 children were included in the study. Anemia was found in 22.7% the children. The percentage of children who consume meat, eggs, vegetables and legumes Frequently were low (53,5%, 47,5%, 40,3% and 30,3% respectively). Fruits were consumed Frequently in the 68.8% of the children. Poultry and Tomato were the most food intake in the respective group (36.7% and 38,1%). Anemia was significantly associated with Low Frequently intake of fruit (OR=2.26 95%CI=1.41-3.62), vegetables (OR=2.24 95%CI=1.35-3.71), legumes (OR=1.85 95%CI=1.09-3.13) and eggs (OR=1.68 95%CI=1.05-2.68).

Conclusions: Anemia is a moderate health problem in eastern provinces of Cuba. Low intake of meat, vegetables, eggs and legumes were found. The Low Frequently intake of food enhancer of iron absorption is the principal factor associated to anemia in children studied.

DIETARY IRON BIOAVAILABILITY: AGREEMENT BETWEEN ESTIMATION METHODS AND ITS ASSOCIATION WITH SERUM FERRITIN CONCENTRATIONS OF WOMEN AT CHILDBEARING AGE

[1]De Carli, Eduardo; [2]Dias, Gisele Cristina; [3]Morimoto, Juliana Massami; [4]Colli, Celia.

[1]PhD. Nutritionist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Sciences. University of São Paulo. Brazil.; [2]BSc. Nutritionist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Sciences. University of São Paulo. Brazil.; [3]PhD. Nutritionist. Center for Biological and Health Sciences. Mackenzie Presbyterian University. Brazil.; [4]PhD. Pharmacist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Sciences. University of São Paulo. Brazil.

Background and objectives: Over the past 40 years, many iron bioavailability models have been developed aiming to re-

late diet and iron status. However, their precision and accuracy are questionable and studies that validate their practical use are scarce. Here, we estimated dietary iron bioavailability of women at childbearing age using a probabilistic approach and meal-based or complete diet-based algorithms. Also, we tested associations of these estimates to each other and to body iron stores, according to serum ferritin concentrations.

Methods: Diet was assessed by three non-consecutive computerized food records from 127 university students (18-42 years old) at apparently steady-state body iron. In a probabilistic model, simulated distributions of iron absorption values from individual diets (1-40%) were contrasted with distributions of iron physiological requirements among users and non-users of hormonal contraceptives, separately. An average iron bioavailability was assumed as that absorption of dietary iron matching with the prevalence of women whose iron requirements were not attended at the moment of evaluation (ferritin < 15 μg/L). Moreover, estimates of five different algorithms (two of them based on complete diets) were determined. The association between measurements and serum ferritin was tested by linear regression.

Results: Iron intake and inadequacy were 10,9 mg/d and 12,6%, respectively. Although correlated (P < 0.001), all algorithm estimates differed from unity. In particular, bioavailabilities from meal-based (11.6-12.8%) or complete diet-based algorithms (8.5-8.9%) differed (P < 0.001). Meanwhile, all these estimates diverged from that calculated by probabilistic approach (17.2%). No significant association was found between serum ferritin and bioavailabilities measured with Monsen et al. (1978), Reddy et al. (2000) or Armah et al. (2013) algorithms. Nevertheless, after adjusting for non-dietary variables, differences from 30 to 37% in means of serum ferritin were found between women classified according to the median or the extremes tertiles of bioavailable iron measured with Hallberg & Hulthén (2000) and Collings et al. (2013) algorithms.

Conclusions: Measures of dietary iron bioavailability disagree when estimated with algorithms or probabilistic model. The association between serum ferritin and estimates of two algorithms suggests good performance in ranking diets and/or meals according to bioavailable iron contents.

Keywords: Iron status; algorithm; probabilistic approach

TRACING DIETARY PATTERNS IN BANGLADESH FROM 1985 TO 2010

[1]*Waid, Jillian;* [2]*Gabrysch, Sabine;* [3]*Sinharoy, Sheela.*

[1]M.S.W., Director - Research, Learning, and Evaluation, Helen Keller International, Bangladesh Country Office, Bangladesh; [2]PD Dr. med., MSc, PhD, Head, Unit of Epidemiology and Biostatistics, Institute of Public Health University of Heidelberg, Germany; [3]MPH, PhD Candidate, Laney Graduate School, Nutrition and Health Sciences Program, Emory University, USA.

Background and objectives: Factor analysis methods using individual dietary data are frequently employed to describe dietary patterns. However, there is a scarcity of data on individual diets while household consumption expenditure surveys (HCES) are available in many countries. So far, factor analysis methods have not been applied to household dietary data. We aim to use this data source to assess changes in diets over time.

Methods: We analyzed data from seven rounds of the Bangladesh Household [Income and] Expenditure Surveys (H[I]ES) from 1985 to 2010, and derived dietary patterns from 52,380 households using principal component analysis. We used logistic regression to assess associations between dietary patterns, survey years, and socioeconomic characteristics of households.

Results: Six dietary patterns were identified which explained 26% of the variance in dietary intake: Modern (6%); traditional fish (5%); traditional vegetables/fruits (4%); milk, snacks, and sweets (4%); and two starchy monotonous diets – one with potatoes and one with taro (3% each). All diets were present in all survey years, though a quarter of households were not associated with any identified dietary pattern. The proportion of households following the "traditional fish" and "milk, snacks, and sweets" dietary patterns declined between 1985 and 2010, while other patterns increased. All dietary patterns, except the starchy monotonous diet with taro, were associated with higher household per capita expenditure. Four diets were associated with rural locality: traditional vegetables/fruits (OR 1.4, p<0.01); milk, snacks, and sweets (OR 1.8, p<0.01); and the two starchy monotonous diets (OR 2.6, p<0.01; OR 4.0, p<0.01). Households with children had greater odds of consuming modern (OR 1.5, p<0.01); traditional vegetables/fruits (OR 1.1, p<0.01); and milk, snacks, and sweets (OR 1.8, p<0.01) diets. Two diets were associated with Hindu households: milk, snacks, and sweets (OR 1.5, p<0.01) and the starchy monotonous diet with taro (OR 1.3, p<0.01).

Conclusions: Dietary patterns can be identified from household consumption data and are similar to those obtained from individual data in number and amount of variance explained. In Bangladesh, dietary patterns have changed gradually over time, but change has been limited among the poorest.

CHARACTERIZATION OF THE NUTRITIONAL STATUS, SUGAR AND TOTAL FAT CONSUMPTION AMONG PRESCHOOL AGE PANAMANIAN CHILDREN

[1]Montero, Ivania; [2]Farro, Katherine; [3]Rios, Israel; [4]De Caballero, Eira.

[1]Nutritionist.Nutrition and Dietetic Department.Medicine School.University of Panama.Panama City. Panama; [2]Nutritionist.Nutrition and Dietetic Department.Medicine School.University of Panama.Panama City.Panama; [3]MSc. Nutritionist. Nutrition and Dietetic Department. Medicine School. University of Panama. Panama City. Panama; [4]MPH. Nutritionist.Nutrition and Dietetic Department. Medicine School. University of Panama. Panama City.Panama.

Background and objectives: The increased prevalence of infant obesity is a current public health concern in Panama. The present study aimed to determine the nutritional status, sugar and total fat consumption among preschool-age children in institutional kinder gardens in Panama.

Methods: A cross-sectional study with 100 preschool-age children in three institutional kinder gardens at Panama District (Pedregal, San Francisco and Parque Lefevre). Data was collected from January-March 2016. A semi-quantitative food frequency questioner was used to estimate sugar and total fat consumption and was sought from the Institute of Nutrition for Central America and Panama Food Composition Table. Anthropometric (weight and height) were using to calculate HAZ and BAZ according with WHO2008 growth standards.

Results: Mean age and standard deviation (SD) was 49.6±14.0 months (45%) female. The forty percent was classified as overweight, 62.5% reported a high and very high consumption of sugar. Sugar consumption geometrical mean and ±1SD was found higher in overweight 531 (293.2-961.2) g/week than in non-overweight 237 (132.1-426.2) g (ttest, p<0.05).

Conclusions: High prevalence of overweight was observed. The sugar and total fat consumption was very high taking into consideration the WHO recommendations. Nutrition policy should be put in place in order to regulate the consumption of ultra-processed and sugar drinks among preschool age children. Nutrition education could be used to promote healthy eating habit among overall school community (parents, teachers, principal and community).

Keywords: Infant Obesity, Nutrition, Dietary intake, Malnutrition.

KNOWLEDGE AND PRACTICES OF PROTEIN SUPPLEMENTS CONSUMPTION AMONG PEOPLE WHO ATTEND GYMS IN PANAMA

[1]De La Cruz, Danaé; [1]Cargill, Ariel; [2]Rios-Castillo, Israel.

[1]Nutritionists, Nutrition and Dietetic Department, Medicine School, University of Panama, Panama City, Panama; [2]MSc, Nutritionist, Nutrition and Dietetic Department, Medicine School, University of Panama, Panama City, Panama.

Background and objectives: The aim of this study was to describe the knowledge and practices of consumption of protein supplements in people who exercise in gyms in Panama City and the relationship between the protein supplementation and the knowledge that individuals have about it.

Methods: It was a cross-sectional descriptive study. A total of 163 subjects who exercise in five gyms of Panama City were part of this study. A survey of 24 questions was applied divided in three categories: demographic information, knowledge of protein and information on the protein consumption. The univariable statistical analysis was performed by means of the Chi2 test.

Results: Forty nine percent of the participants were using protein supplements. Of those who consumed protein 41.3% had adequate knowledge and 58.8% had inadequate knowledge. The main reason for the consumption of protein supplements was to increase muscle mass (36%). The most commonly used protein supplement was whey protein and the person who encouraged the consumption of these supplements was the trainer. No significant relationship was found in relating the knowledge of the participants regarding the previous knowledge of side effects at the p = 0.078. In assessing whether participants continue to use protein supplements despite knowing the risks associated with excessive intake, 60% said no, while 40% would continue use. The intake of protein supplements has become a common practice among people attending the gym.

Conclusions: The results show that the use and consumption pattern of protein supplements among those who attend gyms in Panama City, were found to be similar to those who exercise at gym around the world. It is needed more scientific evidence to know if they are actually working and not attributing the achievement to a placebo effect or some other external factor. As future research discovers additional problems with excessive supplementation, it will be important to educate people about the known risks and how they can obtain the right amount of protein through food and avoid consuming supplements.

Keywords: protein supplements, gym, knowledge, consumption of supplements, physical activity.

DIETARY INTAKE OF TRANS FATTY ACIDS IN PARAGUAYAN UNIVERSITY STUDENTS. PRELIMINAR STUDY

[1]Araujo Pino, Silvia Stella; [2]Mereles Ceuppens, Laura Graciela; [2]Coronel Mendez, Eva Eugenia; [2]Wiszovaty, Lourdes; [2]Caballero, Silvia; [2]Piris, Patricia; [2]Michajluk, Javier Boris; [3]Gonzalez Cespedes, Laura Elizabeth; [3]Aguilar Rabito, Ana Carolina; [3]Morínigo Martínez, Macarena.

[1]Nutritionist. Department of Nutrition Research. Faculty of Chemical Sciences. National University of Asuncion. Paraguay; [2]Departamento de Bioquímica de Alimentos. Dirección de investigaciones. Facultad de Ciencias Químicas. Universidad Nacional de Asunción. Paraguay; [3]Departamento de Nutrición. Dirección de investigaciones. Facultad de Ciencias Químicas. Universidad Nacional de Asunción. Paraguay.

Background and objectives: The trans fatty acids (TFA) intake is related to the development of noncommunicable diseases (NCD). The consumption of foods with high fat content is popular in university students; however, consumption of trans fatty acids is not yet established in this population. The aim of the work was to estimate the intake of TFA in a selected sample of university students from Facultad de Ciencias Químicas (FCQ) of the Universidad Nacional de Asunción in 2017.

Methods: A qualitative and quantitative Food Consumption Frequency (FCF) survey was applied in university students (n=63), designed according to the availability of food in the country and the portions established in the Paraguayan Food Guidelines. In order to determine the AGT contribution by foods, 38 foods were analyzed by infrared spectrometry to determine the TFA content (AOAC. method), and we used tables of composition of TFA from references in foods (Griguol et al., 2007; Robledo de Dios et al., 2015; Moreno et al., 2014).

Results: The age average was 21.7±2.6 years, 88.9% were women. TFA intake mean was 7.43g/d (IC95%: 6.99-9.76), the 85.7% of the population studied exceeded the recommended limit of TFA intake (n=54). Considering a diet of 2000 kcal/d, the TFA intake caloric mean was 3.34% (IC95%: 3.15-4.39%). The TFA intake´s mean in women was 7.28g/d (IC95%: 6.86-9.76 g/d) and 7.43g/d for men (IC95%: 3.02-14.81) (p>0.05).

Conclusions: Foods that contribute the highest TFA intake was the typical foods, as Paraguayan soup, "chipa guazú", "milanesa" y " marinera". The TFA intake in the population studied exceeds the 1% of total energy per day, according to WHO recommendations.

Keywords: Trans fatty acids, intake, Food Consumption Frequency, university students.

VALIDITY OF TWO BIOELECTRICAL IMPEDANCE ANALYSIS EQUATIONS IN THE ESTIMATION OF FAT AND FAT-FREE MASS IN CLASSICAL BALLET DANCERS

[1]Leal, Leilane; [2]Avelino, Erikarla; [2]Barbosa, Giovanna; [2]Ferreira, Rannapaula; [3]Nunes, Adriana; [4]Vale, Sancha; [5]Leal Lima Maciel, Bruna.

[1]MSc Student. Postgraduate Nutrition Program, Nutrition Department. Federal University of Rio Grande do Norte. Brazil; [2]Undergraduate Student. Nutrition Department. Federal University of Rio Grande do Norte. Brazil; [3]PhD. Clinical Medicine Department. University Onofre Lopes Hospital. Federal University of Rio Grande do Norte. Brazil.; [4]PhD. Nutrition Department. Federal University of Rio Grande do Norte. Brazil.; [5]PhD. Postgraduate Nutrition Program. Federal University of Rio Grande do Norte. Brazil.

Background and objectives: Body composition is part of the nutritional status and is recognized as a key factor determining athletic performance. Although bioelectrical impedance analysis (BIA) is considered an accessible and cheap method to partially measure body composition, few studies have addressed its validity for classical ballet dancers. This study aimed to test the validity of two BIA equations for fat (FM) and fat-free mass (FFM) estimation against dual-energy X-ray absorptiometry (DXA) in classical ballet dancers.

Methods: Thirteen female classical ballet dancers were evaluated. BIA was assessed using a RJL® tetrapolar device. FM and FFM were calculated using the manufacturer's and NHANES III equations. DXA was performed using DPXL/GE Lunar®, including pediatric and forearm software. One sample T test was used to evaluate mean differences between BIA and DXA estimates. Linear regression was used to observe how much BIA formulas predicted DXA. Bland-Altman analysis was performed when BIA estimates showed agreement in the previous tests.

Results: One sample T test showed that FM and FFM calculated by the NHANES III BIA formula had good agreement with DXA (p > 0.05). The manufacturer's BIA formula had good agreement with DXA only for FM (p > 0.05). Linear regression analysis was done for BIA measures with agreement to DXA. Correlations was found only in FM for both BIA equations (r2 = 0.4600, p = 0.0446 for the manufacturer's and r2 = 0.4539, p = 0.0466 for NHANES III). Bland-Altman test revealed that the manufacturer's equation underestimated FM by -2.20 ± 4.15%, whereas the NHANES III equation overestimated FM by 1.84 ± 3.95%.

Conclusions: Neither one of the two tested BIA equations was efficient in predicting FFM. Nevertheless, both equations presented good agreement with DXA for FM estimation. We conclude that BIA may be a feasible method to asses FM in ballet dancers when these equations are used.

Keywords: body composition, absorptiometry.

URINARY SODIUM AND POTASSIUM EXCRETION IN ADULT POPULATION FROM QUITO

[1]López, Pablo; [2]Muñoz, Fabián.

[1]MD. MSc. Professor. Human Nutrition Undergraduate Program. Pontifical Catholic University of Ecuador (PUCE).; [2]Estadístico. VISOR Statistical Analysis. Quito.Ecuador.

Background and objectives: High sodium intake and potassium reduction in the diet are associated with the increase of blood pressure. Identifying sodium and potassium intake is important in order to estimate the risk of high blood pressure

Methods: Through a sectional study of 117 cases, 43.6% males (n = 51) and 56.4% (n = 66) females, aged between 25-64 years, we analyzed 24-hour urine samples using the automated Ion-selective electrodes (ISE) to measure urinary sodium and potassium levels. The participants, Quito residents, did not report diagnosis of hypertensive disease, heart disease, nephropathy or change in their eating habits three months before the study.

Results: The average consumption of sodium estimated by 24-hour urinary excretion is 169.2 mEq/L, being higher in males (187.8 mEq/L) than in females (154.7 mEq/L). Moreover, the indicated values far exceed the safety recommendations for normotensive populations (90 to 130 mEq/L). The average of salt intake reached was 9.7 g / day, higher in men than in women (10.8 g/d and 8.9 g/d, respectively). Moreover, 94.1% of the men exceed the safe levels of their consumption (<6 g/d), in the case of women reached 72.7%. On the other hand, potassium consumption reached 44.4 mEq/L, below the recommended minimum of the ion (50 mEq/L). Overall, we noticed a significant imbalance of the sodium: potassium relation that is 3.8: 1, well above of the tolerable optimal ratio (1.4: 1).

Conclusions: The adults from the study show high sodium intake and low potassium that would result in adverse effects to maintain blood pressure levels and increased risk of cardiovascular disease.

Keywords: sodium, potassium, intake dietary

ENERGY AND MACRONUTRIENTS DIETARY INTAKE IN FEMALE SEMI-PROFESSIONAL CLASSICAL BALLET DANCERS

[1]Barbosa, Giovanna; [1]Ferreira, Rannapaula; [1]Avelino, Erikarla; [2]Leal, Leilane; [3]Nunes, Adriana; [4]Vale, Sancha; [5]Leal Lima Maciel, Bruna.

[1]Nutrition Student. Nutrition Department. Federal University of Rio Grande do Norte. Brazil; [2]MSc Student. Postgraduate Nutrition Program, Nutrition Department. Federal University of Rio Grande do Norte. Brazil; [3]PhD. Clinical Medicine Department. University Onofre Lopes Hospital. Federal University of Rio Grande do Norte. Brazil.; [4]PhD. Nutrition Department. Federal University of Rio Grande do Norte. Brazil.; [5]PhD. Postgraduate Nutrition Program. Federal University of Rio Grande do Norte. Brazil.

Background and objectives: Classical female ballet dancers are dependent in aesthetic and weight for performance, which may increase the risk for energy intake imbalance. Nevertheless, little is known about eating behaviors of trained classical ballet dancers. This study aimed to investigate energy and macronutrient intake of semi-professional female classical ballet dancers.

Methods: Twelve female classical ballet dancers were evaluated for energy and macronutrients intake, comparing the results with sedentary women, matched by age (total mean age 26.05 ± 9.94 years). Three 24 h recall were done for each participant. Energy intake and requirements were estimated using the Institute of Medicine recommendations. Differences between dietary intakes and daily requirements were performed for data analysis. Shapiro-Wilk normality test was performed and results are shown as median – interquartile range. Wilcoxon test was used to compare differences in energy and macronutrients intake vs requirements in the same group. Mann-Whitney test was used to compare the two studied groups.

Results: Classical ballet dancers showed a high energetic imbalance when compared to sedentary controls (-857.71 – 1027.57 Kcal vs -126.61 – 891.56 Kcal, p = 0.034). Carbohydrate energy contribution in dietary intake was lower in classical ballet dancers when compared to sedentary controls (52.13 – 7.18% vs 56.03 – 8.12%, p = 0.047). Lipid and protein energy contribution in dietary intake were not different between groups, with medians of 29.01 – 9.55% and 17.40 – 6.41%, respectively. Nevertheless, classical ballet dancers consumed significantly more protein per body weight when compared to sedentary controls (1.64 – 1.24 g.Kg-1 vs 1.31 – 0.51 1.24 g.Kg-1, p = 0.025). Fiber intake was lower than recommended in both groups, and classical ballet dancers intake was -8.39 – 7.36 g less than recommended (p = 0.005).

Conclusions: We conclude that the evaluated semi-professional ballet dancers energy intake is significantly less than recommended and that macronutrient balance can be improved. Thus, energy and macronutrients intake are important aspects for further investigation and analysis in this group.

DEVELOPMENT AND EVALUATION OF A RE-DUCED PROTOCOL FOR THE DEUTERIUM OXIDE DOSE-TO-MOTHER TECHNIQUE TO ASSESS EX-CLUSIVE BREASTFEEDING PRACTICES

[1]Houghton, Lisa; [2]Liu, Zheng; [3]Preston, Thomas; [4]Slater, Christine; [5]Diana, Aly; [6]Gibson, Rosalind; [7]Duffull, Stephen.

[1]Department of Human Nutrition. University of Otago. New Zealand; [2]PhD. Pharmacometric modeller. School of Pharmacy. University of Otago. New Zealand.; [3]PhD. Professor. Scottish Universities Environmental Research Centre. University of Glasgow. United Kingdom.; [4]PhD. Nutritionist. Independent. United Kingdom.; [5]MD, MSc, PhD candidate. Department of Human Nutrition. University of Otago. New Zealand; [6]PhD. Emeritus Professor. Department of Human Nutrition. University of Otago. New Zealand.; [7]PhD. Professor. Department of Human Nutrition. University of Otago. New Zealand.

Background and objectives: Exclusive breastfeeding (EBF) practices can be assessed by quantifying infant water intake from sources other than human milk using a stable isotope deuterium oxide dose-to-the-mother (DTM) technique. While the DTM technique is non-invasive and relatively simple to perform, seven days of post-dose saliva sample collections from mother and infant over a 14-day study period makes it unsuitable for routine use in a public health setting. The purpose of this study was to determine if the DTM protocol could be reduced to a more practical design, which correctly classifies EBF practices with acceptable accuracy.

Methods: An existing DTM dataset collected using a stand-ardised protocol from 9 countries was available and consisted of 790 mother-infant pairs. For the purpose of development and evaluation of a reduced protocol, the data were randomly split into i) model building (565 pairs) and ii) evaluation (225 pairs). The model building dataset was considered the gold standard to assess the reduced protocol. For each potential reduced design, a previ-ously established model was fitted to the data, using a fully Bayes-ian framework, and mother-infant pairs were assigned to EBF or non-EBF categories based a non-milk water intake cut-off. The op-erating characteristics of the reduced protocol were assessed using sensitivity and specificity.

Results: One-day post-dose sample designs from days 3-9 were considered, however model fitting was unsuccessful in all cases. All combinations of two-day post-dose designs resulted in successful assignment of infants to a breastfeeding category and could be evaluated. The best EBF practice allocation characteris-tics were demonstrated (i.e., >95% sensitivity and specificity) for a single sample at any time between each of days 7-9 and days 13-14. Evaluation of this design provided acceptable agreement. In addi-tion, a number of two-day post-dose designs over a shorter period (days 5-9) were also considered satisfactory with >90% sensitivity and specificity.

Conclusions: A less time and resource intensive DTM two-day post-dose sampling design was found to be capable of separat-ing EBF from non-EBF practices in infants and was comparable to

the full sampling protocol. The design included sampling window periods to allow flexibility for field use.

ASSESSMENT OF NUTRIENT QUALITY OF SE-LECTED ASIAN DISHES USING THE HEALTHY RECIPE FRAMEWORK CRITERIA

[1]Sacdalan-Africa, Leila Sacdalan-Africa; [2]Ramos-Buenviaje, Rhoda Joy; [3]Principe, Meyrick.

[1]Associate Professor. Institute of Human Nutrition and Food. College of Human Ecology. University of the Philippines Los Baños; [2]Nutrition and Health Manager. Unilever. Philippines; [3]Nutrition Executive. Unilever. Philippines.

Background and objectives: The Healthy Recipe Frame-work (HRF) contains nutrition criteria to assess the nutrition quality of a dish, meal or food item as encouraging, good-for-you; or healthy-for-you. The criteria are based on international gener-ally accepted dietary recommendations as recommended by the Joint FAO/WHO/UNU Expert Consultation on Diet, Nutrition and Prevention of Chronic Disease. This study was conducted to assess the nutrient quality of selected 75 popular dishes from Chi-na, India, Indonesia, Philippines, Malaysia, Singapore, Thailand, and Vietnam using the HRF criteria.

Methods: The nutrient content analysis of each recipe was done using the recipe calculator specially developed by Unilever in Microsoft Excel for the HRF analysis. The recipe calculator compute the energy, nutrients and the following: percentage of the amount of recommended ingredient; total amount of vegetable per serving; percentage of energy content from protein, carbohy-drates, sugar, fats, saturated, and trans fatty acid; amount of fibre per 100 kcal energy content; amount of sodium per 100g of reci-pe; and amount of sodium per energy content. Most importantly it indicates if the recipe satisfies the encouraging; good-for-you; and healthy-for-you criteria and identify the component(s) why the recipe did not pass. The nutrient database was mostly from the United States Department of Agriculture Food Composition Table.

Results: Results showed that more than half(67%) of the rec-ipes are encouraging; but only 12 recipes(16%) and one(1%) dish were considered as good-for-you and healthy-for-you recipes, re-spectively. The common reason why 33% of the recipes did not pass any criteria was the use of meat with fat (48%) and refined

carbohydrate sources(36%). Almost three quarter(74%) of the encouraging recipes did not qualify to be good-for-you recipes primarily because of higher amount of sodium(76%) and saturated fats(25%) in the dishes. Only one recipe was considered healthy because the others have unmet requirements for vegetable(91%), carbohydrates(83%) and fibre(75%), among others.

Conclusions: Most of the Asian recipes analysed in this study conformed with the encouraging but only few(<15%) satisfied the good-for-you criteria. The HRF framework is useful for healthy recipe development and for improving recipes and meals to be healthier.

Keywords: Healthy recipe framework criteria, nutrition quality of recipe, nutrient content analysis, recipe calculator

SENSITIVITY OF THE DEVELOPMENT OF FOOD-BASED RECOMMENDATIONS USING LINEAR PROGRAMMING TO MODEL PARAMETER AND CONSTRAINT DECISIONS

[1]Borgonjen-van den Berg, Karin; [2]de Vries, Jan; [2]Kujinga, Prosper; [2]Brouwer, Ingeborg.

[1]Research Dietician. Division of Human Nutrition. Wageningen University. The Netherlands.; [2]PhD. Nutritionist. Division of Human Nutrition. Wageningen University. The Netherlands.

Background and objectives: Optifood is a tool to develop food-based recommendations (FBR) and identify problem nutrients by linear programming. Model parameters and constraints are derived from local dietary intake data and determine to a large extent the outcomes of the programming. However, the sensitivity of outcomes to decisions on dietary intake data to be used, is largely unknown.

Methods: Based on repeated 24-h recalls of 62 Kenyan children (4-6) Optifood was used to develop food-based recommendations and identify problem nutrients for scenarios using model parameters and constraints defined by one or two recalls and reported or estimated weekly frequencies of foods consumed. For all scenarios foods consumed by >3% of the children were selected and median daily servings were calculated. Minimum and maximum weekly frequencies for (sub)foodgroups and foods were defined as resp. 5th and 95th percentile of the intake distribution.

Results: Using two repeated recalls and reported weekly frequencies 37 non-condiment foods were selected for linear programming analyses. Draft FBR consisted of 21 daily servings of grains, 4 servings of legumes/nuts, 28 servings of vegetables, 7 servings of fruits, and 8, 7 and 7 servings of dairy, fish/eggs and added fats per week, respectively. Folate, vitamin A and zinc were identified as problem nutrients. Using estimated frequencies resulted in an increase of foods included in analyses (59) and increased minimum and maximum weekly frequencies of most (sub)foodgroups. This resulted in the addition of 3 servings of

starchy roots to the draft FBR and disappearance of folate as problem nutrient. Including only first recalls resulted in 7 additional foods selected and increased or reduced daily servings depending on the food compared to repeated recalls. This resulted only in a modest increase of maximum weekly frequencies. The same problem nutrients were identified.

Conclusions: The decision to use reported frequencies instead estimated frequencies influenced the draft FBR and problem nutrients to a larger extent than the decision to use one or two recalls. To improve feasibility of FBR it is recommended to include the recall of frequencies in the dietary assessment method.

Keywords: sensitivity, linear programming, 24-h recalls, frequencies, food-based recommendations

FAT MASS INDEX VERSUS BODY MASS INDEX TO ASSESS OBESITY IN MEXICAN CHILDREN

[1]Barrios, Pamela L.; [2]Rivera, Juan; [3]Garcia-Feregrino, Raquel; [4]Barraza-Villarreal, Albino; [5]Romieu, Isabelle; [6]Gonzalez-Casanova, Ines; [6]Stein, Aryeh.; [6]Ramakrishnan, Usha; [7]Hoffman, Daniel J.

[1]MSc. Department of Nutritional Sciences, New Jersey Institute for Food, Nutrition, and Health, Rutgers University. United States.; [2]PhD. Health and Nutrition Research Center. National Institute of Public Health. Mexico.; [3]MSc. Health and Nutrition Research Center. National Institute of Public Health. Mexico.; [4]PhD. Population Health Research Center. National Institute of Public Health. Mexico.; [5]MD. Population Health Research Center. National Institute of Public Health. Mexico.; [6]PhD. Hubert Department of Global Health, Rollins School of Public Health, Emory University. United States.; [7]PhD. Department of Nutritional Sciences, New Jersey Institute for Food, Nutrition, and Health, Rutgers University. United States.

Background and objectives: Body mass index (BMI, weight (kg)/height (m)2) is frequently used to classify a child as overweight or obese, but it cannot distinguish fat mass (FM) and lean body mass. The fat mass index (FMI, FM (kg)/height (m)2) can be derived using bioelectrical impedance. The aim of this study was to determine differences in estimation of childhood obesity using BMI Z-score or FMI in children.

Methods: Children had participated in the POSGRAD (Prenatal Omega-3 fatty acid Supplements, GRowth, And Development) study. At age 8-10 years, height and weight were measured according to standard protocols and body composition was assessed using a tetrapolar bioelectrical impedance analyzer (Impedimed DF50) with validated equations for Mexican children. FM calculated was then used for FMI final calculation, (FM (kg)/height (m)2). BMIZ was calculated using WHO reference and obesity was defined as BMIZ > 2 SD or FMI ≥ 6.6 kg/m2 in boys and ≥ 9.5 kg/m2 in girls, values previously used in literature.

Results: We included 281 boys and 255 girls. Mean body weight, percent body fat, BMIZ, and FMI were 32kg, 28.5%, 0.71,

and 5.3 and 31kg, 31.5%, 0.60, and 5.8, for boys and girls respectively. Using BMIZ, approximately 25% of boys and 16% of girls were classified as obese compared to 5% and 31%, respectively, using the FMI.

Conclusions: The use of BMIZ resulted in a higher estimate of obesity among boys and a lower estimate of obesity among girls compared to the FMI. These results are important as population studies and program evaluations using BMIZ may generate inaccurate estimates of childhood obesity. An important policy change could be to promote the use of relatively inexpensive body composition methods to improve estimates childhood obesity by using FMI instead of BMIZ.

Chile.; [7]MD. MSc. Universidad de la República. Uruguay.; [8]MD. MSc. ScD. Department of Global Health and Population. Department of Epidemiology. Harvard T.H.Chan School of Public Health. United States of America; [9]BS. MD. MPH. PhD. Tufts University Friedman School of Nutrition Science and Policy. United States of America.

Background and objectives: Mate, a beverage made from the leaves of Ilex paraguariensis, is widely consumed in South America. High intakes of mate, and the habit of adding sugar may affect diet by replacing meals and increasing total sugar intake. We assessed whether mate consumption is associated with diet quality and quantity among adults aged 35-74 years in four South American cities in Argentina (Bariloche and Marcos Paz), Chile (Temuco) and Uruguay (Canelones).

Methods: Cross-sectional analysis on data from baseline of CESCAS (Centro de Excelencia en Salud Cardiovascular del Cono Sur) I, a population-based prospective cohort study. We included participants with available socio-demographic and dietary data (n=5458). Diet was assessed using a validated 126-item food-frequency questionnaire. Diet quality was evaluated with the Alternate Healthy Eating Index (AHEI-2010), the Dietary Approaches to Stop Hypertension (DASH) and the Alternate Mediterranean Diet (AMeD) Scores, with higher scores indicating greater adherence to these patterns. Multivariable linear regression models were used to examine the associations of quartiles (Q) of mate consumption with energy-adjusted food and nutrient intakes and diet quality scores (converted to a 0-100 scale) adjusting for age, gender, education, and city. Subgroup analysis was conducted (participants that added sugar/ those that didn't.)

Results: 57% of participants drank mate daily; those who drank mate had an average intake of 1.3 liters per day and 34% of them added sugar to at least half of their mate beverage servings. Mate consumption was associated with more bread intake($p<0.001$). Among participants who didn't add sugar, diet quality and consumption of other foods were independent of mate consumption. However, participants in Q4 with the habit of adding sugar reported higher intakes of sweet and sugars, energy and carbohydrates, and lower intakes of dairy products, fiber, vitamins C, retinol, calcium, zinc and iron compared to participants in Q1($p<0.001$). In addition, in the same subgroup, differences between Q4vs.Q1 in diet quality scores were: AHEI-2010:-3.73 (95%CI -4.95;-2.50); DASH:-3.75(-5.81;-1.81) and AMeD:-8.77(-6.00;-11.56).

Conclusions: Higher consumption of mate was significantly associated with higher consumption of bread. When the habit of adding sugar was present, food and nutrient intakes as well as adherence to healthy diet patterns were negatively affected.

SODIUM AND IODINE URINARY EXCRETION AND YOUR RELATION WITH BLOOD PRESSURE LEVELS AND NUTRITIONAL STATUS ON SCHOOLCHILDREN IN RIO DE JANEIRO

[1]Rodrigues, Lúcia; [2]Aguiar, Cynthia; [1]Teodoro, Anderson; [3]Rodrigues, Maria de Lourdes.

[1]PhD University Teacher of Nutrition at Federal University of Rio de Janeiro State, Brazil; [2]Nutritionist graduated at Federal University of Rio de Janeiro State, Brazil; [3]MsD University Teacher of Nutrition at Federal University of Rio de Janeiro State, Brazil.

Background and objectives: Excess consumption of iodine and sodium has been studied due to high consumption of ultraprocessed and processed foods and its relation with the development of diseases in early stages of life. The objective of this study was to describe the urinary excretion of sodium and iodine in schoolchildren related to pressure levels and anthropometric profile.

Methods: It was a cross-sectional study realized with schoolchildren aged 6–16y at Rio de Janeiro city. Anthropometric data, blood pressure levels, familial historic of arterial hypertension and spot urine samples was collected. The urine samples were analyzed by Flame Photometry to obtain sodium concentration and by Spectrophotometry by the Sandell-Kolthoff method for iodine. Descriptive (mean, SD, median, maximum and minimum) and inferential (Mann Whitney for mean comparison and Pearson and Spearman correlation) statistics were realized. The significance level was 0.05.

Results: The sample consisted in 109, which 52,4% were man and 78% adolescents. Overweight and obesity was present in 35,4%. There was 9.2% of changes in BP and 23.6% had parents with AH. The sons of hypertensive parents had an average of SBP higher than those whose parents weren´t hypertensive (P=0.012). The daily sodium intake was 2448.4±2186.8mg/day and 41.9% had ingestion above the UL. The daily salt intake was 6.2±5.6g/day and 48.4% was classified with higher intake. The iodine intake was 381.5±185,9μg/day, being classified as insufficient (3.2%), more than adequate (17.2%) and excessive (65.6%). The sodium intake prevalence ≥1500mg/day was about 55,9% and the iodine intake ≥200μg/day was about 82,8%.

Conclusions: Sodium and iodine intake weren't different by sex, anthropometric status and blood pressure classification. Schoolchildren which parents had hypertension showed sodium mean intake upper than that which parents hadn't. The sample showed excessive sodium intake like salt and iodine. This fact is a risk factor to chronic noncommunicable diseases, like AH, kidney, heart and thyroid diseases. Studies like that may increase the use of this measure as an indicator of the level of these minerals and can give directions to intervention strategies, in the field of health and education.

Keywords: Iodine – Sodium – Urine – Schoolchildren

ANTHROPOMETRIC CHARACTERISTICS, DIET QUALITY AND DIFFERENCE IN FOOD INTAKE BETWEEN WOMEN WITH AND WITHOUT POLYCYSTIC OVARY SYNDROME

[1]Bernardes da Cunha, Nayara; [2]Mendes Silva, Catarina; [3]Toffoli Ribeiro, Camila; [4]Japur de Sá Rosa e Silva, Ana Carolina; [5]Abadia De-Souza, Daurea.

[1]Nutritionist. Postgraduation Program in Health Sciences. School of Medicine. Federal University of Uberlandia. Uberlandia/MG. Brazil.; [2]Nutritionist. Postgraduation Program in Health Sciences. School of Medicine. Federal University of Uberlandia. Uberlandia. Brazil.; [3]MSc. Doctor. Department of gynecology and obstetrics. School of Medicine. Federal University of Uberlandia. Uberlandia. Brazil; [4]PhD. Doctor. Department of gynecology and obstetrics. School of Medicine. University of Sao Paulo. Ribeirao Preto. Brazil.; [5]PhD. Doctor. School of Medicine. Federal University of Uberlandia. Uberlandia. Brazil.

Background and objectives: Scientific evidence indicates overweight/obesity in women with polycystic ovary syndrome (PCOS). Excess weight aggravates the syndrome through metabolic disorders. It is likely that one of the contributing factors to overweight in women with PCOS is inadequate food intake. The objective of this study was to evaluate the food intake and the nutritional status of patients with and without PCOS treated at School Hospital, Federal University of Uberlandia.

Methods: A case-control study was conducted with 67 women (34 cases). For anthropometric evaluation, the measurement of weight and height, used to calculate body mass index (BMI), and waist circumference (WC) were made. Both values obtained were evaluated by the classification of the World Health Organization. To evaluate body composition, especially to quantify lean mass and body fat, electric bioimpedance was performed. To evaluate the quality of food intake, a 24-hour food recall was made. Subsequently, the data was used to obtain the score using the Brazilian Healthy Eating Index (BHEI).

Results: There was no significant difference between the mean of the age (25.24±0.68 vs. 25.12±0.71; p=0.899), WC (88.0 vs. 79.0; p=0.158), BMI (25.8 vs. 22.9; p=0.221), percent lean tissue mass (68.4 vs. 70.5; p=0.175) and body fat (31.6 vs. 28.7; p=0.078) of the PCOS group and healthy women, respectively. In dietary analysis, the consumption of total energy (1425 vs. 1666; p=0.075), carbohydrate (627.3 vs. 735.4; p=0.137), protein (269.9 vs. 313.2; p=0.055), fat (407.6 vs. 554.6; p=0.208), cholesterol (150.7 vs. 188.2; p=0.060) and saturated fat (10.6 vs. 9.3; p=0.981) were similar between the groups. However, the PCOS group had lower consumption of fiber compared to the control group (8.8 vs. 11.6, respectively; p=0.018). Regarding the BHEI, in the PCOS group 72% (n=24) showed "needs improvement", 24% (n=8) showed "inadequate diet" and only one participant showed "good diet" while in the control group 76% (n=26) showed "needs improvement" and 24% (n=8) showed "inadequate diet".

Conclusions: Both groups showed no significant difference in anthropometric evaluation and dietary pattern. However, women with PCOS presented lower consumption of fiber compared to women without the syndrome. Therefore, women with and without PCOS need to improve eating habits to avoid overweight/obesity.

A LATERAL FLOW IMMUNOASSAY FOR QUANTIFICATION OF ALPHA-1-ACID GLYCOPROTEIN AS A DIAGNOSTIC TOOL FOR RAPID, MOBILE-BASED DETERMINATION OF INFLAMMATION

[1]Gannon, Bryan Gannon; [2]Erickson, David; [3]Mehta, Saur.

[1]PhD. Institute for Nutritional Sciences, Global Health, and Technology (INSiGHT). Division of Nutritional Sciences. Cornell University. USA.; [2]PhD. Institute for Nutritional Sciences, Global Health, and Technology (INSiGHT). Sibley School of Mechanical and Aerospace Engineering. Cornell University. USA.; [3]MBBS ScD. Institute for Nutritional Sciences, Global Health, and Technology (INSiGHT). Division of Nutritional Sciences. Cornell University. USA.

Background and objectives: Alpha-1-acid glycoprotein (AGP) is an acute phase protein, and its measurement is recommended for adjustment of nutritional biomarkers for inflammation by the Biomarkers Reflecting Inflammation and Nutritional Determinants of Anemia (BRINDA) working group. Traditional AGP quantification is not widely available in resource limited settings and uses assays that require sample processing and shipment, laboratory and personnel resources, and hours to days to complete a test. We sought to develop an inexpensive, mobile-based, and rapid diagnostic test to quantify AGP.

Methods: We developed a lateral flow immunoassay (LFIA) designed to work in conjunction with the Cornell NutriPhone platform. In the LFIA, gold nanoparticles are conjugated to anti-AGP antibodies and generate a variable colorimetric signal based on the concentration of AGP in the sample. This can be quantified by the processing of an image captured by a mobile camera. We evaluated whether the LFIA could discriminate a range of concentrations of purified AGP in buffer and subsequently evaluated the assay's ability to quantify AGP and discriminate elevated concentrations (i.e. > 1 mg/mL) in diluted human serum (n=7) and serum spiked with purified AGP (to increase by 2 mg/mL, n=7) relative to an automated immunoturbidimetric assay.

Results: The first stage of the LFIA was able to distinguish purified AGP with a quantification range of 0.25 – 2.5 μg/mL (R^2=0.89). Mean ± SD unspiked serum AGP concentration by immunoturbidimetric assay was 0.36 ± 0.05 mg/mL (range 0.28 – 0.42 mg/mL). The LFIA results were significantly correlated with the immunoturbidimetric assay for all samples (y=0.76x + 0.37,

R^2=0.84). Initial sensitivity and specificity were compliant with World Health Organization specifications for a point of care diagnostic test.

Conclusions: The AGP LFIA demonstrated reasonable accuracy when compared to a commercial immunoturbidimetric assay and is inexpensive, portable, and can provide results within 15 minutes. This assay can be integrated into the NutriPhone platform to obtain multiple biomarkers of nutrition and inflammation in diverse and resource limited settings. Further development will focus on evaluating human serum with a wider range of endogenous AGP concentrations and ensuring the LFIA can distinguish elevated AGP concentrations closer to the suggested cutoff.

Keywords: AGP, biomarker, lateral flow assay, point-of-care

Conflict of Interest Disclosure: DE and SM have equity interest in a diagnostic start up focused on measurement of nutritional biomarkers at the point-of-care utilizing the results from their research.

VITAMIN B12 INTAKE AND STATUS IN EARLY PREGNANCY IN WOMEN IN SOUTHERN INDIA

[1]Guetterman, Heather; [2]Kurpad, Anura; [2]Dwarkanath, Pratibha; [3]Bose, Beena; [2]Thomas, Tinku; [4]Finkelstein, Julia.

[1]BSc. Division of Nutritional Sciences. Cornell University. Ithaca NY. United States.; [2]PhD. St. John's Research Institute. Bangalore. India.; [3]MSc. St. John's Research Institute. Bangalore. India.; [4]PhD. Division of Nutritional Sciences. Cornell University. Ithaca NY. United States. St. John's Research Institute. Bangalore. India.

Background and objectives: Vitamin B12 deficiency is common during pregnancy and is associated with adverse maternal and child health outcomes. The objective of this study was to examine dietary correlates of vitamin B12 status in a cohort study of pregnant women during the first trimester in Southern India.

Methods: Pregnant women (n=419) were enrolled before 12 weeks of gestation and monitored to assess dietary intake and vitamin B12 status during pregnancy. A validated food frequency questionnaire (FFQ) was used to evaluate dietary intake during the past three months. Plasma vitamin B12 concentrations were assessed via electrochemiluminescence in maternal samples at enrollment. Linear and binomial regression models were used to evaluate the associations between dietary intake of nutrients and food groups with vitamin B12 concentrations and deficiency (<150 pmol/L) during the first trimester.

Results: Median dietary intake of vitamin B12 was 1.73 g (IQR: 1.10-2.45) per day, and median maternal vitamin B12 concentrations were 126.9 (IQR: 89.6, 172.2) pmol/L at baseline. A total of 64% of women were vitamin B12 deficient (<150 pmol/L) at their first prenatal visit. Increased consumption of refined grains, fish, red meat, egg-based foods, organ meat, and total meat; and vitamin B12, methionine, iodine, cholesterol, saturated fat, and polyunsaturated fatty acids were associated with increased vitamin B12 concentrations (p<0.05). In analyses of vitamin B12 deficien-

cy, animal-source foods, including fish, egg-based foods, and organ meat were associated with lower risk of vitamin B12 deficiency (p<0.05). In nutrient analyses, increased intake of vitamin B12 (RR: 0.87, 95% CI: 0.80-0.93, p=0.0001), methionine (RR: 0.73, 95% CI: 0.54-0.98, p<0.05), selenium (RR: 0.99, 95% CI: 0.99-0.99, p<0.05), cholesterol (RR: 0.99, 95% CI: 0.99-0.99, p<0.001), and saturated, monosaturated, and omega-3 (linolenic acid, eicoasapentanoic acid, docosahexanoic acid) and omega-6 (docosapentanoic acid, arachidonic acid) polyunsaturated fatty acids (p<0.05) were associated with lower risk of vitamin B12 deficiency.

Conclusions: The prevalence of vitamin B12 deficiency was high early in pregnancy in this population. Inadequate dietary intake of animal-based foods and low consumption of vitamin B12, methionine, cholesterol, saturated fat, and polyunsaturated fatty acids predicted increased risk of vitamin B12 deficiency.

PERCENT BODY FAT PREDICTION USING BODY MASS, STATURE AND ABDOMINAL CIRCUMFERENCE IN ADULTS SEEN IN THE FAMILY DOCTOR PRIMARY CARE PROGRAM UNITS IN NITERÓI, RIO DE JANEIRO, BRASIL

[1]*Wahrlich, Vivian;* [2]*Anjos, Luiz Antonio;* [3]*Contino, Mariana;* [3]*Oliveira, Mariana;* [4]*Vasconcellos, Mauricio.*

[1]PhD. Laboratório de Avaliação Nutricional e Funcional. Universidade Federal Fluminense. Niterói. Rio de Janeiro. Brasil.; [2]PhD. MD. Laboratório de Avaliação Nutricional e Funcional. Universidade Federal Fluminense. Niterói. Rio de Janeiro. Brasil.; [3]BSc. Laboratório de Avaliação Nutricional e Funcional. Universidade Federal Fluminense. Niterói. Rio de Janeiro. Brasil.; [4]PhD. Escola Nacional de Ciências Estatísticas. IBGE. Rio de Janeiro. Brasil.

Background and objectives: Body mass (M), stature (S) and abdominal circumference (AC) are routinely measured in adults seen in Primary Health Care Units. Indicators are developed from these measures and used in nutritional and risk assessment for diseases. They could also be used to estimate percent body fat (%BF) if validated prediction equations (PE) are available for the specific population. To this end, the purpose of the present study was to validate a series of %BF in adults (≥45y) seen in the Family Doctor Primary Care Program (FD) units in Niterói, Rio de Janeiro, Brasil.

Methods: The tested %BF PE were developed in a probability sample of adults (≥20y) from Niterói and included BM, S and AC (R2 between 0.83 and 0.88). A sample of 518 subjects (329 women) seen in the FD units in Niterói participated in the study. BM, S and AC measures were obtained by trained researchers in the FD units. BMI (BM/S2) was used to assess the nutritional status. The subjects were invited to come to the research laboratory where %BF was obtained by DXA. The significance of the difference (bias) between predicted (%BFp) and measured (%BFm) %BF was determined by paired t-Student tests. The % bias [(%BFp -%BFm/%BFm)*100] was calculated. In addition, multiple regression models to predict %BF against the anthropometric measures were conducted with the data from the 518 subjects.

Results: Age of the 518 subjects varied from 45-92y (mean±SD, 59.6±9.7y). Mean %BFm was 41.8 (±5.7) and 28.3 (±6.8) for women and men, respectively. Overweight (25≥BMI<30kg/m²) was observed in 38.9% of the women and 39.8% were obese (BMI ≥30kg/m²). In men, these prevalences were 43.9 and 19.6%, respectively. Non-significant %BF biases were observed in 45-60y-old men (-0.5±5.4 representing -0.6±23.0%); 60-70y-old women (0.5±3.3 representing 1.5±8.3%); and ≥70y-old women (0.2±3.7 representing 1.3±10.1%). The developed %BF PE was [31.453-(350.294*1/BMI)-(12.558*Sex(Male=1;Female=0))+(0.242*AC)]; R2=0.82 and SEE=3.75.

Conclusions: The population specific %BF PE was not adequate for all segments of patients seen in the FD units. The developed PE includes BM, S and AC and might be an useful instrument to estimate the %BF using routine anthropometric measures obtained in adults seen in FD units.

Keywords: Nutrition Assessment, Anthropometry, Body Composition, Public Health

VALIDITY OF SKINFOLD PREDICTIVE EQUATIONS TO DETERMINE BODY COMPOSITION IN ADULTS FROM PRIMARY HEALTH CARE UNITS IN NITERÓI, RIO DE JANEIRO, BRASIL

[1]*Wahrlich, Vivian;* [2]*Anjos, Luiz Antonio;* [3]*Contino, Mariana;* [3]*Oliveira, Mariana.*

[1]PhD. Laboratório de Avaliação Nutricional e Funcional. Universidade Federal Fluminense. Niterói. Rio de Janeiro. Brasil.; [2]PhD. MD. Laboratório de Avaliação Nutricional e Funcional. Universidade Federal Fluminense. Niterói. Rio de Janeiro. Brasil.; [3]BSc. Laboratório de Avaliação Nutricional e Funcional. Universidade Federal Fluminense. Niterói. Rio de Janeiro. Brasil.

Background and objectives: Body composition (BC) information is important for nutritional assessment but its widespread use depends on accurate and feasible methods. The aim of the present study was to assess the validity of skinfold predictive equations to determine BC in adults (≥ 50 years) seen in Primary Health Care Units or enrolled in physical activity programs.

Methods: Two-hundred-eight-six adults (203 women) were recruited. Body mass, stature and skinfolds (triceps, TS; biceps, BS; and subscapular, SS) were measured. Nutritional status was determined by body mass index (BMI). Percent body fat (%BF) density was estimated using the prediction equations developed by Durnin & Womersley (DW_equations) for adults aged 50 to 72 years using one skinfold (TS or BS or SS) or a combination of skinfolds (TS+BS or TS+BS+SS). Fat mass (FM) and fat free mass (FFM) were calculated from the estimated %BF and the obtained

by DXA. Paired Student t-tests were used to determine the significance of the means.

Results: Mean (SD) measured %BF, FM and FFM was 41.4 (5.7) %, 27.7 (8.2) kg and 38.0 (5.6) kg for women and, 28.9 (7.2) %, 22.2 (9.6) kg e 52.0 (7.0) kg, for men, respectively. %BF and FM mean values were significantly underestimated by all equations in women (bias between 38 and 39.5% for %BF and 39.4 to 40.4 kg for FM), while FFM was overestimated. However, mean skinfold-estimated values of %BF, FM and FFM using BS or SS or BS+SS were not different from DXA in women aged 50 to 60 years or for those with BMI < 25 kg/m². The same occurred in women with BMI between 25-30 kg/m² for BC estimated using only SS. For all men, %BF, FM and FFM mean estimated values using TS, BS or TS+BS combination were not different from DXA. The same pattern was observed for the 50-70y age men and the ones with BMI < 25 or between 25-30 kg/m².

Conclusions: DW_equations can be used to estimate BC in groups of men and women depending on age and nutritional status but it is recommended that new equations be developed for this population.

DEVELOPMENT OF A NON-MILK WATER INTAKE CUTOFF TO IDENTIFY EXCLUSIVE BREASTFED INFANTS USING THE DEUTERIUM OXIDE DOSE-TO-MOTHER TECHNIQUE

[1]Diana, Aly; [2]Liu, Zheng; [3]Luftimas, Dimas; [4]Rahmannia, Sofa; [5]Preston, Thomas; [6]Slater, Christine; [7]Duffull, Stephen; [8]Gibson, Rosalind; [9]Houghton, Lisa.

[1]MD, MSc, PhD candidate. Department of Human Nutrition. University of Otago. New Zealand; [2]PhD. Pharmacometric modeller. School of Pharmacy. University of Otago. New Zealand.; [3]MD. Lecturer. Faculty of Medicine. Universitas Padjadjaran. Indonesia; [4]MD. MSc student. Faculty of Medicine. Universitas Padjadjaran. Indonesia; [5]PhD. Professor. Scottish Universities Environmental Research Centre. University of Glasgow. United Kingdom.; [6]PhD. Nutritionist. Independent Consultant. United Kingdom.; [7]PhD. Professor. Department of Human Nutrition. University of Otago. New Zealand.; [8]PhD. Emeritus Professor. Department of Human Nutrition. University of Otago. New Zealand; [9]PhD. Associate Professor. Department of Human Nutrition. University of Otago. New Zealand.

Background and objectives: Assessing the rates of exclusive breastfeeding (EBF) until age six months is an important public health priority; however, feeding practices are based mostly on caregiver recall and often affected by self-reporting bias. The deuterium oxide dose-to-the-mother (DTM) technique can be used to distinguish EBF based on a cut-off (<25 g/d) of water intake from sources other than human milk. This value reflects the error (25±62 g/d) associated with the assumptions made in the calculation but has yet to be verified in mother-infant pairs known to be truly EBF. Thus, the aim of the present study was to estimate the apparent volume of non-milk water intake measured by deuterium dilution for infants known to be EBF.

Methods: Healthy, apparently EBF infants (n=121) aged 2.5-5.5 months were recruited from Sumedang, West Java, Indonesia. After administration of deuterium to the mothers, saliva was sampled from mother and infant pairs over a 14-d period. Validation of infant feeding practices was conducted via home observation over six non-consecutive days with recall of foods or liquids consumed by the infant during the respective previous 24 hours. A fully Bayesian approach was used to estimate the marginal posterior distribution of the population non-milk water intake over all mother-infant pairs.

Results: Of the 121 infants enrolled, 113 were reported as EBF during the study period, consisting of 1502 observations. Eight infants were administered medicines yet remained in the final sample as per the WHO EBF definition. Seven infants were identified as non-EBF: 3 swallowed bath water, 4 consumed other foods and/or liquids; and one infant was excluded due to physiologically implausible values. Using the 90th percentile of the distribution of the population non-milk water intake distribution, we estimated a cut-off value of 82.6 g/d, with a lower limit 95% CI of approximately 54 g/d.

Conclusions: The current study is the first to estimate the distribution region of deuterium exposure in mother-infant pairs using a known EBF infant cohort, with the classification of EBF defined as the proportion of the posterior distribution of non-milk water intake <82.6 g/d. This cut-off is substantially higher than previously recommended (<25 g/d).

PREVIOUS STEP TO ANALYZE 24-H DIETARY RE-CALLS: STANDARDIZATION OF THE FOOD COMPOSITION DATABASE FOR THE "GROWTH AND OBESITY COHORT STUDY"

[1]*Martínez Arroyo, Angela;* [2]*Palma Molina, Ximena;* [2]*Ceballos, Ximena;* [3]*Pereira Scalabrino, Ana;* [3]*Reyes Jedlicki, Marcela;* [3]*Corvalán Aguilar, Camila;* [4]*Lopes Pereira França, Jaqueline;* [5]*Mara Fisberg, Regina.*

[1]PhD student. 1. Evaluation of Food Consumption Research Group. Department of Nutrition. School Public Health. University of São Paulo (USP). São Paulo. Brazil.; [2]Msc. Nutritionist. School of Nutrition and Dietetics. Faculty of Pharmacy. University of Valparaíso. Valparaíso. Chile; [3]PhD. Center for Prevention of Obesity and Chronic Diseases (CEPOC). Institute of Nutrition and Food Technology (INTA). University of Chile. Santiago. Chile; [4]PhD. Student. Evaluation of Food Consumption Research Group. Department of Nutrition. School Public Health. University of São Paulo (USP). São Paulo. Brazil.; [5]PhD. Nutritionist. Evaluation of Food Consumption Research Group. Department of Nutrition. School Public Health. University of São Paulo (USP). São Paulo. Brazil.

Background and objectives: Analyzing 24-h dietary recalls is a enormous challenge when appropriate tools for dietary data collection are not available. Validated nutrition analysis software are often based on foreign database, data from literature sources and/or manufacturer´s data. These sources can differ from local food composition and therefore require a previous harmonization process.

Objective: To describe a protocol for adjusting the local food composition to nutritional analysis software database prior analyzing the 24-h dietary recalls applied to children from the "Growth and Obesity Cohort Study" (GOCS).

Methods: Nutrition Data System for Research (NDS-R) was used for harmonization process. This database includes over 18.000 foods and 165 nutrient and other food components, and it is updated annually to reflect marketplace changes and new analytic data. Dietitians identified food items reported in the 24-h dietary recalls collected during 2013-2014 and grouped them according to nutritional characteristics. Foods were matched in the NDS-R database through its general description (i.e., by name, type and mode of preparation). Recipes were added for commonly consumed processed foods that were not in the software database. Energy and macronutrient values available in Chilean food composition tables (TCA), local food industry composition tables and/or nutrition labels were compared to values described in the software. A concordance rate between 80 and 120% for each parameter analyzed was required to accept food harmonization.

Results: 766 foods, beverages and recipes were harmonized. Major obstacles were observed in local foods, for example, fish and seafood, processed foods, such as cookies, cakes, candies and fast food, among others. In addition, there were problems with the large variety of recipes and preparation of typical Chilean meals; however, NDS-R allows entering new recipes to its database.

Scarce information of new food and lack of updated TCA information constituted additional difficulties.

Conclusions: Software adaptation to analyze 24-h dietary recalls is an arduous task that must be performed by trained dietitians to minimize systematic and random errors in nutrient intake estimations. Local updated nutrient composition databases are key to enhance the quality of dietary assessment.

ASSESSMENT THE NUTRITIONAL STATUS AND FOOD INTAKE OF ATHLETES OF THE HANDBALL TEAM OF THE OF GUARULHOS CITY- SP

de Araujo, Mariangela; Korukian Freiberg, Clara; da Silva Jr, Luiz Henrique; dos Santos Novaes, Patrícia; Simões, Juliana; Oliveira, Roberta; de Oliveira Barcellos, Bianca.

MSc. Nutritionist. Nutrition Departament. Guarulhos University. São Paulo. Brazil.

Background and objectives: Handball is a collective, dynamic and fast-growing sport in Brazil. Because it is a high-performance sport and a great caloric expenditure, its practitioners undergo physical stress and great wear and tear, which must be compensated with adequate food consumption that promotes health, improves performance and recovery physical and muscular development of these individuals. The aim was to assess the nutritional status through anthropometric measures and adequate intake of food considering energy, macro and micronutrients of athletes of the handball team of the of Guarulhos City- SP

Methods: Cross-sectional study, approved by the committee of ethics in research. For this study, were evaluated Fifteen male handball athletes aged 18 to 26 years. For the determination of body fat, it has applied the sum of nine skin folds between them: subscapular, tricipital, bicipital, axillary, suprailiac, pectoral, abdominal, leg calf and thigh, determined by Heyward and Stolarczyk (1996) and Siri (1961), adapted by Lohman (1986). For the calculation of the caloric expenditure, the formula of Harrys & Benedict was applied, in addition of the calories of daily physical activities (NRC, 1989) and food-induced thermogenesis. For macronutrient suitability, the FAO/OMS recommendation (2003) was considered. For the assessment of the vitamins and minerals intake, it was applied the DRIs, - Dietary Reference Intakes (NRC, 2000).

Results: The percentage of fat body found in the majority of the athletes within the values considered adequate (80%). About the food intake showed that 73.33% of the group had a caloric intake below of recommended energetic requirements and 26.67% above of them. Other important point was that they have stayed long periods fasting, not doing an adequate fractionation of meals. It was found predominance of hyperlipidic and hyperprotein diets.

Considering the diversification of nutrients, the diets were considered monotonous with low intake of fruits and vegetables especially those that could influence directly in the performance of the Athlete during the training.

Conclusions: It was verified that there is a need to adapt the menu of the athletes, both energy and macro as well as micronutrients, so that healthy eating reflects on their income on the court.

Ibn Tofail University-Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [5]PhD.Professor. Joint Unit of Nutrition and Food Research. Ibn Tofail University-Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.

Background and objectives: Body composition is important as a marker of both current anf future health. Bioelectrical impedance analysis (BIA) is a simple and accurate method for estimating body composition, but requires population-specific prediction equations. The aim of the present study was to examine the validity of published BIA equations for assessing total body water (TBW) and fat-free mass (FFM) using deuterium oxide dilution (D2O) as the reference method and to develop new FFM-BIA and TBW-BIA equations in Moroccan children.

Methods: Data were collected from 250 healthy children aged 8-11 year-old. BIA variables were measured by a tetra-polar device. TBW and FFM were assessed by the D2O. The participants were sorted by gender and randomly split into development and validation subgroups. The validity of other published equations was also tested using Bland and Altman procedure, proportional bias and pure error.

Results: Prediction equations were generated, incorporating height, impedance index, weight, age and sex as predictors ($R^2 = 0.91$). The new equations provided non-significant proportional bias values, and better agreement than other tested equations. Bias and pure error values were -0.17 and 2.47 l for boys and -0.04 and 2.46 l for girls, for TBW equation. For FFM equation, bias values were 0.14 and -0.12 kg, and pure errors were 3.25 and 2.92 kg for boys and girls, respectively.

Conclusions: The new BIA prediction equations have high accuracy on Moroccan children and are recommended for use in these populations.

Keywords: body composition; bioelectrical impedance; prediction equation; Moroccan children.

BLOOD PRESSURE IN RELATIONWITH BMI AND BODY FAT IN MOROCCAN SCHOOL CHILDREN: A CROSS SECTIONAL STUDY

[1]El Harchaoui, Imane; [2]Baddou, Issad; [2]Benjeddou, Kaoutar; [2]Saeid, Naima; [3]Belghiti, Hakim; [4]El Kari, Khalid; [4]El Mzibri, Mohammed; [4]El Hamdouchi, Asmaa; [5]Aguenaou, Hassan.

[1]PhD Student. Joint Unit of Nutrition and Food Research. Ibn Tofail University - Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco; [2]PhD Student. Joint Unit of Nutrition and Food Research. Ibn Tofail University-Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [3]MD. Nutritionist. Hôpital Militaire d'Instruction Mohammed V. Morocco.; [4]PhD. Researcher in Nutrition. Joint Unit of Nutrition and Food Research. Ibn Tofail University-Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.; [5]PhD.Professor. Joint Unit of Nutrition and Food Research. Ibn Tofail University-Centre National de l'Energie des Sciences et des Techniques Nucléaires. Morocco.

Background and objectives: Excess adiposity, which is well-recognized a risk factor for non communicable diseases such as hypertension, has become a major health problem in many developing countries, particularly among schoolchildren.

Therefore, the purpose of this study is to examine witch variables in the nutritional state are associated with blood pressure (BP).

Methods: A cross-sectional survey involving 250 children's (50.4% boys and 49.6% girls), were chosen randomly from 5 public schools in 2 cities of Morocco. Body composition was assessed using bioelectrical impedance analysis (BIA) and anthropometry.

Anthropometric data were taken using standardized equipment. Obesity was defined by the WHO reference body mass index (BMI)-for-age. Hypertension was defined as the occurrence of BP levels greater or equal to the 95th percentile of height- and sex-adjusted reference levels.

Results: Median age 9.58 (8.83–10.33) years; mean z-score BMI (-0.15±1.31) kg/m2. According to the BMI 13.3% of children was overweight and 7.2% was obese. The prevalence of hypertension was 11.1% and that of high percentage fat mass 26.6%.

All of the correlations of the systolic and diastolic blood pressure with variables in the nutritional state (BMI and fat mass) showed to be significant.

Significant correlation were found for fat mass (r = 0.16, p<0.005) (r = 0.15, p<0.005) with systolic and diastolic blood pressure respectively. Whereas BMI showed a stronger association with systolic blood pressure (r=0.21, p<0.001).

Conclusions: This study made it possible to notice that the anthropometric indicator that best is related to the existence of high BP is the BMI. This seems to be an easy method that is noninvasive and of low cost to detect the risk of high BP in schoolchildren.

Keywords: Blood pressure, hypertension, fat mass, body mass index, schoolchildren.

ASSOCIATION BETWEEN DIETARY INTAKE AND DEMOGRAPHIC AND CLINICAL ASPECTS OF BRAZILIAN CANCER PATIENTS

[1]Bernardes Spexoto, Maria Cláudia; [2]Serrano, Sérgio Vicente; [1]Campos, Juliana Alvares Duarte Bonini.

[1]PhD. Departamento de Alimentos e Nutrição. Faculdade de Ciências Farmacêuticas. Universidade Estadual Paulista "Júlio de Mesquita Filho" (UNESP). Brazil.; [2]MD. Hospital de Câncer de Barretos. Brazil.

Background and objectives: Patients with cancer are also compromised by a variety of symptoms like nausea, vomiting, diarrhea, constipation, food aversions, fatigue, dyspnea, and pain, which may construct barriers that make dietary intake challenging. The cancer itself and added to the toxic effects of oncology treatment, it may increase the severity and persistence of symptoms and affect the dietary intake of patients. It is widely known that the tumor site, clinical stage, some symptoms and use of chemo/radiotherapy are factors that are associated with dietary intake. The objective was estimate the energy and macronutrient intakes of cancer patients and their relationship with the patients' demographic and clinical characteristics.

Methods: This is a cross-sectional study of 772 patients with cancer in treatment at Barretos Cancer Hospital. Demographic (personal interview) and clinical's information were collected (patient record). The study used the Food Frequency Questionnaire (FFQ). Univariate analysis of variance (ANOVA) followed by the Tukey post-hoc test determined whether the patients' energy and macronutrient intakes related to their demographic and clinical characteristics. The patients' energy and macronutrient intakes were compared with their nutritional requirements by point estimates and 95% confidence intervals (CI95%). The significance level was set at 5%.

Results: Most participants were females (63.1%) with a mean age of 53.2 (SD=12.7) years. Thirty-nine percent of the patients had stage III disease, 72.4% were undergoing chemotherapy, and 40.5% had metastases. Dietary intake differed significantly by employment status (p=0.009; p<0.001), socioeconomic class (p<0.001; p=0.002; p=0.004), cancer specialty area (p=0.008; p=0.003), type of treatment (p=0.023; p<0.001), and body mass index (BMI) (p=0.004). The mean of energy intake was 1346.5 (SD=332.0) (IC95%=1323.1-1370.0) kcal/day, the mean of protein intake was 57.0 (SD=20.0) (CI95%=55.6-58.5) g/day, the mean lipid intake was 27.3 (SD=10.0) (CI95%=26.6-28.0) g/day and 223.3 (SD=55.7) (IC95%=219.4-227.3) g/day of carbohydrates. The patients had inadequate energy and macronutrient intakes.

Conclusions: The patients' dietary intake was inadequate and differed significantly by employment status, socioeconomic class, cancer specialty area, type of treatment, and BMI.

Keywords: dietary intake, cancer, nutrients

ANTHROPOMETRIC STUDY BY GENDER IN SEMI-URBAN SCHOOLCHILDREN IN KENITRA CITY-MOROCCO

[1]Agoutim, Naima; [2]Aboussaleh, Youssef; [3]Ahami, Ahmed Ot; [4]Sbaibi, Rachid.

[1]PhD. Nutrition.Health and environement . University Ibn Tofail of Kenitra.Morocco.; [2]Pr.PhD.Nutrition. Laboratory of Nutrition. Health and Environment. Department of Biology. Faculty of Sciences. University Ibn Tofail of Kenitra.Morocco. BPa; [3]Pr.PhD.Neurosciences.Behavioral and Cognitive . Laboratory of Neurosciences. Behavioral and Cognitive. University Ibn Tofail. Kénitra.Morocco; [4]PhD.Nutrition. Laboratory of Nutrition. Health and Environment. Department of Biology. Faculty of Sciences. University Ibn Tofail of Kenitra. Morocco.BPa.

Background and objectives: The nutritional requirements of school-aged children vary from one age group to another and according to gender, because their energy expenditure is different . For this reason, it was chosen as a study objective to assess the nutritional status of schoolchildren and see if there is a significant difference between girls and boys in anthropometric indicators.

Methods: The anthropometric survey was carried out among 239 schoolchildren of average age (10.22 years ± 2.10),weight and height were measured according to the WHO (World Health Organization), Anthropometric indices which adopted are: weight-for-age, and height-for-age and body mass index (BMI), determined by the Z score calculated according to WHO growth references 2007 (5-19 years).

Results: Results of anthropometric studies revealed an underweight reach 4.3%: girls (5.6%), boys (6.3%) (10 years), stunting 6.3%: girls (6.1%), boys (5.6%), thinness 3.8%: girls (6.1%), boy (4.8%), low risk for overweight 4.3%: girls (11.3%), boy (10.5%), Obesity 0.9%: girls (3.5%), boys (2.4%). χ2 analysis did not show any significant differences between girls and boys regarding the various anthropometric indicators (P>0).

Conclusions: The population studied suffered from a slight malnutrition as well as a lack of influence of sex on the nutritional state of the school children.

Keywords: schoolchildren, semi-urban, nutritional status, gender

DEVELOPMENT OF A NEW TOOL FOR DIETARY DATA COLLECTION: SER-24H, SOFTWARE FOR 24 HOURS RECALL

[1]Quintiliano Scarpelli Dourado, Daiana; [2]Martínez Arroyo, Angela; [3]Jara, Macarena; [3]Cornejo, Catalina; [4]Avendaño, Ramon; [5]Pereira Scalabrino, Ana; [5]Reyes Jedlicki, Marcela.

[1]PhD. Nutritionist. Center for Prevention of Obesity and Chronic Diseases (CEPOC), Institute of Nutrition and Food Technology (INTA), University of Chile, Santiago, Chile.; [2]PhD. Student. Evaluation of Food Consumption Research Group. Department of Nutrition. School Public Health. University of São Paulo (USP). São Paulo. Brazil.; [3]Nutritionist. Center for Prevention of Obesity and Chronic Diseases (CEPOC). Institute of Nutrition and Food Technology (INTA). University of Chile. Santiago. Chile.; [4]CITEC®. Santiago. Chile.; [5]PhD. Center for Prevention of Obesity and Chronic Diseases (CEPOC). Institute of Nutrition and Food Technology (INTA). University of Chile. Santiago. Chile.

Background and objectives: Analyzing 24-h dietary recalls involves several challenges such as standardized data collection, conversion of household measures, linkage of foods/beverages with nutrient content data, among others. There is no available Software for dietary data collection customized to Chilean needs.

Objective: To report the development of the software for dietary data collection "SER-24h" (Software de Encuestas Recordatorio 24 horas).

Methods: The software development started in 2015 and it was led by CEPOC at INTA, University of Chile. We build on the dietary data collected on 24-h dietary recalls since 2012. We identified foods, beverages and recipes to organize the food database. The recipes were disaggregated in ingredients. The National Nutrient Database Standard Reference of the United States Department of Agriculture (USDA) was used as nutrient content data. We linked our data to the USDA, assuming a concordance between 80 and 120% of energy and macronutrients, based on the nutrition facts of packaged foods and Chilean food composition data. A private company (CITEC®) provided technological support and generated the software.

Results: SER-24h includes a questionnaire designed for collecting interviewer 24-h dietary recalls using the "Automated Multiple-Pass Method". Foods/beverages are selected from a list of from 4682 options, with specific portion sizes for each one; the software allows to add new foods/beverages or portion sizes if needed. Recipes can be also selected from the ones available (n=838) or added if necessary. SER-24h provides reports with nutrient information at the food/beverage level, origin from the food or preparation, meal time, location and activities during the meals. The program was ready to collect data after 16 months of preparation and it can be executed online or offline from any operating system previously authorized by the webmaster.

Conclusions: The new software allows collecting standardized dietary information and it links it with nutrient content. As far as we know, SER-24h is the only Chilean dietary software which outputs provide dietary analyses discriminating different sources of nutrients (i.e. at the level of food groups, meals, time of the day, or others). The use of this tool should increase our scarce knowledge on local dietary patterns.

Keywords: dietary assessment, food intake, 24-h dietary recall, SER-24h.

WORKING ON ATYPICAL SCHEDULES AND ITS NEGATIVE IMPACT ON FOOD INTAKE IN BRAZILIAN SHIFT WORKERS

[1]Cristina Silva, Graciele; [2]Cristina Tibiletti Balieiro, Laura; [3]Alves Guimarães, Rafael; [4]Gonçalves Resende, Sabrina; [5]Bernardes da Cunha, Nayara; [1]Aparecida Crispim, Cibele.

[1]PhD. Nutritionist. Faculty of Medicine. Federal University of Uberlandia. Uberlandia. Brazil.; [2]MSc. Nutritionist. Faculty of Medicine. Federal University of Uberlandia. Uberlandia. Brazil.; [3]Msc. Nurse. Faculty of Nursing. Federal University of Goias. Goiania. Brazil.; [4]MSc. Pharmaceutical. Faculty of Medicine. Federal University of Uberlandia. Uberlandia. Brazil.; [5]Nutritionist. Faculty of Medicine. Federal University of Uberlandia. Uberlandia. Brazil.

Background and objectives: Although the shift worker is predisposed to nutritional disorders such as obesity, the association between atypical working hours and food intake patterns is poorly described in the literature. This study aimed to evaluate the associations between shift work and the dietary pattern in Brazilian shift workers.

Methods: A cross sectional study was conducted with 1.215 (461 early morning, 233 day, 146 evening and 375 night workers) shift workers. The food intake pattern was evaluated by a semi-quantitative Food Frequency Questionnaire (FFQ) validated for Brazilian adults. The prevalence of inadequate intake of eight food groups was calculated as a reference to the portions recommended using the "Food Pyramid Adapted for the Brazilian Population". Measurements were taken for weight, height, waist circumference, as well as calculations of the Body Mass Index (BMI). Binary logistic regression was performed and adjusted for potential confounding variables in order to verify the association between the shifts worked and inadequate food intake using the day shift as reference.

Results: An association was found between working in the early morning shift and inadequate food intake over various food groups, such as milk and dairy products (Adjusted odds ratio [AOR]: 2.49; 95% CI 1.29, 4.81; $p < 0.01$), meat and eggs (AOR: 1.61; 95%CI 1.07, 2.42; $p < 0.05$) cereals and pasta (AOR: 1.44; 95% CI 1.01, 2.05; $p < 0.05$) and fruit and fruit juices (AOR: 2.04; 95% CI 1.06, 3.93; $p < 0.05$). The night shift present 2.25 times (AOR: 2.25; 95% CI 1.19, 4.25; $p < 0.05$) greater odds of inadequacy for milk and dairy products, meat and eggs (AOR: 1.62; 95% CI 1.07, 2.45; $p < 0,05$) and cereals and pasta (AOR: 1.56; 95% CI 1.09, 2.24; $p < 0,05$).

Conclusions: The food intake pattern of all other food groups were not associated with the work shifts. Early morning and night shift workers are more vulnerable to inadequate intake from various food groups. These results demonstrate the need to develop food intervention programs concerning food patterns in workers that work atypical schedules.

Keywords: Food intake. Shift workers. Work schedule. Unhealthy eating habits. Poor diet.

NUTRITIONAL STATUS OF RURAL YOUTH IN THE PROVINCE OF TUCUMÁN, ARGENTINA

[1]Salazar Burgos, Ramiro; [2]Oyhenart, Evelia; [3]Paolasso, Pablo.

[1]BSc. Nutricionist. Instituto Superior de Estudios Sociales. Conicet. Universidad Nacional de Tucumán. Argentina.; [2]PhD. Anthropologist. Cátedra de Antropología Biológica IV. Facultad de Ciencias Naturales y Museo – IGEVET CCT La Plata, CONICET - Facultad de Ciencias Veterinarias. Universidad Nacional de La Plata. Argentina; [3]PhD. Geographer. Instituto Superior de Estudios Sociales. Conicet. Universidad Nacional de Tucumán. Argentina.

Background and objectives: Tucumán has twice the rural population than the national average. A third are young people between 10 and 24 years old and 28% have some basic unmet need. This indicates that they live in conditions of vulnerability, which can have an impact on their health. Nutritional status is the result of the balance between nutrient intake and the requirements of an individual. The imbalance in some of these aspects, due to the deficit or excess, can generate malnutrition. The objective was to evaluate the nutritional status of young people attending rural schools in the province of Tucumán

Methods: The cross-sectional study included 383 cases, ranging from 9 to 15 years old, from seven rural schools in the province of Tucumán, Argentina. Four schools belonging to the department of Rio Chico, two to Tafí Viejo and one to Lules. The selection was for convenience. The exact age was determined from the data in the school records. Anthropometric measurements were performed according to standardized protocols. Portable digital balance (precision of 100g) and vertical anthropometer (precision 0.1cm) were used. The Who Anthro Plus software was used to process the data.

Results: With respect to the nutritional deficit, it was found 3.9% of stunting and 1% of wasting. At the departmental level, the following prevalences were observed, respectively: Lules 5.9% and 2.9%; Tafí Viejo 4.3% and 1.1% and Rio Chico 3.5% and 0.8%.As for overweight, we found 22.2% and 17% of obesity. The analysis by departments indicated the following prevalences of overweight and obesity: Lules 26.5% and 5.9%; Tafí Viejo 27.2% and 19.6% and Río Chico 21% and 17.5%.

Conclusions: The presence of malnutrition in rural areas, predominantly due to excess, accounts for the magnitude of the existing nutritional problems. The prevalence of overweight is high and similar in all areas. In contrast, obesity manifests itself in a heterogeneous form and reaches its maximum value, as well as being overweight, in the department of Tafí Viejo. Regarding the presence of stunting and wasting, they are presented differently by area, however, they show their greater value of both indicators, in the department of Lules.

Keywords: Nutritional status - youth - rural - Tucumán

CREATING THE NEW LEXICON FOR THE NEXT GENERATION OF DIETARY ASSESSMENT METHODS

[1]Boushey, Carol; [2]Kerr, Deborah; [3]Delp, Edward; [4]Zhu, Fengqing Maggie.

[1]PhD. Associate Research Professor. Epidemiology Program. University of Hawaii Cancer Center. Honolulu. HI. USA; [2]PhD. Research Academic. Research Leader for Food, Nutrition and Health. School of Public Health. Curtin University. Perth. WA. Australia.; [3]PhD. The Charles Williams Harrison Distinguished Professor of Electrical and Computer Engineering. Purdue University. School of Electrical and Computer Engineering. West Lafayette. IN. USA.; [4]PhD. Assistant Professor of Electrical and Computer Engineering. Purdue University. School of Electrical and Computer Engineering. West Lafayette. IN. USA.

Background and objectives: Quantifying how much people eat and drink remains an open research question. Mobile technology development has created a new era for assessment of dietary intake. These new methods show promise with regard to improved cooperation from study participants or patients and translation to more accurate results of energy and nutrient intakes. Benefits of these methods also include the additional detail about food and contextual information surrounding eating occasions. However, the reporting and the repeatability of these methods are hampered by the lack of standardized terminology associated with these new mobile methods. Therefore, the objective of this presentation is to outline a framework for identifying these new promising dietary assessment methods.

Methods: Efforts to standardize the language of this transition from traditional to mobile methods are needed

Results: Images taken with handheld devices or wearable cameras have been used to assist traditional dietary assessment methods (image-assisted methods). Image-assisted approaches can supplement dietary records or 24-hr dietary recalls. In recent years, image-based approaches using mobile devices or wearable sensors with embedded cameras have been developed (image-based methods). Image-based approaches capture all eating occasions with images as the primary record of dietary intake. The challenges of implementation of these new methods, their benefits, interoperability, and standardization will be covered.

Conclusions: Guidance in communicating these new methodologies will enhance their adoption and progression. The recommendations presented will improve reporting and the ability of

researchers and practitioners to identify best use method based on goals, study design, and sample characteristics.

144/2200

PREVALENCE OF OVERWEIGHT AND OBESITY AND ITS ASSOCIATION WITH SOCIODEMOGRAPHIC FACTORS AMONG A NATIONAL REPRESENTATIVE SAMPLE OF ECUADORIAN CHILDREN AND ADOLESCENTS

[1]Andrade Tenesaca, Dolores Susana; [2]Ochoa Avilés, Angelica; [3]Freire, Wilma; [1]Andrade Tenesaca, Dolores Susana; [4]Donoso Moscoso, Silvana Patricia.

[1]MSc. PhD. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Ecuador.; [2]MD. PhD. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Ecuador.; [3]MSc. PhD University San Francisco Quito. Ecuador.; [4]Bioq. MSc. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Ecuador.

Background and objectives: Overweight and obesity during childhood are important risk factors for noncommunicable diseases. We aim to assess the prevalence of overweight and obesity among children and adolescents and its associations with sociodemographic factors in a National representative sample from a middle-income country.

Methods: A national representative sample of 2-18 years old children and adolescents from the 2012 Ecuadorian National Health Survey (ENSANUT-ECU) was analyzed. Overweight, and obesity were defined applying the IOTF cut offs. Logistic regression models were set to identify sociodemographic factors (i.e. sex, rurality, geographic region, ethnicity, household income quintile and age) associated with overweight/obesity. The models were adjusted for the cluster design applying the svy command in Stata version 13.0.

Results: In total, 24,224 children and adolescents (8.2±5.1 years old) from the four geographic regions in Ecuador (Pacific-Coast, Andean-Region, Amazon-Rainforest and the Galápagos Islands) were included in the analysis. Overweight, obesity and morbid obesity affected 14.5% (95% CI, 13.2-16.4), 3.5% (95% CI, 2.7-4.6), and 2.2 % (95% CI, 1.8-2.8) of the studied population. Urban participants were 1.2 times (P=0.001; 95% CI, 1.1-1.3) more likely to be either overweight or obese in comparison with their rural pairs. Similarly, children and adolescents living in households in the higher income quintiles (P<0.001; OR: 1.7; 95% CI, 1.4-2.0) and adolescents (P=0.045; OR: 1.4; 95% CI, 1.0-1.8) were more likely to be either overweight or obese in comparison participants in the lower income quintiles and children respectively. No significant associations were found between overweight and obesity with either sex or geographic region.

Conclusions: The reported overweight/obesity prevalence are in line with those reported in the Latin American region. This

health problem seems to affect the whole country and to be predominant among urban and wealthier populations as well as when the population reaches adolescence. Although some actions have been already taken such as such the implementation of traffic light food labels and health promotion programs, more actions are still needed.

144/2210

NUTRITIONAL STATUS EVALUATION BY ANTHROPOMETRIC ASSESSMENT OF A GROUP OF WORKERS IN SÃO PAULO CITY, BRASIL

[1]Pieri, Patricia de Campos; [1]Assis, Gustavo Marchese; [1]Forti, Bruno Luis Peixoto; [1]Giori, Fabiana Ferreira; [1]Camargo, Maria Azevedo de; [1]Neves, Lorena Piquini; [1]Brito, Isabella Aguiar de; [2]Freiberg, Clara.

[1]Undergraduate Student. Nutrition. Universidade São Camilo. Brasil; [2]MSc. Nutricionist. Nutrition Department. Universidade São Camilo. Brasil.

Background and objectives: Since the 1970s, Brazil has undergone a reduction of malnutrition associated with an increase in obesity, a process called nutritional transition. The aim of the study was to evaluate the nutritional status of adult workers (19-59 years) of a shopping mall in the city of São Paulo, comparing the anthropometric evaluation data between those with sedentary (S) and non-sedentary (NS) work.

Methods: This was a descriptive cross-sectional study with primary data collection of 107 volunteers (64 females; 43 males), who met the inclusion criteria and had signed the informed consent. Data included: Weight; height; arm, waist (WC), wrist and hip circumferences; triceps (TSF), bicipital, subscapular and supraeiliac skinfolds, arm muscle circumference (AMC), sum of 4 skinfolds (S4SF) and the indexes BMI, central obesity (CO), waist to hip (WHR) and conicity index (CI). The S4SF was used to estimate the percentage of body fat and the results were compared to the BMI. Nutritional status and cardiovascular risk (CVR) was determined.

Results: BMI and WC showed a positive correlation with age in both sexes; 62,8% of men of all ages were overweight (46,5%) or obese versus only 34,4% women (29,7% overweight) irrespective of age differences between sex groups. AMC, TSF and S4SF does not correlate with BMI for neither sexes. For women, WC and WHR identified 18% and 3% of CVR respectively. The CI showed positive correlation with age in both sexes and a good correlation and precocity in the identification of CVR, especially for men. Of women at NS (n=38) and S (n=26) type of work, 68,4% and 57,7% presented with normal BMI respectively, even though in both groups a higher than average fat percentage (HPFM) was observed (NS=81,6%; S=92,3%). Similar results were observed for men (NS=9; S=34), with 66,6% of NS and 94,1% of S presenting HPFM.

Conclusions: BMI is an easy method to evaluate nutritional status of populations, but should be associated to other variables chosen in accordance to the ethnic group studied. The type of work might play an important role in the nutritional status and percentage of fat mass, but the present work fail to show it.

Keywords: Anthropometric evaluation. Nutritional Status. Cardiovascular risk.

ENERGY EXPENDITURE OF SELECTED DAILY ACTIVITIES IN ADULTS FROM NITERÓI, RIO DE JANEIRO, BRASIL

(1)Anjos, Luiz Antonio; (2)Mariz, Virginia; (2)Silva, Edimara; (3)Wahrlich, Vivian.

(1)MD, PhD. Professor. Universidade Federal Fluminense.; (2)Undergraduate student. Laboratório de Avaliação Nutricional e Funcional. Universidade Federal Fluminense.; (3)PhD. Nutritionist. Laboratório de Avaliação Nutricional e Funcional. Universidade Federal Fluminense.

Background and objectives: The assessment of the energy expenditure (EE) plays an important role in the assessment of the nutritional status and the treatment strategies of the population. The purpose of the present study was to measure the EE of selected daily activities and to compare the values with the code MET values of the Compendium of Physical Activities (CPA). The activities were: typing, organization of shelves, climb up and down 8 flights of stairs and walk on the treadmill at two self-selected speeds (pleasure, PV and exercise, EV) and PV-0.8.

Methods: This is a preliminary analysis of data of 33 adult (≥20y) subjects (25 women) recruited to participate in a larger study aimed to assess total daily EE by various methods. Resting EE (METm) was assessed with the subject sitting during 12'. The EE of each of the selected activities were measured for six minutes and expressed as multiple of METm (MMETm) or estimated MET (METe=3.5mLO2/kg/min). Body mass (BM) and stature (S) were also obtained. Body mass index (BMI) was calculated as BM/S2. Percent body fat (%BF) was measured by DXA.

Results: Mean (SD) age and BMI were 26.2 (6.6) and 23.7 (3.7) kg/m². Mean %BF was 32.7 (5.0) and 25.0 (9.3) for women and men, respectively. EE (kcal/min) of organizing shelves, climbing up and down the stairs was 3.0 (1.1), 7.0 (1.5) and 3.7 (1.0), respectively. MMETm was higher than MMETe by approximately 9% for all activities. Organizing shelves and PV-0.8 were classified as moderate activities (≥3 METs) only when METm was used. MMETm was 3.1 (0.6), 3.5 (0.6) and 4.8 (0.9) for PV-0.8 (3.8±0.5), PV (4.6±0.6) and EV (6.1±0.6km/h) and equal to the CPA codes for the last two. However, EE calculated by METe and the CPA codes was significantly greater that measured (mean difference of 0.51±0.69 and 0.65±0.9kcal/min, respectively). Climbing up stairs was the only activity classified as heavy (MMETm=6.9±0.8).

Conclusions: It is concluded that walking at PV can be considered as a moderate activity. Even though the CPA code MET values for walking at PV and EV were correct, their use will significantly overestimate the EE.

Keywords: Energy expenditure. Physical activity. Daily activities. Nutrition assessment.

REFERENCE INTERVAL FOR METHYLMALONIC ACID IN DRIED BLOOD SPOTS OF YOUNG, ADULT WOMEN TO FACILITATE SCREENING OF VITAMIN B-12 DEFICIENCY IN FIELD SETTINGS

(1)Schroder, Theresa; (2)Quay, Teo; (3)Lamers, Yvonne.

(1)PhD. Nutritionist. Food, Nutrition and Health Program. University of British Columbia. Canada.; (2)MSc. Nutritionist. Food, Nutrition and Health Program. University of British Columbia. Canada; (3)PhD. Professor. Food, Nutrition and Health Program. University of British Columbia. Canada.

Background and objectives: Maternal vitamin B-12 (B-12) status in early pregnancy has been inversely associated with impaired fetal development, including neural tube defects, and positively with infant B-12 status. Periconceptional B-12 adequacy is thus critical. Dried blood spots (DBSs) allow for convenient and cost-effective collection of biological samples in field settings. We have developed a method to quantify methylmalonic acid (MMA), the most specific functional B-12 biomarker, in DBSs. The objective was to calculate a reference value of DBS MMA in young adult women suggestive of functional B-12 deficiency.

Methods: In a convenience sample of 208 healthy women (19-35 years) living in Vancouver, Canada, DBSs were collected after pricking either middle or index finger. DBS MMA was quantified from an 8-mm spot by liquid chromatography-tandem mass spectrometry; plasma MMA and serum total B-12 and holotranscobalamin concentrations were determined. Dietary B-12 intake was assessed by food frequency questionnaire, and dosage of supplemental B-12 recorded. A reference value was computed from a reference population (mean ± SD age: 26.7±4.2 y), i.e. a subset of women with plasma MMA concentrations <370 nmol/L (92% of study population) and DBS MMA data (n=174), following clinical guidelines (CLSI EP28-A3c).

Results: The upper limit (90% CI) of the central 95% reference interval, computed after Box-Cox transformation and removal of 5 outliers (Tukey's test), was 8.9 (8.2-9.6) pmol/8-mm spot. The reference population had a median (IQR) DBS MMA concentration of 5.2 (4.2-6.3) pmol/8-mm spot. DBS MMA concentration was correlated with plasma MMA (ρ=0.65; P<0.0001) and serum total B-12 (ρ=-0.17; P=0.02) and holotranscobalamin (ρ=-0.22; P=0.004) concentrations. The median (IQR) plasma MMA and serum total B-12 and holotranscobalamin concentration of the reference population was 148 (114-185) nmol/L, 278 (200-373) pmol/L, and 66.5 (51.4-87.7) pmol/L respectively; the median (IQR) dietary and total (dietary and supplementary; 30%

supplement user) B-12 intake was 2.7 (1.9-4.0) µg/d and 3.7 (2.4-7.6) µg/d, respectively.

Conclusions: This is the first study to present a reference value for elevated DBS MMA computed from a healthy reference population of young adult women. Analysis of DBS MMA has the potential to be a convenient and field-applicable method that facilitates B-12 deficiency screening in reproductive-aged women.

Keywords: vitamin B-12 deficiency, methylmalonic acid, dried blood spots, reference interval, periconceptional

REDUCTIONS IN DIET QUALITY WITH TIME IN SINCE BENEFITS IN LOW INCOME WOMEN PARTICIPATING IN THE SUPPLEMENTAL NUTRITION ASSISTANCE PROGRAM IN THE UNITED STATES

[1]Freeland-Graves, Jean; [2]Sangeevi, Namratas.

[1]PhD. Bess Heflin Centennial Professor. Department of Nutritional Sciences. University of Texas at Austin. United States of America.; [2]PhD Candidate. Department of Nutritional Sciences. University of Texas at Austin. United States of America.

Background and objectives: The Supplemental Nutrition Assistance Program (SNAP) is the largest food assistance program in the United States, serving approximately 46 million individuals with program benefits. It transfers financial benefits once a month via an electronic card that can be utilized to purchase foods. Within the first 3 days of the month, a spike in food expenditure is noted, followed by redemption of 80% of the benefits within 2 weeks. The objective is to investigate changes in dietary quality in 151 women that occurred in response to fewer financial resources toward the end of the monthly cycle of SNAP benefits.

Methods: Subjects were recruited from low-income housing sites and neighborhood centers, informed consent was obtained, and a demographic survey was administered. At 1 week intervals, four more visits were conducted in which the participants completed a food frequency questionnaire (FFQ). It was validated for a reference period of 1 week and consisted of 95 food items, with varying frequency and serving size options. The initial administration of the FFQ was based on timing of the initiation of the monthly program benefit. The indicator of diet quality was the Healthy Eating Index-2010. Scores ranged from 0-100, based on 12 dietary subgroups, with nine adequacy and three moderation components. A mixed linear model was conducted with time as the independent variable, and diet quality and foods as the dependent variables. When significant main effects were detected, Bonferroni adjustments were conducted.

Results: Diet quality scores significantly declined as the month progressed, from 57.4 + 0.9 at week 1 to 45.6 + 1.0 at week 4. This was accompanied by a decrease in intakes of fruits, vegetables and dairy, and a higher consumption of whole grains. Total protein foods remained unchanged. Also, fewer home-prepared meals and increased eating outside the home were reported towards the end of the month.

Conclusions: The decline in dietary quality with time over the month from receipt of SNAP benefits might be mitigated by their allocations on a bimonthly basis. A more frequent distribution could provide a more even food supply and alleviate inconsistencies over time.

Keywords: diet quality, food assistance

EXCESS BODY FAT IN EUTROPHIC ADOLESCENTS AND RISK OF BLOOD PRESSURE CHANGE

[1]de Lucena Ferretti, Roberta; [2]de Pádua Cintra, Isa; [2]Aparecida Zanetti Passos, Maria; [2]Fisberg, Mauro.

[1]PhD Student. MSc. Nutritionist. Federal University of Sao Paulo. Brazil. Department of pediatrics. University of Taubate.; [2]PhD. Nutritionist. Federal University of Sao Paulo. Department of Pediatrics.

Background and objectives: The current adolescents lifestyle has collaborated for the body fat accumulation and chronic diseases development, such as hypertension. It is widely known that, in overweight individuals, there is a greater risk of blood pressure change. However, this risk is directly associated with excess body fat, which can occur in eutrophic individuals as well. The main objective of this study is to evaluate eutrophic adolescents body fat and the relation with the risk of development of blood pressure change.

Methods: A cross-sectional study that assessed adolescents aged 10 to 17 years old. The collected variables were weight (kg), height (cm) to calculate BMI (kg/m2), and were considered eutrophic adolescents ranked between -1 and +2 z-score of BMI according to the World Health Organization, 2007. To assessment of body fat, were used triceps and subscapular skinfold thickness, according to standard techniques, and body fat percent calculated according to the equations of Slaughter and classified by Lohman. To measurement of blood pressure Measurement protocol was followed, according to the V Brazilian Guidelines on Hypertension. The values of blood pressure were classified according to American Academy of Pediatrics recommendations - The fourth report on the diagnosis, evaluation, and treatment of high blood pressure in children and adolescents. Crude analysis between excess body fat and the independent variables were performed by univariated logistic regression. The binary regression analysis was used to estimate the values of chance (odds ratio–OR).

Results: Among 1774 adolescents assessed, 1123 eutrophic adolescents were selected, and 55.8% (n = 627) were female. The prevalence of excess body fat in eutrophic adolescents, boys and girls, were, respectively, 64.3% e 71.4%. It was verified that the risk of these eutrophic adolescents presenting a change in Sistolic Blood Pressure was 1.43 higher in relation to adolescents who did not present excess body fat (OR: 1.43 (0.98-2.09)), and for Diastolic Blood Pressure, this risk was 2.70 higher [(OR: 2.70 (1.78-4.10)].

Conclusions: It is concluded that there is elevated risk of eutrophic adolescents with excess body fat present alterations in

blood pressure, and this outcome is higher for diastolic blood pressure.

Keywords: Body fat. Nutricional Status. Eutrophy. Adolescent. Blood Pressure

NUTRI-CAMPECHADA 2016: NUTRIMETRY APPLICATION TO HIGH-SCHOOL ADOLESCENTS

[1]Selem Solis, Jorge Enrique; [2]Sandoval-Castellanos, Fernando Jose; [3]Alcocer-Gamboa, Alberto; [4]Hattori-Hara, Mónica.

[1]MPH. Medical Doctor. Tenabo's Health Center. Campeche Ministry of Health. México.; [2]MPH. Medical Doctor. Rector. Instituto Campechano. Mexico.; [3]MSc. Medical Doctor. PIAIOY, Ministry of Education of the Government of Yucatan State. México.; [4]PhD. Psychology. PIAIOY, Ministry of Education of the Government of Yucatan State. México.

Background and objectives: Mexico is world first place in childhood overweight and obesity, four out of ten Mexican adolescents are overweight or obese and the trend is increasing, that's why Mexico is strongly committed to contributing any element that helps curb this epidemic. The objective of the study was to establish the use of Nutrimetry as an instrument for clinical and epidemiological surveillance of malnutrition as the first part of a program called "Nutri-Campechada" in a sample of high-school adolescents.

Methods: Nutrimetry is a tool that combines BMI/age with height/age and generates nutricodes that identify groups of nutritional risk allowing a timely malnutrition prevention. According to WHO z-scores values were assigned, for height/age: $z \leq -2 = 1$, $z \geq 2 = 5$, or 3 to the rest, and for BMI/age: $z \leq -1 = 0$, $1 \leq z < 2 = 6$, $z \geq 2 = 12$ or 3 to the rest, values were crossed and 12 codes that combine short, normal and high height with underweight, normal-weight, overweight and obesity were obtained.

Results: Data of 822 students of the "Instituto Campechano" between 15 and 18 years of age were evaluated. Weight and height were measured, BMI/age and height/age were calculated, and applying Nutrimetry, risk groups were classified in odd (1/3/5: underweight, 7/9/11: overweight and 13/15/17: obese) and even (4/6/8: normal weight) numbers. Prevalence were: 1 (n=6) 0.73%, 3 (n=29) 3.53%, 5 (n=0) 0.00%, 4 (n=46) 5.60%, 6 (n=292) 35.52%, 8 (n=0) 0.00%, 7 (n=44) 5.35%, 9 (n=222) 27.01%, 11 (n=0) 0.00%, 13 (n=22) 2.68%, 15 (n=161) 19.59%, and 17 (n=0) 0.00%.

Conclusions: Prevalence of overweight and obesity in the studied population (54.62%) is higher than the national average (36.3%). The problem of overweight and obesity is higher in males (57.36%) than in females (52.88%).

High height is very uncommon since no student was reported with this condition, also low height affects 14.36% of this sample, but only 0.73% of them were underweight and 8.03% overweight and obese.

Based on the results, Nutri-Campechada requires a permanent training intervention in the Mediterranean diet and physical activation addressed to the students to improve their nutritional condition.

DEVELOPMENT OF AN INTERACTIVE TECHNOLOGICAL TOOL THAT USE THE LEAP MOTION CONTROLLER, AS A TOOL TO ESTIMATE FOOD PORTION SIZE: A VIABILITY PILOT STUDY

[1]Gutierrez Gomez, Yareni Yunuen; [2]Escarcega Centeno, David Alejandro.

[1]PhD. MSc. Nutritionist. Nutrition Department. School of Medicine and Health Sciences. Tecnologico de Monterrey. Mexico City. Mexico.; [2]PhD. Software Engineering. Computer Department. Engineering School. Tecnologico de Monterrey. Mexico City, Mexico.

Background and objectives: Estimation of food portion sizes has been a big challenge in dietary assessment. The aim of this work was to design and develop an interactive technological tool for the estimation of food portions through a virtual reality based on the Leap Motion® controller.

Methods: The interactive technological tool development was carried out in three phases: 1) Creation of food portions and photographs. We include 121 food portions sizes (fruits, vegetables, cereals, legumes, animal foods and fats). The food was cooked, weighed and in some cases measured before taking photographs. 2) 3D modeling food. In this phase the food portion sizes were 3D modeling with the next software: MAYA Autodesk 2016, Autodesk Mudbox 2016 and Adobe Photoshop. 3) Software development. To create the functional prototype of the Virtual Reality based in the Leap Motion® controller, we used the Unity software that is used for the creation of videogames.

Results: We designed and developed an interactive technological tool for estimation of food portion size based on the Leap Motion controller. Anyone can model with his/her bare hands a food portion size and the software could predict the portion size in grams. The first validation tests showed small differences between the food portion size estimated by the software and the real food portion size (weighed) for some food (watermelon, beans, cottage cheese, shredded coconut, read meat and chicken). The average differences was 8.4 g (SD 12.7 g) for the food mentioned before.

Conclusions: The interactive technological software that use the Leap Motion controller developed here, is a promising tool for a better food portion sizes estimation. Further work and investigation is needed in order to improve our development.

Keywords: Portion size estimation, dietary assessment, leap motion.

IODINE NUTRITIONAL STATUS IN FERTILE AGE WOMEN IN THE PROVINCE OF JUJUY, ARGENTINA

[1]Lopez Linares, Sonia; [2]Lopez Linares, Sonia; [3]Silva Croome, Maria del Carmen.

[1]PhD. Biochemistry. Centro Nacional de Investigaciones Nutricionales-ANLIS; [2]PhD. Biochemistry, Center National of Nutritional Research-ANLIS "Malbrán". Salta. Argentine; [3]PhD. Endocrinology. Hospital Ramos Mejias. Province of Buenos Aires. Argentina.

Background and objectives: INTRODUCTION: An iodine deficient diet is cause of hypothyroidism, mental retardation and IDD (iodine deficiency disorders). During pregnancy, iodine requirements increases. Adequate iodine supply must be achieved in preconception. Previous survey reported that pregnant population in Jujuy was iodine deficient.

OBJECTIVE: To establish iodine nutritional status in women of childbearing age in the province of Jujuy measuring urinary iodine concentration (UIC) and salt for consumption iodization levels

Methods: MATHERIAL AND METHODS: We randomly selected 98 healthy women between 14 and 40 years, living in Jujuy (without thyroid disease, pregnancy or taking iodine containing supplements). After informed consent, urinary casual sample and a household salt sample were obtained. The UIC was quantified by Persulfate method and iodine in salt by qualitative kit. A subsample (n = 77) by titration with thiosulfate. Median and percentiles of UIC were calculated and percentage of salts with adequate low or absent iodine content. We compared UIC of women taking salts of national and regional salts. We considered indicators of sustained IDD elimination if UIC median was between 100 to 199 UImg/l and > 90% of household salt iodine ≥15ppm. Statistic SPSS

Results: RESULTS: UIC median: 119 µg/L, range: 12-365 µg/L, distribution: 41.2% < 100ug/L, 52.6% between 100-199 µg/L, 4.1% between 200-299 µg/L and 2.1% > 300 µg/L; percentile 20: 54.4 µg/L, percentile 80: 165 µg/L.

Regional salts were consumed by 71.3%. The Kit detected 84.5% positive iodine and 15.5% without iodine (only detected in regional salts). Iodine content: 22.4 ± 15.39 ppm; 0.0-95.2 ppm range, >15 ppm the 74.0% between 20-40 ppm 61% and 17% without iodine measurable. UIC median was significantly higher in women consuming salt of national origin compared to regional salts (123 ug/L vs 117 ug/L respectively, p = 0.001).

Conclusions: CONCLUSIONS: Median urine iodine concentration in this study indicate iodine sufficiency. But iodine levels are under the recommended levels in 42% of the women. The goal of 90% of salt containing iodine ≥15ppm at household levels was not achieved. A preventive official plan must be implemented

Keywords: micronutrients, deficiency iodine, urine iodine, iodized salt.

NEW DIETARY ASSESSMENT TECHNOLOGY FOR INDIVIDUAL-LEVEL DIETARY DATA COLLECTION IN LOW-INCOME COUNTRIES: THE DEVELOPMENT PROCESS OF INDDEX24

[1]Coates, Jennifer; [2]Colaiezzi, Brooke; [3]Bell, Winnie; [4]Wafa, Sarah; [5]Prata, Cathleen; [6]Rogers, Beatrice.

[1]PhD. Associate Professor. Tufts University Friedman School of Nutrition Science and Policy. USA.; [2]MSc. Assistant Researcher. Tufts University Friedman School of Nutrition Science and Policy. USA.; [3]MSc. MPH. PhD Candidate and Assistant Researcher. Tufts University Friedman School of Nutrition Science and Policy. USA.; [4]MPH. RD. Assistant Researcher. Tufts University Friedman School of Nutrition Science and Policy. USA.; [5]MPH. Project Manager. Tufts University Friedman School of Nutrition Science and Policy. USA.; [6]PhD. Professor. Tufts University Friedman School of Nutrition Science and Policy. USA.

Background and objectives: Large-scale individual-level dietary surveys are infrequently conducted in low-income countries (LICs). Barriers include high resource requirements and limited research infrastructure for dietary assessment. As part of a multi-year effort to scale-up dietary assessment in LICs, the International Dietary Data Expansion (INDDEX) Project is investing in INDDEX24, a novel dietary assessment platform modeled on a multiple pass 24-hour dietary recall (24HR) and targeted to users in LICs. This study presents the systematic process used to identify INDDEX24's technical specifications and the results of preliminary testing carried out Bangladesh and Burkina Faso.

Methods: A multi-pronged approach was used to draft the INDDEX24 technical specifications. First, an initial list of technical specifications was drafted by a dietary assessment expert with in-depth knowledge and experience conducting 24HR surveys in LICs. Second, a literature review and qualitative research on existing 24HR platforms were conducted. Third, the INDDEX Project's Technical Advisory Group (TAG) and external technology experts evaluated the feasibility and validity of the technical specifications in terms of their appropriateness in the context of LICs.

Results: The INDDEX24 platform consists of a mobile application (app) for data collection and an integrated database website app for housing context-specific information required for processing 24HR data. It contains an interviewer-administered format, offline data collection capability, and is designed to be easily adapted to new contexts. INDDEX24 will also facilitate dietary

data processing by enabling researchers to link their food list to a contextually appropriate food composition database. A beta-version of INDDEX24 was developed and then evaluated by members of the INDDEX Project and TAG. Following revisions to the beta-version, the performance and user experience of a beta version of INDDEX24 was assessed in Bangladesh and Burkina Faso. Researchers in these countries suggested modifications to improve the usability of the platform. Additional in-depth feedback from cognitive debriefing with both survey respondents and enumerators was incorporated.

Conclusions: INDDEX24 has been developed by integrating feedback from a broad range of stakeholders and through extensive testing in a range of contexts. The efforts will help ensure INDDEX24 is a high quality, evidence-based tool for dietary assessment researchers in LICs.

Keywords: Dietary assessment. Food consumption data. 24-hour dietary recall. Low-income countries.

BIG DATA METHODS AND PUPILLARY RESPONSE: CRACKING THE CODE OF DARK ADAPTOMETRY FOR VITAMIN A DEFICIENCY

[1]Mehra, Sucheta; [2]Healy, Katie; [3]Shaikh, Saijuddin; [4]Soltanianzadeh, Amir; [2]Zeller, Kelsey; [3]Ali, Hasmot; [2]Schulze, Kerry; [2]Wu, Lee; [2]West, Keith; [5]Labrique, Alain Labrique.

[1]Nutritionist, Center for Human Nutrition, Department of International Health, Bloomberg School of Public Health, Johns Hopkins University; [2]Center for Human Nutrition Department of International Health Bloomberg School of Public Health Johns Hopkins University; [3]The JiVitA Project, Johns Hopkins University, Bangladesh.; [4]Masters Student, Department of Bioengineering Innovation, Whiting School of Engineering, Johns Hopkins University; [5]Global Disease Epidemiology and Control, Department of International Health Bloomberg School of Public Health Johns Hopkins University.

Background and objectives: The World Health Organization estimates that 9.7 million pregnant women exhibit night blindness, a severe form of dark adaptation, due to vitamin A deficiency (VAD). We have developed an innovative digital, quantitative field method leveraging pupillary responsiveness to structured light stimuli to assess functional VAD. Breakthroughs in image analysis and pattern recognition have revealed details of pupillary dynamics of up to 3000 consecutive data points on each subject's pupillary response over a 90 second window among pregnant women in rural Bangladesh.

Methods: We conducted an individually randomized, controlled trial among 488 women in late pregnancy in Gaibandha, Bangladesh from April 2015 to May 2016, supplementing half the women with a daily dose of 5,000 IU of vitamin A for 15 days. A blood sample was collected and women were assessed pre-and post-supplementation using a portable field dark adaptometer to record pupillary response to varying light stimuli (-2.9 to 0.1 c/m2). We present results of both conventional statistical analysis and machine learning and image analysis approaches to identify characteristic pupillary dynamic signatures associated with VAD and possibly, specific serum Vitamin A levels.

Results: 241 control and 247 supplemented women participated in the trial. Gestational age (28 weeks) and plasma retinol ($0.34 \pm 0.1 \mu g/mL$) levels did not differ between groups at baseline, though we see an intervention effect of increased plasma retinol levels among the supplemented group (difference of $+0.03 \pm 0.08$ versus -0.01 ± 0.08, p=0.002). Pupillary responsiveness was similar across groups at baseline and is being analyzed at follow-up. We have captured 1800-3000 pupillary response diameters on women with an example of early data on an individual participant included at this link (https://tinyurl.com/pupildata) to illustrate the heretofore uncaptured granularity and precision of pupillary dynamics captured in a rural, remote population.

Conclusions: We hope to demonstrate the practicality of digital field dark adaptometry as a method for point-of-population vitamin A status determination using the dynamics of pupillary responsiveness. Breakthroughs in mobile computing capacity and analytics continue to improve the feasibility of the method.

Keywords: Vitamin A deficiency, dark adaptometry, pupillary response, night blindness,

IODIZATION OF SALT AS SUCCESSFUL STRATEGY, COMBATING IODINE DEFICIENCY DISORDERS (IDD) IN AFGHANISTAN

[1]Aminee, Ahmadwali; [2]Hassam, Wasiullah; [3]Samadi, Khalil.

[1]MD.MPH. Global Alliance for Improved Nutrition. Kabul office. Kabul.Afghanistan; [2]MD. MPH. Global Alliance for Improved Nutrition.Kabul.Afghanistan; [3]MD.Public Nutrition Department of Ministry of Pubic Health.Kabul.Afghanistan.

Background and objectives: Iodine Deficiency Disorder (IDD) is serious public health problem among Afghan school aged children and reproductive age women. The Universal Salt Iodization (USI) program as main strategy combating IDD started in 2003 by operating of the first salt iodization factory and became a great success in Afghanistan, currently there are 31 salt iodization factories functioning in 14 out of 34 provinces with the capacity of 5-8 Metric Ton /hour each. The iodization of salt for edible consumption becomes mandatory in 2011 after enactment of national regulation by the government. The objective of this study is to present the success effect of salt iodization program on reduction of iodine deficiency in Afghanistan.

Methods: Reviewing the results of two National Nutrition Surveys (NNS) conducted in 2004 and 2013, to assess the impact of USI program, over the reduction of iodine deficiency in the country.

Results: According to the NNS 2013 reports, up to 66% of the households all over the country have access to and are using adequately iodized salt (>15 ppm) in the diet, and a significant improvement from 28% reported by the NNS 2004, the report also indicated that the prevalence of iodine deficiency among children 7-11 years and reproductive age women decreased to 29.5 % and 40.7% respectively, remarkable progress from 72% and 75% respectively among the same age groups. The comparisons of two data showing a remarkable iodine deficiency reduction of 35 percentage points (55%), as a result of 10 years successful salt iodization program implementation, furthermore, it will contribute to saving the brine damage and preventing the reduction of 10-15 IQ points of almost 395,000 out of 94, 2000(72% of total live births/year) afghan new-born children each year, causing as iodine deficiency.

Conclusions: since there is no any national program influencing the reduction of iodine deficiency, the salt iodization has been a successful strategy combating IDD in Afghanistan.

DIET, ANTHROPOMETRY AND GUT PERMEABILITY IN MEXICAN CHILDREN WITH AUTISM SPECTRUM DISORDERS

[1]Pedroza García, Karina Alejandra; [1]Ronquillo, Dolores; [2]Anaya-Loyola, Miriam Aracely; [2]Rosado, Jorge L.

[1]MD. Facultad de Ciencias Naturales. Universidad Autónoma de Querétaro. México; [2]PhD. Facultad de Ciencias Naturales. Universidad Autónoma de Querétaro. México.

Background and objectives: Autistic Spectrum Disorders (ASD) comprise a group of developmental disorders, characterized by deficits in social interaction, communication, and behavioral patterns. Children with ASD may present nutritional challenges, specially as a result of their restrictive behaviors such as selective food intake, increased sensory sensitivity leading to rejection of food, disruptive behavior to specific foods and refusal to accept new foods. Aditionally, nutritional status can be affected by gastrointestinal problems that may be related to a leaky gut. The aim of the study was to evaluate diet, anthropometry and intestinal permeability of ASD children and teenagers.

Methods: A cross-sectional study was crried out in 22 ASD children and adolescents aged 4 to 18 years from the cities of Aguascalientes and Querétaro, México. Diet was evaluated by means of three 24-hour recalls a food frequency questionnaire. Weight and height were measured by duplicate and BMI was stimated and compared with WHO z score. Intestinal permeability was evaluated by a lactulose/mannitol test and its subsequent measurement in urine by HPLC.

Results: At the end of the study it was observed a high prevalence of malnutrition, 18.2% of the participants have low weight for height and 50% have overweight or obesity; the diet was unbalanced with a high content of fat and refined sugar, and a poor consumption of fiber (13.0g ± 5.2), vitamin E, vitamin D, potassium, calcium and zinc. Intestinal permeability was in average 0.01 ± 0.02 and it was adequate in 80% of the sampe.

Conclusions: In this study it was found that participants have deficient consumption of some vitamins and minerals, but high ingestión of fat and sugar, and a hight percentage of participants have overweight or obesity, its advisable to developt food counseling strategies for children with ASD. In contrast with previous studies, intestinal permeability was adecuate in Mexican children with ASD.

Keywords: Autism spectrum disorders, anthropometry, diet, gut permeability.

ASSOCIATION BETWEEN INDIAN DIABETES RISK SCORE (IDRS) AND NON IDRS COMPONENTS AMONG INDIAN ADULTS

[1]Joshi Reddy, Kejal; [2]Takalkar, Siddhi.

[1]Assistant Professor. Nutrition and Dietetics Department. Symbiosis School of Biomedical Sciences. Symbiosis International University. India; [2]B.Sc.,M.Sc.Nutrition and Dietetics Department. Symbiosis School of Biomedical Science. Symbiosis International University. Pune-412115. Maharashtra. India.

Background and objectives: Prevalence of Type 2 diabetes is increasing at an alarming rate globally. It is a major risk factor for death and other non-fetal complications. WHO reports that one fifth (19%) of the total diabetics, reside in India (35 million). It is projected that it will increase to 80 million 2030. Indian Diabetes Risk Score is a simple, cost effective tool devised by MDRF to determine high risk individuals at an early stage. There is a need to assess a correlation between the risk score and other modifiable non-IDRS components which can be further focused on to reduce the risk of Diabetes and CHDs in future. Thus, a study with an aim to derive an association between IDRS and Non-IDRS components in urban population of Pune was developed.

Methods: A cross-sectional study involved N=185 healthy individuals aged between 20 and 50 years, randomly selected from a free living setting in Pune city. Other than IDRS components (Age, Waist Circumference, physical activity and family history), non IDRS components like anthropometric measurements, dietary data, random blood sugar level (BSL), blood pressure (BP) and lipid profile were also assessed.

Results: The findings revealed that 24.9% of the population had high risk of diabetes; where as 33% had moderate risk of diabetes. IDRS showed a significant positive association (p<0.01) with BMI, carbohydrate intake, blood pressure, random BSL, change in appetite and FRS. However, a negative association (p<0.05) was found between IDRS and protein and fat intake, flax seed consumption and nature of physical activity.

Conclusions: IDRS and non-IDRS components are strongly associated, which indicates an increased risk of Diabetes, if not modified with due attention. To reduce ever increasing burden of diabetes in the community, it is essential to undertake mass screening program. So that appropriate interventions can be delivered to prolong occurrence of Type 2 diabetes in productive population.

SELENIUM PATHWAY GENOTYPES ARE ASSOCIATED WITH COLORECTAL CANCER RISK AND MODIFIED BY SELENIUM STATUS

[1]Hughes, David; [2]Fedirko, Veronika; [3]Méplan, Catherine; [3]Hesketh, John; [4]Schomburg, Lutz; [5]Jones, Jeb; [4]Hybsier, Sandra; [6]Riboli, Elio; [7]Jenab (on behalf of EPIC group), Mazda.

[1]PhD. Department of Physiology and Centre for Systems Medicine. Royal College of Surgeons in Ireland. Dublin. Ireland; [2]PhD. Rollins School of Public Health. Emory University. Atlanta. USA.; [3]Phd. Institute of Cell and Molecular Biosciences. Newcastle University. Newcastle. UK.; [4]PhD. Institute for Experimental Endocrinology. Charité – Medical University. Berlin. Germany.; [5]MSc. Rollins School of Public Health. Emory University. Atlanta. USA.; [6]MD, PhD. School of Public Health. Imperial College London. London. UK.; [7]PhD. Section of Nutrition and Metabolism. International Agency for Research on Cancer. Lyon. France.

Background and objectives: Suboptimal intakes of the essential micronutrient selenium (Se) and selenoprotein genetic variation may contribute to colorectal cancer (CRC). Here, we examined the associations of single nucleotide polymorphisms (SNPs) in the Se pathway and their Se status interactions with CRC risk in the European Prospective Investigation into Cancer and Nutrition (EPIC) study.

Methods: Using an Illumina Goldengate assay, we simultaneously genotyped all SNPs in 164 Se pathway genes (comprising all 25 selenoprotein genes, selenoprotein biosynthesis / transport genes, and metabolic pathway genes) using 1264 candidate functional and common tagging SNPs. From these assays, 1040 variants in 154 genes were successfully assayed in DNA samples from 1478 CRC case-control pairs matched within EPIC. Multivariate logistic regression was used to determine the association of SNPs in the Se pathway with CRC risk. Pathway and gene based analyses were also performed using the PIGE package Adaptive Rank Truncated test.

Results: Genotypes for 144 SNPs in 63 genes were associated with an altered CRC risk However, none of the associations in the selenoprotein genes remained significant after Benjamini-Hochberg multiple-testing correction, although the Thioredoxin Reductase 1 (TXNRD1) rs11111979 SNP retained significance with gene-wide PACT (P values adjusted for correlated tests) considerations. SNP genotypes in cell-signaling pathway genes (FRZB, SMAD3, and SMAD7) known to be affected by Se intake were also significantly associated with CRC risk after multiple testing adjustments. Additionally, genetic variations were shown to interact with biomarkers of Se status (as assessed by serum Se and Selenoprotein P concentration) to alter CRC risk. Pathway analyses also suggest that SNP only and SNP X Se interactions in selenoprotein, antioxidant, apoptosis and TGF-beta signaling pathways may alter CRC susceptibility risk.

Conclusions: Detailed investigation of Se intake levels and metabolism is needed to further explore relevance for CRC

etio-pathogenesis, especially for individuals of particular Se pathway genotypes and/or those with suboptimal Se status.

Keywords: selenium, selenoproteins, colorectal cancer, single nucleotide polymorphisms, prospective cohort

SORGHUM COOKIES ENRICHED WITH CAROTENOIDS FROM SWEET POTATO KEEP HIGH IRON BIOAVAILABILITY IN WISTAR RATS

[(1)]Martino, Hercia; [(2)]Infante, Rufino Antônio; [(3)]Natal, Dorina Isabel Gomes; [(4)]Moreira, Maria Eliza de Castro; [(5)]Nutti, Marilia R; [(6)]Queiróz, Valéria Aparecida Vieira; [(4)]Bastiani, Maria Inês Dantas.

[(1)]PhD. Professor; [(2)]M.Sc Departamento de Nutrição e Saúde. Universidade Federal de Viçosa. Brazil; [(3)]M.Sc. Departamento de Nutrição e Saúde. Universidade Federal de Viçosa. Brazil.; [(4)]Ph.D. Departamento de Nutrição e Saúde. Universidade Federal de Viçosa. Brazil; [(5)]Harvert plus Manager of Latin America & Caribbean- EMBRAPA Tecnologia de Alimentos. Brazil.; [(6)]PhD Research of EMBRAPA Milho e Sorgo. Brazil.

Background and objectives: Iron deficiency anemia is the most common nutritional disorder worldwide and reaches over 30% of the world's population. Sorghum is a cereal which contain many phenolic compounds and vitamin E, but has low iron levels. Evidences indicated which the carotenoids can increase the iron diet absorption, the mobilization in the liver storage and the erythropoietic process. So the Embrapa is producing in its experimental fields the sweet potato Beauregard biofortified with carotenoids since the sweet potato is a popular root rich in carbohydrates with low glycemic index. The aim of this study was to evaluate the iron bioavailability of the cookies development with sorghum and sweet potato biofortified with carotenoids.

Methods: In the first phase of the experiment, 21 rats were fed with depletion diet Fe-free during three weeks. Following, the rats were divided in three groups: a control ferrous sulphate (AIN-93G) and two tests with the cookies enriched with carotenoids (D-ECD, dry enriched cookie diet; and E-ECD, extruded enriched cookie diet) for two weeks. Were analyzed the biometry, iron bioavailability, total antioxidant capacity (TAC) and genes expression of the duodenum and liver.

Results: The body weight did not differed among the experimental groups, although the weight gain was lower in the group fed with dry enriched cookie diet. In addition, the group fed with D-ECD also had lower food intake but the feed efficiency ratio did not differed among the three groups. Although the difference in iron intake, all bioavailability parameters, hemoglobin, hemoglobin gain, hemoglobin regeneration efficiency, and its relative biologic value were similar to the three experimental groups. TAC in plasma was similar between the groups fed with D-ECD and E-ECD and higher when compared with the AIN-93G due the antioxidant compounds intake. In addition, the expression of the enzymes related with iron metabolic pathways, ferroportin, hephaestin, divalent metal transporter-1 and duodenal cytochrome B,

investigated in the duodenum increased and ferritin investigated in the liver decreased.

Conclusions: Therefore, the addition of sweet potato biofortified with carotenoids increased nutritional value of the sorghum cookies and became potential functional food to prevent or control iron deficiency anemia.

PREVALENCE OF HOSPITAL MALNUTRITION IN CHILDREN UNDER FIVE YEARS OF AGE IN A HOSPITAL OF REFERENCE

[(1)]Peralta Miranda, Lujan Eumelia Margarita; [(2)]Sanabria, Marta.

[(1)]Dra. MSc. Hospital de Clinicas. Facultad de Ciencias Medicas. Universidad Nacional de Asuncion. Paraguay.; [(2)]Dra. MSc. Hospital de Clinicas. Facultad de Ciencias Medicas. Universidad Nacional de Asuncion. Paraguay.

Background and objectives: Malnutrition in hospitalized pediatric patients remains a common finding and a frequent cause of increased morbidity and mortality in children and adolescents. The percentage of intra-hospital infant malnutrition ranges from 6% to 35% and in Latin American hospitals on average 11%. The main objective was to determine the prevalence of hospital malnutrition among children under five years of age admitted to the Pediatric Service of the Clinic Hospital, FCM-UNA.

Methods: Prospective descriptive, longitudinal, observational study included patients of both sexes older than 1 month and under 5 years admitted to the Pediatric Service of the de Clinic Hospital, FCM-UNA during the period from January 1, 2016 to June 30, 2016, whose hospital stay was greater than 48 hours. Sampling: Non-probabilistic of consecutive cases, for convenience. Variables: age, sex, origin, birth weight, gestational age, weight at admission and discharge, height, breastfeeding, beginning of complementary feeding, maternal schooling, maternal occupation, diagnosis of admission, complications, hospitalization days, enteral feeding and / or parenteral, fasting, evolution. Sample size: 361 patients less than five years of age. The nutritional status was evaluated by z Weight/Age, z Weight/Size, z Size/Age) (WHO 2006, ANTHRO). Statistics: parametric and non-parametric measurements. T Student. Significance: p <0.05.

Results: Of a total of 1,183 hospitalized patients, 607 (51.4%) were younger than 5 years, 361 met the inclusion criteria. 51.5% Male; 56% were younger infants, 21% were older infants and 23%

were preschoolers; Age range 1-59 months (average 15.2 m). $\overline{X}$ Days of hospitalization: 7.1 days (2-47 days) At admission, the prevalence of global malnutrition was 25.8%, acute malnutrition 22.4% and chronic malnutrition 28.8%; Hospital malnutrition: 8.2%. Children with malnutrition were characterized by: low birth weight, breastfeeding of less than five months, parents with a monthly family income of a minimum wage, who consulted for a basic pathology. The association of enteral nutrition use and weight gain was significant (p = 0.02). No child presented kwashiorkor. No deaths were recorded.

Conclusions: The prevalence of hospital malnutrition in children under five years of age is 8.2% in a referral hospital. It is higher in the infants group.

Keywords: hospital malnutrition, nutritional status, Infants

University of Hawaii. Hawaii USA; [5]DrPH. Specialist. University of Hawaii Cancer Center. Hawaii. USA; [6]MPH. Data Coordinator. College of Tropical Agriculture and Human Resources. University of Hawaii. Hawaii.; [7]PhD. Professor. College of Natural and Applied Sciences. University of Guam. Guam.; [8]PhD. College of Tropical Agriculture and Human Resources. University of Hawaii. Hawaii.; [9]MPH. Epidemiologist. Pacific Island Health Officers Association. American Samoa.; [10]PhD. Professor. School of Natural Resources and Extension. University of Alaska at Fairbanks. Alaska.

Background and objectives: The US Affiliated Pacific Islands are underserved by the US national health and nutrition monitoring system. The importance of having reliable anthropometric data was highlighted with the recent Zika virus outbreak in the region, with critical sequelae identified with infant head circumference measurements (microcephaly), and for monitoring obesity in a region with the highest rates of obesity and non-communicable disease in the world. The Children's Healthy Living (CHL) Network has expanded its partnership beyond Colleges and Headstart programs to include Departments of Health, in partnership with the Pacific Island Health Officers Association (PIHOA)(CHL USDA/AFRI Grant#: 2011-68001-30335, Novotny R, PI; PIHOA CDC/NACDD Cooperative Agreement # 1412016, Techur-Pedro

A, PI). The CHL Network aims to develop and maintain a regional anthropometric monitoring system through partnerships of land grant colleges and health departments to provide data for decision-making.

Methods: Training, standardization and coordination of research and health program personnel in anthropometric measures were done in 11 jurisdictions, according to protocols developed by CHL and later expanded to 3 age groups: 0-1 y (length, weight, head circumference), 2-10 y (height, weight, waist circumference at the umbilicus), 11+ y (height, weight, waist circumference at the iliac crest)(Li et al. 2015).

Results: Each US affiliated Pacific jurisdiction now has at least 1 standardized anthropometric measurer in at least 1 age group. With a core of regional anthropometric measurers in the 2-10 y range (145 height, 154 weight, 109 waist), measurers are now being trained in infant (24 length, 24 weight, 24 head circumference) and adult measures (52 height, 50 weight, 1 waist circumference). Increasing the number of standardized measurers and developing a sustainable anthropometric monitoring system that includes quality assurance is in process for the region.

Conclusions: College and health leaders in the US affiliated Pacific region have formed a network to provide on-going training and skill development in order to gather and maintain standardized anthropometric information useful for decision making related to non-communicable and communicable diseases critical to the region.

Keywords: Pacific, anthropometry, height, weight, circumferences

THE IMPACT OF TASTE PREFERENCES ON MACRONUTRIENT INTAKE

[1]Dikmen, Derya; [1]Inan-Eroglu, Elif; [2]Ozdemir, Aslihan; [2]Madali, Berna; [3]Ellahi, Basma.

[1]PhD, Nutrition and Dietetics Department, Hacettepe University, Turkey.; [2]MSc, Nutrition and Dietetics Department, Hacettepe University, Turkey.; [3]Prof, PhD, Faculty of Health and Social Care, University of Chester, United Kingdom.

Background and objectives: Recent evidence has suggested that there are multiple links between taste preferences and food choices and the amount of food consumed. In this study, we aimed to investigate whether there is an impact of taste preference on macronutrient consumption in healthy adults.

Methods: This study compromised 46 adults aged between 18-40. Socio-demographic characteristics and anthropometric measurements of the individuals were taken by dietitians. Participants' 24 hour food recall was also taken for determining the nutrient intakes by specialized dietitians. The results were evaluated by the statistical program SPSS.

Results: The great majority of participants reported that they like sweet taste (93.5%). Participants 69.6 % like soury taste and 60.9 % salt taste. Because umami taste is a new taste for consumers, it was found that 50.0% of the participants did not have an idea

about the taste of umami and 28.3% disliked it. The mean energy intake of the participants was 2038.4 ± 678.34 kkal. According to the participants' 24-hour food recalls, the average percentage of energy from carbohydrate, fat and protein intake were 47.9 ± 9.31%, 37.2 ± 8.66% and 14.9 ± 3.50% respectively. The fat intake of the participants who like sweet taste (37.%) was higher than non-likers of the sweet taste (26.3%) (p=0.02). Also participants who like bitter taste fat intake were higher than non-likers of bitter taste (p>0.05). Fat intake levels were lower who likes mostly soury and salty taste when compared to sweet and bitter taste likers. Daily protein intake of the salty (p>0.05) and soury taste (p<0.05) likers were higher than the sweet and bitter taste likers. The participants like salty taste daily protein intake were 5 g higher than the non-likers salty taste (p>0.05).

Conclusions: There was a relation between fat, protein intake of the participants with taste preferences. There are evidence on oral and pharyngeal recognition of the nutrients is proposed as a mechanism for regulating nutrient intake. Further experimental studies need to investigate the taste preference and its affect on nutrient intake .

USE OF COMPUTER VISION TECHNIQUES FOR AUTOMATIC FOOD CLASSIFICATION BY SIZE

[1]Miranda, Juan Carlos; [2]Gonzalez Cespedes, Laura Elizabeth; [3]Aguilar Rabito, Ana Carolina; [4]Vázquez Noguera, José Luís; [4]Legal Ayala, Horacio.

[1]Facultad Politécnica. Universidad Nacional de Asunción; [2]San Lorenzo; [3]Department of Nutrition Research. Facultad de Ciencias Químicas. Universidad Nacional de Asunción; [4]Facultad de Politécnica. Universidad Nacional de Asunción.

Background and objectives: Computer vision (VC) techniques are a novel tool for the food and nutrition area. The classification of foods according to size using VC techniques would allow the estimation of portion sizes and grams, optimize the evaluators time and reduce subjectivity, but research in this area is still incipient. Therefore, we set out to develop an automatic and reproducible method of food classification by size.

Methods: To evaluate the method we used oranges, which are much consumed and are available in the local market. We measured the dimensions (greater diameter) of the oranges with a caliber and weighed each one of them, later we classified them in: small, medium and large. We created a closed environment to obtain high quality images, and developed a program that takes the obtained images as input data and we applied VC techniques which includes image processing, segmentation, extraction of characteristics and classification using the algorithm KNN. Finally we estimated the sensitivity and specificity of the results obtained through the program.

Results: We obtained photographs of 207 oranges (124 used for training of the program (60%) and 83 for the corresponding tests of the same (40%)), the average greater diameter according to the measurements of the expert was 69.1 ± 4.4 millimeters and the obtained from the program was 68.9 ± 4.1. The Pearson correlation showed r = 0.68 (p <0.001). The average difference between the expert and the program measurements was 0.20 ± 3.4 (p> 0.05). After 100 training with random assignment of oranges in the ratio of 60% to 40%, the program had a sensitivity and specificity equal to 1.0.

Conclusions: The proposed method could provide assistance to nutrition professionals in the process of estimating the size of foods and consequently portions and grams. The database of images and physical measurements generated would enable more studies in the area.

IDENTIFYING DIETARY STRATEGIES TO IMPROVE NUTRIENT ADEQUACY AMONG ETHIOPIAN INFANTS AND YOUNG CHILDREN USING LINEAR MODELLING

[1]Samuel, Aregash; [2]Osendarp, Saskia; [3]Ferguson, Elaine; [4]Borgonjen, Karin; [5]Alvarado, Brenda M.; [6]Neufeld, Lynnette M.; [7]Adish, Abdul Aziz; [8]Kebebe, Amha; [9]Weuhler, Sara; [10]Brouwer, Ingeborg.

[1]Msc. Nutritionist. Division fo Human Nutrition. Wageningen University. The Netherlands. Ethiopian Public HEalth Institute. Addis Ababa. Ethiopia.; [2]PhD. Nutritionist. Division of Human Nutrition. Wageningen University. The Netherlands. Micronutrient Initiative. Canada.; [3]PhD. London School of Health and Tropical Medicin. United Kingdom; [4]Bsc. Research Dietician. Division of Human Nutrition. Wageningen University. The Netherlands.; [5]MSc. Division of Human Nutrition. Wageningen University. The Netherlands; [6]PhD. Global Alliance for Nutrition. Geneva. Switserland; [7]Micronutrient Initiative. Addis Ababa. Ethiopia.; [8]Ethiopian Public Health Institute. Addis Ababa. Ethiopia.; [9]Micronutrient Initiative. Canada.; [10]PhD. Nutritionist. Division of Human Nutrition. Wageningen University. The Netherlands.

Background and objectives: Optimal Infant and Young Child Feeding practices are crucial for child survival but lack guidance from local food-based dietary guidelines, that incorporate fortified products, to ensure nutrient adequacy in Ethiopia.

Methods: Based on data from the Ethiopian National Food Consumption Survey, linear programming (LP, Optifood) was used to identify nutrients lacking in local diets of young children (6-8, 9-11 and 12-23 months) and to formulate realistic Food Based Dietary Recommendations (FBDR) for improved nutrient adequacy in four regions by comparing alternative approaches of local complementary foods, micronutrient powders (MNPs), Small quantity Lipid based Nutrient Supplement (Sq-LNS) and combinations of these.

Results: Optimised local diets provided inadequate zinc in all regions and age groups, inadequate iron for infants < 1 year of age

in all regions, and inadequate calcium, niacin, thiamin, folate, vitamin B12 and B6 in some regions and age-groups, but not in all. The set of regional FBDRs were significantly different for the four regions thus development of one general national FBDRs will be a challenge. Promoting a more diverse diet such as increasing vegetables, legumes and animal source food consumption improves nutrient profile of the diet to a certain extent. Nevertheless even after the FBDRs; some nutrient intakes remain suboptimal.

Conclusions: The best nutritional option to solve the nutrient gaps identified is a combination of regional FBDRs with MNP supplementation. It is important to emphasize that MNP should not replace the feeding recommendations, but should be promoted in addition to these FBDRs together with breast-feeding on demand during the first two years of age.

Keywords: Complementary food, Optifood analysis, food based dietary recommendations, problem nutrients, young children.

Universidade Federal de São Paulo. São Paulo. Brazil; [7]MD. Nutrition and Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina.

Background and objectives: Obesity's comorbidities are the major cause of morbidity and less quality of life in adult population all over the world. The aim of this study was to evaluate the prevalence of overweight (OW), obesity (OB) and underweight (UW) in a representative sample population of Argentina.

Methods: Data were obtained from 1266 Argentines participating in The Latin American Health and Nutrition Study (ELANS), a multicenter study of a nationally representative randomized sample of urban population of 8 LA countries between November 2014 and July 2015. The sample had a multistage design stratified by geographical location (6 regions), age (15-65 y), gender and Socio Economic Level (SEL). A standard study protocol was designed to evaluate 6 anthropometric measurements including weight and height. A questionnaire to classify SEL was administered. Sample expansion factors were calculated and descriptive statistical data analysis was performed with SPSS Statistics 20.

Results: Overall OW, OB and UW prevalence were 32.2%, 23.2% and 4.9% respectively. Analyzing by gender, up to 20 years of age, the prevalence of OW including OB was higher for men, but OB prevalence was higher for woman between 35 and 49 y (32.1% vs. 23.3%). On the other hand, the prevalence of UW, up to 20 years old, was higher for women (12.4% for 20-34 y). Comparing by SEL (high, medium and low) OW including OB prevalence was 61.8%, 57.4% and 52.7% respectively, while the highest prevalence of UW (5.7%) was observed on low SEL population. Analyzing by region the prevalence of OW including OB was higher for men in Buenos Aires Metropolitan Area, Cuyo and South regions (65.2%, 72.8%, 65.2%), while for women was higher in Pampeana, Northwest and Northeast regions (58.5%, 56.8%, 55.7%). South region had the highest prevalence of OW including OB (63.1%) while Pampeana region had the highest prevalence of UW (8.1%).

Conclusions: More than 50% of the Argentine population is above the BMI considered healthy. Minimal differences were found between genders and regions but a special public health consideration should be centered in the trans-generational tracking of adiposity in woman.

Keywords: Nutritional Status, Argentine population, multicenter study

Universidade Federal de São Paulo. São Paulo. Brazil; [7]MD. Nutrition and Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina.

Background and objectives: The consumption of calcium is associated both with the prevention of many diseases and also with quality of life (1). This study aimed to identify the adequacy of calcium intake among Argentine population.

(1) Mueller, N. T., & Appel, L. J. (2017). Attributing Death to Diet: Precision Counts. Jama, 317(9), 908-909.

Methods: Data were obtained from 1266 Argentines participating in Latin American Health and Nutrition Study (ELANS), a multicenter study of a nationally representative randomized sample of urban population of 8 LA countries, developed between November 2014 and July 2015. The sample by country had a multistage design stratified by region, age (15-65 y), gender and SEL. A standard study protocol was designed to evaluate nutritional intake assessed by two 24-hour recalls, analyzed with the Nutrition Data System for Research (NDS-R) from Minnesota University, after a standardization process between local food and NDS-R database. Calcium usual intake was estimated with the Multiple Source Method (MSM) statistic package (https://nugo.dife.de/msm) and adequacy estimated in comparisons with Recommended Dietary Allowances (RDA) (IOM standards). Sample expansion factors were calculated and descriptive statistical data analysis was performed with SPSS Statistics 20.

Results: Median of usual consumption of the whole sample was 777 and 689 mg/day in men and women respectively. Both female adolescents and women above 50 consume a median of 50% of RDAs: 646.1 and 655,4 mg/day respectively, adding that 99% and 98,5% of the population of those groups of ages were below recommendations. Although the RDA decreases at 20-49 y, the prevalence of inadequate usual intake was 90.9%-86.9%. Younger males (15-19) and older ones (50-65) consume more calcium than women of same ages (855.7 mg/day and 746,7 respectively) but, the prevalence of inadequate usual intake was 94.4% and 90.3% respectively, for equal RDAs.

Conclusions: The prevalence of inadequate usual intake of calcium for Argentine population, at every age range and gender is very high. These results reinforce the importance of public health programs focused on increasing calcium consumption and implementing micronutrients fortification specially in women.

Keywords: Calcium, inadequate usual intake, Argentinian population, multicenter study.

CHARACTERISTICS OF THE DIET IN THE ARGENTINE POPULATION. RESULTS OF ELANS STUDY

[1]Favieri, Andrea Lorena; [2]Guajardo, Viviana Beatriz; [3]Nogueira Previdelli, Agatha; [4]Gerardi, Alejandro; [5]Gómez Salas, Georgina; [6]Fisberg, Mauro; [7]Kovalskys, Irina.

[1]BSc. Nutritionist. Nutrition and Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina; [2]BSc. Psychologist. Nutrition and Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina; [3]PhD. Professor. Faculdade de Ciências Biológicas e da Saúde. Universidade São Judas Tadeu São Paulo. Brazil; [4]BSc. Sociologist. Nutrition and Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina; [5]MSc. Professor. Departamento de Bioquímica. Escuela de Medicina. Universidade Federal de São Paulo. São Paulo. Brazil; [7]MD. Nutrition and Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina.

Background and objectives: The diet is determinant in the development of chronic diseases. The aim of this study was to assess energy intake (EI) and macronutrients intake (MI) and distribution (MD) of the Argentine population

Methods: Data from 1266 Argentine people (15-65 y) participating in the Latin American Health and Nutrition Study (ELANS), a multicenter study developed in urban areas of 8 LA countries. Intake was assessed by two face to face 24-hour recalls (November 2014-July 2015), and processed by the software Nutritional Data System for Research (NDS-R). Daily intake was analyzed by age, gender, socioeconomic level (SEL) and region (Buenos Aires Metropolitan Area, Cuyo, Pampeana, Northwest,

Northeast and South). The median values of EI and MI and percentages of MD were calculated. Sample expansion factors were calculated and descriptive statistical data analysis was performed with SPSS 20.

Results: The median of EI was 2154 kcal/day (2434 kcal/day in men and 1911 kcal/day in women). The MI was 271 g/day of carbohydrates, 85 g/day of protein and 78 g /day of fat (51%, 16% and 33% of EI respectively). Saturated fats accounted for 11.5%, monounsaturated fat 10.3% and polyunsaturated fat 7.7% of EI. The cholesterol intake was 375 mg/day. The added sugar was 15% of the EI. It was observed that EI decreased inversely with age (2667 kcal/day in men aged 15 to 19 years and 1712 kcal/day in women between 50 and 65 years)., EI values showed no differences by SEL. In men, differences were found in MD: high SEL men increased proportion of fats and proteins (35% and 17% respectively) in comparison with low SEL men (32 and 15%). EI was not different due to a compensation effect of CHO. By region, EI ranged from 1994 kcal/day in the Pampeana region to 2307 kcal/day in the Northwest. No significant differences were found in MD by age.

Conclusions: In Argentina, population diet showed high levels of critical nutrients as saturated fats, cholesterol, and added sugars, all related to cardiovascular disease and metabolic syndrome. Differences by region and by SEL were found and should be taken into account by public health stakeholders.

Keywords: Energy intake, macronutrients, Argentine population, multicenter study.

fat distribution. In this regard, a new index, called the Lipid Accumulation Product (LAP), has been proposed. The aim of this study was to compare LAP and BMI measurements and to determine cutoff point values for LAP and BMI in apparently healthy Brazilian adults men.

Methods: A cross-sectional study was conducted with 130 apparently healthy Brazilian adults men (20-59 years). Anthropometric data, including weight, height and waist circumference, were determined. Triglycerides were determined by enzymatic colorimetric method. The lipid accumulation product was calculated as (waist circumference [cm] − 65) × (triglycerides concentration [mM]). Percentage of body fat mass was obtained by Tetrapolar Bioelectrical Impedance Analysis. It was considered as cutoff point for elevated percentage of body fat mass values ≥ 25%. The statistical analysis consisted in construction of ROC curves (Receiver Operating Characteristic Curve) and was carried out using Medcalc version 12.7.

Results: A strong correlation was found between BMI and percentage of body fat mass (r=0.71; p<0.001). BMI and LAP also showed a strong correlation (r=0.67; p<0,001), as well as, LAP and percentage of body fat mass (r=0.69; p<0,001). According to these results, the ROC curve analysis showed accuracy for BMI (AUC=0.886±0.057) and for LAP (AUC=0.823±0.068) regarding the discriminatory ability for detect elevated percentage of body fat mass. The cutoff point value of 39.3 cm.mmol/L for LAP provided a sensitivity of 73.3% (95% CI: 44.9-92.0%) and specificity of 81.7% (95% CI: 73.4-88.3). Whereas, the cutoff point value of 27.1 kg/m2 for BMI provided a sensitivity of 86.7% (95% CI: 59.5-98.0) and specificity was 88.7% (95% CI: 81.4-93.8%).

Conclusions: The LAP may be an alternative to measure adiposity; however, the BMI is a simple, inexpensive and reliable tool that showed great ability in discriminating elevated values of percentage of body fat mass in apparently healthy Brazilian adults men.

ANTHROPOMETRY AND THE MEAL PATTERNS AMONG UNIVERSITY STUDENTS IN KENITRA CITY, MOROCCO

[1]madane, salwa; [2]Sbaibi, Rachid; [2]Aboussaleh, Youssef.

[1]PhD.Laboratory of Nutrition Health and Environment. Department of Biology. Faculty of Sciences. University Ibn Tofail. Kénitra. Morocco; [2]PhD. Nutritionist. Laboratory of Nutrition Health and Environment. Department of Biology. Faculty of Sciences. University Ibn Tofail.Kénitra. Morocco.

Background and objectives: Morocco, in full economic, social and cultural transition, experiencing urbanization increasingly greater causing changes in lifestyle and dietary habits. The objective of this study was to evaluate nutritional status by Anthropometry and determines the meal patterns of university students in Kenitra city, Morocco.

Methods: The anthropometric survey was conducted on 150 university students with average age (24.15years ± 4.6). Body Mass Index (BMI) was adopted to evaluate nutritional status by Anthropometry. A self-administered questionnaire was used to collect data about sociodemographic features of the students and their families, as well as meal habits of students.

Results: The finding showed an average Height of subject (1,64m ± 0,1 cm), the mean weight was (60.9 kg ± 10.7 kg); the mean of IMC (22.36+3.5); stunting (10%), thinness (9.3%), a risk of overweight (16%) and obesity (1.3%). About 73.7% of students eat three meals per day (70,7% for breakfast, 87,7% for lunch and 62,7% for diner). Snacks were eaten daily by 60 % of students. The majority drinks at breakfast tea (39.3%), coffee (13.3%) and eat Bread, cheese and olive oil (53. 3%).At the lunch, students eat bread (84%) with Tajine of meat (39%) and fruits (71.3%). At the dinner, most students eat bread)66.7%(and the pasta or tajine with meat (48%). 68.7% hydrate daily (1.7L per day),62% consume daily fruits and vegetable.

Conclusions: Students practice meals based on cereals. Interventions are needed to promote healthy eating habits among students.

NECK CIRCUMFERENCE TO IDENTIFY EXCESS ADIPOSITY IN HOSPITALIZED PATIENTS

[1]Aparecida da Silva Alvarenga, Adriana; [1]Mendes Lisboa, Adriana; [2]de Lucena Ferretti, Roberta.

[1]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil; [2]PhD student. MD. Federal University of Sao Paulo. Department of Pediatrics. University of Taubate. Sao Paulo. Brazil.

Background and objectives: Obesity has a great impact on health, due to its complications. Anthropometric measures are able to identify the upper-body subcutaneous fat accumulation, such as neck circumference (NC), which presents a strong correlation with adiposity. The objectives of this study was to evaluate the prevalence of adult and elderly patients hospitalized with excess adiposity through NC, and verify the correlation of NC with BMI (Body Mass Index) in these patients.

Methods: A cross-sectional study, with secondary data from a hospital in the city of Taubate, Sao Paulo, which evaluated hospitalized adults and elderly, among February 2015 and May 2016. The variables analyzed were weight, height, BMI, NC, sex and age . For classification of nutritional status, the cutoff points proposed by the World Health Organization (1995), for adults and Lipschitz for the elderly (1994), were used. The cutoff points for elevated NC were 37 and 34 cm, for men and women, respectively. Data analysis was performed using descriptive statistics. Pearson's correlation test was performed to verify the correlation between NC and BMI.

Results: Among 628 patients selected, 579 were the final sample, of which 53.88% (n = 312) were female. The mean age, for the female and male sex was 66.2 ± 15.78 and 63.48 ± 13.88, respectively. It was verified that 76% of the female patients and 67.4% of the male patients presented elevated NC. Considering the groups of patients with and without overweight by BMI, 65.82% and 34.17% of the women, 64.44% and 35.55% of the men presented elevated NC, respectively. There was a strong correlation between NC and BMI for males (r = 0.85) and female (r = 0.90).

Conclusions: It was concluded that there was high correlation between NC and BMI for both sexes, and higher prevalence of overweight women who presented elevated NC. In relation to the non-overweight patients, there was a higher prevalence of males for this outcome.

Keywords: Neck Circumference, Anthropometry, Excess Adiposity, Hospitalized Patients.

UNDERREPORTING OF ENERGY INTAKE IN A PROBABILITY SAMPLE OF THE BRAZILIAN ADULT POPULATION

Anjos, Luiz Antonio.

MD, PhD. Professor. Universidade Federal Fluminense.

Background and objectives: Energy intake (EI) is an important measure in detailed nutritional assessment in clinical and re-

search settings. However, there has been recent strong criticism on the self-reported methods used to obtain EI in populations, which yield low, unexplained, and sometimes unusable, values primarily in women and obese. The EI/basal metabolic rate (BMR) ratio has been suggested to provide clues on who underreports EI. In 2008, EI was obtained in a probability sample of the Brazilian 10y+ population by a 24h dietary recall (24HDR). This study reports the relationship between EI and BMR of the sub-sample of Brazilian adults (≥20y) in an attempt to quantify the level of EI underreporting.

Methods: Data from 25949 subjects (14052 women) aged 20-104y were used in the analysis. BMR was estimated by two set of equations: 1) the Schofield equations using body mass and stature (SCHO) suggested to be used internationally by FAO/WHO and 2) equations developed in a probability sample of the adult population of Niterói, a urban area in the Metropolitan area of Rio de Janeiro, Brazil (BRA). The latter equations have been validated in adults from the same town. EI/BMR of 1.53 was used as the cutoff to identify underreporting. The values were weighted to represent the Brazilian adult population.

Results: Overall mean (95%CI) EI was 1728.6 (1719.3;1737.9) kcal/day, being higher in men (1941.4, 1926.4;1956.5) than in women (1521.6, 1510.9;1532.2) kcal/day. Estimated BMR by the SCHO equations (1523.6, 1520.6;1526.5kcal/day) was significantly higher than the BRA equations (1259.5, 1257.0;1262.0kcal/day). Mean EI/BMR ratio varied from 1.06 to 1.21 depending on age and sex when the SCHO equations were used and between 1.26 and 1.48 with the BRA equations. EI underreporting varied from 78 to 88% when using the SCHO equations and 59 to 74% when the BRA equations were used. Using the latter equations, underreporting was 64% and 69% in all men and women, respectively.

Conclusions: EI assessed by a 24hDR is underestimated by more than 60% of the Brazilian adult population. Caution is warranted when using 24hDR to estimate EI in adults in Brazil.

ger, satiety and binge eating scale scores on caloric estimation in healthy subjects.

Methods: This study was conducted with 46 healthy volunteers in Ankara, Turkey. Anthropometric measurements, body compositions were examined. Binge eating scale was evaluated on participants to identify the risk of binge eating disorder. Moreover, 24-hour recall food records were taken from subjects. To determine the effect of hunger and satiety situations on caloric estimations of some specific foods, a protocol was developed. Participants were asked to estimate the energy content of the foods in hunger and satiety status.

Results: The mean age of subjects was 22,9±4,4, and mean BMI was 22,5±2,6 kg/m2. According to Binge Eating Scale, 84,8% of participants' binge eating scores were low. Non-binging subjects estimated calorie content of CHO-based foods eg. green beans, chocolate, potato chips, and fried potatoes lower when they were hungry (p<0,05). Subjects who had moderate binge eating scores estimated calorie content of apple higher when they are satiated (p<0,05) when compared with hunger situation. According to data obtained from food records, 60,9% of subjects consumed higher energy from CHO. Estimations on calorie contents of CHO content foods apple, bread, and fried potatoes of these subjects were statistically different in hunger and satiety conditions (p<0,05).

Conclusions: This study shows that there is a significant association between hunger status and caloric estimations. Especially carbohydrate consumption affects predictions about foods that contain more carbohydrate. Further studies are required to investigate the relation between binge eating, carbohydrate consumption and caloric estimations.

Keywords: hunger, satiety, binge eating, caloric estimation

HUNGER, SATIETY AND BINGE EATING ; IS THERE A DIFFERENCE ON CALORIC ESTIMATION OF CHO-BASED FOODS?

[1]Ozdemir, Aslihan; [2]Madali, Berna; [3]Dikmen, Derya; [4]Inan-Eroglu, Elif; [5]Ellahi, Basma.

[1]MSc, Nutrition and Dietetics Department, Hacettepe University, Turkey; [2]MSc. Nutrition and Dietetics Department. Hacettepe University. Turkey; [3]PhD. Nutrition and Dietetics Department. Hacettepe University. Turkey; [4]PhD. Nutrition and Dietetics Department, Hacettepe University, Turkey; [5]PhD. Faculty of Health and Social Care. University of Chester. United Kingdom.

Background and objectives: Estimation of calories in foods is crucial in the maintenance of body weight and energy regulation. Binge eating is defined as eating an unusually large amount of food in a short period and experiencing a loss-of-control over eating. In this study, we aimed to investigate the effects of hun-

ACCURACY AND RELIABILITY OF A LOW-COST, HANDHELD 3D IMAGING SYSTEM FOR CHILD ANTHROPOMETRY

[1]Conkle, Joel; [2]Ramakrishnan, Usha; [2]Suchdev, Parminder S.; [3]Alexander, Eugene; [2]Martorell, Reynaldo.

[1]MPH, Doctoral Program in Nutrition and Health Sciences. Laney Graduate School. Emory University, USA; [2]PhD. Hubert Department of Global Health. Rollins School of Public Health. Doctoral Program in Nutrition and Health Sciences. Laney Graduate School. Emory University. Atlanta, GA, USA; [3]Body Surface Translations, Inc.

Background and objectives: Body measurement, or anthropometry, is used to assess child growth and body composition. Anthropometry is used in clinical settings to identify and manage malnutrition, and in national surveys to guide nutrition programs. The usefulness of anthropometry however is undermined by poor measurement quality, which has led to calls for improved quality and/or new approaches. We evaluated the potential of a three-dimensional (3D) imaging system to replace the current gold standard of non-digital, manual measurements for child stature (length or height), head circumference (HC) and mid-upper arm circumference (MUAC).

Methods: Five trained anthropometrists measured 474 apparently healthy children 0-5 years of age in Atlanta, USA from September 2016 to February 2017. For manual measurements, we followed training and measurement techniques used to develop the 2006 WHO Growth Standards. Anthropometrists took 3D scans of children using an iPad Air® with Occipital Structure Sensor and custom software developed by Body Surface Translations. We analyzed the quality of manual measurements using the 2006 WHO Growth Standards to calculate z-scores and define biological plausibility. We evaluated the accuracy of scan-derived measurements against manual measurements using average bias and Bland-Altman Plots; for reliability, we calculated intra- and inter-observer Technical Error of Measurement (TEM) and Coefficient of Reliability.

Results: 99.8% of manual measurements were biologically plausible, and the z-score standard deviations (SD) were close to 1.0 for all anthropometric indices, ranging from 0.92 for weight-for-height to 1.07 for height-for-age. Z-score variances among children under 2 years did not differ from those 2 or more based on Levene's Test. Inter- and intra-observer TEM was below 0.35 cm for all manual measurements. We are still analyzing the accuracy and reliability of scan-derived measurements.

Conclusions: We collected high quality manual anthropometry. If accurate and reliable, 3D imaging could help to improve the efficiency, precision and accuracy of child anthropometry. Expensive 3D imaging systems are already used in the garment industry for adult anthropometry. The 3D scanner and associated software we used in this study are low-cost, mobile and can handle movement; possibly extending the use of 3D imaging for diagnostic purposes.

Keywords: anthropometry; 3D; imaging; accuracy; reliability

THE PILOT KOREAN KEY FOODS BASED ON DIET CONSUMPTION

[1]Chang, Moon Jeong; [2]Shim, Jee Seon; [1]Lee, Jung Sug; [3]Kim, Hye Young; [4]Lee, Hyun Sook; [5]Kim, Ki Nam.

[1]PhD. Department of Food and Nutrition. Kookmin University. Republic of Korea.; [2]PhD. Medical College. Yonsei University. Republic of Korea.; [3]PhD. Department of Food and Nutrition. Yongin University. Republic of Korea.; [4]PhD. Department of Food and Nutrition. Dongseo University. Republic of Korea.; [5]PhD. Department of Food and Nutrition. Daejeon University. Republic of Korea.

Background and objectives: This study was performed to develop the Key Foods approach to select foods for nutrient analysis of up-to-date National Food Nutrient Composition Database. The primary objective of nutrient composition database in Korea is to provide the information to represent the nutrients consumed by Korean population, especially the nutrient profile for each food identified as important in the food consumption. The Key Food approach assists database system to prioritize foods that contribute significant amounts of nutrients of public health interest to the diet.

Methods: The Key Foods approach used 16 nutrients and energy (Key Nutrients) of public health significance identified in the intake data from Korea National Health and Nutrition Examination Survey(KNHANES) 2013-2014. The recipe file from KNHANES containing the list of ingredients and their amounts was used to identify the Key Foods. At first, foods list that contributed to the intake of each nutrient was selected using recipe code from raw data of KNHANES. Then, we determined foods that contributed the most to intake across all key nutrients. After selecting foods list, Key Foods were identified as those food components that contribute up to 85% of any one nutrient of Key Nutrients.

Results: From this procedure, 570 primary Key Foods were aggregated, which account for approximately 90.5% of the contribution of the nutrient consumption for the Korean diet. 456 Key foods were identified after further refinement procedure to insure that we have a representative list of what Korean eat by considering some foods that are not widely consumed by the Korean population.

Conclusions: This Key Foods list will be used for updating and revising the National Food Nutrient Composition Database from 2017 and concentrating resources for food composition analysis in Korea. We expect the updating database will give representative data for researchers, etc.

BRAZILIAN NUT INTAKE HAS NO INFLUENCE ON BODY COMPOSITION IN OBESE WOMEN

[1]Biude Silva Duarte, Graziela; [2]Zavarize Reis, Bruna; [3]Cercato, Cintia; [4]Macedo Rogero, Marcelo; [5]Maria Franciscato Cozzolino, Silvia.

[1]MSc. Nutritionist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Science. University of São Paulo; [2]MSc. Nutritionist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Science. University of São Paulo.; [3]PhD. Department of Endocrinology. Faculty of Medicine. University of São Paulo.; [4]PhD. Nutritionist. Department of Nutrition. School of Public Health. University of São Paulo; [5]PhD. Nutritionist. Department of Food and Experimental Nutrition. Faculty of Pharmaceutical Science. University of São Paulo.

Background and objectives: Nuts are considered to have an optimal energy density and a good source of lipids, especially unsaturated fatty acids. One Brazilian nut provides approximately 35,3kcal and 3,24g of total lipids, mainly monounsaturated fatty acids. The daily consumption of this food has been associated with the improvement of lipid profile and risk reduction of cardiovascular diseases. However, there is a concern about the possible effects of the daily intake of nuts on weight gain. Thus, the aim of this study was to investigate the effects of Brazilian nuts (Bertholletia excelsa H.B.K.) intake on body composition of obese women.

Methods: We enrolled 72 obese women recruited in the outpatient clinic of endocrinology from Clinics Hospital of São Paulo, Brazil. They were randomly assigned to either ingestion of Brazil nuts (BN) group or control (CO) group and they were followed up for 2 months. Participants of the treatment group consumed one Brazilian nut daily and the control group avoided the intake of any food containing the nut for the same period of time. On baseline and after two months of follow-up were assessed weight and height for the calculation of body mass index (BMI), waist circumference (WC) and percentage of body fat (%BF). Repeated measures ANOVA analyses were performed using SPSS 18.0 software to evaluate the effect of supplementation time with Brazilian nuts on the variables mentioned above.

Results: Twenty-nine participants of the treated group (BN) and twenty-six of the control group (CO) completed the trial. The mean age of BN and CO group was 40,3±9,0 and 39,4±9,5 (P=0,714) respectively. For BN and CO groups, no significant differences were observed for weight (ΔAfter-Before= -0,50) (ΔAfter-Before= 0,20) (P=0,723), BMI (ΔAfter-Before= -0,10) (ΔAfter-Before=0,10) (P=0,784), WC (ΔAfter-Before= -1,10) (ΔAfter-Before= 2,50) (P=0,111) and %BF (ΔAfter-Before= 0,30) (ΔAfter-Before= -0,10) (P=0,587).

Conclusions: The data show that Brazilian nut consumption for two months has no effect on the body composition of obese women.

A MODEL FOR DIGITALIZATION OF THE NUTRITION JOURNEY – CASE INSIGHTS FROM THE NUTRIDIA APP DEVELOPMENT FOR CANCER PATIENT COUNSELLING

[1]Mikkelsen, Bent Egberg; [1]Mikkelsen, Bent Egberg; [2]Clausen, Katja Serup; [3]Holst, Mette.

[1]PhD. Professor. Department of Clinical Medicine. Captive Foodscape Studies. Aalborg University. Copenhagen. Denmark.; [2]MSc. Department of Civilengineering. Aalborg University. Denmark; [3]PhD. Center for Nutrition and Bowel Disease. Department of Gastroenterology. Aalborg University Hospital & Department of Clinical Medicine, Aalborg University. Denmark.

Background and objectives: Shared decision making is relevant to nutrition counselling for patients who have diminished food intake, and suffer from cancer and therapy related riskfactors. Shared decision making however requires the patient to be well informed, and the professional to have access to updated information on the patients foodintake and riskfactors as nausea, mouthproblems i.e. So far nutritional apps seem to have been inspired more by experience economy than by nutrition science. The objective of NutriDia was to digitalize the nutrition counselling in a transparent and beneficial manner for the client while at the same time making the most of the expert knowledge of nutritionists and app developers, in order to enhance shared decision making for the individualised nutrition plan.

Methods: Development was set in the University Hospital Nutrition Centre with a professional app developer as partner and with university scientific team as evaluators. Evaluation performed observation and interviews with patients and professionals in consecutive app intermezzo's. The "sprint" concept from Agile software development was adopted. It defines principles for software development under which user requirements are specified and solutions are returned through efforts of a multidisciplinary team. It is adaptive and aims at early delivery and continuous improvement to secure flexible and rapid response to user wishes. Two versions were developed – one for the counsellors and one for patients supporting the dialogue in the presence of both patient and counselor.

Results: Patients took high interest in the patient APP that ended up user friendly to a large group of cancer patients, regardless of age and diagnose. Professionals were in general in agreement that the professional future will be "app'tized" and patient focused. For both groups early and instructed introduction was viewed as important. For both groups the visual appearance and straightforwardness of the app was found essential to user loyalty. Professionals however found it difficult that the software under the development did not "speak" with other clinical software, and has to be opened separately.

Conclusions: The sprinted mode of working involving clients, practitioners and developers in an evidence based environment is a useful method for future nutrition app'tisation.

MAN OR MACHINE – A REVIEW OF SMART ICT ASSISTED REALTIME DIETARY ASSESSMENT TECHNOLOGIES (RDAT) FOR AUTOMATED DIETARY DATA ASSESSMENT

Mikkelsen, Bent Egberg.

PhD. Professor. Department of Clinical Medicine. Captive Foodscape Studies. Aalborg University. Copenhagen. Denmark.

Background and objectives: Data collection in dietary intake studies using traditional methods is costly and time consuming. As a result ICT assisted measurement of dietary behavior has attracted interest from the nutrition research community and a number of groups across the world has through different trajectories tried to reduce the workload related to determining food intake. The aim of the study it to present an overview of smart ICT assisted devices for automated dietary data assessment – here referred to as Realtime Dietary Assessment Technologies (RDAT

Methods: A literature search was conducted using the key words ICT assisted, app, devices, technology assisted automated, dietary data, food intake, assessment collection. In order to exclude ICT based solutions only replacing paper based methods with screen based ones, the study used as inclusion criteria was that methods should be based on < 1 hardware component. In addition, a network search was carried out based on snowballing technique in which known authors, research groups and technology acronyms was used as search terms. Only technologies that was reported scientifically was included. The search identified 8 technologies that was analyzed further

Results: The literature search identified the following Realtime Dietary Assessment Technologies (RDAT): eButton, Dietary intake Monitoring System (DIMS), Splendid, Smart Meal, Mandometer Technology and Technology Assisted Dietary Assesment (TADA). The review showed that the following specialized hardware based components was used in order to automatize the recognition of types and amounts of food: scales, jawbone motion, fork motion, imaging, picture recognition, spectrophotometry, Near InfraRed (NIR) technology and Near Field Communication (NFC).

Conclusions: The technologies identified all minimizes human involvement and involve novel combinations of various technology-solutions. All technologies are based on combinations of "intake signals" and uses a mix of different intake proxies. They include measuring jawbone and or fork movement as proxies, measuring chewing noise, measuring weight of plated food, math-based algorithms for automated or semi automated pictures recognition and artificial intelligence based recognition. The technologies are currently undergoing validation and feasibility studies. We conclude that more interdisciplinary research involving both nutritionists and digital media scientists is needed as well as more cooperation and knowledge sharing between involved research groups.

NUTRITIONAL PROFILE OF JIU JITSU FIGHTERS AND ANALYSIS OF ITS KNOWLEDGE REGARDING DIET GRACIE

[1]*Auler, Flavia;* [2]*Macedo, Ana Carolina Gonçalves de;* [2]*Meucci, Nayara Ramos.*

[1]PhD. Nutricionist. Pontifical University Catholical of Paraná; Argentina [2]Nutricionist. Pontifical University Catholical of Paraná. Argentina.

Background and objectives: The Gracie Diet, created by Carlos Gracie (precursors of Brazilian jiu-jitsu), has as main objective to maintain a slightly alkaline blood pH through food combinations divided into groups in order to prevent chemical reactions harmful to the organism. Thus, the objective was to analyze body composition and diet under the principles of the Gracie Diet in jiu-jitsu fighters.

Methods: A cross-sectional field study with a descriptive analysis and a quantitative approach involving jiu-jitsu fighters, only men between 18 and 29 years of age, enrolled in a state competition, excluding those classified as obese by BMI (WHO, 1997). Data collection was based on individual interview about personal details, food and knowledge of the Gracie Diet. The anthropometric assessment was carried out by GC% arising from Guedes protocol (2010) with Fleck classification (1983) and Wilmore (1983) and BMI (WHO, 1997).

Results: Information of 69 fighters were collected, and 84% had excess body fat and 51% overweight and 80% did not conform to the recommendations of the Food Guide for the Brazilian Population (BRAZIL, 2005). As for the Gracie Diet, 67% claimed to know it, but only one fighter followed. Most followed principles as washing hands before meals (88%), at bedtime drink water (59%), not to consume alcohol (56%) and 10% non-mixed grains and / or starches together. The dietary maneuvers were used by 30% of the fighters, and supplements by 46%, of which, 44% under nutritionist prescription.

Conclusions: In view of these results, it was concluded that the majority of the study participants did not present a body composition comparable to the established standards for the sports modality and did not conform to the recommendations of the Brazilian Population Food Guide. A greater number of connoisseurs and followers of the Gracie Diet was expected, as this is widely known in the midst of martial arts. Therefore, it is believed that there is a disinterest of the fighters or lack of knowledge related to diet, and an urgent need to raise awareness about the role of nutritional guidance in sports performance, so that there is performance allied to health.

Keywords: Jiu jitsu, nutrition, body composition, anthropometry, Gracie Diet.

COMPARISON OF SOCIODEMOGRAPHIC AND NUTRITIONAL CHARACTERISTICS BETWEEN VEGETARIANS, VEGANS AND MEAT EATERS FROM THE NUTRINET-SANTÉ STUDY

[1]Allès, Benjamin; [2]Baudry, Julia; [2]Méjean, Caroline; [2]Touvier, Mathilde; [2]Péneau, Sandrine; [3]Hercberg, Serge; [2]Kesse-Guyot, Emmanuelle.

[1]Equipe de Recherche en Epidémiologie Nutritionnelle, Centre de Recherche en Epidémiologie et Statistiques, Inserm (U1153), Inra (U1125), Cnam, Université Paris 13, COMUE Sorbonne Paris Cité, Bobigny. France.; [2]PhD. Université Paris 13.Equipe de Recherche en Epidémiologie Nutritionnelle, Centre de Recherche en Epidémiologie et Statistiques. Inserm (U1153), Inra (U1125), Cnam. France; [3]Prof. MD. Université Paris 13.Equipe de Recherche en Epidémiologie Nutritionnelle, Centre de Recherche en Epidémiologie et Statistiques. Inserm (U1153), Inra (U1125), Cnam. France.

Background and objectives: Vegetarian and vegan diets are a growing trend in many western countries. Epidemiological evidence suggesting that such diets may help in maintaining a good health is rising. However, dietary and sociodemographic characteristics of vegetarian and vegan consumers are not well known. The aim of this cross-sectional study was to describe sociodemographic and nutritional characteristics of vegetarians and vegans adults, compared to meat-eaters, from the French NutriNet-Santé study.

Methods: Participants were classified into 3 diet groups based on self-reported information: 90,664 meat eaters, 2,370 vegetarians and 789 vegans. Dietary data were collected using repeated 24 h dietary records. Multivariable polytomic logistic regression models were perfomed to assess the association between the sociodemographic characteristics and type of diet. The prevalence of nutrient intake inadequacy was estimated, by sex, age and type of diet categories.

Results: Compared with meat eaters, vegetarians were more likely to be highly educated, and unlike vegans had lower education level. Vegetarians and vegans substituted animal protein dense products by higher consumption of plant protein dense products (e.g.: soy based products such as tofu or legumes). Vegans had

the most balanced diets in terms of macronutrients. Vegetarians exhibited lower estimated prevalence of inadequacies for micronutrient such as antioxidant vitamins (e.g.: for vitamin E, 28.9% for vegetarian women <55y vs. 41.6 in meat eaters) while vegan exhibited higher estimated prevalence of inadequacies for some nutrients in particular vitamin B12 (69.9% in men and 83.4% in women <55y), compared to meat eaters.

Conclusions: Our study highlighted that vegetarian and vegan diets may overall allow reaching nutritional recommendations. Although such diets may be culturally difficult to accept, at least in some subgroups, well-planned vegetarian dietary patterns could be considered as sustainable diets including potential health benefits and a lower environmental impact.

Keywords: vegetarians, vegans, diet, sociodemographic characteristics, dietary nutrient inadequacy

VITAMIN D VALUES IN SERUM IN RELATION TO THE NUTRITIONAL STATUS AND LIFE HABITS IN A GROUP OF HEALTHY VOLUNTEERS FROM MEDELLÍN, COLOMBIA

[1]Giraldo Giraldo, Nubia; [2]Idárraga, Yelithza; [2]Ramirez, Carolina; [3]Restrepo Moreno, Angela; [3]Cano, Luz Elena; [4]Mejía, Susana.

[1]MSc. Epidemiologist. Escuela de Nutrición y Dietética. Universidad de Antioquia. Medellín.; [2]Nutrition Student. Escuela de Nutrición y Dietética. Universidad de Antioquia. Colombia; [3]PhD. Grupo de Micología médica y Experimental Corporacion para Investigaciones Biológicas (CIB). Colombia; [4]MsC. Grupo de Micología médica y Experimental Corporacion para Investigaciones Biológicas (CIB). Colombia.

Background and objectives: Vitamin D serum values depend mainly of its synthesis after solar light exposition and alternatively, from the ingestion of food rich in this vitamin. Factors such as age, skin pigmentation, use of anti sun-protecting agents, lenght of light exposition also influence its synthesis.

To determine Vitamin D serum values and explore their relation wiht the nutritional status and life habits in a group of healthy volunteers from the city of Medellín, Colombia

Methods: A cross sectional study was carried out in a group of 53 healthy volunteers. Data pertaining sociodemographic, anthropometric and life habits were collected. Vitamin D serum values were determined by means of the High Efficiency Liquid Chromatography (HPLC) technique with ultraviolet detection. To quantify Vitamin D intake we used frequency of ingesta, evaluated the nutritional status, took athropometric mesasurements and determined the skin phototype by means of the Fitzpatrick and Von Luschan scales. In order to explore the relationship among the nutritional status, the life habits and certain socio-demographic conditions such as vitamin D serum classification, the Chi square test was used. Correlations among vitamin D serum values and certain quantitative variables were measured by the Spearman r test.

Results: Women predominated in this study, 79,2%, with 41,5% of them belonging to social strata 3. Median age was 32

years, the predominating skin phototype was IV (49,1%), the most subjects (72,2%) used sun blockers once a day. The mean vitamin D ingesta was 191,7±142,0 UI day and mean lenght of light exposition was 36±28 minutes/day. According to the Body Mass Index (BMI), 39,6% were either overweight or obese. Deficient or insufficient vitamin D serum values were found in 67,9%. Age was found to be the only variable that showed an inverse correlation with Vitamin D defficient or insufficient values (r=-0,279; p=0,43).

Conclusions: The proportion of healthy volunteers that showed deficient or insufficient vitamin D values was very high. Vitamin D intake was lower than recommended. No relationship was found among the nutritional status and life habits with these values. Age was found to be the only factor that showed a negative correlation.

Keywords: Vitamin D, serum values, nutritional status, intake

Regional directorate for the West, National Research Institute in Health Sciences, Bobo-Dioulasso, Burkina Faso.; [6]MD. Senior Program Officer. Bill & Melinda Gates Foundation. USA. Distinguished Professor. Program in International and Community Nutrition. Department of Nutrition. University of California, Davis. USA.

Background and objectives: Cross-sectional (CS) surveys indicate that individuals with acute inflammation have higher plasma ferritin (pF) concentrations than those without, possibly due to either inflammation-induced increases in pF or a heightened risk of inflammation among individuals with higher iron status. To determine the validity of adjusting pF for inflammation using CS data, we assessed the effects of short-term changes in inflammation status on pF, based on the assumption that body iron stores were unlikely to change during the study period.

Methods: Two blood samples were obtained 21d apart from 451 asymptomatic 6-23mo Burkinabé children; plasma was ana-

lyzed for ferritin, C-reactive protein (CRP) and alpha-1-acid glycoprotein (AGP). Inflammation was defined as CRP>5mg/L and/or AGP>1g/L. Additionally, a regression correction (RC) approach was used to adjust pF to a presumably healthy reference point within the study population (10th percentile CRP/AGP concentrations). Cross-sectional RCs were estimated from a naïve regression model which treated observations from the same children as independent. Longitudinal RCs, to estimate effects of intra-individual changes in CRP/AGP were estimated from structural equation models, accounting for repeated measures.

Results: pF was significantly greater in children with inflammation (44.9±2.9µg/L) than those without (13.6±1.0µg/L; P<0.0001). Similarly, pF differed intra-individually in longitudinal models, based on changes in inflammation status (with inflammation: 37.0±3.2µg/L vs. without: 15.3±1.2µg/L; P<0.0001). The RC approach from CS models over-adjusted slightly for the effects of inflammation on pF compared to longitudinal models (P<0.001); adjusted pF were 9.5±0.3µg/L and 10.5±0.4µg/L, respectively, vs. unadjusted 25.0±1.0µg/L. The estimated prevalence of iron deficiency (pF<12µg/L) was comparable between CS and longitudinal models (61.0% and 56.5%, respectively vs. unadjusted, 27.7%).

Conclusions: In this population, pF changed intra-individually in relation to inflammation. Cross-sectional RC models tended to over-adjust for the effects of inflammation on pF compared to longitudinal models, suggesting that pre-illness iron status was slightly higher in those with inflammation than those without, or that adjustments did not capture the full effect of inflammation. However, estimated mean pF and prevalence of iron deficiency were similar, especially when compared to unadjusted values, suggesting that CS adjustments are valid for survey data collection and programmatic decisions in comparable populations.

IRON AND VITAMIN C INTAKE IN SCHOOL-AGE CHILDREN IN POLAND

Stos, Katarzyna; Oltarzewski, Maciej; Glowala, Aneta; Ziolkowska, Izabela; Jarosz, Miroslaw; Krygier, Bogumila.

National Food and Nutrition Institute, Warsaw, Poland.

Background and objectives: Iron is required for oxygen transport, electron transfer, oxidase activities and energy metabolism. The main components of the body that contain iron are erythrocyte haemoglobin and muscle myoglobin, liver ferritin, and haem and non-haem enzymes.

One of the main factors that increase the absorption of non-heme iron is vitamin C. Vitamin C has also a number of biochemical and physiological functions in the body. There is still ongoing problem of not sufficient iron and vitamin C intake in Poland. The aim of the study was to assess the iron and vitamin C content in daily diets of Polish school-age children.

Methods: The study was carried out between 2006 and 2011 among 981 girls and boys aged 9-13 years with the use of one-day

dietary recall method. The data on iron and vitamin C content in food products were based on the National Food Composition Database. The results of iron and vitamin C intake were compared to the Estimated Average Requirements (EAR).

Results: The median total daily iron intake in the group of pupils was 7.7 mg and ranged from 7.3 mg (girls) to 7.9 mg (boys). The comparison of individual iron intake to EAR values showed that 38.6% diets were below EAR. The main sources of iron in pupils' diets were cereal products (31.4%), vegetables and fruits (21.1%) and meat and meat products (11.1%). The median total daily vitamin C intake in the group of studied pupils was 46.0 mg and ranged from 43.7 mg (boys) to 48.8 mg (girls). In comparison to EAR, the 46.9% of diets were below EAR. The main sources of vitamin C in pupils' diets were juices (27.1%), vegetables and pulses (25.6%) and potatoes and their products (23.3%).

Conclusions: The study showed that many diets of school children aged 9-13 years in Poland were low in iron and vitamin C in relation to the requirements.

Keywords: iron, vitamin C, intake, girls, boys

cholesterol, HDL-cholesterol level, albumin and hemoglobin significantly lower (all p less than 0.05). Forns index value, aspartat-aminotransferase, alaninaminotransferase, and gamma-glutamyl transpeptidase were statistically significantly higher in patients with denutrition (all p less than 0.05). The average concentrations of pro-inflammatory cytokines (TNF-α, IL-6) were higher in patients with denutrition. Multivariate analysis identified two independent risk factors for denutrition: mean duration of CHC (odds ratio [OR] = 1.3; 95% confidence interval [CI] = 1.03-2.4), and Forns index (OR = 1.2; 95% CI = 1.02-2.5).

Conclusions: The results of this study demonstrated that patients with chronic hepatitis C associated denutrition in a high percentage. Nutritional screening using both clinical and especially biochemical methods is necessary in this population.

Keywords: chronic hepatitis C, denutrition, nutritional risk index, instant nutritional assessment score

University of Medicine and Farmacy "Carol Davila". Bucharest. Romania.; [4]MD. PhD. Emergency Military Hospital "Carol Davila". Bucharest, Romania.; [5]MD. PhD. Medas. Bucharest. Romania.; [6]MD. PhD. Bucharest. Romania.

Background and objectives: The objective of the study was to assess nutritional status in patients with chronic hepatitis C (CHC) by different methods and to evaluate the risk factors for denutrition in this population.

Methods: This observational study, held in three medical centers from Bucharest, Romania, included 173 patients. We followed anthropometric indices and biochemical parameters for each patient. Clinical and biological assessment of nutritional status was performed using body mass index (BMI), nutritional risk index (NRI) and instant nutritional assessment score (INA). Each patient completed Mini Nutritional Assessment (MNA). We also recorded a denutrition combined score. We considered patients to be malnourished according to the combined score if any score indicated denutrition. Hepatic fibrosis was assessed using Forns index.

Results: The mean average age was 54.14±9.1 years. The mean duration of CHC was 7.21±3.23 years. Using the combined score, denutrition was present in 17 patients (9.8%). Patients with denutrition had weight, body mass index, waist circumference, total

PREVALENCE OF MALNUTRITION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

[1]Canicoba, Marisa; [2]Colon, Carolina; [2]Spiazzi, Renata; [2]Milano, Claudia.

[1]Nutritionist. Department of Nutrition and Division of Gastroenterology. Hospital Nacional "Prof. A. Posadas". El Palomar. Provincia de Buenos Aires. Argentina; [2]MD. Department of Nutrition and Division of Gastroenterology. Hospital Nacional "Prof. A. Posadas". El Palomar. Provincia de Buenos Aires. Argentina.

Background and objectives: Inflammatory bowel disease (IBD) including ulcerative colitis (UC), Crohn's disease (CD) and inclasificable colitis(IC). Patients with IBD are at risk of malnutrition (MN), the nutritional assessment plays a crucial role in the practice of care of patients with IBD. The aim was to determine prevalence of MN in patients with IBD

Methods: Analyzed data from a cohort of patients with clinical and histopathological diagnosis of IBD treated at the Division of Gastroenterology, with a multidisciplinary care model, from January 2013 to March 2017. Nutritional assessment were calculated in each ,consisted of anthropometric measurements of body mass index (BMI) and Subjective Global Assessment (SGA) as a systematic method of integrating nutritional history data, gastrointestinal symptoms and physical examination,3 diagnoses were obtained: A. eunutrids, B. at risk or moderate malnutrition and C. severe malnutrition. To determine the clinical activity of CD, the Harvey-Bradshaw index was used and for the UC the modified Truelove-Witts index

Results: 151 patients with IBD were included: median age was 44, 32 (±16, 9) year, 56, 4% female, 30.2% had CD, 66, 9% UC and 2, 9% IC, year diagnosis median 6 year (1- 43).

Parameters nutritional with SGA were not statiscally significantly different in UC, CD well nourished (p=0.67), patients moderately and severely malnourished (p=0.67) and with BMI overweight or obese CD 27, 26%, UC 40, 77% (p=0.17). Patients with ±10 years evolution between CD and UC(P=0.34). The disease situation had a high percentage in the Remission stage, for UC (71.8%), CD (90.9%) and the rest in broad stage for UC (28.2%) and CD (9.1%)

Conclusions: In this population we found an adequate nutritional status between the two populations CD and UC. The optimization of the nutritional status can improve the results in patients with IBD, for which it is necessary to detect and treat MN, for which an interdisciplinary team is needed.

ANALYSIS OF THE USAGE AND CHARACTERISTICS OF DIETARY SUPPLEMENT CONSUMERS OF URBAN COSTA RICAN POPULATION. RESULTS FROM ELANS STUDY

[1]Guerrero Calderon, Fabiola; [2]Pacheco Arteaga, Maria Amalia; [3]Gómez Salas, Georgina

[1]Bch. Nutritionist. School of Nutrition. University of Costa Rica.; [2]Bch. Nutritionist. School of Nutrition. University of Costa Rica; [3]MSc. Nutritionist. Department of Biochesmitry. School of Medicine. University of Costa Rica.

Background and objectives: Previous studies reveal that dietary supplement (DS) consumption has increased in the Western world in all ages groups and is influenced by gender, age, educational level, socioeconomic status and other factors. In Costa Rica there is no information regarding DS use in the general population. The present study was focused on assessing the prevalence of use and determining the socio-demographic, anthropometric and nutritional characteristics of urban Costa Rican DS consumers, and to explore the reasons for their consumption.

Methods: Data were obtained from Latin American Nutrition and Health Study (ELANS), is a cross-sectional study including a representative sample of urban population from eight LA countries (Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela). In Costa Rica 798 participants were asked about DS use, and six months after the first contact a second questionnaire was applied by telephone to subjects who had previously reported DS use, in order to delve on the characteristics and perceptions involved in DS consumption. Chi-square test was used to compare observed and expected frequencies.

Results: Approximately 6% (n=48) of the population surveyed reported the use of DS, mainly in the form of multivitamins. No significant differences for sex, age, socioeconomic status (SES), educational level and body mass index (BMI) were found for DS intake. DS consumers reflected significantly higher intakes of dietary calcium in both sexes, and dietary vitamins C and vitamin E

in women, compared to nonusers. Reasons for consumption of DS focused on health benefits, prevention of illness, improved immunity, and energy boost. Although perceived as beneficial for 58% of the cases, the use was discontinued after six months.

Conclusions: The prevalence of DS usage was lower than reported by other studies in the field. A pattern similar to that described in the literature (BMI <25 kg/m2, physically active, healthy lifestyles and favorable socio-demographic backgrounds) was not found in this study.

ACCURACY OF ACCELEROMETER FOR PREDICTION OF ENERGY EXPENDITURE AND ACTIVITY INTENSITY IN ATHLETIC ELEMENTARY SCHOOL CHILDREN DURING SELECTED ACTIVITIES

[1]Choi, suji; [2]An, Hae-Sun; [2]Lee, Mo-Ran; [3]Lee, Jung-Sook; [4]Kim, Eun-Kyung.

[1]Graduate student. Department of Food and Nutrition. Gangneung-Wonju National University. South Korea; [2]Graduate student. Department of Food and Nutrition, Gangneung-Wonju National University. South Korea; [3]PhD nutritionist. Gangneung seongdeok Elementary School. South Korea; [4]Professor. Department of Food and Nutrition. Gangneung-Wonju National University. South Korea

Background and objectives: Athletic children may have higher risk of energy deficiency in comparison to their non-athlete counterparts, due to their higher energy expenditure. In this context, accurate assessment of energy expenditure is important for estimation of requirements. The objective of this study was to evaluate the accuracy of accelerometer for prediction of energy expenditure and activity intensity in athletic elementary school children, during selected activities.

Methods: The present study involved 31 elementary school children (16 boys and 15 girls), aged 9-12 years. During the measurements, children performed 8 selected activities while simultaneously wearing the accelerometer and carrying the portable indirect calorimeter. Five equations were assessed for prediction of energy expenditure from accelerometer counts (Freedson / Trost,

Treuth, Pate, Puyau, Mattocks), while Evenson equation was added for prediction of activity intensity, making 6 equations in total. The accuracy of accelerometer energy prediction was assessed by comparing measured and predicted values, using the paired t-test. Based on their METs, activities were classified as sedentary, light, moderate or vigorous. The intensity classification accuracy was evaluated with κ statistics and ROC-Curve.

Results: For activities of lying down, watching TV and reading, Freedson / Trost and Treuth equations were accurate in predicting energy expenditure. Regarding Pate equation, it was accurate for vacuuming and slow treadmill walking energy prediction. Puyau predictive equation was inaccurate in all activities, while Mattocks' equation was accurate in all treadmill walking activities. Concerning activity intensity classification accuracy, Pate equation had the best performance across the 4 intensities (κ = 0.72), while the remaining equations had low accuracy (κ = 0.14~0.37). In case of the sedentary activities, all equations had a good prediction accuracy (ROC-AUC = 0.83-0.89), while in light activities, Pate equation had an excellent accuracy (ROC-AUC = 0.91). For moderate activities, all equations showed a poor performance whereas in vigorous activities, Pate equation had an excellent prediction accuracy (ROC-AUC = 0.94).

Conclusions: In conclusion, no equation was accurate in predicting energy expenditure across all assessed activities in children athletes. For activity intensity classification, Pate equation had the best prediction accuracy.

BODY MASS INDEX OF PATIENTS WITH DENTO-FACIAL DEFORMITIES BEFORE AND AFTER MONO AND BIMAXILLARY ORTHOGNATHIC SURGERY

[1]Thieme, Rubia Daniela; [2]Silva Benato, Leonardo; [3]Oliveira Carlos, Ligia; [4]Madalozzo Schieferdecker, Maria Eliana; [5]Rebellato, Nelson.

[1]MSc. Nutritionist. Nutrition Department. Universidade Positivo. Brazil.; [2]Master of Science student. Oral and Maxillofacial Maxillofacial Surgeon. Odontology Department. Universidade Federal do Paraná. Brazil.; [3]MSc. Nutritionist. Nutrition Department. Universidade Federal do Paraná. Brazil.; [4]PhD. Nutritionist. Nutrition Department. Universidade Federal do Paraná. Brazil.; [5]PhD. Oral and Maxillofacial surgeon. Odontology Department. Universidade Federal do Paraná. Brazil.

Background and objectives: Orthognathic surgery is a treatment for patients with dentofacial deformity. After surgical procedure, diet restriction is recommended and, consequently, weight loss is common. The objective was to compare Body Mass Index (BMI) of patients with dentofacial deformities before and after mono and bimaxillary orthognathic surgery.

Methods: Prospective clinical study with 69 adults with dentofacial deformity submitted to mono or bimaxillary orthog-

nathic surgery (December 2013 to March 2016). Data collection was performed a week before surgery and 10, 40, and 90 days post operatory (PO). BMI (kg/m2) was estimated with the equation: weight (kg)/height (m)2, and classified in: < 18.5, underweight; 18.5–24.9, eutrophic; 25.0–29.9, overweight; and >30.0, obesity. Statistical analysis was performed with Chi-Square test and Student t-test for independent samples, with a confidence interval of 95%.

Results: Mean age was 29.42±8.72 years, 56.5% (n=39) of the patients were women, and 56.5% (n=39) were monomaxillary surgeries. In the preoperative period, 51.30% (n=20) and 43.30% (n=13) of the patients submitted to mono and bimaxillary, respectively, were eutrophics, and 90 days PO 61.50% (n=24) and 46.70% (n=14) of the patients submitted to mono or bimaxillary, respectively, were eutrophics. There were no difference between BMI classification in mono and bimaxillary before (p=0.551) and after surgery (p>0.05). BMI before monomaxillary was similar to bimaxillary surgery (24.84±4.23 and 26.11±4.52, respectively, p=0.237,). At 10, 40 and 90 days PO, BMI were also similar to mono and bimaxillary surgery (PO10: 23.94±4.16 and 24.97±4.41, respectively; PO40: 23.86±3.96 and 24.65±4.37, respectively; PO90: 24.34±4.00 and 24.85±4.19, respectively; p>0.05).

Conclusions: BMI are similar to mono and bimaxillar in pre and postoperative periods. BMI alone is not enough to predict body composition, and BMI classification is unable to verify fast and small weight variations.

Keywords: Orthognathic surgery. Nutritional status. Nutrition assessment. Body Mass Index.

DIETARY INTAKE AND SOURCES OF ADDED SUGAR AMONG BRAZILIAN POPULATION: RESULTS FROM ELANS/EBANS STUDY

[1]Fisberg, Mauro; [2]Nogueira Previdelli, Agatha; [3]Gómez Salas, Georgina; [4]Guajardo, Viviana Beatriz; [5]Zalcman Zimberg, Ioná; [6]Kovalskys, Irina.

[1]1 MD. Instituto Pensi. Fundação Jose Luiz Egydio Setubal. Hospital Infantil Sabara. São Paulo. Brazil 2 PhD. Professor. Departamento de Pediatria. Universidade Federal de São Paulo. São Paulo. Brazil; [2]PhD. Professor. Faculdade de Ciências Biológicas e da Saúde. Universidade São Judas Tadeu São Paulo. Brazil; [3]MSc. Professor. Departamento de Bioquímica. Escuela de Medicina. Universidad de Costa Rica. Costa Rica; [4]Bs. Nutrition and Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina; [5]PhD. Departamento de Psicobiologia. Universidade Federal de São Paulo. São Paulo. Brazil; [6]MD. Nutrition and Health Area. International Life Science Institute (ILSI). Buenos Aires. Argentina.

Background and objectives: Added sugar (AS) intake is highly associated with the epidemic of overweight and obesity. This study aimed to identify the dietary intake and sources of AS among Brazilian population.

Methods: Latin American Health and Nutrition Study (ELANS) is a multicenter study developed in urban areas of 8 Latin American countries: Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela. Data were obtained from 2,000 Brazilians (15-65 y.o) participating in EBANS (Brazilian Health and Nutrition Study). Two 24-hour recall were used to identify the intake of AS and the major food items accounting for AS, using the weighed-proportions formula developed by Block (1985) in which the relative contribution (RC) of a given food item/food group is defined as: RC=[(Total AS grams from a food item x 100)/Total AS grams from all food items]. Median intake and sources of AS were performed by age group, gender, socioeconomic level (SES) and nutritional status.

Results: Median AS and AS percentage of energy intake were 52.4g/day and 12.6%, respectively. More than 63% of the subjects had %energy from AS >10%. Comparison of median AS intake (g/day) between age groups, nutritional status and SES showed that the highest intake was found among male adolescents, obese male and high SES. Carbonated soft drinks accounted for the highest contribution of AS intake in whole sample, providing from 26.8% to 40.1% of total AS intake. Infusions were the second main source, except for adolescents that had cookies and cakes as the second contributor of AS intake. Sugar-sweetened beverages (SSBs) represented 68% of total AS intake among Brazilians, based on gender it was 69.2% for male and 57.5% for female.

Conclusions: Brazilians are consuming AS above the level recommended by the World Health Organization (10%). The main source of AS was SSBs independent of gender, age group, SES and BMI status. This results reinforce the importance of reducing sugar content in manufactured foods. However product reformulation alone may not be enough, public health programs should also focus on strategies that reduce the quantity and frequency of others sources of AS, such as homemade drinks, cakes, cookies and desserts.

ASSOCIATION BETWEEN DIETARY CALCIUM INTAKE AND NUTRITIONAL STATUS AND WAIST CIRCUMFERENCE IN URBAN COSTA RICAN POPULATION: RESULTS FROM THE LATIN AMERICAN STUDY OF NUTRITION AND HEALTH (ELANS)

[1]*Piedra, Fiorela;* [2]*Chinnock, Anne;* [3]*Gómez Salas, Georgina.*

[1]Bch. Nutritionist. School of Nutrition. University of Costa Rica.; [2]PhD. Nutritionists. School of Nutrition. University of Costa Rica; [3]MSc. Nutritionist. Department of Biochemistry. School of Medicine. University of Costa Rica.

Background and objectives: Several cross-sectional studies have shown an inverse relationship between dietary calcium intake and both body mass index (BMI) and waist circumference. Possible mechanisms for such associations include increased fecal fat excretion, changes in adipocyte metabolism and increased thermogenesis. The aim of this study was to investigate the association between total dietary calcium, body mass index and waist circumference in Costa Rican population living in urban areas during the period between 2014-2015 as part of the Latin American Study of Nutrition and Heath (ELANS).

Methods: Data were obtained from 798 subjects from urban Costa Rican population, between the ages of 15 and 65 participating in ELANS, a multicentric study developed in urban areas of Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela. Food intake assessment included two 24-hour recall (Multiple Pass Method), from non-consecutives days and processed by the software Nutritional Data System for Research (NDS-R). Calcium usual intake was estimated with the Multiple Source Method (MSM) statistic package (https://nugo.dife.de/msm). Anthropometric measurements were obtained and BMI and BMI-for-age percentiles were calculated. Population was divided into tertiles according to dietary calcium consumption, and association with nutritional status were analyzed. Logistic regression was use to calculate the probability of having excess weight or waist circumference above recommendation.

Results: The probability of having excess weight (≥24.9 kg/m2) was 39% less for those in the second tertile of calcium intake, and 55% less for those in the highest tertile of calcium intake. The risk of having a waist circumference above the recommendation (men ≥102 cm; woman ≥ 88 cm) was 34% less for the second tertile and 42% less for the higher tertile of calcium intake.

Conclusions: Evidence suggests that a low dietary calcium intake increase the probability to have excess weight and waist circumference above recommendations in urban Costa Rican population.

Keywords: calcium intake; excess weight; waist circumference; Costa Rica

ENERGY, MACRO AND MICRONUTRIENTS ADEQUACY BY SEX IN PERUVIAN ADOLESCENTS AND ADULTS: RESULTS FROM THE ELANS STUDY

[1]*Liria Domínguez, María Reyna;* [2]*Pareja, Rossina Pareja.*

[1]PhD Nutritionist. Instituto de Investigación Nutricional. Peru.; [2]MSc Nutritionist. Instituto de Investigación Nutricional. Peru.

Background and objectives: Evaluation of energy and nutrient consumption allows identifying possible nutritional deficiencies and/or excesses. The aim of this study is to assess the adequacy of energy and nutrients intake by sex in Peruvian population.

Methods: The ELANS (Latin American Health and Nutrition Study) is a transversal study conducted in 8 Latin America countries (Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru and Venezuela), in adolescents and adults (1113 peruvians, 15 to 65 years old). We obtained usual intake (Multiple Source Method) of energy , macro and micronutrients through two 24 hour dietary recall in non-consecutive days. Estimated average requirement (EAR) were used to determine the percentage of adequacy to recommendations. For energy adequacy, basal energy expenditure-BEE was calculated according to age, sex and physical activity level-PAL proposed by Gerrior et al (2006), using results from the long IPAQ. We used mean difference test for continuous variables and chi2 Fisher's exact to assess difference by sex at 95% confidence level.

Results: The energy adequacy was 95% for men vs 105% for women (p<=0.000). The percentages of energy coming from macronutrients by sex were: protein 15% vs 15% (p=0.159), fat 22% vs 23% (p<=0.000) and carbohydrates 64% vs 62% (p<=0.000), for men and women respectively. Adequacy for micronutrient intake: calcium was 57% vs 52% (p<=0.000), iron was 136% vs 72% (p<0.000), vitamin A was 109% vs 131% (p<0.000) and vitamin C was 151% vs 168% (p=0.002). Percentages of population that showed insufficient macronutrients intake were: 28% for fat (men: 35% vs women: 23%, p<0.000), in contrast to the 35% that consumed more carbohydrates than recommended (men: 41 %, women 29%, p<0.000). Micronutrients with the highest percentages of insufficient intake were: calcium (97%, men: 97% vs women 98%, p=0.083) and iron (97%, men: 15% vs women 83%, p<0.000).

Conclusions: While energy consumption does not appear to be a problem in the Peruvian population, the adequacy of fats were low while carbohydrates high, the micronutrients with greater inadequacy were calcium and iron. Given the nutritional problems in the country: micronutrient deficiencies and high carbohydrate intake, strategies that cover both problems at the same time are required.

ASSOCIATIONS BETWEEN NUTRITION STATUS AND THE DEGREE OF INDEPENDENCE IN DEMENTIA ELDERLY'S ACTIVITY OF DAILY LIVING IN THE ELDERLY IN NURSING CARE FACILITIES IN JAPAN

[1]*Yukiko, Oe;* [2]*Toshinao, Goda.*

[1]phD. Institute of Health Longevity Science and Nutrition, Watami Corporation, Ltd, Japan; [2]phD. School of Food and Nutritional Sciences, University of Shizuoka, Japan.

Background and objectives: Most of elderly who requires nursing care has chronic disease, and due to a diminished food intake and physical activity, they tend to show decreased skeletal muscle mass. As a result, there is a great increase in the risk of fall and malnutrition in the elderly. Malnutrition is known to worsen the prognosis after infection and delay healing of disease in the elderly due to decreased immune function.

Methods: We have examined the associations between nutrition status and blood biochemical parameters, the degree of independence in dementia elderly's activity of daily living, the nursing care levels, and the form of food in 1,823 elderly persons aged 61-106 y (average 86.7 y) who lives in nursing care facilities were analyzed using Spearman's rank correlation coefficient analysis and steel-dwass test.

Results: The percentages of the elderly at risk of malnutrition according to GNRI (Geriatric Nutritional Risk Index) were 67.0% for men and 66.2% for women. The GNRI scores tended to be lower according to an increase in the nursing care level. In elderly men, the GNRI scores were remarkably lower in the groups categorized as nursing care levels 4 and higher than those in nursing care level 3 or lower. In elderly women, the GNRI scores were

greatly decreased in the groups categorized as nursing care levels 2 and higher. The lower the degree of independence in dementia elderly's activity of daily living was, the lower the GNRI, and the GNRI scores of the groups categorized IIIa and over were significantly lower than those categorized as of IIb or under. The GNRI scores were associated with the provided form of food, according to the transition from regular to liquid form.

Conclusions: The results of this study suggest that the nutrition status of elderly who requires nursing care in nursing homes was associated with the degree of independence in dementia elderly's activity of daily living, the nursing care level, and the form of food, and it may be attributable to a decrease in physical function required for activity of daily living.

School of Midwifery.Faculty of Medicine. University of Chile. Santiago. Chile; [4]PhD,MPH. Midwifery. Department of Women's and Newborn Health Promotion. School of Midwifery. Faculty of Medicine. University of Chile. Santiago. Chile.

Background and objectives: The migration in Chile increased by 28% between the years 2012 and 2015. As there are no studies in the country that describe the pre-pregnancy nutritional status (NS) and perinatal outcomes of immigrant (GI) versus Chilean (GI) pregnant women, the objective of this study was to compare the NS and to analyze its association with maternal and newborn pathologies in GNI versus GI who attended their delivery at the Hospital Clínico San Borja Arriarán (2015).

Methods: A comparative study carried out at 1,078 GI and 1,520 GNI. The data were obtained from: 1.the clinical records 2.The health agenda and a survey made to the pregnant woman. The variables studied were NS (underweight, normal, obesity and overweight) determined by Atalah standard; Gestational diabetes (GD), preeclampsia (PE), intrauterine growth retardation (IUGR) and preterm birth (PTB). Data were presented as prevalences and compared with CHI2 test. Crude and adjusted (by sociodemographic, obstetric and of maternal diseases variables) logistic

regression models were performed to evaluate the association between NS and maternal and newborn pathologies.

Results: The GNI had significantly more likely to have obesity 3.0 [2.4 - 3.8] and overweight 1.7 [1.4 - 2.1] at the beginning of gestation than GI, in relation to have a normal nutritional status (50% GI and 34% In GNI, p <0.001), with no differences in the risk of underweight 1.1 [0.8 -1.5]. GI had a higher prevalence of anemia than GNI (12.6% vs 7.7, p <0.001). On the other hand, the GNI had higher prevalences of GD (8.7% vs 4.4%, p <0.001) and preeclamsia (8.3% vs 4.9%, p <0.05) than GI, while their children had a higher prevalence of PTB (14.0% vs. 6.6%, p <0.001) and IUGR (6.9% vs. 3.7%, p <0.001) than GI. Crude and adjusted logistic regression models showed that GD was associated with maternal obesity and overweight; PE was associated with obesity; while maternal underweight was associated with IUGR.

Conclusions: The GNI presented higher prevalences of obesity, DG, PE, IUGR and PTB than GI. Obesity was associated with DG and PE and the latter with PTB.

Romania.

Background and objectives: According to all guidelines, metformin is the frontline treatment and the most prescribed drug for type 2 diabetic patients, that can be associated with other oral medication or insulin. Treatment with metformin may lead to a decreased absorption of vitamin B12. The purpose of this study is to evaluate serum vitamin B12 levels in patients with type 2 diabetes, treated chronically with metformin.

Methods: We evaluated 119 patients with type 2 diabetes, aged 33-86 years, who underwent annual periodic evaluation at our center. Patients provided their socio-professional and medical history, their history of diabetes treatment and supplements taking. We obtained anthropometric data: weight, height, abdom-

inal circumference (AC), body mass index (BMI), blood pressure, measured vitamin B12 serum levels and performed biochemical analyses regarding the metabolic control of diabetes. B12 vitamin deficiency was defined at serum levels below 193 pg/ml. Descriptive statistics provided frequencies, means, standard deviations and medians. Anova and Mann-Whitney U tests were used to analyze the differences between the variables.

Results: Of the 119 enrolled patients, the 87 treated with metformin for at least six months had a higher mean BMI (32.9 kg/m2 vs. 29.2 kg/m2, p = .001), a higher mean AC (99 cm vs 108 cm, p = .001) and a lower mean vitamin B12 serum level (352.28 pg/ml vs 450.09 pg/ml, p = .016). 12 patients (13.8%) on metformin had values below the lower limit of vitamin B12, compared to 3.1% from those on other treatments. No statistically significant differences were found regarding treatment duration and control, nor the dose of metformin. No evidence was found to support the diagnosis of anemia. In the metformin patients, taking supplements containing B12 was associated with a reduction in the prevalence of B12 deficit, however, those taking supplements had an average of the B 12 levels of 472.50 pg/ml vs 329.22 pg/ml, p = .05.

Conclusions: Our results found 13.8% of the patients treated with metformin had a vitamin B12 deficit. We recommend periodic evaluation of the level of vitamin B12 for patients receiving chronic metformin treatment. B12 supplementation may be protective against B12 deficiency.

Keywords: B12 vitamin, type 2 diabetes, metformin

ASSESSMENT OF FOOD CONSUMPTION AND NUTRIENT INTAKE OF OUTPATIENTS WITH CHRONIC DISEASES AT A UNIVERSITY FEDERAL HOSPITAL IN RIO DE JANEIRO

[1]*Duas, Juliana Furtado;* [2]*Leão, Leila Sicupira Carneiro de Souza;* [3]*Silva, Renata de Souza;* [4]*Pereira, Alessandra Pereira;* [2]*de Aquino, Luana Azevedo;* [2]*Santos, Claudia Roberta Bocca.*

[1]PhD, Professor, Departamento of Aplicated Nutrition, Nutrition School, Rio de Janeiro Federal State University, Brazil; [2]PhD, Professor, Departamento of Nutrition and Public Health, Nutrition School, Rio de Janeiro Federal State University, Brazil; [3]Nutrition Student, Departamento of Nutrition and Public Health, Nutrition School, Rio de Janeiro Federal State University, Brazil; [4]Professor. UNIRIO. Rio de Janeiro. Brazil.

Background and objectives: The assessment of food consumption is often carried out to develop and implement nutritional advice. Due to the high prevalence of chronic diseases and its relation with nutrient intake, the objective of this study was to assess food consumption and nutrient intake of patients with chronic diseases.

Methods: During the consultation, two nutritional questionnaires were applied (non-consecutive two days 24 hour and food frequency) in 45 outpatients from February 2016 to April 2017. Daily food consumption, and quantity of energy, macro and mi-

cronutrients related to chronic diseases were estimated. Socio-economic and anthropometric information were also collected.

Results: Most respondents (85%) were female, 67% were 50 years or older (58,8 ± 12,1 years), 40% were white, 36% had 4 to 7 years of study, and 82% presented more than one chronic disease. Obesity was observed in 45%, Hypertension in 62%, and Diabetes in 54%. Soft drinks (11%) and sweets (20%) daily consumption were significant; fruits (60%), vegetables (37%), beans (47%) and milk (64%) consumption were considered insufficient. Elevated salt consumption was observed in 13% of individuals. Average energy intake was 1400±420,2 kcal, protein 20,2±6,6%, carbohydrate 52,3±13,8%, lipids 27,5±10,6%. It was observed high prevalence of inadequate nutrient intake for vitamin D (72,2%) and calcium (95,5%) and expressive prevalence for vitamin C (42,8%) and zinc (18,4%).

Conclusions: Food consumption and nutrient intake in this group of outpatients with chronic diseases was considered not healthy and preoccupant due to expressive presence of simple sugars and salt as well as insufficient amount of fiber and micronutrients such as calcium and zinc, and vitamins C and D.

IS NECK CIRCUMFERENCE A GOOD INDICATOR TO IDENTIFY MUSCLE WASTING IN CHILDREN AND ADOLESCENTS WITH MALIGNANT NEOPLASMS?

[1]*Lucena Ferretti, Roberta;* [2]*Santos Maia-Lemos, Priscila;* [3]*Jaloretto Teixeira Guedes, Karen;* [4]*Maria Monteiro Caran, Eliana.*

[1]PhD Student. MSc. Nutritionist. Federal University of Sao Paulo. University of Taubate. Sao Paulo. Brazil.; [2]PhD. MSc. Nutritionist. Federal University of Sao Paulo. Sao Paulo. Brazil.; [3]Nutritionist. Federal University of Sao Paulo. Sao Paulo. Brazil.; [4]PhD. MSc. Doctor. Federal University of Sao Paulo. Sao Paulo. Brazil.

Background and objectives: Children and adolescents with malignant neoplasms may present muscle wasting early, and this finding may be underestimated when only the Body Mass Index is considered, due to the various metabolic changes, and the side effects caused by antineoplastic therapy. It has been considered in the literature that even Arm Muscle Area (AMA) or Calf Circumference (CC) present strong correlation with muscle mass stores. Neck circumference (NC) is a measure of easy gauging and applicability in clinical practice. The main objective of this study was to verify if there is a correlation between NC with AMA and CC.

Methods: A cross-sectional study that assessed children and adolescents from 0 to 20 years old with malignant neoplasms at a Pediatric Oncology Specialized Institute between October 2015 and March 2017. Measurements of NC and CC were evaluated, all performed by trained evaluators, following anthropometric techniques standardized by the literature, besides middle upper arm

circumference and triceps skinfold (to calculate AMA). For statistical analysis, Pearson's correlation and one-way ANOVA were used, with significance level p<0.05.

Results: Among the 1656 assessments, 56.9% (n=943) were male. The mean age, for male and female were 9.0 ± 5.8 and 8.5 ± 5.4, respectively. The median NC, AMA and CC, for male and female were 28.4 ± 4.62 vs 27.4 ± 3.84 cm; 21.2 ± 12.47 vs 21.6 ± 10.1 cm2; 26.0 ± 7.16 vs 26.8 ± 8.58 cm, respectively. Significant differences were observed between sexes in AMA (p=0,017) and NC (p=0,000). It was also observed that there were no significant difference for CC (p=0,064), considering sexes. The correlation between NC with AMA and CC was positive, very strong and significant (r=0.9 vs r=0.8; p=0,000) respectively.

Conclusions: It is concluded that NC has a strong correlation with AMA and CC, being a promising indicator to identify muscle wasting in children and adolescents with malignant neoplasms.

ENERGY DENSITY AND NUTRITIONAL ADEQUACY IN DIET OF CHILDREN AND ADOLESCENTS IN A SUMMER CAMP, 2017

[1]*Garcia Peloggia de Castro, Adriana;* [2]*Castelo Branco, Fernanda;* [3]*Gomes Rodrigues, Carolina;* [4]*Ferreira Giori, Fabiana;* [4]*Rogerio Otaga, Luis.*

[1]PhD. Nutritionist. Curso de Nutrição. Centro Universitário São Camilo. Brazil; [2]BSc. Nutricionist. ADJ Diabetes Brasil. Brazil; [3]BSc. Nutricionist. Brazil; [4]Student. Centro Universitário São Camilo. Brazil.

Background and objectives: Diabetes type 1 (DM1) results from cell-mediated autoimmune destruction of pancreatic B-cells. Its treatment includes insulin therapy, meal planning and physical activity. Educational measures are fundamental to reach the best metabolic control and the Summer Camps for Diabetic Youngster can contribute for the instruction of these measures. The aim of this work was to analyze the diet offered to participants of Summer Camps with DM1 of the 2017 season.

Methods: The 37th season of the 2017 Summer Camps was held in Sapucaí Mirim, a city of Minas Gerais, Brazil, for six days. The menu was elaborated by nutritionists for the 81 participants with DM1, from 8 to 16 years old, considering the educational play activities during the season. The nutritional value of the meals was

calculated based on food composition tables and nutritional information from manufacturers. The classification of macronutrients was made according to the current guidelines of the Brazilian Society of Diabetes and the calories were obtained by adding the nutrients multiplied by their respective caloric values. The energy density (ED) of the meals was calculated by two methods: the first (M1) considered all foods and caloric liquids, the second (M2) excluded all liquids except milk and both were evaluated according to the American Institute for Cancer Research (2007).

Results: From M1 to M2, a reduction in calories and an increase in ED were observed due to the absence of caloric liquids. However, both were found to be adequate on almost all days, except for dinner on the third day and breakfast on the fourth, that presented values higher than the reference, by both methods. Regarding the macronutrients, the hyperlipidic distribution of the third day and the predominance of adequate values on the other days are emphasized. Pizza was served for dinner at the third day. Possibly, the presence of fruits and vegetables in the main meals contributed to this suitability and all participants were encouraged to consume it daily by stimulating healthy eating.

Conclusions: Most meals during the 37th Summer Camp were adequate for the campers, highlighting the importance of consuming a variety of fresh foods including fruits and vegetables.

ELEVATED NECK CIRCUMFERENCE IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

[1]*Pereira da Silva, Caroline;* [2]*Ortiz da Silva, Ronaldo;* [3]*Lisboa Mendes Roman, Adriana;* [3]*Aparecida Silva Alvarenga, Adriana;* [4]*Lucena Ferretti, Roberta.*

[1]Nutritionist. University of Taubate. Sao Paulo. Brazil.; [2]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil; [3]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil.; [4]PhD Student. MSc. Nutritionist. Federal University of Sao Paulo. University of Taubate. Sao Paulo. Brazil.

Background and objectives: Type 2 Diabetes Mellitus (DM2) has a great impact on public health due to its complications. Anthropometric measures are able to predict nutritional status and excess adiposity, such as neck circumference (NC). The main objective of this study was to evaluate the prevalence of excess adiposity considering Body Mass Index (BMI) and NC, and verify its correlation.

Methods: A cross-sectional study that evaluated adults and elderly patients, above 20 years old, with diagnosis of DM2 in a hospital in Taubate, Sao Paulo, from June 2015 to May 2016. The data collected were weight, height, body mass index (BMI), NC, sex, age, diagnosis of Type 2 Diabetes Mellitus. For classification of nutritional status, the cut-off points proposed by the World Health Organization (WHO) for adults and Lipschitz for the elderly were

used. The cut-off points of NC used to identify excess adiposity were 34 and 37 cm, for female and male respectively. Data analysis was performed using descriptive statistics. The correlation between NC and BMI was determined by the Pearson`s correlation, with significant value p<0.05.

Results: Among the 175 patients with DM2 evaluated, 52,57% (N=92) were male. The mean age, for female and male were 67.73 ± 14.71 vs 67.71 ± 14.67, respectively. There was high prevalence of excess adiposity, considering BMI, even in adults (60%) or in elderly patients (78.52%). Regarding to the NC, it was verified that 62.5% of the adults and 75.5% of the elderly showed elevated NC. There was a positive, moderate, and significant correlation between NC and BMI for the female and male sex (r = 0.52 vs 0.61, p<0,05).

Conclusions: It is concluded that the majority of adult and elderly patients with DM2 presented excess adiposity according to BMI and NC. There was a moderate correlation between NC and BMI for the female and male sex. NC is a measure of easy gauging and applicability in clinical practice, especially with hospitalized patients.

displaying served food in plates, based on Regular Hospital meals to give it content validity. Relative weights were determined for different domains (portion estimation: absolute/relative and nutritional content: qualitative/quantitative) and a dichotomy checklist were established for test correction. Test was designed to be performed by observing photographs of served food on a computer and completing the results on printed paper grids. Pilot test with Registered Dietitians (RD) experts was performed for internal consistency. Discriminative validity was assessed by "known groups" comparison technique between RD as a reference group, and novice (N) and intermediate (I) students. Man Whitney test was applied.

Results: Test was performed between Dec 2014 and Dec 2015. RD (n: 27), N (n: 30) and I (n: 73). Students performed the test without qualification conditioning. Cronbach's Alpha was 0.70 in the RD. Between RD and N there was a significant difference in total score (p< .000) with median = 57% (86.7% - 38.8%) and 39.9% (50.8% 22, 9%) respectively. Difference between RD vs. I (p< .000) and I vs. N (p< .000) could also be observed.

Conclusions: Test's reliability was acceptable in reference population (RD) and proved discriminative validity when comparing extremes groups (RD vs. S). This result would support construct's contents and the way they were measured.

Photography is an available easy to use and unexpensive resource. Knowing its strengths and weaknesses, contextualizing and developing skills in food management is possible. This Test could be useful in grade level students as a diagnostic, learning and reflection-oriented instrument for improvement. It is necessary to continue with the validation process and to determine when the students become competent.

OBJECTIVE STRUCTURED TEST TO EVALUATE FOOD INTAKE ASSESSMENT SKILLS ON NUTRITION & DIETETIC STUDENTS

[1]Guastavino, Paula; [2]Lema, Silvia; [3]García Diéguez, Marcelo.

[1]MSc. Nutricionist. School of Nutrition. Salvador University. Bs. As. Argentina.; [2]PhD. Nutritionist. School of Nutrition. Buenos Aires. University. Argentina; [3]MSc. MD. Graduate School. University Institute of the Italian Hospital. Buenos Aires. Argentina.

Background and objectives: An important requirement for health professions education is to develop a framework integrating theory and practice for professional competencies' achievement. Evaluating Competencies requires valid and reliable instruments. The aim of this study was to design a Test for nutrition & dietetic students (S) to evaluate Food Intake Assessment Skills (FIAS) and to initiate the validation process by determining internal consistency and discriminative capacity.

Methods: A construct was defined including dimensions attributable to FIAS. Test's Cases were represented by photographs

COMPARISON OF PREDICTIVE EQUATIONS OF LEAN MASS IN WOMEN

[1]Nahas, Paula; [1]De Paula, Andressa; [1]De Branco, Flávia; [2]Rossato, Luana; [3]Orsatti, Fábio; [4]De Oliveira, Erick.

[1]Nutritionist. School of Medicine. Federal University of Uberlandia (UFU). Brazil.; [2]MSc. Nutritionist. School of Medicine. Federal University of Uberlandia (UFU). Brazil.; [3]PhD. Physical educator. Department of Sport Sciences. Federal University of Triangulo Mineiro (UFTM). Brazil.; [4]PhD. Nutritionist. School of Medicine. Federal University of Uberlandia (UFU). Brazil.

Background and objectives: Adequate lean mass (LM) measurement is important since it is a predictor of functional capacity, daily activities, morbidity and mortality. Therefore, the aim of the present study was to evaluate which predictive equation estimates correctly the LM of women.

Methods: Eighty-one women with 19 to 81 years were recruited. The anthropometric variables evaluated were body weight, height, waist circumference and skin folds (bicipital, tricipital, subscapular and suprailiac). The LM was assessed by dual ener-

gy x-ray absorptiometry scanning (DXA) and was also estimated using the predictive equations: Hume I and Hume II; Salamat et al. and Kulkarni et al. I and Kulkarni II. ANOVA one-way and Tukey's post-hoc test was performed to compare the values of LM measured by DXA and estimated by equations. Pearson's correlation was performed to verify the correlation of LM quantified by equations and DXA. Bland-Altman analysis evaluated the percentage of underestimation and overestimation of the equations.

Results: It was observed that Salamat et al and Kulkarni II equations resulted in the same values of LM as measured by DXA (36.62±4.47; 38.86±5.67 and 36.59±4.56, respectively). The equations of Hume I and Kulkarni I estimated higher values (41.71±5.23 and 46.29±6.47, respectively), while Hume II lower values (19.72±4.00) of LM than that quantified by DXA. Hume I, Salamat et al., Kulkarni I, Kulkarni II and Hume II equations showed a positive correlation with LM values of DXA (r=0.89; r=0.69; r=0.87; r=0.89, and r=0.81, respectively). In the Bland-Altman analysis it was observed that Salamat and Kulkarni II equations overestimated in the LM 0.12% and 5.75%, respectively. Additionally, it was observed that the Hume I and Kulkarni I overestimated the LM in 13.07% and 23.22%, respectively and Hume II equation underestimated in 60.77%.

Conclusions: The equations that presented better prediction of LM were Salamat and Kulkarni II, but it should be used in clinical practice with caution.

MUSCLE WASTING AND NUTRIENT INTAKE ASSESSMENT OF PATIENTS HOSPITALIZED WITH PRESSURE INJURY UNDER ORAL AND ENTERAL NUTRITIONAL THERAPY

[1]Diniz Camargo, Marcela Aparecida; [1]Mourão, Letícia; [2]Gonçalves Camargo, Isabela; [3]de Lucena Ferretti, Roberta.

[1]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil; [2]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil.; [3]PhD Student. MSc. Nutritionist. Federal University of Sao Paulo. University of Taubate. Sao Paulo. Brazil.

Background and objectives: Inadequate nutrients intake for hospitalized patients is of paramount importance and it is related to complications in the clinical setting, higher mortality rate, higher costs and length of hospitalization, and the occurrence of pressure injury (PI).The main objective of this study was to evaluate the muscle wasting and nutrient intake of adult and elderly patients hospitalized with PI under oral and enteral nutritional therapy.

Methods: A cross-sectional study was carried out with adult and elderly patients above 20 years old in a hospital in Taubate, Sao Paulo, with PI under oral or enteral nutrition therapy between February and June 2016. To assessment of muscle wasting, Calf Circumference measure was evaluated, considering cutoff point below 31 cm to this outcome. To evaluate the nutrient intake were considered type of nutritional therapy used. For patients under Oral Nutrition Therapy, percentage of food acceptance and a food composition table (TACO) were used to calculate nutrition intake while for patients under Enteral Nutritional Therapy, a total amount of diet infused, according to the formula used, were considered. Regarding evaluation of nutrients intake (vitamin A, E, C, selenium, zinc) was considered as reference the Estimated Average Requirement (EAR) proposed by the Dietary Reference Intakes (DRIS) developed by the Foods and Nutrition Board/Institute of Medicine of the United States. Descriptive statistics were used to analyze the data.

Results: Among the 29 patients evaluated, 72.41% were male. It was verified that 58.6% of the patients presented muscle wasting. In relation to nutrients intake, 55.17% presented vitamin C intake above, 41.37% below and 3.44% within EAR values; 86.20% presented vitamin E intake above, 10.34% below, and 3.44% within EAR; Regarding to vitamin A, 68.96% presented above, 33.42% below and 3.44% within EAR; 55.17% presented selenium intake above EAR, 31.03% below and 13.79% within EAR; 82.75% of the patients had zinc intake above, and 17.24% below EAR.

Conclusions: It was concluded that the majority of patients presented muscle wasting, and there was predominance of patients with higher intake than EAR for vitamins C, E, A, zinc and selenium.

PREVALENCE OF MALNUTRITION IN HOSPITALIZED PATIENTS WITH PRESSURE INJURY

[1]Mourão, Letícia; [1]Camargo Gonçalves, Isabela; [2]Diniz Camargo, Marcela Aparecida; [2]de Souza da Cruz, Francine; [2]Moura dos Santos Botan, Gabriela; [3]de Lucena Ferretti, Roberta.

[1]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil; [2]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil.; [3]PhD Student. MSc. Nutritionist. Federal University of Sao Paulo. University of Taubate. Sao Paulo. Brazil.

Background and objectives: The hospitalized patients, especially malnourished, are likely to develop Pressure Injury (PI). Early identification of risk situations in nutritional diagnosis allows adequate planning of actions for prevention and treatment of diseases. The main objective of this study was to identify the prevalence of malnutrition in adult and elderly hospitalized patients with PI.

Methods: A cross-sectional study that evaluated adult and elderly above 20 years old in a hospital in Taubate, Sao Paulo, between February and June 2016. To nutritional status assessment, the measure of Calf Circumference was obtained (cutoff value below 31 cm to identify malnutrition). The Braden scale was used to identify the risk, hight and moderate, to development of another PI. C Reactive Protein (CRP) values were obtained from patient`s chart to assess inflammation status (reference value above or equal 0.5 mg/dL to identify inflammation). Statistical Descriptives were used to analyse the data.

Results: Among the 40 patients evaluated, 62.5% were male. The mean age were 65.8 ± 16.12 and 68.0 ± 15.88 years, for female and male sex, respectively. Regarding nutritional status, 62.5% of the patients were malnourished. It was verified that 87.5% had one PI and 12.5% developed two PI, and the highest percentage of lesions found in the sacral region (69%). In relation to the risk assessment for the development of PI, 55% of patients were at high risk and the remainder 45% presented moderate risk. Considering the patients classified as having moderate and high risk of another PI development, 61.11% and 63.63% were malnourished, respectively. Regarding CRP levels, 97.5% of the patients presented high values.

Conclusions: It is concluded that 65.5% of the patients presented malnutrition, being propitious to the development of new PI and worse clinical outcomes.

BIOEQUIVALENCE OF MICRONUTRIENT POWDERS TO CONVENTIONAL FORTIFICATION ON SERUM ZINC LEVELS OF MODERATELY MALNOURISHED CHILDREN IN THIKA INFORMAL SETTLEMENTS, KENYA

[1]Juliana, Kiio; [2]Sophie, Ochola; [3]Ruth, Nduati; [2]Elizabeth, Kuria.

[1]University of Nairobi. Kenya.; [2]PhD. Department of Food. Nutrition and Dietetics. Kenyatta University. Kenya.; [3]MBChB. MMed. MPH. Department of Paediatrics. University of Nairobi. Kenya.

Background and objectives: Corn Soy Blend (CSB) is the standard protocol of treating malnourished children. CSB however, has poor micronutrient bioavailability and may result into poor outcomes during nutrition recovery of the children. Micronutrient powders (MNPs) have a potential to improve micronutrient nutrition. Zinc(Zn) is an essential micronutrient for immune-protection, growth and sensory development. Scientific evidence on the efficacy of MNPs in improving Zn status among moderately malnourished children is scarce. the study aimed at establishing bioequivalence of MNPs to conventional fortification in improving Zn status of moderately malnourished children in Thika Informal settlements, Kenya.

Methods: In a cluster randomized trial, twelve villages were randomized to four study groups. Three experimental groups received different formulations of MNPs added to CSB; multiple micronutrients (MMN) containing Zn (CSB-sprinkle-MMNZn), MMN without Zn (CSB-sprinkle-MMN) and Zn singly (CSB-sprinkle-Zn). The control group received conventionally Zn-fortified CSB containing MMN. CSB was prepared centrally in the participating villages and enrolled children fed daily. Dietary intake was assessed using 24-hour recall. Enrolled children underwent physical examination and anthropometric measurements. Serum Zn levels were determined pre-post intervention. Daily consumption of CSB was monitored for a period of six months. Sample size was calculated to show bioequivalence within ±20% limit. A total of 346 children (MUAC ≥11.5 - <12.5cm) were enrolled ; CSB-sprinkle-MMNZn (N=84), CSB-sprinkle-MMN (N=88), CSB-sprinkle-Zn (N=93) and control group (N=81). Analysis was by intention-to-treat.

Results: At baseline, 64.2% of the children were Zn deficient, Zn intake was sub-optimal for 95.7% of children. A mixed effects linear regression was used to model pre-post change in serum Zn levels, adjusting for age, sex and socio-economic status. Compared to control group, the change was significantly lower for CSB-sprinkle-MMN (β= -20.0µg/dL; 95% CI: -26.5, -13.5) and significantly higher for CSB-sprinkle-MMNZn (β=5.9 µg/dL; 95% CI: 0.5, 11.3). No significant difference was observed between CSB-sprinkle-ZN and control group (β=-2.1; 95% CI: -8.3; 4.2). Conventional fortification was not bioequivalent to MNPs in improving serum Zn levels (t-tests 95% CI: -2.2; 8.9 p>0.05).

Conclusions: MNPs were more effective in improving Zn status of malnourished children compared to conventional fortification and are therefore recommended in fortification programmes.

NUTRITIONAL STATUS OF ADULT AND ELDERLY HOSPITALIZED WITH SYSTEMIC ARTERIAL HYPERTENSION

[1]de Souza da Cruz, Francine; [1]Moura dos Santos Botan, Gabriela; [2]Nunes Novais Calisto, Ariane; [2]Resende de Aguiar, Livia; [3]de Lucena Ferretti, Roberta.

[1]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil; [2]Nutritionist. University of Taubate. University Hospital of Taubate. Sao Paulo. Brazil.; [3]PhD Student. MSc. Nutritionist. Federal University of Sao Paulo. University of Taubate. Sao Paulo. Brazil.

Background and objectives: Systemic arterial hypertension (SAH) is the leading cause of cardiovascular disease in adults and the

elderly, according to the World Health Organization, and may worsen the clinical picture of hospitalized patients. Excess weight is strongly associated with elevated blood pressure. The main objective of this study was to evaluate the nutritional status of hypertensive adult and elderly patients admitted to a hospital in Taubate, Sao Paulo.

Methods: A cross-sectional study that evaluated adults and elderly patients diagnosed with hypertension, aged over 20 years, at a Hospital in Taubate, São Paulo, between February 2015 and May 2016. The variables evaluated were sex, age, weight and height for the calculation of body mass index (BMI). Nutritional status classification was made through World Health Organization criteria for adults, and Lipschitz criteria for the elderly, considering as parameter BMI. For statistical analysis, the t-test for independent samples and one-way ANOVA were used, with a Tukey post hoc analysis, with a significance value $p < 0.05$.

Results: Among the 176 patients evaluated, 63% (n = 111) were female. The median age for the female and male sex was 65.3 ± 11.3 and 67.4 ± 13.1, respectively. There was a significant difference between the sexes ($p < 0.05$). With data analysis, 63% (n = 71) of women were overweight, 27.9% (n = 31) presented eutrophy and the others were underweight. Regarding the males, 61% (n = 40) were overweight, 30.7% (n = 20) presented eutrophy and the others were underweight, and this difference was observed among all groups, through post hoc analysis ($p < 0.001$).

Conclusions: It is concluded that there is a high prevalence of overweight in hypertensive adults and elderly, and this outcome was higher to female sex. This is considered an injury to the hypertensive patient, and intervention measures are necessary to reduce excess adiposity.

NUTRITIONAL STATUS AND WEIGHT LOSS EVOLUTION IN CHILDREN WITH MALIGNANT NEOPLASMS SUBMITTED TO RADIOTHERAPY UNDER SEDATION

[1]*Jaloretto Teixeira Guedes, Karen;* [2]*de Lucena Ferretti, Roberta;* [3]*dos Santos maia-Lemos, Priscila;* [3]*Garófolo, Adriana.*

[1]Nutritionist. Federal University of Sao Paulo. Brazil; [2]PhD student. MSc. Nutritionist. Federal University of Sao Paulo. Sao Paulo. Brazil.; [3]PhD. MSc. Nutritionist. Federal University of Sao Paulo. Sao Paulo. Brazil.

Background and objectives: Patients with cancer submitted to radiotherapy (RxT) often are undergo prolonged fasting, which may favor the development of malnutrition. The objectives of this study were to identify the fasting time performed by patients submitted to RxT under sedation and to verify nutritional status evolution in three moments.

Methods: A longitudinal study that assessed children with malignant neoplasms, aged 2 to 8 years old, at a Specialized Institute of Pediatric Oncology, Sao Paulo, from July 2015 to September 2016. Data were collected in three moments, Pre, During ans Post RxT . Weight, height/length were analyzed, to calculate the Body Mass Index (BMI). Measures of middle upper arm circumference and skinfold tricptal were obtained to calculate Arm Muscle Area (AMA). Nutritional Status was assessed through z-score of BMI, according to World Health Organization recommendation. Patients were divided into two groups, A (fasting up to 14hours) and B (above 14 hours). Δ BMI z-score were calculated (variation of BMI z-score among three moments).

Results: Among the 19 patients assessed, 57.8% were male. In group A (n=11), during 3 moments, there was 9%(1st),9%(2nd),9%(3rd) of leanness, respectively, 82%(1st), 82%(2nd) and 91%(3rd) of eutrophy and 9%(1st), 9%(2nd) and 0%(3rd) of obesity. Regarding to AMA percentile<5, there were 9%, 9% and 18% of patients, respectively. In group B (n=8), in 3 moments were observed 0%(1st),12.5%(2nd),12.5%(3rd) of leanness, respectively,100%(1st), 87.5%(2nd), 87.5%(3rd) of eutrophy. Regarding to AMA below adequate there were, in 3 moments,12.5%, 12.5% and 37.5%, respectively. Weight loss was present in 47.5%, 73.5% and 52.6% in three moments, respectively. Regarding to the Δ BMI z-score, there was a greater variation for worsening of the BMI z-score, for group B (Δ BMI z-score=0.8) while Group A Δ BMI z-score=0.4.

Conclusions: It is concluded that the mean fasting time exceeded the recommendations of ACERTO project. Nutritional Status was predominantly eutrophic with AMA within normal range, however, there was weight loss (larger decrease of the BMI z-score) in a large part of the sample, being this endpoint higher in the group of patients who underwent longer fasting.

ASSESSMENT OF NUTRITIONAL STATUS, COMPARATIVE STUDY. CONCORDANCE BETWEEN MULTIFREQUENCY, MONOFREQUENCY BIOELECTRICAL IMPEDANCE ANALYSIS AND ANTHROPOMETRY

[1]Venczel, Analía Verónica; [2]Cristina, Monica; [2]Yuma, María; [2]Aragona, Hilda Susana; [3]Posadas Martines, Lourdes; [3]Perez, Lucía; [3]Giunta, Diego; [2]Gutt, Susana.

[1]Nutritionist. Internal Medicine Service. Italian Hospital of Buenos Aires. Argentina; [2]Nutrition Section – Internal Medicine Service - Italian Hospital of Buenos Aires. Argentina; [3]Clinical Research Section - Internal Medicine Service - Italian Hospital of Buenos Aires.

Background and objectives: To determine the nutritional health of an individual, we used nutritional assessment with anthropometric techniques and bioelectrical impedance analysis (BIA), two of the field methods most used for their easy application, good reproducibility and low cost.

We aimed to establish the concordance between two cohorts who were assessed by anthropometry and BIA.

Methods: We included 2871 patients between 18 and 90 years old in two cohorts of patients according to availability of bioimpedance equipment (2013-2015). Nutritional status was assessed by monofrequency BIA, multifrequency BIA and anthropometry with 4 skinfold thickness measurement. The Bland and Altman method was used to evaluate concordance between groups.

Results: 1168 studies were performed by BIA monofrequency, 69% (n = 807) female. Mean age 41 years (DS 15), mean BMI of 30 kg / m2 (DS 8). Mean % of body fat measured was 33.12% (DS 11), mean % of body fat measured by anthropometry was 34.3% (DS 10).

1703 multifrequency bioimpedance were performed, 70% (1187) female. Mean age was 44 years (DS 16) and mean BMI 30.5 (DS 7.7). Mean % of body fat was 37.7 (SD 11), mean % of body fat measured by anthropometry was 35.3 SD (12).

Bland-Altman comparison Limits of agreement (-11.587 to 9.317) Mean difference: -1.135 (CI -1.335 to -0.936) Range: 4.750 to 55.550 Pitman's Test of difference in variance: r =0.411, n = 2638, p =0.000

The limits of agreement were broad. At highest fat percentage averages there were difference in means between methods. This variability is not consistent across the graph.

Conclusions: Body composition assessment estimates by BIA monofrequency, multifrequency and skinfold method were different especially at greater body fat, concluding that these methods are not interchangeable

Keywords: Bioelectrical impedance analysis (BIA)

CORRELATION OF VISCERAL FAT LEVEL WITH WAIST CIRCUMFERENCE IN PATIENTS WITH NORMAL WEIGHT

[1]Gutt, Susana; [1]Cristina, Monica; [1]Yuma, María; [1]Aragona, Hilda Susana; [1]Schraier, Silvio; [2]Posadas Martines, Lourdes; [2]Perez, Lucía; [2]Giunta, Diego; [1]Venczel, Analía Verónica.

[1]Nutrition Section - Internal Medicine Service - Italian Hospital of Buenos Aires. Argentina; [2]Clinical Research Section - Internal Medicine Service - Italian Hospital of Buenos Aires.

Background and objectives: The aim of assessing nutritional status is to determine the general health of a patient from a nutritional point of view. Anthropometric techniques and bioelectrical impedance analysis (BIA) are two of the most widely used field methods due to their easy application, good reproducibility and low cost.

Knowing the size of visceral compartment allow us to predict metabolic risks.

We aimed to correlate visceral fat level with waist circumference in patients with normal weight.

Methods: We analyzed data from retrospective studies of patients undergoing nutritional assessment in the period 2015 by multifrequency BIA according to medical criteria. Anthropometry with 4 skinfold thickness and waist measurement was evaluated. The Spearman method was used to evaluate correlation between groups.

Results: 1470 multifrequency bioelectrical impedance were performed. 19% (281) patient with normal weight 72% (202) female, Media BMI 22.4 kg/m2, 22% (44) of female population had a % of total body fat ≥ 35% and a 25% (50) had visceral fat higher than normal limit.

28% (79) were male, Media BMI 22,1 kg/m2, 5,1% (4) had a total body fat ≥ 25%.

Global Rho spearman = 0.38 p 0.0000. By groups Female Rho spearman 0.64 p 0.000 and Male Rho spearman 0.73 p 0.0000

The Clinical Research and Bioethics Committee of the Hospital Italiano de Buenos Aires approved the study.

Conclusions: In all patients evaluated a weak linear relationship can be seen, concluding than waist circumference should not be used as a single method for an estimate of visceral fat in normal weight patient probably because it does not take into account height.

The visceral fat size was independent of anthropometric indicators of adiposity such as BMI and waist circumference. Data analyzed by sex, evidenced an increased correlation in women.

Keywords: Bioelectrical impedance analysis (BIA)

PREVALENCE OF MANLNUTRITION IN ENRICH PROGRAM SITES OF BANGLADESH, KENYA, MYANMAR, PAKISTAN AND TANZANIA

[1]Tolossa, Asrat; [2]Thomas, Abena; [3]Gillespie, Melanie; [4]Sellen, Daniel.

[1]MD, MPH, Chief of Party. ENRICH Program. World Vision Canada. Canada; [2]Grant Manager/DME advisor. ENRICH Program. World Vision Canada. Canada; [3]DME Team Lead. World Vision Canada. Canada; [4]Prof. Director The Joannah and Brian Lawson Centre for Child Nutrition. University of Toronto. Canada.

Background and objectives: ENRICH is a Maternal Newborn and Child Health and Nutrition program funded by the Government of Canada and implemented in Bangladesh, Pakistan, Myanmar, Kenya and Tanzania. ENRICH will use nutrition pathway to reduce U5M by strengthening health systems and improving basic nutrition and nutrition sensitive services and addressing nutrition-related causes such as: poor breastfeeding, stunting, wasting, and vitamin A and zinc deficiencies (Lancet, 2013). One of the strategies is promotion of production and consumption of biofortified micronutrient-rich crops which help to reduce vitamin A deficiency and improved iron status among CU5

Methods: The anthropometric nutrition assessment was done as part of baseline household survey of the ENRICH program. The sample size for each country was estimated using ENA for SMART software. A proportional stratified multi-stage cluster method was used to select respondents. Ethical approval was secured from University of Toronto and from the concerned authorities at country level. Anthropometric measurements were done among 6-59 months old children.

Results: Prevalence of stunting was 31.0% in Bangladesh, 33.1% in Kenya, 31.5% in Tanzania, 44.6% in Pakistan, and Myanmar 39%. The prevalence of wasting was 6.5%, 5.3%, 4.9%, 10.2% and 7.0% in Bangladesh, Kenya, Tanzania, Pakistan and Myanmar respectively. Under weight prevalence was also 20.8%, 17.8%, 15.3%, 29.7% and 28.2% in the same order. Poor infant and young child feeding practices, food insecurity and poor access to nutrition and health services were found to be some of the contributing factors. The proportion of severely food insecure households ranged from 11% to 32.3% among the five countries.

Conclusions: Malnutrition is a serious public heath problem in ENRICH project sites of the implementing countries. Chronic food insecurity and poor infant and young child feeding practices are some of the factors contributing to the high level of malnutrition. Integrated nutrition specific and sensitive interventions which are effective in reaching the poor are required to address critical underlying determinants of malnutrition. Assessment of other local determinates of poor feeding practices and tailored interventions can also play a central role in preventing undernutrition.

THYROGLOBULIN IN CHILDREN WITH LONG-TERM EXPOSURE OF IODINE EXCESS

[1]Zhang, Wanqi; [2]Chen, Wen; [2]Wang, Wei; [3]Hao, Yunmeng; [3]Wu, Yalan; [4]Bian, Jiancao; [2]Lin, Laixiang; [2]Tan, Long; [3]Shen, Jun; [4]Wang, Xiaoming.

[1]Public Health College, Tianjin Medical University; [2]PhD. Department of Food nutrition and hygiene, Tianjin Medical University, Tianjin, China; [3]MD. Department of Food nutrition and hygiene, Tianjin Medical University, Tianjin, China; [4]The Shandong Institute for Endemic Disease Control and Research, Shandong, China.

Background and objectives: This study investigated thyroglobulin (Tg) concentrations in children with long-term exposure of iodine excess from water.

Methods: In a multi-stage cross-sectional survey, we collected, on two nonconsecutive days, two 24-h urine samples and determined 24-h urinary iodine excretion (24-h UIE, µg/d) and then calculated habitual daily iodine intake. Tg of children was detected.

Results: In this study, 2034 children had Tg measured including 1001 boys and 1033 girls. The water iodine content in this study was 181 µg/L (67.1-403) µg/L.. The habitual daily iodine intake of children was 298 µg/d (188-436) µg/d. The median Tg concentration of children was 16.0 µg/L (9.8-26.1) µg/L in this study, and 237 (12%) children had Tg>40 µg/L while 85 (4.2%) children had Tg<4 µg/L. Tg was not associated with iodine intake concentrations up to the threshold value of 120 µg/d. When the iodine intake concentration was >120 µg/d, Tg was associated with increased iodine intake (β: 0.5; 95% CI: 0.4, 0.6; P<0.001). Taking iodine intake of 100-149 µg/d as the reference, logistic regression analysis for the association between iodine intake and Tg>40 µg/L, indicating that children from iodine intake range of ≥600 had higher risk of TGR compared to iodine intake of 100-149 µg/d (OR: 2.4 95% CI: 1.2, 4.9; P=0.018) while no differences were observed in other iodine intake ranges.

Conclusions: Tg concentrations of children who were exposed to high iodine intake were higher, however, the risk of Tg>40µg/L was not different among different iodine intake levels.

DETERMINATION OF IODINE CONTENT BY ICP-MS FOR IODINE BALANCE STUDY

Zhang, Wanqi; Cui, Tingkai; Shen, Jun; Pan, Ziyun; Tan, Long.

Department of Nutrition and Food Hygiene. School of Public Health. Tianjin Medical University. Tianjin. China.

Background and objectives: Iodine balance study on adults, neonates, pregnant and lactating women is essential to provide strong evidence for Dietary Reference Intakes (DRIs. Thus iodine content in a host of food, water, table salt, urine, breast milk and feces samples need to be analysed. Meanwhile demand for assessment of iodine content in serum and saliva samples is increasing due to the rising awareness of iodine status. Inductively Coupled Plasma Mass Spectrometry (ICP-MS) prevails in determining elements, including iodine, as its rapidity, low detection limits and minimal sample amount needed for analysis. This study aims to develop a fast, simple, and cheep method to determine iodine concentration in massive samples for iodine balance study and iodine status survey or evaluation.

Methods: Weigh 0.2g shredded food or feces samples and digest with 4.8mL 1% tetramethylammonium hydroxide (TMAH) in 5mL eppendof (EP) tube at 90°C for 24h, then transfer 0.5mL supernatant into 2mL EP tube after centrifuge at 3000 rpm for 15min, dilute with 1.5mL ultra-purified (UP) water, and finally centrifuge at 12000 rpm for 5min. Transfer 0.25mL breast milk samples into 5mL EP tube while with 2.75mL 0.5% ammonia at 90°C for 3h, then centrifuge at 3000 rpm for 15min and transfer 0.5mL supernatant into 2mL EP tube followed by diluted with 1.0mL UP water. Driking water, salt, serum, urine, and saliva samples are directly diluted with 7mmol/L ammonia. The final sollution can be injected into ICP-MS for iodine analysing.

Results: The precision (RSD: 2.65%-8.85%) and recovery rate (88.08%-115.04%) of the method for assessment of above samples were satisfactory.

Conclusions: These sample treatments make iodine determination in a large number of samples fast, simple and cheep and it can be used for iodine status survey or evaluation, especially for iodine balance study.

Keywords: Iodine; determination; ICP-MS

NEW INSIGHTS INTO THE PANDEMIC OF LOW VITAMIN "D" LEVELS AND ITS ASSOCIATION WITH SEMEN QUALITY AND HORMONAL LEVELS IN FERTILE AND INFERTILE MALE SUBJECTS

[1]*Ciccone, Inari;* [2]*Pariz, Juliana;* [3]*Costa, Elaine;* [4]*Hallak, Jorge.*

[1]MS Student. Androscience. Faculdade de Medicina da Universidade de São Paulo.; [2]PhD Student. Biomedical. Androscience. University of Sao Paulo Medical School FMUSP. Brazil; [3]Associate Professor of Endocrinology. Division of Endocrinology. Hospital das Clinicas of University of Sao Paulo. Brazil; [4]PhD. Andrologist. Associate Professor Of Urology. Department of Pathology. University of Sao Paulo Medical School. Androscience. Brazil.

Background and objectives: Vitamin D is a versatile signaling molecule, that targets also male reproductive organs, in addition to effects on bone, calcium and phosphate homeostasis. Accumulating evidence from animal and human studies suggests that it is involved in reproduction metabolism. Objective: To evaluate the influence of vitamin D status on semen quality and hormonal profile in male fertility and infertility.

Methods: We evaluated 100 men (aged 18 to 50 y.o.) from a private medical clinic. Infertility (n=70) and fertility (n=30) groups. According to vitamin D level status all of them were classified in sufficient (group 1 - 25OHvitD ≥ 30ng/ml), insufficient (group 2 - 25OHvitD from 21 to 29ng/ml) and deficient (group 3 - 25OHvitD ≤20ng/ml). Blood samples were collected to analyze serum vitamin D, LH, FSH, estradiol, total and free testosterone, prolactin and SHBG levels. Semen was analyzed according to WHO guidelines, strict criteria and sperm functional tests were performed (ROS, CK, beads). In addition, karyotype, frequency of varicocele, smoking, alcohol ingestion, and body composition were considered. Statistical analysis was performed by SPSS program version 19.0 (SPSS Inc., Chicago, IL). T-test was used for unpaired samples for statistical analysis. Statistical significance was considered with P value < 0, 05.

Results: According to vitamin D status, patient distribution was: Infertile: group 1 - 28.5% (20/70), group 2 - 43% (30/70) and group 3 - 28,5% (20/70). Fertile: group 1 - 34% (10/30), group 2 - 40% (12/30) and group 3 - 26% (8/30). Sperm motility was significantly lower in group 3 in comparison to group 1 in infertile patients. Regarding fertile men, we found higher sperm volume in group 3 than the group 1, a significant reduction of sperm concentration and worse morphology by strict criteria in group 3 in comparison to group 1. Hormonal levels were similar in all vitamin D groups.

Conclusions: Our results demonstrated that sufficient vitamin D levels has a positive influence on spermatogenesis and semen quality, suggesting that vitamin D replacement should highly be concerned on male fertility treatment and that low vitamin D have reached epidemic proportions in industrialized cities.

Keywords: Nutrition and Male infertility. Male fertility treatment. 25OHvitaminD deficiency.

EVALUATION OF HEMOGLOBIN MEASUREMENT TOOLS FOR CHILD ANEMIA SCREENING IN RWANDA

[1]Parker, Megan E Parker; [2]Han, Zhen; [3]Abu-Haydar, Elizabeth; [4]Matsiko, Eric; [4]Iyakaremye, Damien; [5]Tuyisenge, Lisine; [6]Magaret, Amalia; [7]Lyambabaje, Alexandre.

[1]PATH; [2]BSc, PhD. Nutrition Innovation, PATH. USA.; [3]BSc, MPH. Devices & Tools, PATH. USA; [4]BSc, MSc. Human Nutrition and Dietetics Department, University of Rwanda, Kigali, Rwanda; [5]BSc, MD, MSc. Pediatrics. Centre Hospitalier Universitaire de Kigali, Kigali, Rwanda; [6]BSc, MSc, PhD. Departments of Lab Medicine and Biostatistics, University of Washington, Seattle, WA; [7]BSc, MSc, PhD. Mathematics and Applications. University of Rwanda, Kigali, Rwanda.

Background and objectives: Blood hemoglobin (Hb) level is a common indicator for diagnosing anemia and is often determined through laboratory analysis of a venous or capillary blood sample. Drawing blood samples, however, poses challenges in young children, increases the risk of infection and disease transmission, and is sometimes unacceptable to caregivers. One alternative to laboratory-based methods is use of the handheld HemoCue® Hb 201+ device, which requires a finger prick and wicking of blood into a pretreated cuvette for analysis. This wicking method is commonly used in clinic and community settings, but an alternative HemoCue® gravity method is being investigated for improved accuracy. Further, recent developments in noninvasive technologies could provide an accurate, rapid, safe, point-of-care option for Hb estimation while addressing some limitations of current tools, but the performance of these devices has not been assessed in low-resource settings. This study evaluated the performance of two HemoCue® Hb 201+ blood sampling methods and a noninvasive device (Pronto® with DCI-mini™ sensors) in a Rwandan pediatric outpatient clinic.

Methods: Reference Hb values were determined in 132 children 6 to 59 months of age by using a standard hematology analyzer (Sysmex KN21). 66 children were tested using the HemoCue® wicking method and 66 were tested using the HemoCue® gravity methods. 112 of the children had successful Hb readings with Pronto® DCI-mini™. Statistical analysis was used to assess the level of bias generated by each method and the key drivers of bias.

Results: The HemoCue® gravity method was the least biased compared with the HemoCue® wicking method and the Pronto® with DCI-mini™ sensors. The biases of the HemoCue® wicking and Pronto® DCI-mini™ methods were inversely related to the Sysmex KN21 results. Both HemoCue® sampling methods correctly classified patients' anemic status at or above 80%, while the Pronto® DCI-mini™ device had a correct classification rate of only 69%.

Conclusions: The HemoCue® gravity method was more accurate than the traditional HemoCue® wicking method in this study, but its accuracy and operational feasibility should be confirmed by future studies. The Pronto® DCI-mini™ devices showed considerable promise but require further improvements in sensitivity and specificity before wider adoption.

DETERMINATION CONTENTS OF THE DIGESTIBLE INDISPENSABLE AMINO ACIDS (DIAAS) OF NINE KINDS OF GRAIN CEREAL USING RAT MODEL

[1]Han, Fei; [1]Han, Fei; [2]Han, Fenli; [3]Chen, Xi; [3]Song, Ge; [4]Fan, Liuping.

[1]PhD. Nutritionist. Academy of State Administration of Grain. P.R.China; [2]Master. Food College. Jiang Nan University. P.R.China; [3]Master. Academy of State Administration of Grain. P.R.China; [4]PhD. Nutritionist. Food College. Jiang Nan University. P.R.China.

Background and objectives: Recently, for the grains, most of the researches are mainly focus on the antioxidation, prevention of chronic diseases and processed food as well as its nutritional compositions. However, there are few researches about the grain amino acid in vivo digestibility and formula design with digestible indispensable amino acid (DIAA) of grains. This research studies the contents of the digestible indispensable amino acids (DIAAS) of the nine typical grain cereals from different provinces in China.

Methods: The research has been made on the impacts of the protein sources in such nine kinds of grains on the apparent, true ileal amino acid digestibility and DIAA using rat model. To prepare diets using 9 grains for atmospheric pressure cooked that meet the nutritional needs of rats according to NRC requirements.

Results: The results showing that the average total apparent ileal amino acid digestibility values in the whole wheat and coix groups are significantly higher than other grain groups (P < 0.05) and the ileal true amino acid digestibility and ileal apparent amino acid digestibility values are characterized by a basically consistent trend; the available lysine digestibility is highest in the whole wheat and millet groups but lowest in the tartary buckwheat group and there is no significant difference in others groups (P > 0.05). Moreover, the research has been made on the ileal DIAA and available lysine contents of the protein sources in different grains, with the results showing that the digestible lysine contents in the oats and rice groups are higher than the millet, foxtail millet, coix and whole wheat groups but lower than the common and tartary buckwheat groups (P < 0.05) and the amino acids in legumins are more easily digestible than that in prolamins.

Conclusions: The nutritional value of the 9 grains was further evaluated by digestible indispensable amino acid score (DIAAS), the order were as follows: buckwheat group>tartary buckwheat group>oat group>brown rice group>polished rice group>whole wheat group>coix group>millet group>proco-millet group.

Keywords: grain cereals; protein; digestible indispensable amino acids (DIAAS)

QUALITY INDICATOR IN THE NUTRITIONAL CARE OF CRITICALLY ILL PATIENTS IN A PRIVATE HOSPITAL - BRAZIL

[1]Konkolisc Pina de Andrade, Grasiela; [2]Chaloub Chediac Rodrigues, Ana Lucia; [2]Silva, Luanye Karla; [3]Nadolskis Severine, Ariane; [4]Junqueira Amarante, Gustavo Adolpho.

[1]Nutritionist. Division of Nutrition. Hospital Sírio Libanês. Brazil; [2]Nutritionist. Division of Nutrition. Hospital Sirio Libanes. Brazil; [3]Msc. Nutritionist. Division of Nutrition. Hospital Sirio Libanes. Brazil; [4]MBA. Doctor. Division of Critical Care Medicine.

Background and objectives: Patients on nutritional therapy should be monitored routinely, and this evaluation should ensure that the best therapy is being offered for clinical recovery. Our objective was to create a tool to measure and monitor the quality of therapy provided to the critical patient aiming at nutritional recovery.

Methods: All hospitalized patients underwent a nutritional evaluation and were classified into 2 groups: with or without nutritional risk. Patients with nutritional risk were reevaluated every 7 to 10 days, taking into account: tolerance of the oral, enteral or parenteral therapy, biochemical tests and anthropometric measures. Based on the results, the patient was classified into three categories: worsening, maintenance or improvement of nutritional status. The monthly goal was to achieve at least 75% maintenance or improvement of nutritional status in these patients.

Results: The proposed target was reached between January and June 2016 (mean 92.1%), so in July a new target of 92% was proposed. Between July 2016 and April 2017, only 2 monthly measurements showed results below the expected target: October 2016 (91.5%) and January 2017 (89.3%). Analyzing the data, specific actions were implemented to reverse the critical points of nutritional care like early oral supplementation or enteral therapy.

Conclusions: Nutritional therapy is essential for the critical patient and the implementation of tools to measure the quality of care contributes to an effective and individualized nutritional therapy aiming at the clinical recovery of patients, at a lower cost.

BIOMARKERS OF INFLAMMATION AND MICRONUTRIENT CONCENTRATIONS IN RESPONSE TO A NOROVIRUS IMMUNOLOGIC CHALLENGE

[1]Williams, Anne; [2]Leon, Juan S.; [3]Lopman, Benjamin A.; [4]Tangpricha, Vin; [5]Whitehead, Jr., Ralph D.; [6]Flores-Ayala, Rafael; [7]Suchdev, Parminder S.

[1]PhD. Centers for Disease Control and Prevention; [2]PhD, MPH. Hubert Department of Global Health. Emory University. USA.; [3]PhD. Department of Epidemiology. Emory University. USA.; [4]MD, PhD. Department of Medicine. Emory University School of Medicine. USA.; [5]PhD. International Micronutrient Malnutrition Prevention and Control. Centers for Disease Control and Prevention. USA.; [6]DrPH. Nutrition Branch. Centers for Disease Control and Prevention. USA.; [7]MD, MPH. Department of Pediatrics. Emory University School of Medicine.

Background and objectives: Characterizing the effects of inflammation and the acute phase response on nutrient biomarkers is a critical research gap to improve accurate assessment of micronutrient status. The objective of this study was to quantify the relationship between Norovirus infection and common biomarkers used to assess inflammation [C-reactive protein (CRP) and alpha-1-acid glycoprotein (AGP)] and micronutrient status.

Methods: A longitudinal norovirus challenge study was conducted among apparently healthy adults at Emory University from 2006-2009. Of 64 volunteers, 26 became infected (norovirus detectable in stool by RT-PCR). Sandwich ELISA technique was used to measure proteins in banked serum collected at ten time points including one pre-challenge and nine post-challenge samples (1,2,3,4,7,14,21,28 and 35d post-exposure). A repeated measures study of 52 subjects (age, gender matched) was conducted to assess change in CRP, AGP, ferritin, transferrin receptor (sTfR), and retinol binding protein (RBP) over time by norovirus infection status. We calculated range of biomarker concentrations across the 35d period and report median range biomarker values. The non-parametric rank median test was used to assess differences in range of concentrations over time by infection status.

Results: Among infected individuals, CRP, AGP and ferritin concentrations rose to peak values by day 3-4 post-exposure, while uninfected individuals did not show increased concentrations post-exposure. RBP concentrations of infected individuals declined up to day 4-7 post-exposure. Median (quartile1, quartile3) range of biomarker concentrations [uninfected; infected] over time were CRP(mg/L) [1.8 (0.8, 3.2); 17.0 (7.8, 29.3) (p<0.001)], AGP(g/L) [0.4 (0.2, 0.5); 0.6 (0.5, 0.8) (p=0.001)], ferritin (μg/L) [30.7 (15.8, 46.3); 58.1 (48.0, 85.3) (p=0.001)], sTfR (mg/L) [1.5 (1.2, 3.1); 1.8 (1.4, 2.4) (p=0.27)], and RBP(μmol/L) [0.7 (0.4, 0.9); 0.8 (0.6, 1.2) (p=0.10)].

Conclusions: The median concentrations ranges of CRP, AGP, and ferritin were greater among infected than uninfected volunteers. Quantifying the magnitude and duration of micronutrient concentration changes, over the course of norovirus infection, will improve the understanding of micronutrient status in areas with high prevalence of inflammation and common infection from gastroenteritis.

Instituto Nacional de Alimentación y Nutrición-INAN. Ministerio de Salud Pública y Bienestar Social. Paraguay; [5]MSc. Mendoza de Arbo Laura. Medical Doctor. Instituto Nacional de Alimentación y Nutrición-INAN. Ministerio de Salud Pública y Bienestar Social. Paraguay.

Background and objectives: Introduction: Nutritional assessment of adolescent pregnant women is vital to ensure maternal and fetal health. Most countries in Latin America use Atalah et al. charts to assess nutritional status of pregnant women. In Paraguay Rosso-Mardones criteria is used. Objectives: to evaluate the agreement between two nutritional assessment methods for pregnant women, Rosso-Mardones and Atalah et al.

Methods: Material and Methods: analytical cross sectional study. Analysis of sociodemographic and anthropometric data of pregnant adolescents collected in 2015 from the Food and Nutrition Surveillance System (SISVAN by its Spanish acronyms) at public health services of 18 Sanitary Regions. Nutritional status was assessed by Rosso-Mardones and Atalah et al criteria. The results were compared using percentages and the concordance between both methods was determined by Cohen's Kappa. A p value <0,05 was considered significant.

Results: 2.208 pregnant adolescents between 15 and 19 years old were included. The average age was 17, 4±1,3 years old; 58,2% lived in urban areas (n=1284) and 78% were in a couple relationship. Nutritional status according to Rosso- Mardones vs Atalah et al. criteria was: underweight 43, 8% (n=966) vs 34% (n=750), normal weight 31,5% (n= 696) vs 46,6% (n=1.028), overweight 10,2% (n=226) vs 14,1% (n=311) and obesity 14,5% (n=320) vs 5,4% (n=119). Cohen's Kappa indicated a good agreement between both methods: 96,4% for underweight, 65,2% for normal weight, 38,3% for overweight, and 100% for obesity(0,617; p=0,0001).

Conclusions: Even though underweight and obesity were higher according to Rosso-Mardones, a good concordance was observed between both methods. At the national level there is no consensus on the best criterion for nutritional assessment of pregnant adolescents. Therefore, it is essential to analyze the epidemiological situation of this population and to establish the objectives to be achieved at the public health level in order to select the most appropriate method.

Keywords: Nutrition Assessment, nutritional status, pregnancy in adolescence.

COMPARATIVE STUDY OF THE AMINO ACID COMPOSITION OF PEELS, PULP AND CORE OF SEEDLESS BREADFRUIT (ARTOCARPUS ALTILIS)

Esekheigbe, Ayemhenre.

PhD. Senior Lecturer. Ambrose Alli University. Ekpoma. Nigeria.

Background and objectives: Seedless breadfruit (Artocarpus altilis) is a large, round, starchy fruit which is usually eaten either boiled or fried. Originally native to the West Indies, it has found its way to Africa including Nigeria. The pulp of the seedless breadfruit which is generally consumed is known to be rich in nutrients notably carbohydrates. However, there is no much information on the nutrient content of the parts not commonly consumed hence the need for the study.

Methods: Samples of mature seedless breadfruit were purchased from the market at Ekpoma (6.7491oN, 6.0732E), Edo State, Nigeria. In the laboratory, the samples were peeled and the pulp separated from the core. Thereafter, they were pulverized and dried in an oven at 60oC for 48 hours before being milled. They were then stored in air tight containers at 4oC in the refrigerator before analysis. Protein (N x 6.25) was determined by the Kjedahl method while the amino acid profile in the different seedless breadfruit samples were determined using the ion exchange chromatographic method (Technicon sequential multi-sample amino acid analyzer).

Results: From the results obtained, breadfruit was found to contain both essential and non essential amino acids. The total amino acid content was highest in the core, followed by the pulp and peel with values of 714.1, 617.7 and 589.0 mg/g protein respectively. Interestingly however, although the core was found to have the highest concentration of amino acids, the peel which is usually discarded was found to contain the highest percentage of essential amino acids (48.64%) This was followed by the core (45.97%) and the pulp (44.83%). Every portion of the seedless breadfruit is thus important with respect to amino acid content.

Conclusions: There is therefore the need to harness the essential amino acids in the peel of the seedless breadfruit for both man and animal consumption.

Keywords: Amino acid, Breadfruit

Ministry of Public Health and Social Welfare. Asunción, Paraguay.

Background and objectives: Salt fortification with iodine is mandatory to prevent, control and eradicate iodine deficiency disorders. It is important to monitor iodine consumption and its content in salt, but it is also necessary to prevent the excess of its intake.

The aim was to evaluate the association between iodine status in children and adolescents, with sodium intake through its urinary levels and with the content of iodine in salt available at household level.

Methods: Cross –sectional, descriptive and analytic study. Previous written consent, urinary iodine was dosed in children and adolescents (ammonium persulfate method) and evaluated for status according to WHO/VMNIS (Vitamin and Mineral Nutrition Information System) criteria. Sodium (Na) was also measured in early spot urine samples by the Ion-Selective Electrode (ISE) method as an indicator of salt consumption. Iodine levels were determined in salt samples (volumetric method-Thiosulfate). ANOVA and Chi square Test was used, p value <0.05 was considered significant.

Results: old); 53,1% were woman. The median urinary iodine level was 301.2 mg/L (51-646 mg/L), according iodine status 4,8% had mild iodine deficiency (50-99mg/L), 16.4% was adequate (100-199mg/L), 32.1% was more than adequate (200-299mg/L), 46.7% shows risk of adverse health consequences (>300mg/L). Average urinary Na was 161.2 mmol/L (9.0–459.2mmol/L), it was lower for children with mild iodine deficiency (113.6mg/L) versus those with risk of adverse health consequences (170.5 mg/L), more than adequate (168.1 mg/L) or adequate (147.2mg/L) iodine status (ANOVA, p<0.0001). Iodine levels were adequate (20-40 mg/k) in 60% of salt samples, insufficient (<20 mg/k) in 14.8% and excessive (>40mg/k) in 25.2%, none was negative. The percentage of risk of adverse health consequences of iodine status was 29% when iodine content in salt was excessive vs 20% when salt iodine was adequate (c2, p=0,02). Correlation between urinary Na and iodine was no found (Pearson correlation r=0,145).

Conclusions: By iodine urinary, 1 of each 2 child/adolescent present iodine status of risk of adverse health consequences, which is associated with higher intake of salt and when salt contains iodine above the recommended.

Keywords: iodine, salt, iodine urinary, children, adolescents

USE OF DRIED MATRIX SPOTS FOR NUTRITIONAL BIOMARKER ANALYSIS

[1]*Arredondo, Francisco X.;* [2]*Craft, Neal E.;* [3]*Fleshman, Matthew K.*

[1]MD/PhD. Biomarkers Group. Craft Technologies, Inc. USA.; [2]PhD. President. Craft Technologies, Inc. USA.; [3]PhD. Mass Spectrometry Group. Craft Technologies, Inc. USA.

Background and objectives: Background

Dry Matrix Spots (DMS) are dried spots of fluids, including blood, serum, urine, saliva and breast milk, which have been used for remote collection. A device separating RBCs from plasma without centrifugation would be useful for nutritional assessment in developing countries.

Objectives

To obtain and evaluate blood collection devices (BCDs) for measurement of nutritional biomarkers (NBs). Using DMS, to determine the best methods to measure NBs, including: ferritin, folate, retinol binding protein (RBP), 25OH-D, B12, thyroglobulin (Tg), zinc, methylmalonic acid (MMA), homocysteine (HCY), alpha-1-acidglycoprotein (AGP), and C-reactive protein (CRP).

Methods: Criteria were established for successful BCDs and analytical methods. Nine BCDs were obtained and tested. Analytical methods included single-plex enzyme immunosorbent assays

(EIA), microbiological assays (folate, B12), chemiluminescence multiplex EIA, and LC-MS/MS (25OH-D, MMA and HCY).

Short-term folate stability was tested in the ViveBio-collected RBCs using a microbiological assay. Both dry cells and liquid-stabilized were tested at 23°C, 37°C and 45°C. RBC volume was calculated using the measurement of potassium.

Results: None of the BCDs met the selection criteria. Many exhibit chromatographic effects, provide too little plasma for analytical testing, or do not separate RBCs from plasma.

A prototype BCD from ViveBio (Alpharetta, GA) that separates RBCs in a vertical format yielding hemoglobin-free plasma on a collection pad was used, permitting analysis of serum-based components and RBC markers.

RBC folate was most stable in the dry cells. A cocktail containing sodium azide and bovine serum albumin (BSA) provided the best results of the liquid stabilizers.

Some NBs could not be measured using single-plex EIAs due to sample dilution, therefore, the QuanSys multiplex was used successfully. It offers the advantage of obtaining results for 6 NBs (AGP, CRP, Ferritin, Tg, RBP, and TfR) simultaneously.

Using LC-MS/MS, MMA, HCY and 25OH-D were successfully measured in eluates from DMS and in extracts stored at 23°C, 37°C and 45°C.

Conclusions: ViveBio DMS collection device was identified which separates RBCs from plasma. Both compartments were used to test NBs. The stability of 12 NBs at 5 temperatures is being measured in DMS using QuanSys multiplex, microbiological, and LC-MS/MS methods.

EVALUATION OF NEW TECHNOLOGY-BASED TOOLS FOR DIETARY INTAKE ASSESSMENT

[1]Eldridge, Alison; [2]Cade, Janet; [3]Gibney, Mike; [4]Gurinovic, Mirjana; [5]Illner, Anne-Kathrin; [6]Piernas, Carmen; [7]Smith, Benjamin; [8]Taberner, Jonathon; [9]de Vries, Jeanne.

[1]PhD. Institute of Nutritional Science. Nestlé Research Center. Switzerland.; [2]PhD. School of Food Science and Nutrition. University of Leeds. United Kingdom.; [3]PhD. Institute of Food and Health. University College Dublin. Ireland.; [4]PhD. Centre of Research Excellence in Nutrition and Metabolism. Institute for Medical Research. University of Belgrade. Serbia.; [5]PhD MPH. Department of Nutrition and Health Sciences. Polytechnic Institute UniLaSalle Beauvais. France.; [6]PhD. Nuffield Department of Primary Care Health Sciences. University of Oxford. United Kingdom.; [7]PhD. Toxicology and Scientific Services. Firmenich. United States of America.; [8]Student. School of Food Science and Nutrition. University of Leeds. United Kingdom.; [9]PhD. Department of Agrotechnology and Food Sciences. Wageningen University. The Netherlands.

Background and objectives: There is growing pressure in the area of dietary intake assessment to improve the accuracy and reduce costs of data collection and processing. New technology-based tools are available and more are under development, including web-based programs, mobile applications, and digital image-assisted and digital image-based tools, among others. The ILSI Europe Dietary Intake and Exposure Task Force launched this project to characterize and evaluate technology-based dietary assessment tools in order to develop general quality standards for future applications.

Methods: A comprehensive literature review identified new technology-based tools using key word searches with the following inclusion criteria: publications were in English, papers were published from 2011-2016, and the tool features, functions and uses were detailed. A total of 29 dietary assessment tools were identified. Scoring criteria were developed to evaluate tool features, results outputs, sources and completeness of food composition data, target audience and suitability for research. Each tool was rated on 27 features.

Results: Most of the tools identified (23/29) relied on self-reporting of dietary intake data, either through web-based programs or mobile apps. Eleven used digital images to help identify and quantify foods consumed, and one used a barcode scanner. Most tools reported energy (22/29) and macronutrients (21/29), but fewer reported micronutrients (19/29) and food groups (17/29). Only 16/29 allowed for data to be exported to researchers or other health professionals. Few publications on the tools included details about food composition tables or the ability to add missing items (5/29) or custom recipes (2/29). Scores for the tools ranged from 4 to 18 with an average of 11 out of 27 possible attributes.

Conclusions: Dietary assessment methods that utilize technology provide rapid feedback to users and offer potential cost-savings for researchers. There remain gaps in many of these tools before they will be ready to replace more traditional interview-based

methods for research purposes, and most require validity testing, additional description of the food composition tables used and details on how the foods are identified and quantified. This project will provide perspective on quality standards that could be recommended for future development and reporting of technologies in the area of dietary intake assessment.

Keywords: Dietary assessment, digital images, mobile app, web-based tools.

Track 6: Functional Foods and Bioactive Compounds

EFFECTS ON POSTPRANDIAL BLOOD GLUCOSE AND INSULIN LEVELS AND HYDROGEN EXCRETION THROUGH THE INHIBITORY EFFECTS OF 1, 5-ANHYDROGLUCITOL ON DISACCHARIDASES IN RATS AND HEALTHY HUMANS

[1]Oku, Tsuneyuki; [2]Tanabe, Kenichi; [3]Yoshinaga, Kazuhiro; [4]Shimura, Fumio; [4]Nakamura, Sadako.

[1]Jumonji University; [2]PhD. Department of Food Science and Nutrition. Nagoya Women's University. Japan.; [3]PhD. Developing Laboratory of New Materials. Nihon Starch Co. Ltd. Japan.; [4]PhD. Institute of Food, Nutrition & Health. Jumonji University. Japan.

Background and objectives: 1,5-Anhydro-D-glucitol (1,5-AG) is found in low levels in natural plant foods and also produced sparingly from glycogen in the liver. 1,5-AG which is mostly contained in the body is used as a marker of blood glucose control in patients with diabetes mellitus. The objective is to investigate whether 1,5-AG, which is ingested excessively as a food ingredient, has a specific physiological function.

Methods: The inhibition by 1,5-AG was determined on disaccharidases of small intestine of rats and humans, and compared with that of rare sugars. To investigate the metabolism and fate of 1,5-AG, 1,5-AG was administered orally to rats prior to human experiments and the effects on blood concentrations and urinary excretion of 1,5-AG and hydrogen excretion were determined. In addition, a sucrose or glucose solution with or without 1,5-AG was administered orally to rats, and the suppressive effects on postprandial blood glucose and insulin was determined. Similar physiological functions were also investigated using healthy human participants.

Results: 1,5-AG distinctly inhibited the activity of sucrase, maltase, trehalase and lactase, while D-sorbose and L-arabinose strongly inhibited sucrase but barely inhibited trehalase and lactase. The inhibition of 1,5-AG on sucrase and maltase were similar between humans and rats. 1,5-AG in serum showed a peak 30 min after ingestion of 1,5-AG (10 g) by healthy subjects, and decreased gradually over 180 min. About 60 % of 1,5-AG was excreted into the urine for 9 h following ingestion, while mostly 100 % of 1,5-AG was excreted into the urine 24 h after administration in rats. Hydrogen was scarcely excreted in both rats and humans 24 h after administration of 1,5-AG. 1,5-AG significantly suppressed the elevation of blood glucose and insulin by the ingestion of sucrose or glucose. A large amount of 1,5-AG (20 g) caused no side effects among healthy participants. Ingested 1,5-AG was readily absorbed from the small intestine and excreted rapidly into the urine. Thus, the available energy of 1,5-AG is 0 kcal/g and 1,5-AG does not cause osmotic diarrhoea.

Conclusions: 1,5-AG which has a very low toxicity and is safe, could be use as low energy bulking sweetener in food products.

Keywords: 1,5-anhydroglucitol; postprandial blood glucose; disaccharidase; hydrogen excretion; inhibitory effect.

EFFECTS OF 1,5-ANHYDROGLUCITOL-FEEDING ON GROWTH, ORGAN WEIGHT, BLOOD BIO-CHEMICAL MARKERS AND OXIDATIVE STRESS IN RATS

(1)Oku, Tsuneyuki; (2)Nakamura, Sadako; (3)Tanabe, Kenichi; (4)Miyahara, Akemi; (5)Izumi, Chiyoko; (6)Yoshinaga, Kazuhiro; (7)Yamazaki, Yuko; (2)Sasaki, Naho.

(1)Jumonji University; (2)PhD. Institute of Food, Nutrition & Health. Jumonji University. Japan.; (3)PhD. Department of Food Science and Nutrition. Nagoya Women's University. Japan.; (4)BSc. Graduate School of Human Health Science. University of Nagasaki. Japan.; (5)MSc. Developing Laboratory of New Materials. Nihon Starch Co. Ltd. Japan.; (6)PhD. Developing Laboratory of New Materials. Nihon Starch Co. Ltd. Japan.; (7)PhD. Institute of Food, Nutrition & Health. Jumonji University. Japan.

Background and objectives: 1,5-anhydro-D-glucitol (1,5-AG) which has 60 % of the sweetness of sucrose, is found in low levels in natural plant foods and also produced sparingly from glycogen in the liver. 1,5-AG which is mostly contained in the body, is used as a marker of blood glucose control in patients with diabetes mellitus. The objective is to investigate whether 1,5-AG, which is ingested excessively as a food ingredient, does not cause the harmful effect and has a specific physiological function.

Methods: Male Wistar rats aged 4-wk were raised using consecutive feeding of diets (AIN93G) containing 5% and 10% of 1,5-AG for 31 days (n=5 in each group). Erythritol, which is easily absorbable and excreted in the urine without degradation, and fructooligosaccharide (FOS), which is non digestible and completely fermentable were used as controls. Body weight and food intake were determined every day and blood was collected on 24th day of experiment to measure oxidative stress. The urine and feces were collected between 27th and 29th day of experiment using metabolic cage.

Results: The growth and organ weights of the rats were not significantly different between the control group and the other 4 groups, because the amount of dietary intake was adjusted to become identical by light restricted feeding. In the experiment of revenue and expenditure, almost 100% of the 1,5-AG ingested was recovered from urine collected for 24 h. These results demonstrate that almost 1,5-AG ingested is absorbed from the small intestine and is excreted in the urine without degradation, with the available energy being 0 kcal/g. 1,5-AG did not affect the concentration of blood glucose or triacylglycerol following consecutive feeding for 31 days and also did not induce morphological abnormalities in organs and tissues without cecal enlargement in the FOS group. The anti-oxidative potential and oxidative index of plasma and the urinary excretion of 8-hydroxy-2'-deoxyguanosine were not significantly different between the five groups.

Conclusions: Ingestion of 1.6 g of 1,5-AG/kg body weight per day (average intake during experiment) does not have harmful effects on the growth and physical condition of rats. Taken together these results demonstrate that 1,5-AG is a safe ingredient in food.

ACCEPTABILITY OF FORTIFIED WHEY PROTEIN CONCENTRATE SUPPLEMENTS WHEN ADDED TO CUSTOMARY THIN GRUELS (ATOLES) BY WOMEN IN THE WESTERN HIGHLANDS OF GUATEMALA

(1)Arriaga, Claudia Lorena; (2)Fuentes, Deborah; (2)Diaz-Ruiz, Elena; (3)Garcia-Meza, Rosario; (4)Solomons, Noel W; (5)Hirst, Daniel; (6)Bonorden, Melissa.

(1)Researcher. Center for Studies of Sensory Impairment, Aging and Metabolism.; (2)Nutritionist. Center for Studies of Sensory Impairment, Aging and Metabolism.; (3)MA. Nutritionist. Center for Studies of Sensory Impairment, Aging and Metabolism.; (4)Scientific Director. Center for Studies of Sensory Impairment, Aging and Metabolism.; (5)MSc. Food Scientist - Product Development Hormel Foods Corporation; (6)MSc. Senior Food Scientist - Product Development Hormel Foods Corporation.

Background and objectives: Dietary surveys have shown a gap in the daily intake of protein and other micronutrients, among lactating women in the western highlands of Guatemala. Culturally, during lactation, women consume additional amounts of thin gruel beverages (atoles), which can serve as a vehicle to secure the missing nutrients. Simple addition of whey-protein concentrate (WPC) supplement to thin gruels has been found acceptable; nonetheless addition of micronutrients could change some organoleptic characteristics. We sought to determine, among women of different socio-demographic settings, the acceptability of fortified WPC supplements added to thin gruels.

Methods: 55 women aged 17-70y were recruited locally across two socio-demographic settings in Quetzaltenango, Guatemala. They were asked to bring a home-prepared gruel of their preference.

Three cups containing 100 ml of the gruel and different WPC presentation were served for sensory evaluation: alone; fortified with recommended dosage of micronutrients for lactation (FWPC); and fortified with twice the recommended dosage of micronutrients for lactation (2xFWPC). Sensory evaluation involved responding as to any detectable differences in taste and selecting their most and least preferred options.

Results: 91% of the women detected a difference in taste among the beverages. Participants were equally inclined to choose either WPC or 2xFWPC as their preferred beverage, both reported at 38%, with 24% favoring FWPC. For the least preferred beverage,

44% chose 2xFWPC and WPC and FWPC tied with 28% each. When responding to the question of voluntarily drinking either of the fortified offerings on a regular basis, 97% of the women responded that they would do so willingly.

Conclusions: A fortified WPC supplement, mixed with thin traditional gruels, proves to be not only a culturally-pertinent, but also a plausible vehicle for the micronutrients needed to fill the existing gaps to reach recommended intakes for lactation.

COMPUTER-AIDED TOOLS IN THE ANALYSIS OF TASTANT/BIOACTIVE PEPTIDES OCCURRING IN FOOD-ORIGINATING PROTEIN SEQUENCES

[1]Iwaniak, Anna; [2]Darewicz, Malgorzata; [3]WOŁOWSKA, Ewelina; [2]Minkiewicz, Piotr.

[1]Professor.Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Food Biochemistry. Olsztyn. Poland; [2]Professor. Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Food Biochemistry. Olsztyn. Poland; [3]MSc. Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Food Biochemistry. Olsztyn. Poland.

Background and objectives: Peptides significantly affect the sensory attractiveness of foods, because they feature the taste properties of products by affecting the following taste sensations: umami, sour, sweet, salty and bitter. The latter one can be regarded by consumers as undesired, especially when thinking about ripening cheeses and formulas composed of protein hydrolysates.

Methods: The aim of the study was the computer analysis of food derived protein sequences being potential source of tastant peptides. Analyses included: elaboration of the profiles of potential sensory activity of proteins as well as the computer simulation of hydrolysis of proteins to generate tastant/bioactive peptides. The selected plant and animal protein sequences (derived from oil and leguminous plants, crops, milk, fish, and meat) were taken for the bioinformatic studies. Methods: **Results:** Based on the profile of potential sensory activity of proteins, we found that majority of peptides located in proteins were bitter. Moreover, potentially the largest number of tastant peptides was present in milk and carp proteins (caseins and myosin, respectively). The data concerning the milk proteins as the source of bitter peptides were consistent which the results confirmed in in vitro studies. Many peptides located in proteins were dipeptides. It was found that ficin and papain were the proteases, which potentially released the largest number of taste peptides from all protein sequences analyzed. It was also concluded that some peptide tastants revealed biological potential as the dietary components supporting the metabolic syndrome prophylaxis. Our studies confirmed the suitability of selected bioinformatic tools in studying the proteins as the food components being the source of tastant/bioactive peptides.

Conclusions: Our studies confirmed the suitability of selected bioinformatic tools in studying the proteins as the food components being the source of tastant/bioactive peptides.

Keywords: sensory peptides, proteins, in silico analysis, hydrolysis

DIFFERENTIAL PERIPHERAL BLOOD METHYLATION BY ALPHA-LIPOIC ACID AND EPA SUPPLEMENTATION IN OVERWEIGHT/OBESE WOMEN DURING A WEIGHT LOSS PROGRAM

[1]Huerta Hernández, Ana Elsa; [1]Riezu Boj, José Ignacio; [1]Milagro Yoldi, Fermín Ignacio; [2]Guruceaga Martínez, Elizabeth; [1]Moreno Aliaga, María Jesús; [3]Martínez, J. Alfredo.

[1]PhD. Department of Nutrition, Food Science and Physiology. University of Navarra. Spain.; [2]MsC. Proteomics & Bioinformatics Unit. Center for Applied Medical Research (CIMA). Spain.; [3]MD. PhD. Department of Nutrition, Food Science and Physiology. University of Navarra. Spain.

Background and objectives: It has been reported that α-lipoic acid (LA) supplementation alone or in combination with eicosapentaenoic acid (EPA) may help to promote body weight loss and reduce inflammatory and cardiovascular disease–related risk markers in conjunction with hypocaloric diets. The present study aimed to assess methylation modifications in white blood cell genes induced by EPA and/or LA supplementation, as well as their possible relationship with metabolic risk biomarkers in obesity during weight loss.

Methods: Apparently healthy overweight/obese women followed a hypocaloric diet (-30%) during 10 weeks after being randomly assigned to 1 of 4 parallel dietary groups: a control group or groups supplemented with 1.3 g EPA/day, 0.3 g LA/day, or both. DNA from white blood cells was hybridized in an Infinium Human 450K methylation microarray.

Results: Differentially methylated changes (after-before) were identified in EPA (228 CpGs), LA (125 CpGs) and EPA+LA (279 CpGs) groups as compared with control group. These included CpG regions from NCK adaptor protein 2 (NCK2), fat storage inducing transmembrane protein 2 (FITM2), transcription domain-associated protein (TRRAP), regulatory associated protein of mTOR (RPTOR) and CREB binding protein (CREBBP). Of note, LA significantly upregulated NCK2, TRRAP and RPTOR mRNA in PBMC, which correlated with changes in body weight and fat mass. The variations in cg10320884 (TRRAP) methylation site were negatively associated with changes in TRRAP gene expression, while had a highly significant positive correlation with the changes in the Framingham score.

Conclusions: These results suggest the involvement of epigenetic mechanisms in LA and EPA metabolic actions.

EARLY LIFE PROGRAMMING BY OMEGA-3 FATTY ACIDS IN OBESITY-ASSOCIATED INFLAMMATION

[1]*Ramalingam, Latha;* [2]*Menikdiwela, Kalhara;* [2]*Allen, London;* [2]*Scoggin, Shane;* [2]*Moustaid-Moussa, Naima.*

[1]PhD, Nutritional sciences, Texas Tech; [2]Nutritional Sciences, Texas Tech.

Background and objectives: Over half of American women of child bearing age are either obese or overweight. Hence, the prevalence of childhood obesity is predicted to increase. Maternal programming through diet is critical for prevention of several diseases in the offspring, including childhood obesity. Clinical trials with n-3 polyunsaturated fatty acids (PUFAs) such as docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) reported various health benefits, including reduced serum triglycerides and obesity-associated inflammation, and increased insulin sensitivity. However, it remains unclear whether maternal consumption of n-3 PUFAs can protect offspring from the adverse metabolic effects of consuming high fat diets during pregnancy. Accordingly, we hypothesized that n-3 PUFAs supplementation during pregnancy will reduce maternal obesity- associated inflammation and reduce/prevent adverse metabolic effects in offspring.

Methods: To test this hypothesis, we fed B6 mice high fat diet (HF) or HF supplemented with fish oil, rich with EPA (HF-EPA) for 8 weeks pre-pregnancy through lactation. After weaning, offspring from HF or HF-EPA dams were either continued on their respective diet or switched to the opposite diet. Five treatment groups were created including a low fat (LF)-LF control group (LF maternal diet and LF post-weaning), HF-HF, HF-EPA, EPA-HF, EPA-EPA, respectively.

Results: Metabolic phenotyping of these mice included body weight and body fat, glucose and insulin tolerance tests. Offspring born to dams fed EPA and continued on EPA (EPA-EPA) showed significantly higher glucose clearance rates compared to other treatment groups but was lower compared to LF animals. Similarly, significant improvements in insulin sensitivity was observed in the EPA-EPA fed group compared to other HF treated groups. EPA-EPA and HF-EPA had lower fat mass compared to HF-HF and EPA-HF. Additional mechanistic studies are ongoing in serum and tissues collected from the offspring to determine molecular mechanisms mediating EPA effects on high fat diet-induced obesity and inflammation in dams and their offspring.

Conclusions: In conclusion, these studies will help to understand the differential contribution of maternal dietary lipids to metabolic health of the offspring.

ANGIOTENSIN I-CONVERTING ENZYME INHIBITORY ACTIVITY OF OAT PROTEINS HYDROLYSATES

[1]*Darewicz, Malgorzata;* [2]*Borawska, Justyna;* [3]*Pliszka, Monika;* [1]*Iwaniak, Anna;* [4]*Minkiewicz, Piotr.*

[1]Prof. Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Biochemistry. Poland; [2]Dr. Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Food Biochemistry. Poland; [3]PhD. Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Food Biochemistry. Poland; [4]Prof. Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Food Biochemistry. Poland.

Background and objectives: The increase of interest in food ingredients with specific health-related activities have been observed. Biopeptides derived from food proteins are considered as regulators of e. g. cardiovascular system. The best known bioactive peptides with antihypertensive properties are angiotensin I-converting enzyme (ACE) [EC 3.4.15.1] inhibitors. They play a role in lowering high blood pressure and regulating the cardiovascular system activity. Oats proteins may be the source of biopeptides. Nutritional value of proteins from oat seeds is comparable to meat, eggs and milk proteins. The aim of the study was to examine the angiotensin I-converting enzyme inhibitory activity of oat proteins hydrolysates.

Methods: The extracts of oat proteins were taken. The study covered the in silico part – with the use of UniProt database, BIOPEP database and tools available within (http://www.uwm.edu.pl/biochemia/), Fragment Ion Calculator application and Sequence Specific Retention Calculator application. The next step of analysis was hydrolysis with the use of commercial enzyme preparations. Bioactive peptides were identify using reversed-phase liquid chromatography with mass spectrometry detector (RP-HPLC-ESI-MS) based on the expected retention times. The SDS-PAGE method was used to verify the progress of hydrolysis. The ACE inhibitory activity of obtained hydrolysates was assayed according to method by Jimsheena and Gowda (2009).

Results: It was found that the degree of hydrolysis and ACE inhibition increased during the hydrolysis process. The sample treated with commercial digestive enzymes demonstrated the highest degree of ACE inhibition (89%, IC50 = 0.42 mg/ml). The degree of ACE inhibition of this sample was higher in comparison with the blank sample (49%, IC50 = 24.89 mg/ml). The proteins

are only partially hydrolysed with pepsin in the stomach, so the sample hydrolyzed by pepsin was characterized by a lower degree of inhibition (77%, IC50 = 4.87 mg/ml) in comparison with the 'gastro-duodenal' samples

Conclusions: The results showed that the oat proteins can be the source of peptides with ACE inhibitory activity that are released during the simulated digestion. The identification of ACE inhibitory peptides in hydrolysates of oat proteins was possible thanks to the combination of computer and experimental methods.

Keywords: ACE, inhibitory peptides, oat proteins

THE BIOPEP - DATABASE OF FOOD BIOLOGICALLY ACTIVE PEPTIDES AND PROTEINS

[1]Darewicz, Malgorzata; [2]Minkiewicz, Piotr; [2]Iwaniak, Anna.

[1]Prof. Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Biochemistry. Poland; [2]Prof. Warmia and Mazury University in Olsztyn. Faculty of Food Science. Chair of Food Biochemistry. Poland.

Background and objectives: Peptides derived from food proteins affect biological, functional, immunological and sensory properties of food products as well as provide information concerning product composition, authenticity or history. Proteins apart from their function as the nutrients act as the precursors of peptides with variety of functions.

Methods: The database of protein and peptide sequences called BIOPEP (http://www.uwm.edu.pl/biochemia) has been designed mainly for scientists working in the area of food and nutrition. BIOPEP database consists of four sequence databases: proteins, bioactive peptides, allergenic peptides with their epitopes and sensory peptides. The information concerning peptide or protein covers its sequence; data about activity or taste; references or in the case of allergenic protein database reference, sequence of experimental and theoretically predicted linear epitopes [Minkiewicz et al. 2012]. Sequence analysis options include: profiles of the potential biological activity, epitopes or sensory activity, calculation of the quantitative parameters A and B useful for evaluation and classification of proteins as precursors of bioactive or sensory peptides as well as immunogenic fragments. The options available in particular databases of BIOPEP include also the simulation and design of proteolysis as well as data mining. BIOPEP contains also the collection of links to other databases and programs ("Useful links" bookmark).

Results: Proposed workflows for use of BIOPEP database of bioactive peptide sequences cover among others: using sequences of peptides as queries for database screening or identification of peptides from BIOPEP among products of protein hydrolysis. Selected examples of applications of the database, described by other authors will be presented. Our intention was to establish BIOPEP as the database integrating information about various properties of fragments originating from food proteins. All subelements of the BIOPEP database are continuously updated with the new se-

quences with experimentally confirmed bioactivities as well as calculation functions helping to evaluate the protein value as the source of biopeptides.

Conclusions: To date, apart from the data concerning different biological properties of peptides, BIOPEP may serve as a tool supporting the experimental and theoretical studies on food-derived biopeptides.

Keywords: bioactive peptides; database; food proteins; hydrolysis

ANTIHYPOXIA AND ANTIOXIDANT EFFECTS OF SMALL MOLECULE OLIGOPEPTIDES ISOLATED FROM PANAX GINSENG C. A. MEYER

[1]Li, Yong; [2]Ren, Jinwei; [3]Li, Di; [3]Xu, Meihong.

[1]Prof. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; [2]Msc. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; [3]PhD. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191.

Background and objectives: To investigate the effect of Panax ginseng oligopeptide of Jilin providence (GOP) on antioxidation in oxidative damaged rats induced by D-galactose and antihypoxia capacity in mice.

Methods: 90 specific pathogen free (SPF) male SD rats are randomly divided into 9 groups: namely blank control group, model control group, whey protein control group, and six groups of GOP at different doses. Except the control group, all other groups are given with 125 mg/kg of D-galactose by intraperitoneal injection for 6 weeks. Then, rats in the six samples groups were gavaged with 0.0625, 0.125, 0.250, 0.500, 1.000, 2.000 g/kg of GOP; rats in control group and model group were gavaged with the same volume of distilled water; and rats in whey protein group were gavaged with 0.250 g/kg of whey protein for 45 d. At the same time, rats are given with D-galactose uninterruptedly. The oxidative stress parameters in serum and liver tissue are then determined. Besides, 180 SPF male mice are randomly divided into three experimental sets for the detection of different indicators. Each set of mice are then randomly divided into 6 groups: namely blank control group, whey protein control group, and four groups of GOP at different doses. Mice in the four samples groups were gavaged with 0.075, 0.150, 0.300, 0.600 g/kg of GOP; mice in bland control group was gavaged with the same volume of distilled water; and mice in whey protein control group were gavaged with 0.300 g/kg of whey protein for 30 d. The survival time of oxygen deprivation, intoxication and cerebral ischemic hypoxia of mice are then determined.

Results: The levels of lipid peroxide and protein peroxide of GOP groups are significantly lower than these of model group, meanwhile, the activities of antioxidant enzyme and the levels of antioxidants significantly increase compared with these of model group, and the effects are better than those of the whey protein.

The survival time of oxygen deprivation, intoxication and cerebral ischemic hypoxia of mice are significantly longer than these of whey protein control group.

Conclusions: GOP has antioxidant effect on D-galactose induced oxidative damaged rats as well as antihypoxia capacity on mice.

Keywords: Panax ginseng oligopeptide of Jilin providence; antioxidant; antihypoxia

THE INFLUENCE AND MECHANISM OF BOVINE COLLAGEN OLIGOPEPTIDE ON WOUND HEALING IN MICE

[1]Li, Yong; [2]Xu, Teng; [3]Li, Di; [3]Xu, Meihong.

[1]Prof. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; [2]Msc. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; [3]PhD. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191.

Background and objectives: To investigate the influence and mechanism of bovine collagen oligopeptide on wound healing in mice.

Methods: A total of 240 ICR mice are randomly assigned to 6 groups, including a control group and 6 bovine collagen oligopeptide intervention groups (0.375, 0.75, 1.5, 3.0, 6.0g/kg bw). And each group is randomly assigned to 4 subgroups. The mice are carried out by mice stomach-lavaging continuously for 16 days after excisional wound model. And the mice will be sacrificed separately at day 4, day8, day12 and day 16. Wound closure is assayed, and the serum SDF-1a parameter is conducted. After fixation of the skin biopsy samples in 4% formalin, they are embedded in paraffin and stained with HE.

Results: It has been found that Bovine collagen oligopeptide treatment could significantly decrease the wound region (p<0.05 or p<0.01) and increase the secret of SDF-1α(p<0.05 or p<0.01).

Conclusions: These findings suggest that Bovine collagen oligopeptide have an obvious promote on wound healing and the underlying mechanism may be related to enhancing SDF-1α.

Keywords: Bovine collagen oligopeptide; wound healing; SDF-1α

THE EFFECTS OF WALNUT PEPTIDE ON LEARNING AND MEMORY ABILITIES IN YOUNG MICE

[1]Li, Yong; [2]Du, Qian; [3]Fan, Rui; [3]Xu, Meihong.

[1]Prof. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; [2]Msc. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; [3]PhD. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191.

Background and objectives: To investigate the improvement effects and their mechanisms of walnut peptide (WP) on learning and memory abilities in young mice.

Methods: 48 male weaning C57BL/6J mice were randomly divided into 4 groups, the control group, low WP intervention group, middle WP intervention group, and high WP intervention group(the concentrations of WP were 110mg/kg·bw, 220mg/kg·bw and 440mg/kg·bw respectively), with 12 mice in each group. After 30 days feeding, the Open-field test, Morris Water Maze, Step-down test and Shuttle test were performed, in order to observe the ability of autonomic activities and emotional responses, spatial memory ability, and the active and passive avoidance reactions in mice.

Results: According to the results of Morris Water maze, the escape latency of high WP group was significantly reduced compared with the control group (P<0.05), and for middle and high WP groups, the times staying in the target quadrant and the numbers of crossing over the position where the platform had been were increased compared with the control group (P<0.05). The Step-down test indicated, after the training 24 hours, compared to the control group, the low and high WP groups had less error times (P<0.05), and three intervention groups had longer step-down latency (P<0.05). After the training 5 days, the declines of learning and memory in the middle WP group was effectively reduced (P<0.05). Shuttle test showed that, compared with the control group, after the intervention of the low, middle, and high doses of WP, the numbers of active avoidance reaction increased (P<0.05), while the times of electric shock decreased in mice (P<0.05). The activities of T-SOD and GSH-Px in three WP groups were higher, and the level of MDA were lower compared with the control group (P<0.05).

Conclusions: The walnut Peptide could enhance the abilities of learning and spatial memory and the abilities of active and passive avoidance in young mice, and WP could delay the declines of learning and memory in mice. The mechanism was related to the antioxygenic property of WP.

LONG-TERM DIETARY NUCLEOTIDES SUPPLEMENTS AND LIVER FIBROSIS IN AGING RATS: A MIRNA INVESTIGATION

[1]Li, Yong; [2]Xu, Meihong; [2]Wang, Junbo; [2]Mao, Ruixue.

[1]Prof. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191; [2]PhD. Nutritionist. Department of Nutrition and Food Hygiene, School of Public Health, Peking University, Beijing 100191.

Background and objectives: Previous studies suggested that nucleotides were beneficial for liver function, lipid metabolism and so on. The present study aimed to investigate the anti-fibrosis effects of dietary nucleotides on aging liver.

Methods: Full liver samples from the rats at the age of 24-26 months (aged control, 0.01% NTs and 0.64% NTs; n=6/group) were excised for analysis. Another group of male S-D rats (n = 8) which were fed with the control diet were sacrificed at the age of 12 months to be used as the middle controls. The liver samples were used for investigation on Hyp, oxidative Stress and cytokines level, as well as the expression levels of miRNA and their target genes.

Results: This study established the association of miR-182 and miR-328a* with NTs in aging liver, meanwhile highlighted the correlation of miRNA expression with their target genes Thbs-2 and Pdgf-b. It also identified that long-term administration of NTs inhibited the age related decrease activity of Hyp, oxidative Stress and inflammatory level in the chronological aged liver.

Conclusions: The present study demonstrated that the anti-fibrosis effects of long-term NTs on chronological liver aging, which possible because NTs affect miR-182 and miR-328a* through their target genes Thbs-2 and Pdgf-b in the aged liver of S-D male rats.

CHARACTERIZATION OF ANTIOXIDATIVE PEPTIDES FROM THE OIL PALM (ELAEIS GUINEENSIS JACQ.) KERNEL PROTEIN HYDROLYSATE

[1]Chang, Sui Kiat; [2]Ismail, Amin; [3]Yanagita, Teruyoshi.

[1]Department of Nutrition and Dietetics, School of Health Sciences, International Medical University. Kuala Lumpur. Malaysia.; [2]PhD. Professor. Department of Nutrition and Dietetics, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia. Serdang, Selangor, Malaysia.; [3]PhD. Emeritus Professor. Department of Health and Nutrition Sciences, Faculty of Health and Human Welfare Sciences, Nishikyushu University, Kanzaki, Saga. Japan.

Background and objectives: Plant proteins play essential roles in human nutrition. Oil palm fruit is the most important oilseed crops globally where its kernel is obtained as waste after palm oil production. Our previous study demonstrated that oil palm kernel protein hydrolysate (OPKH) obtained after pepsin-pancreatin hydrolysis showed strong antioxidant activity. Hence, this study aims to purify and identify the antioxidative peptides from OPKH.

Methods: First, the OPKH was purified by ultrafiltration, followed by reversed-phase (analytical) and semi-preparative HPLC to collect the bioactive fractions. Subsequently, antioxidant capacities (ACs) of the purified peptides from OPKH were evaluated using ferric reducing antioxidant power (FRAP), β-carotene-linoleate bleaching (BCB) assay and 2,2'-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid) (ABTS) radical scavenging activity assay. In relation, the amino acid compositions of the purified peptide fractions were also determined. Finally, the amino acid sequence of the antioxidative peptide was identified by electrospray ionization/multi-stage mass spectrometry (ESI/MS/MS) coupled with Q-TOF LC/MS and PEAKS studio software using de novo sequencing.

Results: Nine active fractions (F1-F9) were collected and purified. Fraction F6 showed the highest AC. Fraction F6 was collected and re-chromatographed on the same analytical column where three sub-fractions (F6a, F6b and F6c) were obtained. Three antioxidative peptides, Val-Val-Gly-Gly-Asp-Gly-Asp-Val (VVGGDGDV), Val-Pro-Val-Thr-Ser-Thr (VPVTST) and Leu-Thr-Thr-Leu-Asp-Ser-Glu (LTTLDSE) in this fraction F6 were identified using MS/MS. The molecular masses of the peptides VVGGDGDV, VPVTST and LTTLDSE were 717.34, 602.3 and 777.37 Da, respectively. The three peptides did not show any similarity with other antioxidant peptides listed in BLAST database of NCBI.

Conclusions: Three novel peptides with ACs from OPKH were characterized. These active peptides may be useful as ingredients for food products and nutraceutical applicants.

Keywords: oil palm kernel protein hydrolysate (OPKH), antioxidant capacity (AC), peptide, amino acid sequence, LC-MS/MS

EFFECT OF POWDER DRY ADZUKI BEAN PASTE IN PLACE OF WHEAT FLOUR ON RESISTANT STARCH CONTENT AND SENSORY CHARACTERISTICS OF COOKIES

[1]Kamei, Aya; [2]Ito, Tomomi.

[1]PhD. Division of Domestic Science Education. Faculty of Education. Miyagi University of Education. Japan.; [2]BEd. Division of Domestic Science Education. Faculty of Education. Miyagi University of Education. Japan.

Background and objectives: Traditional Japanese sweets have been popular among Japanese, and are often eaten particularly by middle-aged and elderly people. A lot of traditional Japanese sweets contain adzuki bean paste(ABP). Adzuki beans are a good source of carbohydrate as well as of protein, because these are starchy pulse. Furthermore, they contain a lot of dietary fiber and also include resistant starch (RS). RS escapes digestion until reaching colon and acts like dietary fiber. Recently, many studies recommend taking this new type of dietary fiber for health benefits. The purpose of this study was to investigate feasibility of replacing wheat flour to powder dry ABP by analyzing RS contents and sensory characteristics in cookies.

Methods: Cookies were prepared from various blends of wheat flour(WF) and powder dry ABP(100%WF:0%ABP, 50%WF:50%ABP, 25%WF:75%ABP, 0%WF:100%ABP). RS content of these cookies were measured by Resistant Starch Assay Kit (Megazyme International Ireland, Ireland) and ranking test was applied for evaluating sensory characteristics.

Results: RS content of powder dry ABP was 5.3% and RS contents of cookies blended flour with 50%ABP, 75%ABP, 100%ABP were 1.6%, 2.1%, 3.0%, respectively. As a ratio of ABP in the cookies increased, a ratio of RS content also increased. Sensory evaluation indicated that 50%ABP cookies was not different from 0%ABP cookies in terms of flavor, sweetness, texture and overall acceptability.

Conclusions: These results implied that cookies made of powder dry ABP in place of wheat flour increased amount of RS in cookies. Taking account of sensory evaluation, 50% replacement of powder dry ABP cookies were found to be acceptable.

Keywords: dry adzuki bean paste, resistant starch, sensory characteristics, cookies

Background and objectives: The Unified Health System (SUS), whose principles are the pursuit of universality, integrality and equity, forming several productions and questions regarding the assistance adopted. There is a need for more active professionals in the epidemiological reality inserted in the SUS, in this context the Physiotherapy is inserted in the system with an exclusively rehabilitating and curative character. Objective: To analyze the main actions of the physiotherapist of the multiprofessional team, aimed at promoting healthy eating habits.

Methods: This is a literature review in the SciELO (Scientific Electronic Library Online) and LILACS (Latin American and Caribbean Literature in Health Sciences) databases, with the descriptors in health: functional foods AND physiotherapy. Criteria to inclusion and exclusion were applied, and 4 studies were selected for analysis.

Results: The increase of obesity has caused great concern to sanitary skills, presenting as a significant health risk factor, such as: diabetes, hypertension, hypercholesterolemia, among others. Physiotherapy in its work with regard to nutrition aims to promote and raise awareness in the community in promoting healthy eating habits and performance of physical exercises. A balanced diet is essential to health by providing the necessary nutrients and functional foods are the newest frontiers in the food market, as they still perform therapeutic functions. In Brazil 75% of the food sold is linked to health, this audience is divided into classes of A & B, present in the market, among them

we can mention: yogurts with pro-biotics that regulate intestinal function, iron-enriched milks that help in prevention and in treatments Anemias, vitamins and with Omega 3 acid, highlighting eggs and margarines enriched also with Omega-3, among several other foods.

Conclusions: Functional food has low cost and is of great nutritional value, favoring the indication by several professionals in the health area. In this way, physiotherapy in the search for the well-being of its patient, has the duty not only to encourage or accompany the practice of exercises, but also to plan actions related to the theme, together with the multiprofessional team, actions in the prevention and promotion of Health of the individual or community.

Keywords: Physiotherapist, Functional foods, Promotion of health.

EXPLORATION OF BIOFUNCTION OF SIPHO-NAXANTHIN, A CAROTENOID DERIVED FROM GREEN ALGAE, ON HEPATIC LIPOGENESIS

[1]Zheng, Jiawen; [2]Li, Zhuosi; [3]Manabe, Yuki; [2]Kim, Minji; [2]Goto, Tsuyoshi; [2]Kawada, Teruo; [2]Sugawara, Tatsuya.

[1]Kyoto University; [2]Phd. Graduate School of Agriculture. Kyoto University. Japan; [3]MSc. Graduate School of Agriculture. Kyoto University. Japan.

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) is notable for its high morbidity and mortality accompanied by a series of complications including diabetes, hypertension, dyslipidemia etc. Carotenoids have been well-known for their various activities, such as anti-oxidation, anti-photoaging, anti-angiogenesis and anti-obesity. In concern with the diverse functions of carotenoids, their potential to prevent and alleviate NAFLD has also been investigated. Siphonaxanthin is a rare marine carotenoid present in some green algae. In this research, we investigated the potential function of siphonaxanthin on preventing and attenuating NAFLD and its mechanisms.

Methods: We conducted a preliminary assessment of the effect of siphonxanthin on hepatic lipid metabolism by conducting an in vitro study. HepG2 cell line, derived from human liver cancer, was used as a model of liver. We used a synthetic agonist of liver X receptor α (LXRα) to simulate an aggravated lipogenesis in HepG2 cells and investigated the effect of siphonaxanthin on hepatic lipid synthesis from several aspects including triacylglycerol accumulation, mRNA levels of related genes, protein level of a transcription factor named sterol regulatory element binding protein-1c (SREBP-1c) and LXRα activity.

Results: Siphonxanthin significantly suppressed the excess accumulation of triacylglycerol induced by LXRα agonist by down-regulating the expression of SREBP-1c and a set of genes related to de novo lipogenesis. On the other side, fatty acid translocase (CD36) and fatty acid binding protein-1 (FABP1) which regulate fatty acid uptake also showed a significant decrease in

translational levels. Furthermore, we found out that siphonxanthin inhibited LXRα activation induced by its agonist, T0901317.

Conclusions: In the present study, we discovered that a rare carotenoid named siphonaxanthin, possesses a strong inhibitory effect on hepatic lipogenesis. Based on this study, it is plausible to speculate that siphonaxanthin may be promising in nutraceutical application targeting pathological liver disorders such as NAFLD.

Keywords: Siphonaxanthin, Hepatocyte, Lipogenesis, LXRα, SREBP1c.

ASSOCIATION BETWEEN AMINO ACIDS, BIO-MARKERS OF PROSTATE CANCER AND INFLAMMATION IN NORWEGIAN PROSTATE CANCER PATIENTS

[1]Rangel Huerta, Oscar Daniel; [2]Paur, Ingvild; [2]Bastani, Nasser; [2]Kjølsrud Bøhn, Siv; [3]Lilleby, Wolfgang; [4]Smeland, Sigbjørn; [2]Karlsen, Anette S.; [2]Blomhoff, Rune.

[1]PhD. Department of Nutrition. Institute of Basic Medical Sciences. University of Oslo.; [2]PhD. Department of Nutrition. Institute of Basic Medical Sciences. University of Oslo. Norway.; [3]MD.Division of Cancer Medicine. Transplantation and Surgery. Oslo University Hospital. Norway.; [4]PhD.Division of Cancer Medicine. Transplantation and Surgery. Oslo University Hospital. Norway.

Background and objectives: Earlier our research group had shown that a nutritional intervention with tomato products alone or in combination with selenium and n-3 fatty acids soy isoflavones, grape/pomegranate juice, and green/black tea lower prostate-specific antigen (PSA) in patients with non-metastatic prostate cancer. However, the mechanism is still undefined. Dysregulation of amino acids has been reported in cancers. Therefore, our aim was to study the amino acid profile in prostate cancer patients following a tomato products-based intervention in relation to PSA and inflammation.

Methods: For this analysis, we included 74 patients with prostate cancer from a previous study. Prior to curative treatment, the patients were randomized to nutritional interventions with either 1) tomato products containing 30 mg lycopene per day; 2) tomato products plus selenium, omega-3 fatty acids, soy isoflavones, grape/pomegranate juice, and green/black tea (tomato-plus); or 3) control diet for 3 weeks. Plasma samples from baseline and after the intervention were analysed. The level of total PSA was determined on the AutoDELFIA automatic immunoassay system. Plasma carotenoids and amino acids were detected using HPLC. An ANOVA adjusted for the baseline was performed to evaluate differences between groups after the dietary intervention. Correlation between parameters was estimated by computing Pearson's correlation coefficient using the delta (t1-t0). All statistical analyses were performed using SPSS 24.

Results: For all patients, we found a significant correlation between the lycopene change and total PSA (r=-0.247; p=0.034) and

ornithine (r=0.238; p=0.041). Furthermore, the change in ornithine was inversely correlated with total PSA (r=0-0.311, p= 0.007). Finally, the change in total PSA was correlated with C-reactive protein (CRP) (r=0.301; p=0.011).

Conclusions: The increase of lycopene was associated with an increase of ornithine. The change in ornithine showed to be inversely correlated with PSA, which in turn is associated with the inflammatory biomarker, CRP. Further analyses are needed to study a possible link between ornithine and CRP.

IDENTIFICATION OF PROPROTEIN CONVERTASE SUBTILISIN/KEXIN TYPE 9 (PCSK9) INHIBITORS FROM NATURAL PRODUCTS

[1]Hirata, Hiroshi; [2]Kontani, Ami; [3]Takazumi, Koji; [4]Segawa, Shuichi; [5]Tsuchiya, Youichi.

[1]PhD. Biochemist. Frontier Laboratories for Value Creation. SAPPORO HOLDINGS LTD.; [2]MSc. Physiologist. Frontier Laboratories for Value Creation. SAPPORO HOLDINGS LTD.; [3]MSc. Analytical chemist. Frontier Laboratories for Value Creation. SAPPORO HOLDINGS LTD.; [4]PhD. Physiologist. Frontier Laboratories for Value Creation. SAPPORO HOLDINGS LTD.; [5]PhD. Microbiologist. Frontier Laboratories for Value Creation. SAPPORO HOLDINGS LTD.

Background and objectives: Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a new target for lowering serum cholesterol levels. PCSK9 inhibition retards degradation of low-density lipoprotein receptor (LDLR), resulting in enhancement of LDL-cholesterol uptake in the liver. Daily intake of foodstuffs containing compounds which inhibit PCSK9 activity is expected to prevent hypercholesterolemia.

Methods: We constructed a food extracts library and screened for PCSK9 inhibition. A human hepatocellular cell line (HepG2) was treated with test samples and cultured for one day. Secreted mature PCSK9 proteins from the culture medium were determined by western blotting. Active compounds in the food extracts responsible for PCSK9 inhibition were separated and isolated by chromatography. Chemical structures of the compounds were determined by LC-Q-TOF-MS and NMR analyses. To investigate the mechanisms of PCSK9 inhibition in the food items, HepG2 cells were transfected with the siRNA of PCSK9 regulators and then treated with the active compound.

Results: Female hop cones (Humulus lupulus L.) and lemon peel showed PCSK9 inhibitory activity. The active compounds responsible for inhibition of PCSK9 were identified as lupulone and 5-geranyloxy-7-methoxycoumarin from hop and lemon, respectively. The active compounds contained an isoprenoid side-chain and prenyl and geranyl moieties. We also found PCSK9 inhibitors

in natural products: xanthohumol, bergamottin and α-mangostin, all of which contained an isoprenoid side-chain. It is likely that isoprenoid side-chain contributes to PCSK9 inhibition because the basic skeletons of the active compounds are different (phloroglucinol derivative, coumarin, flavonoid, xanthonoid). Of the compounds tested, lupulone showed the strongest PCSK9 inhibitory activity. RNAi experiments showed that knock down of hepatocyte nuclear factor 1α (HNF1α), a positive regulator of PCSK9, impaired the PCSK9 inhibitory activity of lupulone. Furthermore, lupulone decreased HNF1α protein expression in HepG2, suggesting that lupulone inhibits PCSK9 expression through HNF1α downregulation.

Conclusions: We isolated and identified PCSK9 inhibitors from food and natural products and suggest HNF1α is involved in the PCSK9 inhibitory mechanisms of lupulone.

Keywords: PCSK9, Natural product, HepG2, RNAi, HNF1α.

INVESTIGATION OF MICROBIAL FLORA AND RE-GIONAL DIFFERENCE OF KUMISS USING ARISA

[1]Takahashi, Soichiro; [2]Yamaguchi, Akihiro; [2]Ishii, Satomi.

[1]Rakuno Gakuen University Graduate Student; [2]Rakuno Gakuen University PhD.

Background and objectives: Kumiss is a prepared by fermenting fresh horse milk with some lactic acid bacteria and yeasts in dry inland Asia. Kumiss is carbonated beverage containing about 1 to 2.5 % alcohol traditional ethnic drink for nomads in maintain health. In this study, we investigated regional differences in the type and amount of microorganisms using automated rRNA intergenic spacer analysis (ARISA).

Methods: Nucleic acids were extracted from 32 samples of horse kumiss which was transported in frozen state from Mongolia using an automated nucleic acid extractor (magLEAD). The extracted DNA was amplified by PCR using Bac-2 primer set and Fun-1 primer set. Agarose gel electrophoresis was carried out to confirm the PCR amplification band. After that, we requested fragment analysis of PCR product and estimated the kind and quantity of microbial species from the obtained data. We investigated the relationship between these and regional differences.

Results: Similar results were obtained in kumiss in the same area. The presence of various bacteria and fungi was revealed in any kumiss. In many samples there were intense signals of bacteria and fungi near ARISA fragment length (bq) 305 and 701, respectively, whereas samples showing different peaks existed. They were in the range of ± 0.1%, and it was judged that they are the same type of microorganisms.

Conclusions: It is suggested that microorganisms different from each other are involved in kumiss. In the future, we will conduct identification tests of microorganisms in which signal has appeared strongly and proceed with identification of bacterial species. We will also investigate the relationship with general ingredients and analyze the metabolic products of bacteria contained in kumiss.

Keywords: Kumiss, Arisa, Inland Asia, Bacteria.

D-ALLULOSE, FUNCTIONAL RARE SUGAR, NOR-MALIZED BODY WEIGHT VIA REGULATING LIPID METABOLISM IN DIET INDUCED OBESE MICE

[1]Choi, Myung-Sook; [2]Han, Youngji; [3]Choi, Bora; [3]Lee, Seon Jeong; [4]Yong Bok, Park.

[1]PhD. Department of Food science and Nutrients. Kyungpook National University. /Director. Center for Food & Nutritional Genomics. Korea; [2]PhD Candidate. Department of Food science and Nutrients. Kyungpook National University. Korea/ Researcher. Center for Food and Nutritional Genomics Research. Korea; [3]Master Candidate. Department of Food science and Nutrients. Kyungpook National University. Korea/ Researcher. Center for Food and Nutritional Genomics Research. Korea; [4]PhD. Institute of Genetic Engineering. Kyungpook National University. Daegu. Korea.

Background and objectives: Recently there has been a global shift in diet towards increased intake of energy-dense foods that are high sugars. D-psicose, a C-3 epimer of D-fructose, has been reported as one of anti-diabetic food components, however, its mechanism is not yet completely understood.

Methods: Sixty C57BL/6J mice were divided into six dietary groups and fed a normal diet (ND), a high-fat diet (HFD, 20% fat, 1% cholesterol, w/w), HFD with 5% glucose(GLU), fructose(FRU), erythritol(ERY), D-allulose(ALL) supplement for 16 weeks. A pair-feeding approach was used so that all groups receiving the high fat diet would have the same calorie intake.

Results: In our study body weight and body fat mass in ALL group were significantly decreased toward level of normal group with a simulataneous decrease in plasma leptin and resistin concentration. D-allulose lowered plamsa and hepatic lipids while elevating fecal lipids with a decreased mRNA expression of Ppara, CD36, ApoB48 and FATP4 in the small intestine in mice. In the liver, activities of both fatty acid synthase and -oxidation were down-regulated by D-allulose to that of the normal group; however, in WAT, fatty acid synthase was decreased while -oxidation activity was enhanced.

Conclusions: Taken together, our findings suggest that 5% dietary D-allulose led to the normalization of the metabolic status of diet-induced obesity by altering lipid-regulating enzyme activities and their gene-expression level along with fecal lipids.

Keywords: D-Allulose, Obesity, Fecal lipid excretion, Lipogenesis.

COMPARISON OF EFFECT ON LIPID PARAMETERS AND MALONDIALDEHYDE CONTENT BETWEEN WHITE BREAD AND WHITE BREAD ADDED WITH GARLIC AND RESISTANT STARCH IN AN EXPERIMENTAL MODEL IN RATS

[1]Zuleta, Ángela; [2]Weisstaub, Adriana Ruth; [2]correa, jimena; [2]salinas, victoria; [2]Barchuk, M; [2]berg, gabriela; [2]Zuleta, Ángela.

[1]profesor; [2]ciudad autonoma de buenos aires.

Background and objectives: Daily consumption of white bread can contributes to the development of metabolic syndrome because of its high content on carbohydrates of rapid absorption from wheat flour. On the other hand, it may be a good vehicle for the introduction of others components such as garlic, that presents antioxidant effects due to its high content of organosulfur compounds, and resistant starch with a behavior equivalent to of dietary fiber.

The aim of this study was to evaluate in a model rat the effect of three different diets intake during 60 days on lipid-lipoproteins profile and malondialdehyde levels as an indicator of oxidative stress.

Methods: Twenty four male Wistar rats recently weaned (8/ group) were fed with a control diet and two semisynthetic diets prepared with bread formulated with wheat flour (WB) and bread formulated with wheat flour adding garlic (3%) and resistant starch (20%) (GRB) during 60 days. At the end of the study blood was withdrawn and liver was excised. The obtained serum samples were examined for cholesterol, triglycerides, proteins and malondialdehyde concentration.

Results: The results showed that GRB had lower total cholesterol and non HDL-cholesterol than WB without significant differences with C (mg/dL) (86,4± 9,2 vs 118,2± 17,6 vs 87,6 ±10,9 and 53,0 ±10,8 vs 80,9± 12,4 vs 62,9 ± 21,2 respectively). No differences in HDL –cholesterol were observed among groups (36,5 ± 9,1vs 41,1 ± 11,4 vs25,0 ± 13,2) and GRB and WB presented lower triglicerides levels than C without significant differences between them (32,3 ±10,7 vs 29,2± 11,4 vs 96,0± 30,1). Moreover, GRB showed the lowest levels of MDA in serum (nmol/g protein) (24,9 ±4,4 vs 37,0± 7,6 vs 31,4± 5,3) and liver (nmol/100 g protein) (8,75 ± 3,5 vs 26,3 ± 2,1 vs 35,6 ± 7,3) comparing with WB and C (p<0.05).

Conclusions: Bread containing garlic and resistant starch, showed a prebiotic effect improving lipoprotein profile and lowering malodialdehyde content comparing with white bread. The observed beneficial health effects allow us to consider the design of breads healthier than those made only with wheat flour.

Keywords: Garlic , Resistant starch, Prebiotic effect.

EVALUATION OF KNOWLEDGE AND CONSUMPTION OF FUNCTIONAL FOODS BY ADOLESCENTS

[1]Aranha, Flávia; [2]Barretto, Daniela; [2]Burriguel, Gabriela; [2]Mendes, Juliana; [2]Guidorizi, Luana; [2]Barchi, Natalia.

[1]1PhD. Department of Education. Institute of Biosciences. UNESP. Univ Estadual Paulista, Câmpus Botucatu. Brazil.; [2]BSc. Graduation Course in Nutrition. Institute of Biosciences. UNESP. Univ Estadual Paulista. Brazil.

Background and objectives: Functional food in addition to its nutritional value inherent in its chemical composition may play a potentially beneficial role in the prevention and treatment of diseases if consumed frequently and in adequate amounts. The objective of this study was to evaluate the knowledge and consumption of functional foods in the school meal service.

Methods: A Food Frequency Questionnaire (FFQ) was applied with a focus on functional foods for students aged 15 to 18 years of Technical School (n0 139). The questionnaire was divided into two parts, the first part about knowledge, asked the interviewee if he knew what was a functional food (if the answer was "YES" was asked to explain the definition), and the second part was (Soups, fish, milk / dairy products, vegetables / fruits, eggs, sauces / seasonings, and soy / dairy products) were used on a daily basis (daily, weekly, monthly or never). After completing the questionnaire, a lecture was given explaining and exemplifying the definition and importance of the consumption of these foods.

Results: Regarding the results of the first part of the questionnaire: Do you know what functional food is? The adolescents answered 93.5% No and 6.47% Yes. To whom answered Yes was asked the second question: Do you know the importance of functional foods for your health? The students answered: "Foods that help in the proper functioning of the body or organism". The second part of the questionnaire was about the consumption of functional foods (divided into groups and their frequency), we can observe the following results: Soups (70%) and fish (81%) consumption is monthly; Dairy products (69%), vegetables (42%), fruits, eggs (77%), sauces (72%) and seasonings (73%) weekly consumption and soybeans / derivatives (70%) never consume. In relation to the lecture given the adolescents were very interested in the discussion, commenting and asking a lot about the food and its functional action in the body.

Conclusions: The interviewees' lack of knowledge about functional foods was visible, but the interviewed population frequently consumes some foods with functional properties.

Keywords: Feeding, Health, Composite bioactive, Diners.

THE EFFECTS OF RESISTANT STARCH ON BONE LOSS VIA INTESTINAL MICROBIOTA AND INFLAMMATION IN OVARIECTOMISED MICE

[1]Tousen, Yuko; [2]Matsumoto, Yu; [3]Nagahata, Yuya; [2]Yoshiko, Ishimi.

[1]PhD. Researcher. Department of Food Function and Labeling. National institute of Health and Nutrition. National Institutes of Biomedical Innovation. Health and Nutrition. Tokyo.; [2]PhD. Researcher. Department of Food Function and Labeling. National institute of Health and Nutrition. National Institutes of Biomedical Innovation, Health and Nutrition. Japan.; [3]MSc. Researcher. Product Development Laboratory. J-OIL MILS. Inc.. Japan.

Background and objectives: Recent studies have suggested an important role for gut-bone signalling pathways and microbiota in regulating bone health through modification of the immune status. Altered immune status associated with oestrogen deficiency can lead to bone loss; however, the intestinal microbiota can modulate the host metabolism and immune status. Resistant starch (RS) is a type of dietary fibre that is not absorbed in the small intestine of healthy humans, and is fermented to a large extent by microbiota in the colon, resulting in changes in the composition of gut microbiota and pre-biotic effects. Therefore, we hypothesised that intake of RS modulates intestinal microbiota and inflammation of the intestine and bone, resulting in reduced bone loss caused by oestrogen deficiency. The present study evaluated the effect of diet supplemented with RS on intestinal microbiota, bone mineral density (BMD), and inflammatory gene expression in the colon and bone marrow of ovariectomised mice.

Methods: Female ddY strain mice, aged 8 weeks, were either sham-operated (Sham, n = 8) or OVX. OVX mice were randomly divided into the following three groups (8 per group): OVX control (OVX); OVX fed 20 % high amylose cornstarch (HAS) diet (OVX + HAS); OVX fed 20 % acid-hydrolysed high amylose cornstarch (AHAS) diet. AHAS was more resistant to enzymatic digestion than HAS. RS was included as 34% or 60% of dry weight in HAS or AHAS, respectively.

Results: After 6 weeks, treatment with HAS and/or AHAS accelerated fermentation and increased the β-glucosidase activity in the cecum, and increased the rate of Bifidobacterium spp. in the faeces. The mRNA of the anti-inflammatory cytokine IL-10 tended to be up-regulated in the large intestine by treatment with AHAS. Conversely, the mRNAs of the osteoclastogenic cytokine RANKL and inflammation-related IL-7R were downregulated in the bone marrow by treatment with AHAS. Treatment with AHAS protected against OVX-induced bone loss.

Conclusions: Our findings suggest that an AHAS diet might alter the microbiota and immune status of the large intestine and bone marrow, resulting in attenuated bone resorption in OVX mice.

Keywords: Osteoporosis. Resistant starch. Microbiota. Inflammation. Bone.

AMELIORATED EFFECTS OF ETHANOL EXTRACTS FROM CAJANUS CAJAN (L.) MILLSP. ROOTS ON METHYLGLYOXAL-INDUCED INSULIN RESISTANCE IN RATS

[1]Song, Tuzz-Ying; [2]Lin, Yen-Fong; [2]Chen, Chien-Lin; [2]Vo Thi, Thuy-Lan; [3]Hsu, Min-Yen.

[1]PhD. Food Science. Department of Bioindustry Technology. Dayeh University. Taiwan (R.O.C.); [2]MS. Food Science. Department of Bioindustry Technology. Dayeh University. Taiwan. R.O.C.; [3]PhD.Ophthalmologist. Department of Ophthalmology. Taichung Veterans General Hospital. Taiwan. R.O.C.

Background and objectives: Cajanus cajan (L.) Millsp. root cooked with the ribs can cure diabetes is recognized an aboriginal traditional therapies in Taiwan. Previous studies known after a series of separation and purification from ethanol extract of C. cajan root was obtained Betulinic acid, biochanin A, 5,2'-dihydroxy-7,4'-dimethoxyisoflavanone (cajanol), genistein, 2'-hydroxygenistein and other differences flavonoids. Many studies have confirmed the above components such as: genistein has excellent antioxidant capacity and the ability to inhibit the decomposition of carbohydrates.

Methods: We investigated whether ethanol extracts of C. cajan roots (EECR) could protect against methylglyoxal (MGO; 500 mg/kg bw)-induced insulin resistance (IR) in male Wistar rats between days 1 to 84. Rats treated with MGO were used to examine the hypoglycemic effects of EECR. The rats were divided into six groups and orally supplemented with MGO except for group 1 (normal controls). Group 3 was orally supplemented with Metformin (hypoglycemic drugs) (MET;10 mg/kg bw), group 4 with EECR-L (10 mg/kg bw), group 5 with HIP EECR-M (50 mg/kg bw), and group 6 with EECR-H (100 mg/kg bw). MET and EECR were provided daily between days 21 to 84 in rats. Oral glucose tolerance (OGTT) and insulin tolerance (ITT) tests in 6 groups were evaluated every 2 weeks.

Results: The results indicated that body weights, water and food intake for each group revealed no significant difference (P>0.05). In ITT tests, serum glucose levels of MGO-treated group were slightly change during 120 min (no insulin sensitivity) after intraperitoneal injection of insulin, however, L-, M- and H-EECR-treated rats significantly increased insulin sensitivity (P <0.05) and the effects were comparable MET groups. Blood sugar, lipid and glycosylated hemoglobin (HbA1c) as well as serum insulin, glycation end products (AGEs) of MGO-treated groups were significantly higher than that of blank groups (P <0.05). All EECR-treated groups significantly improved above insulin resistance status. Moreover, we also found that malondialdehyde (MDA) formation and SOD activity were significantly improved in the liver of oral treatment EECR of rats (P <0.05).

Conclusions: Overall, EECR effectively improve insulin resistance in rats treated with MGO possibly through attenuation of oxidative damage in living system.

FOLATE AND VITAMINE C CONTENT IN COMMERCIAL FRUIT/VEGETABLES-BASED SMOOTHIE

[1]Gujska, Elzbieta; [2]Czarnowska-Kujawska, Marta; [1]Michalak, Joanna.

[1]PhD. Department of Food Science. University of Warmia and Mazury in Olsztyn. Poland; [2]PhD. Department of Food Science. University of Warmia and Mazury in Olsztyn. Poland.

Background and objectives: Fruit and vegetable are are rich in water-soluble vitamins (vit. C, B-vitamins), provitamin A, phytosterols and show a high variety on minerals and phytochemical. In many countries the daily uptake of fruit and vegetables was estimated to be lower than the recommended dietary intake (RDI). To increase their intake, the food industry offers smoothies as an alternative and/or addition to the consumption of fresh fruit and vegetables. Smoothies are characterized by a high nutrient concentration with low energy content [Watzl, 2008]. However there is a risk that traditional thermal preservation and storage time may lead to loss of nutritional beneficial components. Therefore, the study was undertaken to identify the folate and C vitamers content in selected commercial smoothie available on the Polish market, to provide nutritionists with guidelines how smoothie consumption contributes to the daily folate and vitamin C intake.

Methods: Folates were extracted in a 0.1 M phosphate buffer (pH 6.1), followed by deconjugation (rat serum) and separated by HPLC after clean-up using SAX spe. cartridges. Vitamine C have been measured using HPLC.

Results: In most examined Smoothie only one form of folate was identified. 5-methyltetrahydrofolate content ranged from 0.0 to 55 μg per bottle (250 ml) or approximately 0 to 14% of the RDA for folate, which is 400 μg per day. The vitamin C content of the Smoothie ranged between 0.4 to 36.7 mg/100 g (about 1.0 – 92.0 mg per bottle). Only 3 analysed smoothies were able to supply the recommended dietary allowance (RDA) for adults of vitamin C of around 90 mg per day. Both folate and vitamin content ranged widely, independent whether it was a pure fruit smoothie or a smoothie composed of fruit and some vegetables.

Watzl, B. 2008. Smoothie-wellness aus der Flasche? Ernährungsumschau, 6, 351-353.

Conclusions: Smoothie can be helpful to achieve the recommendation of vitamin C and to some extent of folate. Most bioactive component, however, may be reduced by prolonged storage and destroyed by high temperature used during preparation.

Keywords: Smoothie, Folate, Vit. C

EFFECT OF POMEGRANATE JUICE CONSUMPTION ON THE LEVELS OF GLUCOSE AND LIPIDIC PROFILE

[1]Valdés Miramontes, Elia Herminia; [2]Virgen-Carrillo, Carmen Alejandrina; [3]Martínez-Moreno, Alma Gabriela; [4]Castañeda-Saucedo, María Claudia.

[1]PhD. Chemistry pharmacobiology. Centro de Investigaciones en Comportamiento Alimentario y Nutrición. CUSur. University of Guadalajara. Mexico.; [2]BSc. Physician. Centro de Investigaciones en Comportamiento Alimentario y Nutrición. CUSur. University of Guadalajara. Mexico.; [3]Ph D. Psychologist. Centro de Investigaciones en Comportamiento Alimentario y Nutrición. CUSur. University of Guadalajara. Mexico.; [4]Ph D. Agronomist. Centro de Investigación en Estudios Territoriales y Ruralidad. University of Guadalajara. Mexico.

Background and objectives: Diabetes mellitus represents the second cause of mortality in Mexico and its prevalence continues to increase. Nowadays, an increased interest of functional foods as an alternative treatment is taken place. It has been proposed that pomegranate, through its high content of phenolic compounds, is capable of reducing glucose and also possesses antiatherogenic effects. The aim of this research was to evaluate the consumption of pomegranate juice and its effect on glycemia and lipid profile in diabetic rats.

Methods: A longitudinal and experimental study was performed with 18 wistar rats induced hyperglycemia by streptozotocin and divided into 3 groups exposed to standard diet and water. In addition, the following interventions: group 1 (G1) pomegranate juice. Groups 2 (G2) and 3 (G3) solution with sucrose at the same concentration as the brix degrees of juice. G3 was also given insulin treatment. Liquid consumption was recorded every 24 hours for 28 days. Plasma levels of glucose, cholesterol and triglycerides were measured every 7 days.

Results: An analysis of variance (ANOVA) was performed with a Tukey mean comparison test. G1 consumed on average 33.59 ml of juice. Groups G2 and G3 consumed on average 77.6 and 82.8 ml of sucrose solution respectively. The average glycemia levels at the beginning and the end of the intervention were for G1: 417-365mg/dl, G2: 461-383mg/dl, G3: 429-214mg/dl respectively. At the end, for glucose concentration, the ANOVA showed a statistically significant difference between the groups ($p < 0.05$). The average cholesterol was for G1: 79mg/dl, G2: 92mg/dl, G3: 78mg/dl. The mean triglycerides for G1: 180mg/dl, G2: 248mg/dl, G3: 169mg/dl. No statistically significant differences were found between cholesterol and triglycerides in the groups.

Conclusions: Pomegranate juice had a lower degree of preference with respect to a sucrose solution. In spite of this, the group exposed to juice had lower blood glucose levels, and statistically significant difference between groups were obtained. This suggests that pomegranate juice may act as an alternative complement during the treatment of hyperglycemia.

EFFECT OF MEDICINAL HERB HANGRYON ON GHRELIN SECRETION OF GASTROENTERIC-BRAIN HORMONE MECHNISM

[1]Kim, Inho; [2]Han, Taewon; [1]Lee, Changho; [1]Han, Daeseok.

[1]Ph. D. Functionality Evaluation Research Group of Korea Food Research Institute. Republic of Korea.; [2]MSc. Functionality Evaluation Research Group of Korea Food Research Institute. Republic of Korea.

Background and objectives: Korean medicinal herb Hangryon extract has applied to ghrelin function on gastroenteric-brain hormone mechanism. The ghrelin is a peptide hormone produced by stomach cells in gastrointestinal tract circulating to hypothalamic area through blood brain barrier which regulates food intake.

Methods: Tests have been conducted to use human microvascular endothelial cells (HMVECs) and male Sprague-Dawley (SD) rats in in vitro and in vivo models respectively. Ghrelin was measured by enzyme immunoassay (EIA) in cell culture supernatant or rat serum.

Results: The ghrelin concentration was significantly decreased to $92 \pm 2\%$, in vitro and $73 \pm 9\%$, in vivo compared to control group when Hangryon extracts was applied to model systems. It means low ghrelin level affects to satiety signal and appetite control. Physicochemical characteristics of ghrelin level with sample extract on the extract were tested on cell viability and hormone level in various pH and temperature conditions. Concentration of ghrelin hormone has shown 91% to 96% on pH change 2 to 10 and 92% to 95% on 60ºCto 100ºC. Cell proliferation was 94% to 100% on sample concentration at 500 μg/mL.

Conclusions: It results that the sample has no cytotoxicity as well as inhibition rate of sample extract was no difference significantly and stable on ghrelin suppression in pH or temperature changes. That also suggested that natural medicinal herb Hangryon would be able to developed to functional food ingredient for anti-obesity product related to gastroenteric-brain hormone mechanism with activity maintenance during processing or digestion in our body.

Keywords: Medicinal herb, Ghrelin concentration, Cell and animal test, Physicochemical characteristics.

Conflict of Interest Disclosure: Abstract title: effect of medicinal herb Hangryon on ghrelin secretion of gastroenteric-brain Hormone mechnism

The authors in above the title declare NO conflict of interest.

FOLATE CONTENT IN RED RASPBERRIES

Czarnowska-Kujawska, Marta; Gujska, Elzbieta; Michalak, Joanna.

PhD. Department of Food Science. University of Warmia and Mazury in Olsztyn. Poland.

Background and objectives: Raspberries are widely consumed fruits due to their unique flavor and beneficial health properties. For years were used for the treatment of various ailments including diabetes, inflammatory diseases and as antimicrobial agents. Several studies have shown preventive effect of raspberries in a variety of diseases, including cancer, diabetes, obesity, cardiovascular diseases, macular degeneration, neurodegeneration as well as inflammation and oxidative stress (Carvalho et al., 2013). Most of the research on raspberries focus on their antioxidant properties together with polyphenolic compounds, vitamin C and tocopherols. However, it is of special interest to analyze another health beneficial compounds contents. Therefore, the aim of the study was to determine folate, vitamin B, content in fresh red raspberries.

Methods: Test material (10 samples of raspberries from different cultivators) was obtained from the local fruit processing plant during the harvest period. Folate content was determined according to Czarnowska & Gujska (2012) using HPLC method.

Results: Based on the chromatographic separation of folate standards, two folate derivatives, 5-methyltetrahydrofolate and tetrahydrofolate were identified in raspberries samples. The total folate content expressed as folic acid, ranged from 37.6 to 69.5 µg/ 100 g fresh weight. According to the European Food Safety Authority (EFSA), a Population Reference Intake for folate was established at the level of 330 µg/ day, with an increase to 600 µg/ day during pregnancy or lactation (EFSA, 2014).

Conclusions: Efforts are being directed to improve the nutritional value of raspberries by breeding and biotechnological programs. Therefore, it is important to provide information on the individual bioactive components, including vitamins, which can be found in these fruits. Our study has shown, that the consumption of fresh raspberries can contribute well to the daily intake of folate, which deficiency is common worldwide.

A SOLUTION TO NUTRITIONAL PROBLEMS OF CHILDREN AT PUBERTATE PERIOD

[1]*Hojageldiyev, Taganmyrat;* [2]*Arashova, Bahar.*

[1]Prof. Pharmacology Department. State Medical University of Turkmenistan. Turkmenistan; [2]Assistant. Pharmacology Department. State Medical University of Turkmenistan. Ashgabat. Turkmenistan.

Background and objectives: In recent years the link between diet and health of people has become well established, especially importance of nutrition of children during pubertate period which was one of the main issues of Second International Conference on Nutrition (ICN2) in 2014. This generates the need to develop healthy foods, specifically targeting children which has benefits on children's health as well as their potential in reducing risk of disease. Developing functional foods, instead of mostly consumed unhealthy diets such as fast foods, made by local products will be best choice for school children which will improve physiological functions and health of children.

Methods: Chicken meat, sesame oil, "Extracti Prosopis Farcta fluidum", "Extracti Artemesia Absinthi" and 200 µm powder of Pepper chillis that is grown in Bagyr village of Ashgabat city in 2015 crumbled by special Chilli grinding Machine was used in making sausage was used. Pharmaco-toxicological and antioxidant properties of sausage and its additives studied on experimental animals (rabbits, rats, mice). Antioxidant property studied by measuring the concentration of malondialdehyde in the tissues, organs of experimental animals.

Results: Experiment results conducted on experimental animals showed that no toxicological and high antioxidant effect of sausage and its additives. Because of the insufficiency of unsaturated fatty acids, which are very important for metabolism, in meat products we used sesame oil to compensate this. Also we used "Extracti Prosopis Farcta Fluidum", "Extracti Artemisia Absinthi" and chili pepper as exchange product for usual xenobiotic products that is used in sausage production and at the same time it will increase antibacterial activity and stability of food. Food that is made by using local products and without synthetic substances will affect to the health of people positively, especially children at pubertate period.

Conclusions: Method of preparation of real functional food from chicken meat and local medicinal plants was developed.

Keywords: Functional food, Children, Health, Medicinal plants.

GLABRIDIN INHIBITS MUSCLE ATROPHY THROUGH P38/FOXO3A AND GLUCOCORTICOID RECEPTOR SIGNALS

[1]Ashida, Hitoshi; [2]Kubota, Yusuke; [3]Yoshioka, Yasukiyo.

[1]PhD. Professor. Graduate School of Agricultural Science. Kobe University. Japan.; [2]Ms. Scientist. Graduate School of Agricultural Science. Kobe University. Japan.; [3]PhD. Postdoctoral fellow. Graduate School of Science Technology and Innovation. Kobe University. Japan.

Background and objectives: Deterioration of muscle weight due to muscle atrophy decreased quality of life as one of the social problems. Since skeletal muscle weight is maintained by a balance of the synthesis and degradation of proteins, muscle atrophy caused by this collapses. In this study, we search for the food ingredient which is effective in promoting protein synthesis or preventing protein degradation to improve its balance, and try to elucidate this mechanism.

Methods: C2C12 skeletal muscle cells were treated with each food components and 1.0 μCi L-[3,5-3H]-tyrosine in differentiation medium. Protein synthesis was determined to measure the incorporation of radio activity into cellular proteins. Protein degradation was determined to measure the release of radio activity induced by dexamethasone (Dex) after pulse label L-[3,5-3H]-tyrosine. Protein expression and phosphorylation levels were detected by western blotting.

Results: Among 15 kinds of food compounds glabridin, 4-hydroxyderricin, and xanthoangelol suppressed the Dex-induced protein degradation. On the other hand, all food compounds tested did not promote the protein synthesis. We focused on glabridin and tried to elucidate underlying molecular mechanism. Glabridin inhibited proteolysis through a decrease in the expression levels of MuRF-1 and Cbl-b, which are ubiquitin ligases involving in muscle atrophy. Glabridin also inhibited Dex-induced phosphorylation levels of Foxo3a in nuclear fraction. It is suggested that Foxo3a translocated in nuclear by phosphorylation, resulting in promoted the expression of ubiquitin ligases, MuRF-1 and Cbl-b. We confirmed that glabridin-rich food materials also inhibit muscle atrophy in mice with the same molecular mechanisms.

Conclusions: We found glabridin, 4-hydroxyderricin, and xanthoangelol as the food compounds to improve muscle dysfunction. Of these, glabridin prevented phosphorylation of Foxo3a in nuclear fraction, this would be led to down-expression of ubiquitin ligases MuRF-1 and Cbl-b to prevent Dex-induced protein degradation.

Keywords: Glabridin, Muscle atrophy, Glucocorticoid receptor; p38; FOXO3a.

THERAPEUTIC EFFECTS OF EDIBLE BROWN ALGA UNDARIA PINNATIFIDA (WAKAME) IN THE MICE INFECTED WITH HERPES SIMPLEX VIRUS

[1]Lee, Jung-Bum; [2]Hayashi, Kyoko; [3]Yoshinaga, Keiko; [3]Nakano, Takahisa; [2]Uemura, Kazuhide; [2]Kawahara, Toshio; [2]Hayashi, Toshimitsu.

[1]PhD. Assistant Professor. Graduate School of Medicine and Pharmaceutical Sciences for Research. University of Toyama. Japan.; [2]PhD. Research Institute of Life and Health Sciences. Chubu University. Japan.; [3]PhD. Riken Vitamin Co. Ltd. Japan.

Background and objectives: Herpes simplex virus type 2 (HSV-2) causes genital herpes that is a lifelong infection in populations worldwide. The development of therapeutic agents for preventing genital herpes has become very important in recent years. In the present study, the in vivo anti-HSV-2 effects of wakame proteins (WT), wakame peptides (WP) prepared by protease treatment of wakame and the major dipeptides of WP were assessed.

Methods: Female BALB/c mice were inoculated vaginally with HSV-2. WT, WP and three dipeptides, Val-Tyr (VY), Ile-Tyr (IY) and Phe-Tyr (FY), were administered orally from 3 days prior to virus inoculation until 7 days after inoculation. The vaginal washes collected at 3 days after virus inoculation were subjected to virus titration. Clinical signs of infection and survivors were recorded for 2 weeks. In the other experiments, the anti-HSV-2 activities of sera obtained from the mice administered with WP were evaluated.

Results: WT suppressed the lesion scores and enhanced the survival rates of mice as compared with distilled water-administered control mice. WP showed significant effects in the suppression of herpetic lesions, virus yields and death of mice. WP contains VY, IY and FY as the major dipeptide components. Among them, IY and FY exerted higher therapeutic effects in the suppression of herpetic lesion, virus production and death of mice. When the mice were treated with single oral administration of WP, the sera obtained during 0 – 8 hours after administration showed potent anti-HSV-2 activities.

Conclusions: When the wakame peptide was orally ingested in HSV-2-infected mice, the peptide exhibited potent therapeutic effects. The dipeptides contained in the wakame peptide might play a pivotal role in those effects.

Keywords: Brown alga, Undaria pinnatifida, Herpes simplex virus, Genital infection, Therapeutic effects.

EFFECT OF THE KIWIFRUIT EXTRACT (ACTANNINE®; ACT) ON THE INTESTINAL LIPID ABSORPTION

[1]Iwata, Satomi; [2]Kato, Takako; [2]Yokoyama, Akari; [3]Ogihara, Takuo.

[1]PhD. Research and development. Omnica Co., Ltd. Japan; [2]MSc. Faculty of Pharmacy. Takasaki University of Health and Welfare. Japan; [3]PhD. Faculty of Pharmacy. Takasaki University of Health and Welfare. Japan.

Background and objectives: Actannine® (Act) is a polyphenol enriched Kiwifruit extract. Polyphenols, which are distributed in various plants, are recognized as potent antioxidants and are shown to exhibit a series of other pharmacological effects, (e.g. the lipase inhibitory activity of grape seeds). In this study, we investigated the effect of Act on intestinal lipid absorption in mice fed a high-fat diet.

Methods: Inhibitory activity against lipase of Act was measured using an enzymatic in vitro assay kit. Act was administered orally for 6 weeks in high-fat diet (HFD) fed mice, and the time course of body weight change, food intake, organ weight (fat, liver and kidney), plasma parameters (triglyceride, total cholesterol, glucose, AST, ALT, HDL, LDL, leptin, adiponectin and insulin) and lipid contents in the liver and feces were measured.

Results: Act significantly inhibited lipase activity in a dose-dependent manner in vitro. In HFD fed mice, Act significantly inhibited an increase in body weight and visceral fat weight, and triglyceride (TG) levels in the blood and liver were reduced. Moreover, the TG level of feces was increased.

Conclusions: Our study indicates that Act has the potential to reduce intestinal lipid absorption due to its lipase inhibitory activity.

Keywords: Actannine, Kiwifruit extract, Polyphenol, Lipase inhibitory activity.

Kewpie Corporation. Japan; [6]PhD. R&D Division. Kewpie Corporation. Japan; [7]MD, PhD. Institute of Life Innovation Studies. Toyo University. Japan.

Background and objectives: The egg is a nutrient-dense food and contains antioxidative carotenoids, lutein and zeaxanthin, but its impact on serum cholesterol levels has been a matter of concern. Here, we conducted the intervention studies to investigate whether daily additional consumption of an egg might affect serum lipid profiles and antioxidant parameters in both healthy and moderately hypercholesterolemic males.

Methods: Study 1: Fourteen healthy male adults participated, consuming breakfast including a boiled egg for 4 weeks. Before and at the end of the study period, blood samples were obtained after an overnight fast.

Study 2: Nineteen moderately hypercholesterolemic male adults (TC > 5.2 mmol/L) participated, consuming one soft boiled egg per day for 4 weeks in addition to their habitual diet. Before and at weeks 2 and 4, blood samples were obtained after an overnight fast.

Results: Study 1: At the end of intervention, serum concentrations of total cholesterol (TC) and low-density lipoprotein cholesterol (LDL-C) were unchanged, despite the significant increase in the intake of dietary cholesterol. In contrast, a significant increase in high-density lipoprotein cholesterol (HDL-C) and a reduction of the LDL-C/HDL-C ratio were observed. Interestingly, the malondialdhyde modified-LDL (MDA-LDL)/LDL-C ratio was decreased and the LDL oxidation lag time, reflecting the resistance of free-radical-induced LDL lipid peroxidation (ex vivo), was significantly prolonged.

Study 2: At weeks 2 and 4, the subjects' serum concentrations of TC and LDL-C did not increase. The serum MDA-LDL concentrations was significantly decreased and the LDL oxidation lag times (ex vivo) was prolonged after 2 and 4 weeks. At weeks 2 and 4, the subjects' serum lutein + zeaxanthin concentrations were significantly higher than their baseline values and showed both an inverse relation with MDA-LDL and a positive relationship with the LDL oxidation lag time.

Conclusions: These studies showed that the additional consumption of one egg per day for 4 weeks did not have adverse effects on serum TC or LDL-C, and it might reduce the susceptibility of LDL to oxidation through an increase in the serum lutein and zeaxanthin concentrations.

Keywords: Egg, Dietary cholesterol, Serum lipids, LDL oxidation.

INVOLVEMENT OF THE VAGUS NERVE IN THE ENHANCEMENT OF THERMOGENESIS BY INTRAGASTRIC ADMINISTRATION OF TRPM8 AGONIST

[1]Mori, Noriyuki; [2]Urata, Tomomi; [1]Fukuwatari, Tsutomu.

[1]PhD. Department of Nutrition. the University of Shiga Prefecture; [2]MSc. Department of Nutrition. the University of Shiga Prefecture.

Background and objectives: Obesity increases risk for various diseases and reducing exceeded body fat stores is important for maintaining good health. Thermogenesis contributes to the maintenance of body temperature, and it requires metabolic fuel availability and contributes to energy balance. Therefore, the enhancement of thermogenesis would be important to reduce body fat accumulation. Transient Receptor Potential Melastatin 8 (TRPM8) is a cold receptor activated by mild cold temperature (< 28ºC) and it is involved in cold sensation and thermoregulation. Interestingly, TRPM8 is also activated by edible herb components such as menthol (mint) or 1,8-cineole (found in laurel, basil, rosemary). Previous studies have reported that intragastric administration of menthol and 1,8-cineole induces thermogenesis in anesthetized mice, however, the detailed mechanism is unclear. TRPM8 mRNA is detected in various tissues, including the gastrointestinal mucosa, and in the vagal afferent nerve. Based on these facts, in this study, we aimed to investigate whether TRPM8 expression in the vagal afferent nerve is involved in the enhancement of thermogenesis induced by intake of TRPM8 agonist.

Methods: Male mice (C57BL/6, 7wks) were anesthetized with urethane (1.4 g/kg) and thermistors were set on the tail skin, colon, and intrascapular brown adipose tissue (IBAT). Each temperature was used as an index of heat diffusion, core temperature, and local thermogenesis, respectively. A cannula was then inserted into the stomach or jugular vein to administer the solution. The temperature was measured for 10 min before administrating the 1,8-cineole or vehicle and for 180 min after administration.

Results: Intragastric administration of 1,8-cineole increased IBAT and colonic temperatures, and M8-B-treatment (TRPM8 antagonist) inhibited these responses. Intravenous administration of 1,8-cineole also showed similar effects. In vagotomized mice, the responses induced by intragastric administration of 1,8-cineole were attenuated.

Conclusions: Vagus nerve are involved in the enhancement of thermogenesis induced by intake of TRPM8 agonists.

Keywords: Thermogenesis, TRPM8, Brown adipose tissue, Mice, Vagus nerve.

ENRICHMENT OF PREMIX OF FLOUR SUITABLE FOR CELIAC AND ACCEPTABILITY OF BAKED PRODUCTS

[1]Morínigo Martínez, Macarena; [2]Cubilla Giménez, Pamela Violeta; [2]Monsalvo Benítez, María Belén; [2]Acosta Escobar, José.

[1]Nutritionist. Department of Nutrition Research. Faculty of Chemical Sciences. National University of Asuncion. Paraguay; [2]Nutritionist. Faculty of Chemical Sciences. National University of Asuncion. Paraguay.

Background and objectives: In Paraguay, Law 20.830/98 regulates the enrichment of wheat flour as a strategy for the prevention of anemia. This law does not apply to the premix of flour suitable for celiacs. Anemia in celiac disease is 50%. When enriching foods, one of the criteria states that the organoleptic characteristics must be acceptable or should not be modified. Therefore, our objective was to enrich the premix of flour suitable for celiacs with iron and B vitamins, to evaluate the acceptability of two types of high-demand baked goods (bread and sticks) and to further evaluate compliance with the provisions of law.

Methods: In specialized kitchens, we elaborate 2 types of products: bread and sticks, each in two versions, with vitamin mix and without vitamin mix. Acceptability was evaluate used a hedonic scale of 9 points and evaluated the characteristics of color,

odor, taste, texture, hardness, appearance and overall score (sum of the average characteristics/6) of the 4 samples presented. The products were presented in individual packages, labeled in numerical form. The volunteers tested each of the 4 products and subsequently completed a self-administered questionnaire. Student's t-test was used.

Results: In 105 volunteers with celiac disease (81% female) the mean age was 34.5 ± 10.9 years, 60% reported having had anemia at some point. The evaluated products had the following mean global score: unmixed bread 7.42 ± 1.33 (95%CI 7.17-7.68), bread with mixture 8.00 ± 1.06 (95%CI 7.80-8.21), unmixed stick 7.91 ± 1.05 (95%CI 7.71-8.11), and mixed stick 7.86 ± 1.17 (95%CI 7.64-8.09). The differences were minimal, however, mixed bread was significantly more acceptable than unmixed bread (0.58 points, p=0.001) and between the scores of the sticks there were no significant differences (0.05 points p=0.749). We evaluated the compliance with Law 20.830 / 98 and found that the premix for celiacs complies with the contribution of micronutrients (iron, B1, B2, B3 and folic acid).

Conclusions: We found that the bread with mixture had a high acceptability and that when the premixture for celiacs was soaked, it could be complied with what was established in the law

DIETARY MARINE SPHINGOLIPIDS AS FUNCTIONAL FOOD COMPONENTS

[1]*Sugawara, Tatsuya;* [2]*Tomonaga, Nami;* [3]*Duan, Jingjin;* [4]*Manabe, Yuki;* [5]*Tsuduki, Tsuyoshi;* [6]*Hirata, Takashi.*

[1]PhD. Garaduate School of Agriculture. Kyoto University. Japan; [2]PhD. Graduate School of Agriculture. Kyoto University. Japan; [3]PhD. Department of Cardiology. Boston Children's Hospital. United States.; [4]MSc. Graduate School of Agriculture. Kyoto University. Japan; [5]PhD. Graduate School of Agricultural Science. Tohoku University. Japan.; [6]PhD. Shijonawate Gakuen University. Japan.

Background and objectives: Sphingolipids are ubiquitous in all eukaryotic organisms and have attracted attention as physiologically functional lipids. Recently, various physiological functions of dietary sphingolipids, especially improving the skin barrier function, have been demonstrated. Sphingolipids of marine invertebrates have atypical types of chain length, unsaturation, and hydroxylation in sphingoid bases. In addition, sphingolipids having C-P bonds, such as ceramide 2-aminoethylphosphonate (CAEP) are found in marine invertebrates. In this study, we evaluated the absorption and functions of dietary marine sphingolipids to utilize marine sources for functional foods.

Methods: The intestinal absorption was evaluated via a lipid absorption assay of lymph from the thoracic duct in SD rats. To investigate the effects of dietary sphingolipids on skin, we characterized the recovery of skin barrier using a special Mg-deficient diet induced atopic dermatitis-like hairless mice model.

Results: We previously indicated that the intestinal absorption of dietary plant glucosylceramide is extremely low (J. Lipid Res. 51, 1761-1769, 2010). In the case of sea cucumber cerebroside, the recovery into lymph was similar to plant glucosylceramide. On the other hand, the lymphatic recovery of sphingoid bases from dietary squid CAEP was about ten times higher than those from glucosylceramide, similar to milk sphingomyelin (Lipids 50, 987, 2015). We previously found that dietary plant glucosylceramide and animal sphingomyelin can accelerate the recoveries of damaged skin barrier functions (Exp. Dermatol. 21, 448-452, 2012). Dietary supplementation with marine sphingolipids involved in both sea cucumber cerebroside and squid CAEP to hairless mouse also improved the skin barrier function.

Conclusions: Our findings contribute to our understanding of the absorption of dietary sphingolipids from marine sources and their effects on the host as a dietary integrant. This work was partly supported by the Program for Promotion of Basic and Applied Researches for Innovations in Biooriented Industry (BRAIN) to TS and the Japan Society for the Promotion of Science (JSPS) KAKENHI (Grant No. 16H04923 to TS, YM and TT; Grant No. 15J01143 to NT).

Keywords: Intestinal absorption, Seafoods, Skin barrier, Sphingolipids.

CLINICAL EFFECTS OF EVIDENCE-BASED BILBERRY EXTRACT ON ASTHENOPIA

[1]*Kosehira, Marie;* [2]*Kitaichi, Nobuyoshi.*

[1]Chief Researcher. Research and Development Dept. Omnica Co., Ltd. Japan; [2]MD. PhD. Professor and Chairman. Department of Ophthalmology Health Sciences University of Hokkaido. Japan.

Background and objectives: We evaluated the effect of evidence-based bilberry extract (EBBE) intake for asthenopia.

Methods: Placebo-controlled double-blind randomized clinical trial was conducted in 30 Japanese healthy volunteers (adults: 20-59 years old). Subjects took 160mg of EBBE (contain 37% Vaccinium myrtillus anthocyanin) or placebo daily for 4 weeks. On the first and the last day of the administration, objective examinations were performed three times: before, prompt after, and 20 minutes after video display terminal (VDT) work. They played Tetris game for 30 minutes on iPhone as deemed VDT work. Accommodation was examined by using TriIRIS® C9000.

Results: Two of accommodative functions "Miosis" and "Convergence" were statistically improved in EBBE group compared with controls at 20 minutes after VDT work (P<0.05 and 0.1).

Conclusions: Oral intake of qualified EBBE saved asthenopia objectively when abusing eyes.

Keywords: Asthenopia, Miosis, Convergence, Evidence-based bilberry extract, VMA

ORANGE BAGASSE AS AN INGREDIENT IN THE FORMULATION OF A GLUTEN FREE MUFFIN

[1]Franco Obaldía, Indira del Carmen; [2]Terrero, Paola.

[1]PhD. Professor. Science and Technology College. Technological University of Panama. Panama.; [2]BSc. Science and Technology College. Technological University of Panama. Panama.

Background and objectives: Recently, the number of companies dedicated to the production of natural juices and fruit concentrates is increasing. As a result, an increase in the amount of citrus waste, such as orange bagasse is produced. This orange bagasse can be utilized in animal feed mixes, however it has valuable components for human health, which makes it an appropriate ingredient in the formulation of new food products. The objective of this research is to obtain a nutritional product, gluten free muffin, for a population segment with special needs, as celiac, using as main ingredient the orange bagasse.

Methods: Orange bagasse was obtained from a local juice food plant, and it was dried in a solar dryer. Then it was ground, until it was less than 250 microns in size, obtaining dry orange bagasse powder. The orange bagasse was characterized, doing physicochemical and microbiological analyses. Different formulations to obtain muffins were tested, being the most successful, the one using a mix one part corn, one part rice and one part orange bagasse. The muffin was ginger flavoured. Sensorial analyses were developed with a non-trained panel.

Results: The values for the physicochemical characterization of the orange bagasse flour were in agreement with the literature, being the moisture content of 10%, which increases its shelf life and prevents deterioration. Fat content was low, less than 1% and ash and protein were less than 5% each. Muffin was evaluated and had the characteristics of a flour muffin, and after the sensorial profile, the panel showed a high percentage of acceptance of the product.

Conclusions: The use of natural products, like the orange bagasse, is a new way of using agro-industrial wastes in the food industry, in order to obtain a food product, with high added value, targeting a population with special needs such as celiac people.

Keywords: Orange bagasse, Gluten free muffin, Orange bagasse flour, Celiac, Functional food.

EFFECTS OF THE PARTICLE SIZE OF YOUNG BARLEY LEAF POWDER ON INTESTINAL BACTERIAL FLORA IN RATS

[1]Shimada, Ryoko; [2]Katayama, Masayuki; [3]Takano, Akira; [4]Sugawa-Katayama, Yohko.

[1]PhD. Department of Health and Nutrition. Osaka Aoyama University. Monoo. Japan.; [2]PhD. Visiting Professor. Department of Health and Nutrition. Osaka Aoyama University. Monoo. Japan.; [3]PhD. Research and Development Division, TOYO SHINYAKU Co., Ltd. Tosu. Japan; [4]PhD. Professor aemeritus. Department of Health and Nutrition. Osaka Aoyama University. Monoo. Japan.

Background and objectives: Young barley leaf powder (YBLP) is a component of the popular drink "Aojiru" used as a dietary supplement in Japan. We examined effects of the particle size of YBLP on the patterns of intestinal bacterial flora and fermented products in rats.

Methods: Seven week-old, male Wistar rats were divided into 4 groups (each 7 rats), and fed ad libitum for 14 days on the following AIN93G-based diets containing no cellulose ("fiber-free"), 4.5% cellulose ("C-4.5"), 3% cellulose plus 3% YBLP (fine particles) ("fine YBLP"), and 3% cellulose plus 3% YBLP (coarse particles) ("coarse YBLP"), respectively. Then, the rats were anesthetized with pentobarbital, and their ceca were removed and weighed. The short chain fatty acids of the cecal contents were determined by HPLC (High Performance Liquid Chromatography), and the patterns of intestinal bacteria flora were analyzed by T-RFLP (Terminal Restriction Fragment Length Polymorphism).

Results: The total amounts of the short chain fatty acids in the cecal contents of the " fine YBLP" and "coarse YBLP" groups were significantly greater than those of the "C-4.5" group. The concentration of n-butyric acid of the "fine YBLP" group was greater than that of the "coarse YBLP", and the value was lowest in the "C-4.5" group. As for the intestinal bacterial flora, the ratio of Clostridiales species increased in the "fine YBLP" and in "coarse YBLP" groups while Bacteroidales increased in the "fine YBLP" group.

Conclusions: YBLP is suggested to contain some components favored by Bacteroidales, and the "fine YBLP" may show more clearly the efficacy of YBLP than the "coarse YBLP".

Keywords: Young barley leaf powder, Intestinal bacterial flora, Short chain fatty acids.

EFFECTS OF PEPTIDES FROM JAPANESE BARLEY ON PC12 CELLS GROWTH AND MICROTUBULE FORMING

[1]Kawaguchi, Makiko; [2]Yamanaka-Nakayama, Yukako; [3]Takenouchi, Akiko; [4]Doi, Hiroshi.

[1]PhD. Department of Food Design. Koshien University. Japan; [2]Department of Food Science and Nutrition. Kobe Shoin Women's University. Japan; [3]Department of Food Science and Nutrition. Mukogawa Women's University. Japan; [4]PhD. Department of Food Science and Nutrition. Mukogawa Women's University. Japan.

Background and objectives: Barley is useful as a foodstuff, because it contains high levels of protein, dietary fibers and minerals. We have searched the biological active peptides from Japanese barley flour obtained from the outer layer of the grain. Microtubules are important components of several subcellular structures. Recent reports have demonstrated that impairment of the microtubule system is related to the pathogenesis of Alzheimer's disease. Brain atrophy and decrease in cell number also have observed in Alzheimer's disease. In the present study, we investigated the effects of peptides obtained from barley flour on PC12 cells growth and microtubule assembly.

Methods: Japanese barley flour was extracted in water and the extract was dialyzed with a Cell Sep T1 (nominal MW=3,500). The external solution of dialysis was evaporated and taken to dryness. Then the sample was dissolved in water and subjected to size exclusion chromatography on a Bio Gel P-4 column. The molecular weights of these fractions were confirmed by HPLC analysis with Tosoh TSK 3000SW column.

PC12 cells were cultured in DME medium containing 5% FBS, and 0.3% penicillin/streptomycin and incubated at 37° in a 5% CO_2 in a humidified atmosphere. After 48 h of incubation, the medium was replaced in with a fresh DME medium containing 0-10mg/ml P4-1 fraction. After 24h cultivation, cell viability was assessed using Cell Counting Kit-8. Percentage viability of cells in comparison to control cells was calculated. The GTPase assay was performed by HPLC system.

Results: Five fractions (P4-1, P4-2-1, P4-2-2, P4-3, and P4-4) were identified by the preceding sequential steps. From the results of analysis of molecular weight, P4-1 fraction was considered short peptides with four amino acids. Percentage viability of PC12 cells was increased depending on the levels of P4-1 fraction added.

Conclusions: Fraction P4-1, peptide from Japanese barley flour, is considered as PC12 cell growth factor. This oligopeptides promoted the microtubule assembly in PC12cells.

Keywords: Peptides, Barley, PC12 cells.

A NOVEL A-GLUCAN FROM AN EDIBLE MUSHROOM, GRIFOLA FRONDOSA (MAITAKE), EXERTS THE THERAPEUTIC EFFECTS ON INFLUENZA A VIRUS INFECTION

[1]Hayashi, Kyoko; [2]Tanaka, Akihiro; [3]Lee, Jung-Bum; [1]Kawahara, Toshio; [1]Hayashi, Toshimitsu.

[1]PhD. Research Institute of Life and Health Sciences. Chubu University. Japan.; [2]PhD. Yukiguni Maitake Co. Ltd. Japan.; [3]PhD. Graduate School of Medicine and Pharmaceutical Sciences for Research. University of Toyama. Japan.

Background and objectives: Grifola frondosa (Fr.) S.F. Gray, called Maitake in Japanese, is an edible mushroom that has been consumed in Asian countries. We have isolated efficiently a novel α-glucan with MW of approximately 1 x 107 Da (Maitake α-glucan) from its fruiting body. In the present study, the therapeutic effects of the α-glucan were evaluated in immunocompetent and immunocompromised mice infected influenza A virus (IFV).

Methods: Maitake α-glucan was isolated from the dried materials by extracting with hot water and precipitating with ethanol. Oseltamivir-sensitive (A/NWS/33) and -resistant viruses (H1N-1pdm09) were propagated on MDCK cells. In animal experiments, female BALB/c mice with normal immunity or immunocompromised mice treated with 5-fluorouracil were intranasally infected with IFV, and the α-glucan or oseltamivir was administered orally. Virus yields of the mice were measured at 3 days post-infection, neutralizing antibody titers were determined by plaque assays and virus-specific IgA by ELISA at 14 days post-infection.

Results: When the immunocompetent and immunocompromised mice were infected with an oseltamivir-sensitive IFV, the α-glucan suppressed the weight loss of the mice caused by virus infection and the virus replication, while increasing the neutralizing antibody and secretory IgA levels in both mouse groups. In the mice infected with oseltamivir-resistant IFV, the α-glucan suppressed the viral replication more markedly and produced higher titers of virus-specific antibody as compared with oseltamivir.

Conclusions: The present results suggested that Maitake α-glucan might be useful for therapy and prevention of IFV infections even in the immunosuppressive state.

Keywords: Maitake α-glucan, Influenza virus infection, Animal experiments, Therapeutic effects.

BENEFICIAL EFFECTS OF SMALL MOLECULE OLIGOPEPTIDES ISOLATED FROM PANAX GINSENG C. A. MEYER IN LOW-DOSE ALLOXAN- AND HIGH-CARBOHYDRATE/HIGH-FAT DIET-INDUCED DIABETIC RATS, PARTIALLY BY AMELIORATE PANCR

Li, Yong.

Peking University.

Background and objectives: This study aimed at investigating whether treatment with oligopeptides from ginseng (GOP) could modulate type 2 diabetes mellitus (T2DM)-related hyperglycemia in rats induced by high fat diet and low doses of alloxan and its therapeutic mechanisms.

Methods: Male Sprague-Dawley rats made type 2 diabetic with 1 injections of 105 mg/kg alloxan and 4 weeks of the high-carbohydrate/high-fat diet were fed high-carbohydrate/high-fat diet with or without GOPs administration (0.125 g/kgBW, 0.5 g/kgBW and 2.0 g/kgBW) for 7, 24 and 52 weeks, respectively. Oral glucose test tolerance (OGTT), plasma glucose, serum insulin, the level of antioxidant and the score of b-cell function were measured. Morphological observation was performed by light microscopic analyses. The level of insulin and the expression of NF-κB signaling in pancreatic islets were also studied using western blot. Additionally, the survival time and rate were observed.

Results: After the treatment, the score of b-cell function and the abnormal OGTT of diabetic rats were partially reversed by GOPs treatment. The efficacious effect of GOPs was also manifested in the amelioration of pancreatic damage by microscopic analyses. Moreover, GOPs treatment increased normal insulin content and decreased the expression of NF-κB signaling and the number of apoptotic cells in diabetic islets. Additionally, compared with the model control, the survival time and rate were significantly longer.

Conclusions: These findings suggest that GOPs might have auxiliary therapeutic potential for diabetes, partially by ameliorate pancreatic beta-cell dysfunction and death.

EFFECT OF BLACK TEA DERIVED POLYPHENOLS ON MUSCLE ATROPHY AND RECOVERY IN MICE

[1]*Aoki, Yuki;* [2]*Ozawa, Tetsuo;* [1]*Takemasa, Tohru;* [2]*Numata, Osamu.*

[1]Graduate school of comprehensive human sciences, University of Tsukuba; [2]Graduate school of life and environment sciences, University of Tsukuba.

Background and objectives: Recently, there are some reports that polyphenols have some good effects on muscle. Our laboratory originally purified high-molecular-weight polyphenols extracted from black tea. We named it Mitochondria Activation Factor (hereafter, MAF), because MAF enhanced mitochondrial membrane potential of ciliated protista Tetrahymena pyriformis (Fujihara et al.). We found MAF raises AMPK (regulator of PGC-1 alpha, which stimulates mitochondria biogenesis) phosphorylation level and improves endurance performance in mice (Eguchi et al.). Recently, we extracted crude MAF fraction with 80% ethanol, and named this fraction E80. In this study, we examined whether E80 prevented skeletal muscle of mice during tail suspension or promoted recovery from muscle atrophy.

Methods: Adult mice (8 weeks of age) were fed on food containing 0.5% E80 during 2 weeks of tail suspension and 5 days or 10 days of recovery after 2 weeks of tail suspension. After these process, mice were euthanized by cervical dislocation and excised soleus muscle.

Results: We measured muscle wet weight and molecules regulating muscle mass. Then, we found E80 may have potential for promoting recovery of muscle mass from atrophy by tail suspension.

Conclusions: Previously, we reported E80 promote muscles hypertrophy during functional overload in mice. In this study, we demonstrated E80 has potential for promoting recovery of muscle mass from atrophy.

Taipei Medical University. Taipei. Taiwan.; [3]MSc. School of Nutrition and Health Sciences. Taipei Medical University. Taipei. Taiwan.; [4]PhD. Department of Nutrition. I-Shou University. Kaohsiung. Taiwan.

Background and objectives: The glycative stress is partially responsible for the damage of renal ischemia-reperfusion (IR) injury. Accumulating evidences indicate that resveratrol has beneficial effects on markers of oxidative stress in diseases. In this study, we used a renal IR model to demonstrate pretreatment of resveratrol showed the protective effects on renal IR injury.

Methods: Mice were assigned to sham-operation group, renal IR group, pretreat apocynin, and pretreat resveratrol group. Serum cystatin C and creatinine (Cr) levels were analyzed. The renal methylglyoxal (MG), malondialdehyde (MDA) levels and also glyoxalase 1 (GLO-1) activity were detected. Renal thioredoxin reductase/thioredoxin system and caspase 3 were measured by western blotting.

Results: Our model of renal IR resulted in severe kidney dysfunction 24 hour after reperfusion indicated by significant increases in serum Cr levels. We also determined that mice subjected to IR increased MG accumulation and MDA level and decreased GLO-1 activity in the kidneys. Compared with vehicle control, intravenous tail vein injection of resveratrol (10 mg/kg bw) markedly improved the renal function, reduced oxidative stress, and cell apoptosis in renal IR injury models, strongly suppressed the IR-induced endogenous MG accumulation and increased the activity of GLO-1.

Conclusions: This study suggests that pretreatment of resveratrol could reduce the burden of endogenous MG accumulation-induced by IR with renal impairment and possibly improve the severity of renal injury.

Keywords: Resveratrol, Renal ischemia-reperfusion injury, Glyoxalase 1, Methylglyoxal.

PROTECTIVE ACTION OF PHELLINUS LINTEUS POLYSCCHARIDE AGAINST RADIATION-INDUCED HAEMATOPOIETIC ABNORMALITY IN MICE

[1]Huang, Shu-Ming; [2]Chen, Chin Chu; [3]Hu, Miao Lin.

[1]PhD.Department of nutrition. Nantou Hospital. Ministry of Health and Welfare. Nantou City of Taiwan. R.O.C.; [2]PhD. Biotechnology Center. Grape King Inc. Taoyuan. Taiwan. R.O.C.; [3]PhD. Agricultural Biotechnology Center. National Chung Hsing University. Taichung Taiwan. R.O.C.

Background and objectives: Radiation exposure is one of the potential carcinogenic factors in our living environment. The hematopoietic system damage is the main side effect of radiation exposure. Phellinus linteus (PL), one of the medicinal fungus in East Asia, contains rich polysaccharides, flavonoids and polyphenols , been shown to exhibit anti-cancer, anti-inflammatory and immunomodulative effects. We determined the protective effect of PL polysaccharide (PLP) on low dose of irradiated mice

Methods: Mice were divided into control group (no irradiation), irradiated group (2 Gy), irradiated (2 Gy) + WR2721 (200 mg / kg), irradiated (2 Gy) + low dose group (100 mg / Kg), irradiated (2 Gy) + high dose (500 mg / kg). Blood samples were measured 48 hours after the first irradiation. WBC, RBC, HGB, PLT. Blood samples were collected for 48 hours after each irradiation. The weight was measured weekly and recorded. In the sixth week of sacrifice. Sacrifice after the collection of blood and mouse organs, intestinal, femur for analysis.

Results: Results revealed that PLP administration, especially at high dose, significantly restored radiation-induced loss of WBC and platelets. In addition, PLP supplementation significantly ameliorated radiation-induced femur fibrosis. Similarly, PLP effectively reversed radiation-induced abnormal serum levels of immunological parameters.

Conclusions: Overall, this dissertation research demonstrated that PLP effectively protected against radiation damage by increasing antioxidant activities and ameliorating abnormal hematopoietic in mice.

Keywords: Radiation, Phellinus Linteus, Polysaccharides, Hematopoietic function.

Faculty of Medicine. National Northeastern University (UNNE). Corrientes. Argentina.

Background and objectives: Background: Basic metabolic research of chronic non transmissible diseases often needs the use of different diets in experimental animals, these must be designed for being complete. Given the already observed functional effects of Omega-3 fatty acids and their high content in chia seeds, it is interesting to find a suitable method for their incorporation into the murine diet. Objective: to evaluate the organoleptic characteristics, acceptability and nutritional quality of food rich in Omega-3 fatty acids in Balb-c mice from the Biotherium of Faculty of Medicine, Universidad Nacional del Nordeste.

Methods: Adult mice (2 months) of the Balb-c strain were used. The protocol was approved by the Institutional Committee for Care and Use of Experimental Animals. Mice were randomly distributed in 4 lots with food and water ad-libitum. Experimental groups received a diet rich in Omega-3, while the control lots (A) were provided with a standard commercial feed for 15 days. The diets were prepared manually with natural ingredients according to nutritional requirements: one formulation with egg proteins (B) and one with milk and egg (C).The semi-solid preparations were

molded as standard pellets, which were: 1) dried in an oven for 2 h at 80°C, and 2) autoclaved (103 kPa, 120ºC) 10 min and further dried 5 h at 40°C. Thus, the four diets were: B1, B2, C1, C2. The evaluation of diets include: the organoleptic characteristics of the pellets, its acceptability and digestibility. Measurements involved the progression of mice body weight, the consumption of pellets and the study of feces. Coprologic samples were analyzed with light microscopy (40x).

Results: The smell and color of the food were conventional and similar among different groups. The diet with the greatest acceptability was C. Animals fed with diet B decreased body weight in comparison with those fed with diet C, which maintained or increased it similarly to controls.

Conclusions: This study let us conclude that the best formulation of a pellet rich in Omega-3 from chia seeds is C1. Additionally, this work might be used for evaluating Omega-3 bioavailability in further settings for metabolic models of chronic non transmissible diseases.

RED PITAYA PEEL EXTRACT IMPROVED STEATOSIS AND INFLAMMATION IN ALCOHOLIC LIVER DISEASE

[1]Yang, Hsin-Yi; [2]Yeh, Wan Ju; [3]Tsai, Chia-Chun; [2]Chen, Jiun-Rong.

[1]PhD. Department of Nutrition, I-Shou University. Taiwan.; [2]PhD. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan.; [3]MSc. School of Nutrition and Health Sciences. Taipei Medical University. Taiwan.

Background and objectives: Alcohol consumption leads to liver injury, ectopic fat accumulation in the liver and excretion of proinflammatory cytokines which may promote the progression of liver disease. Red pitaya is one of the popular fruit in Taiwan and its disposed peel is rich in phenolic compounds. Thus, the aim of the study is to investigate the beneficial effects of pitaya peel extract (PE) in a chronic plus single binge ethanol feeding model.

Methods: Twenty-four C57BL/6 mice were assigned to three groups consuming control liquid diet (C), ethanol liquid diet (E) or ethanol liquid diet plus 1000mg/kgBW red pitaya peel extract (P) for 13 days. At day 14, mice were orally gavaged with a single dose of isocaloric maltodextrin (C) or ethanol (5g/kgBW, E & P). After 9h, mice were sacrificed and we collected their blood and liver tissue for analysis. In addition, 20 rats were assigned to two groups to clarify whether PE affected ethanol absorption.

Results: At the end of the study, we found that ethanol diet significantly elevated serum and hepatic lipid concentration and increased the hepatic malondialdehyde (MDA) and proinflammatory cytokines while PE consuming group had lower hepatic lipid, MDA and interleukin (IL)-6 concentrations than the E group. We also found that PE consumption did not directly affecting the ethanol absorption rate.

Conclusions: Our results suggested that PE consumption may improve ethanol-induced hepatic steatosis and inflammation, and may be beneficial in ameliorating the progression of alcoholic liver diseases.

Keywords: Pitaya, Ethanol, Lipid, Liver, Inflammation.

FORMULATION AND CHARACTERIZATION OF A CEREAL BAR AS A FUNCTIONAL FOOD

[1]Vallejo Trejo, Lucia; [2]Vallejo Trejo, Lucia.

[1]mg lic Lucía Vallejo Trejo sistema provincial de salud; [2]San Miguel de Tucuman.

Background and objectives: In recent years mankind has produced the most significant changes in their eating patterns and lifestyle. Just as hunger and malnutrition were the main focus of food policy for decades, malnutrition, anemia, and obesity are today. Increased consumption of saturated fats, simple carbohydrates and decreased fiber intake leads to a higher incidence of chronic noncommunicable diseases (CNCDs). The WHO proposes that industries produce healthier foods.

The objectives of the work were to elaborate a cereal bar fortified with iron, fiber and antioxidants and to determine its physicochemical properties, microbiological stability and sensorial acceptability.

Methods: A cereal bar was made with oats, oat bran, inflated corn, honey, fortified sugar with iron, lemon zest and sunflower oil. Variation and physical chemical and microbiological stability were studied under different storage conditions. The sensorial properties and the acceptability were evaluated by means of the hedonic scale in a population of 100 people between 9 and 78 years of both sexes residing in Tucumán.

Results: The formulation of the cereal bar is made up of 52% carbohydrates, 12% protein and 36% fat. The values of fiber (1.99 grs) and iron (0.4 mg) position it as a functional food.

With respect to acceptability, 96% of the participants considered it excellent and this facilitates their introduction into different age groups.

The study of the physical and chemical characteristics of the product, are stable being the best method to keep the dark wrapping.

Conclusions: Conclusion, a food rich in iron and with antioxidant properties was obtained. The physical and chemical characteristics of the product are stable being the best method to keep the dark packaging. With respect to acceptability, more than half of the participants considered it excellent and this facilitates their introduction into different age groups.

According to scientific evidence fiber and antioxidants have positive effects on CNCDs and iron fortification prevents anemia in schoolchildren and pregnant women. It is proposed to bring to the market a cereal bar with the mentioned compounds.

Keywords: Functional food, Cereal bar, Nutrition, Health.

Pontificia Universidad Católica de Chile.; [4]Biochemist. Centro de Nutricion Molecular y Enfermedades Crónicas. Pontificia Universidad Católica de Chile.; [5]Food Engineering. Centro de Nutricion Molecular y Enfermedades Crónicas. Pontificia Universidad Católica de Chile.; [6]MD. Centro de Nutricion Molecular y Enfermedades Crónicas. Pontificia Universidad Católica de Chile; [7]MSc. Centro de Nutricion Molecular y Enfermedades Crónicas. Pontificia Universidad Católica de Chile; [8]PhD. Centro de Nutricion Molecular y Enfermedades Crónicas. Departamento de Nutrición, Diabetes y Metabolismo, Escuela de Medicina. Pontificia Universidad Católica de Chile.

Background and objectives: Diet is a modifiable factor for prevention of chronic diseases. Antioxidants and fiber are two bioactive components with proven beneficial health properties. Currently, fiber and antioxidants population intake is less than that recommended by the WHO. The objective of this study was to develop a functional food, enriching a high consumption meat-based food with wine grape pomace flour (WGPF), rich in fiber and antioxidants, and to study the effect of its consumption on plasma antioxidants in an intervention study.

Methods: We formulated a beef hamburger (100 g) with 7% of WGPF, containing 3.5% of fiber, 1.2 mg EAG/g of polyphenols and 17.2 μmoles Trolox/g of ORAC (WGPF-hamburger). WGPF was prepared from pressed of grapes after winemaking (Caber-net Sauvignon). A controlled intervention study of 3 months was completed in 27 male volunteers. Volunteers daily consumed one WGPF-hamburger during the first month, interrupted by a month washout period, followed by a control month period where they daily consumed a hamburger without WGPF (control-hamburg-er). Plasma antioxidants (vitamin C, vitamin E, beta-carotene and antioxidant capacity as DPPH) were evaluated at time 0, 1, 2 and 3 months.

Results: Intake of the WGPF-hamburger significantly increased vitamin C ($p<0.001$), whereas intake of control-hamburg-er significantly decreased vitamin C ($p=0.005$), vitamin E (0.050) and beta-carotene ($p=0.040$). No significant effect was observed in plasma antioxidant capacity during WGPF-hamburger and control-hamburger periods.

Conclusions: The consumption of beef hamburger elaborated with 7% WGPF protects against plasma antioxidant expenditure, vitamin C, vitamin E and beta-carotene and enhances vitamin C, showing its potential to prevent oxidative damage and the func-tionality of this food.

MACAÍBA (ACROCOMIA INTUMESCENS DRUDE) DECREASED VISCERAL FAT IN DISLIPIDEMIC RATS

[1]Albuquerque de Souza, Mikaelle; [2]Tavares-de-Melo, Marília; [3]Melo, Flávio; [4]Silva, Jaielison; [4]Oliveira, Shirlayne; [4]Ponciano, Carolina; [4]Silva, Roberta; [5]Bertozzo, Camila; [6]Oliveira, Maria Elieidy; [6]Soares, Juliana.

[1]MsC. Nutritionist. Universidade Federal da Paraíba.; [2]MsC. Nutritionist. Universidade Federal de Campina Grande.; [3]Pediatrician. Hospital Regional de Guarabira. Instituto Cândida Vargas. Círculo do Coração de Pernambuco.; [4]Nutrition Student. Universidade Federal de Campina Grande.; [5]PhD. Pharmacist. Universidade Federal de Campina Grande.; [6]PhD. Nutritionist. Universidade Federal de Campina Grande.

Background and objectives: Macaíba is a palm tree. It has significant percentages of unsaturated fatty acids in its composi-tion, such as oleic and linoleic acid. In addition, it is a source of vitamin as well as high levels of carotenoids and vitamin C. The objective of this work was to evaluate the effects of macaíba pulp intake on murinometric parameters and visceral fat of dyslipidem-ic adult Wistar rats.

Methods: Male rats were divided into four groups: Con-trol (CT), Dyslipidemic (DL), Macaíba (MC) and Dyslipidemic Macaíba (MCDL), using n=9 per group. Dyslipidemia was pre-viously induced during 14 days. The animals received 1000mg/kg of body weight/day of macaíba pulp by gavage during 28 days. The research was conducted according to the Guidelines for the Care and Use of Experimental Animals and was submitted and approved by the Ethics Committee on Animal Use (CEUA) of the Center for Health and Rural Technology - CSTR / UFCG, protocol number CEP 063 / 2016. Data were evaluated with One Way Ano-va followed by Tukey ($p<0.05$) using Sigma Stat software.

Results: Feed intake, abdominal and thoracic circumference, weight, length, BMI and visceral fat were evaluated. The data demonstrated that there was no difference in the physical parame-ters, but a reduction of visceral fat in MC and MCDL was verified. Studies show that monounsaturated fats reduce the amount of cir-culating fats, and therefore fat uptake by adipocytes is reduced, thus reducing visceral fats is associated with an increased risk of developing heart disease. Therefore, macaíba shows to be a prom-ising food for preventing and/or combatting lipidic alterations that may promote correlated pathologies such as dyslipidemia.

Conclusions: Therefore, macaíba shows to be a promising food for preventing and/or combatting lipidic alterations that may promote correlated pathologies such as dyslipidemia.

Keywords: Visceral fat. Acrocomia intumescens Drude. Dys-lipidemia.

BIOCHEMICAL PARAMETERS OF DISLIPIDEMIC RATS CONSUMING MACAÍBA (ACROCOMIA INTUMESCENS DRUDE)

(1)Albuquerque de Souza, Mikaelle; (2)Tavares-de-Melo, Marília; (3)Melo, Flávio; (4)Silva, Jaielison; (4)Oliveira, Shirlayne; (4)Ponciano, Carolina; (4)Silva, Roberta; (5)Bertozzo, Camila; (6)Oliveira, Maria Elieidy; (6)Soares, Juliana.

(1)MsC. Nutritionist. Universidade Federal da Paraíba.; (2)MsC. Nutritionist. Universidade Federal de Campina Grande.; (3)Pediatrician. Hospital Regional de Guarabira. Instituto Cândida Vargas. Círculo do Coração de Pernambuco.; (4)Nutrition Student. Universidade Federal de Campina Grande.; (5)PhD. Pharmacist. Universidade Federal de Campina Grande.; (6)PhD. Nutritionist. Universidade Federal de Campina Grande.

Background and objectives: Macaíba is a palm tree that can be found in the northeastern and southeastern regions of Brazil as part of the Atlantic Forest Biome. The pulp stands out as a source of fiber, fatty acids, such as oleic and linoleic acid and essential aminoacids. In addition, it is a source of vitamin C and contains significant levels of total carotenoids and yellow flavonoids in its composition. Natural antioxidants such as carotenoids, vitamin C, and unsaturated fatty acids present in fruits, greenery, and vegetables have been subject of study in the fight against changes in blood lipid levels, associated with the risk of developing cardiovascular diseases. The objective of this work is to evaluate the effects of macaíba pulp intake on biochemical parameters of dyslipidemic adult Wistar rats.

Methods: Male rats were divided into four groups: Control (CT), Dyslipidemic (DL), Macaíba (MC) and Dyslipidemic Macaíba (MCDL), using n=9 per group. Dyslipidemia was previously induced during 14 days. The animals received 1000mg/kg of body weight/day of macaíba pulp by gavage during 28 days. Data were evaluated with One Way Anova followed by Tukey (p<0.05) using Sigma Stat software. Oxalacetic glutamic transaminase (OGT), pyruvic glutamic transaminase (PGT), creatinine, urea, total cholesterol (TC), triglycerides (TG), low density lipoprotein (LDL), high density lipoprotein (HDL) and atherogenic risk were calculated.

Results: The data demonstrated that there was a reduction of all the biochemical parameters in MCDL and TG in MC. MC and MCDL groups presented increases in HDL and decreases in atherogenic index (p<0.05). MCDL also presented a reduction in PGT and OGT.

Conclusions: Therefore, macaíba shows to be a promising food for preventing and/or combatting lipidic alterations that may promote correlated pathologies such as dyslipidemia.

ORAL ADMINISTRATION OF FREEZE-DRIED POWDERS OF HONEYBEE LARVAE INHIBITS DEVELOPMENT OF ATOPIC DERMATITIS-LIKE SKIN LESIONS IN NC/NGA MICE

(1)Kageyama, Masakatsu; (2)Xing, Guoqing; (3)Li, Kejuan; (4)Zhang, Zhenya; (5)Sugiyama, Akihiko.

(1)Msc. Division 2. DHC Corporation Laboratories. Chiba Prif. Graduate School of Life and Environmental Sciences. Tsukuba University. Ibaraki Pref. Japan.; (2)PhD. Researcher. Nature Industry of Tsukuba Co., Ltd. Japan.; (3)PhD. Researcher. Graduate school of life and Environmental Sciences. Tsukuba University. Japan.; (4)PhD. Professor. Graduate school of life and Environmental Sciences. Tsukuba University. Japan.; (5)PhD. Associate professor. Joint Department of Veterinary Medicine, Faculty of Agriculture. Tottori University. Japan.

Background and objectives: Honeybee larvae was pupa of honeybees and has been eaten since ancient days because human being expects/expected of its high nutrient with rich amino acid score. The suppressive effect of the oral administration of honeybee larvae on the atopic dermatitis (AD)-like skin lesions in NC/Nga mice was evaluated.

Methods: NC/Nga mice are used as the most extensively studied animal model of AD.

Results: Oral administration of 0.5% and 1.0% honeybee larvae-added diet for 46 days inhibit the development of AD-like skin lesions, and elevation of serum IgE levels, accompanying with the declined serum levels of both IL-4 and IFN-γ and IL-18 and IL-12 contents in the skin lesions. These results suggest that honeybee larvae inhibits the development of skin lesions in NC/Nga mice by suppressing both the T-helper (Th) 1 and Th 2 cell responses.

Conclusions: Our results indicate that oral administration of honeybee larvae could provide an adjuvant therapy for the management of AD.

Keywords: Atopic dermatitis, Honeybee larvae, Interferon-γ, Interleukin-4, NC/Nga mice.

THE EFFECTS OF ALMOND (PRUNUS DULCIS) ON THE POSTPRANDIAL BLOOD GLUCOSE LEVELS IN MICE

Kato, Kazuko; Vo, Phuong; Furuyashiki, Takashi; Kamasaka, Hiroshi; Kuriki, Takashi.

Ezaki Glico Co., Ltd. Institute of Health Sciences. Osaka. Japan

Background and objectives: Almond is generally thought to be effective on maintaining and enhancing our health. Recently some reports revealed that almond have an effect for decreasing the postprandial blood glucose level when carbohydrate and al-

mond are ingested simultaneously in human study. However the detail of the effect including functional components and mechanism have still been unclear. In this study, we assessed the functional components and mechanism of the effect.

Methods: After being fasted for overnight, male ICR mice were orally administrated maltodextrin with one of the following diet, depending on the group; (1) whole almond paste (4 g/kg), (2) almond paste without seed coat (4 g/kg), or each fraction fractionated from whole almond; (3) almond oil, (4) water soluble fraction, (5) water insoluble fraction, (6) water as a control. The blood samples were collected from the tail at the time of 0, 15, 30, 45, 60, 90, 120 min after the administration and applied for the measurements of blood glucose and insulin level. To compare the effects of oils, we also tested the effects of other kinds of oils, that is, peanut oil, walnut oil and olive oil.

Results: The mice ingested maltodextrin with almond paste (with and without seed coat) showed significantly lower value of the blood glucose level and higher of the insulin level. Although the soluble and insoluble fractions did not show any effects, only almond oil significantly decreased the postprandial blood glucose level without the increase of insulin level, compared to the control group. Comparing the effect of oils, the walnut and olive oils showed the same tendency as that of almond oil, but peanuts oil did not.

Conclusions: Whole almond suppresses the increase of postprandial blood glucose level via enhancement of insulin secretion. Almond oil also decreased the increase of blood glucose without insulin spike.

Keywords: Almond, Blood glucose, Insulin, Oil, Mouse.

ly correlated with plasma glucose levels and insulin resistance in KK-Ay mice. In the present study, we have attempted to examine antidiabetic and antihyperuricemic effects of TXF in cultured L6 myotubes and KK-Ay mice.

Methods: L6 myoblasts were cultured in 10% fetal bovine serum (FBS)/ Dulbecco's Modified Eagle Medium (DMEM) and differentiated to L6 myotubes in 2% FBS/DMEM. Then, glucose uptake assay was conducted as already mentioned by us (Kawano et al. 2009) in the absence or presence of TXF. KK-Ay mice were maintained on regular pellet diet, and TXF (30 mg/kg body weight) suspended in vehicle (0.5% CMC-Na) was orally administered once a day for 4 weeks. Normal and diabetic control mice were given vehicle alone. At the end of experimental period, the blood was collected under isoflurane anesthesia from the inferior vena cava in the microtube with heparin to obtain plasma. Concentrations of plasma glucose, insulin and uric acid were determined with commercial kits.

Results: TXF dose-dependently (0-200 μM) and significantly promoted glucose uptake in L6 myotubes, and the rise was cancelled by Compound C (10 μM), an AMPK inhibitor, indicating an involvement of AMPK and hence GLUT4 translocation in TXF action. Plasma glucose, insulin, uric acid concentrations and HOMA-IR, an index of insulin resistance, significantly elevated in diabetic control KK-Ay mice as compared with normal ones. All the rises were significantly suppressed by TXF treatment.

Conclusions: TXF is demonstrated to be antidiabetic and antihyperuricemic.

Keywords: AMPK. Diabetes. Hyperglycemia. Hyperuricemia. KK-Ay mice.

ANTIDIABETIC AND ANTIHYPERURICEMIC EFFECTS OF TAXIFOLIN, A POLYPHENOL PRESENT IN OCTAPLOID STRAWBERRY, IN CULTURED L6 MYOTUBES AND TYPE 2 DIABETIC MODEL KK-AY MICE

(1)Yagasaki, Kazumi; (1)Kondo, Shinji; (1)Adachi, Shin-ichi; (2)Yoshizawa, Fumiaki.

(1)PhD. Centre for Bioscience Research and Education. Utsunomiya University. Japan.; (2)PhD. Faculty of Agriculture. Utsunomiya University. Japan.

Background and objectives: The number of diabetic patients is increasing globally. Many trials to suppress hyperglycemia by use of phytochemicals have been conducted so far. The skeletal muscle is the largest tissue in our body and plays an important role in maintaining postprandial glucose homeostasis by uptake of blood glucose through glucose transporter 4 (GLUT4) via AMP-activated protein kinase (AMPK) phosphorylation. We have recently demonstrated that type 2 diabetic (T2D) model KK-Ay mice accompany hyperuricemia as well as hyperglycemia and that taxifolin (TXF) suppresses purine bodies-induced hyperuricemia. We have also found that plasma uric acid levels are positive-

EFFECT OF THE CONSUMPTION OF EPA AND DHA DERIVED FROM MICROALGAE IN CD1 MICE

Martinez-Carrillo, Beatriz Elina; Valdes-Ramos, Roxana; Soto-Piña, Alexandra; Gutiérrez-Pliego, Laura Elisa; Escoto-Herrera, Jorge Alberto; Rosales-Gómez, Cristian.

Universidad Autónoma del Estado de México.

Background and objectives: The alpha-linolenic fatty acid (C18: 3, ALA) belonging to the n-3 family, is an essential fatty acid, cannot be synthesized in the body and should be consumed to maintain health. EPA (ecosapentanoic acid) and DHA (docosahexaenoic acid) have vegetable sources (algae and microalgae) and animals (fish, crustaceans, seafood) of marine origin as a dietary source. Cultured microalgae, a renewable source with high EPA and DHA content, can be consumed lyophilized or microencapsulated and added to food, since they have great potential in human and animal nutrition. The objective is to know the effect of the consumption of EPA and DHA derived from microalgae in CD1 mice.

Methods: 32 db/db mice, 56 days old, divided into 4 groups (n = 8) were used: a) Control (CL), b) EPA and DHA lyophilisate (Li), c) Croquette + 2% EPA and DHA (Cr), d) Coconut oil (CO).

Treatment was given for 8 weeks and sacrificed at day 112. BMI, Body weight, feed intake, water, glucose, total cholesterol, triglycerides and HDL were measured.

Results: No differences were found in BMI (p=0.117); feed intake was higher (p<0.002) in the CO group (66.05 g/day ± 2.1) and lower in the Li group (42.47 g/day ± 4.2); the water intake increased (p<0.001) in the CO group (86.02 ml/day ± 3.9) and decreased in the Li group (55.01 ml/day ± 2.3) compared to the control (67.27 ml/day ± 2.7). The concentration of glucose (p<0.008) increases with Li (127.3 mg/dL ± 5.7), but decreases with Cr (109.5 mg/dL ± 1.2) and CO (106.6 mg/dL ± 1.4). Total cholesterol did not change (p=0.062); HDL-cholest decreased (p<0.001) in the Cr group (39.2 mg/dL ± 8.4) compared to the control (50.25 mg/dL ± 9.8); triglycerides increasing (P <0.001) in the CO group (98.5 mg/dL ± 4.2), decreasing in the Li (60 mg/dL ± 2.4) and Cr (67.5 mg/dL ± 2.2) groups.

Conclusions: The effect of supplementation with EPA and DHA from cultured marine microalgae is beneficial; it does not modify BMI; the lyophilized decreases feed consumption and water; although increasing blood glucose levels, improves the concentration of triacylglycerols.

Keywords: Microalgae, Ecosapentanoic acid, Docosahexaenoic acid.

EPA AND DHA CONSUMPTION EXTRACTED FROM MICROALGAE AND ITS EFFECT ON ANTHROPOMETRIC AND BIOCHEMICAL PARAMETERS

Martinez-Carrillo, Beatriz Elina; Valdes-Ramos, Roxana; García-Rillo, Arturo; Gutiérrez-Pliego, Laura Elisa; Escoto-Herrera, Jorge Alberto; Rosales-Gómez, Cristian.

Universidad Autónoma del Estado de México.

Background and objectives: Long chain polyunsaturated fatty acids (LC-PUFA) are dietary components that participate in multiple physiological processes; the alpha-linolenic fatty acid (C18: 3, ALA) belongs to the n-3 family, cannot be synthesized in the body, a minimum consumption for health should be maintained. The ALA can be transformed into EPA (eicosapentaenoic acid) and DHA (docosahexaenoic acid), its dietary sources are vegetable organisms (algae and microalgae) and animals (fish, crustaceans, seafood) of marine origin. Cultured microalgae are a renewable source with high EPA and DHA content, can be consumed lyophilized or microencapsulated and added to a wide variety of foods as they have great potential in human and animal nutrition. The aim of this study was to determine the relationship between the consumption of EPA and DHA extracted from microalgae with anthropometric and biochemical parameters.

Methods: 32 db/db mice at 8 weeks of age, divided into 4 groups (n = 8): a) Control (CL), b) EPA and DHA lyophilisate (Li), c) Croquette + 2% EPA and DHA (Cr), d) Coconut oil (CO). They were given the treatment for 8 weeks and sacrificed at week 16.

BMI, Body weight, feed intake, water, glucose, total cholesterol, triglycerides and HDL-colest were measured.

Results: No differences were found in BMI (p=0.248); feed intake (p<0.011) was higher in the CO group (36.12 g/w ± 1.85) and lower in the Cr group (28.82 g/w ± 2); the water intake increased (p<0.031) in the Li group (76.32 ml/day ± 4) compared to the control (69.73 ml/day ± 1.32). No differences were found in glucose concentration (p = 0.132); total cholesterol was elevated (p<0.015) in the Li and Cr groups; HDL-cholest increased (p<0.001) in the group that consumed Li (92.1 mg/dL ± 3.9), compared to its control (57.4 mg/dL ± 6); the triacylglycerols were modified (p<0.004), increasing in the Li group (356.2 mg/dL ± 27.4) and decreasing in the CO group (199.6 mg/dL ± 2.88).

Conclusions: In diabetic mice, the effect of supplementation with EPA and DHA is beneficial, as it does not modify BMI, decreases feed intake and does not alter blood glucose, further substantially improves the concentration of HDL-cholest.

Keywords: Microalgae, Eicosapentaenoic acid, Docosahexaenoic acid, Anthropometric parameters.

DIETARY AMINO ACIDS CONTROL LIPID ACCUMULATION IN THE LIVER, SKELETAL MUSCLE OR ADIPOSE TISSUE IN AN AMINO ACID-SPECIFIC MANNER

[1]Yamanaka, Daisuke; [2]Nishi, Hiroki; [2]Goda, Yuki; [2]Kumano, Mikako; [2]Taniguchi, Sakiko; [3]Ito, Koichi; [4]Katsumata, Masaya; [5]Kato, Hisanori; [6]Hakuno, Fumihiko; [3]Takahashi, Shin-Ichiro.

[1]PhD. Assistant Professor. Department of Veterinary Medical Sciences. Graduate School of Agriculture and Life Sciences. The University of Tokyo. Japan; [2]Graduate student. Graduate School of Agricultural and Life Sciences. The University of Tokyo. Japan.; [3]PhD. Associate Professor. Graduate School of Agricultural and Life Sciences. The University of Tokyo. Japan.; [4]PhD. Professor. School of Veterinary Medicine. Azabu University. Japan.; [5]PhD. Professor. Organization for Interdisciplinary Research Program. The University of Tokyo. Japan.; [6]PhD. Assistant Professor. Graduate School of Agricultural and Life Sciences. The University of Tokyo. Japan.

Background and objectives: We have previously shown that dietary protein deprivation or dietary arginine restriction induces accumulation of neutral lipid in the liver, and by contrast dietary lysine restriction resulted in lipid accumulation in the skeletal muscle. These studies suggest that not only amounts but also balance of amino acids control lipid accumulation in a tissue-specific manner. However, effects of a single amino acid on lipid accumulation in the peripheral tissues remain largely unclear, and unveiling these effects can be a clue to understand amino acid-monitoring systems. In this study, we aimed to elucidate effects of supplementation with a single amino acid in an amino acid-deficient diet on lipid accumulation in the peripheral tissues.

Methods: We fed six-week-old male Wistar rats for one week with diets containing sufficient (15%) amino acids (control diet) or insufficient (5%) amino acids (5AA diet), or 20 kinds of single amino acid-supplemented 5AA diets in which a single amino acid was increased to the same levels as the control diet, and then measured neutral lipid content in the liver and skeletal muscle or weight of adipose tissue.

Results: Triglyceride content in the liver was increased in a 5AA group compared to a control group. Feeding of methionine- or cystine-supplemented 5AA diets enhanced this increase. In the skeletal muscle (longissimus thoracis), triglyceride content in the 5AA group was comparable to that in the control group. However, supplementation of leucine or arginine in the 5AA diet increased triglyceride content in the muscle. Analysis of weight of adipose tissue (retroperitoneal fat) revealed that feeding the 5AA diet increased the adipose tissue weight compared to the control group. In addition, supplementation with serine in 5AA diet enhanced the increase in the adipose tissue weight.

Conclusions: In summary, methionine or cystine supplementation increased neutral lipid content in the liver, leucine or arginine increased it in the skeletal muscle, and serine increased the adipose tissue weight. Taken together with other results, we concluded that a single amino acid could control lipid accumulation in a tissue-specific manner in growing rats under conditions of dietary amino acid insufficiency.

FOOD SUPPLEMENTS BASED ON COMPOUNDS FROM THE TRADITIONAL NUTRITION IN BULGARIA

Handjiev, Svetoslav.

MD, Bulgarian association for the study of obesity and related diseases (BASORD).

Background and objectives: Two Bulgarian food supplements are presented which contain compounds characteristic for the national traditions in nutrition, the so called Balkan diet.

Methods: The first one had a beneficial effect on the functions of the gastro-intestinal tract. This is a plant-derived product containing extracts from Golden shower, Cumin, Chebulic myrobalan, Wild grape, Cinnamon, Bay leaft, Cardamom, Ginger, Black pepper, Long pepper, Coriander and Asafoetida. The compounds are rich of etheric oils and resins. It is established that this food supplement has spasmolytic, anti-pain, carminative, antiemetic and antioxidant effects. The second one contains resveratrol which is a polyphenolic compound naturally found in grape, red wine, grape juice, peanuts.

Results: Resveratrol is shown to have a profound antioxidant effects as part of the traditional Bulgarian food products.

Conclusions: Our study suggests that resveratrol could improve specific metabolic parameters in individuals at risk for type 2 diabetes as well as in obese subjects with impaired glucose tolerance.

Keywords: Food supplements, Balkan diet, Resveratrol, Anti-oxidant effect, Obesity.

ENZYMATICALLY-SYNTHESIZED GLYCOGEN INHIBITS INFLAMMATORY RESPONSE IN ANTIGEN-INDUCED BASOPHILIC AND MAST CELLS

[1]*Yoshioka, Yasukiyo;* [2]*Furuyashiki, Takashi;* [3]*Ashida, Hitoshi.*

[1]PhD. Postdoctoral fellow. Graduate School of Science Technology and Innovation. Kobe University. Japan.; [2]MS. Scientist. Institute of Health Sciences. Ezaki Glico Co. Ltd. Japan.; [3]Professor. Graduate School of Agricultural Science. Kobe University. Japan.

Background and objectives: Activation of basophilic cells and mast cells trigger allergic and inflammatory responses through the release of mediators such as histamine and arachidonic acid metabolites, and modulates immune responses through the production of cytokines and chemokines. Recently, allergic patients are increasing all over the world. Thus, food ingredients that suppress and alleviate allergic and inflammatory responses are required. In this study, we, therefore, investigated the effect of enzymatically-synthesized glycogen (ESG) on the degranulation and production of inflammatory cytokines and arachidonic acid metabolites in RBL-2H3 cells and clarified its underlying mechanism.

Methods: Caco-2 cells were differentiated as intestine monolayer to incubate for 2 weeks, bone marrow-derived mast cells (BMMC) were prepared from 10 weeks old mice and incubated in medium supplemented with interleukin (IL)-3 for 3 weeks. Allergic and inflammatory response was performed using not only RBL-2H3 cells and BMMC but also co-culture of Caco-2 cells and RBL-2H3 cells using a transwell system. Degranulation of RBL-2H3 cells or BMMC was monitored by measuring β-hexosaminidase activity. The β-hexosaminidase released into the medium or remaining within the cells (Triton X-100 extract) were determined using a colorimetric assay with p-nitrophenyl-N-acetyl-β-glucosaminide and expressed as the percentage of total activity. Production and release of tumor necrosis factor-α (TNF-α), IL-6 and arachidonic acid metabolites in/from cells were determined using western blotting and enzyme-linked immunosorbent assay system. Phosphorylation of intracellular molecules was detected using western blotting.

Results: ESG inhibited release of β-hexosaminidase from RBL-2H3 cells and BMMC. In Caco-2/antigen-stimulated RBL-2H3 cells, ESG inhibited release of β-hexosaminidase and production of TNF-α, IL-6, and arachidonic acid metabolites. Moreover, ESG inhibited phosphorylation of Syk, Lyn, and PLCγ1/2 as the intracellular mediators for degranulation, that of Akt, p38, and JNK as the mediators for production of TNF-α and IL-6, and that of ERK1/2 and cPLA2 as the mediator for production of arachidonic acid metabolites.

Conclusions: We demonstrated that ESG inhibited allergic and inflammatory response in antigen-stimulated basophilic and mast cells. ESG might be a beneficial food to inhibit type I allergy.

Keywords: Glycogen, Histamine, TNF-α. RBL-2H3. Caco-2 cells.

EFFECT OF DIFFERENT AMYLOSE CONTENT ON THE QUALITY OF FUNORI (GLOIOPELTIS FURCATA) ADDED RICE NOODLES

[1]Yamaguchi, Tomoko; [2]Horita, Nami; [2]Niwano, Mizuki; [3]Eguch, Satomi; [4]Enoki, Yasuaki; [4]Sasagawa, Katsumi; [5]Kadowaki, Motoni.

[1]PhD. Associate Professor. Niigata University. Japan; [2]student. Faculty of Education. Niigata University; [3]Phd. assistant professsor. Yamagata Prefectural Yonezawa University of Nutrition Sciences; [4]Researcher. Bourbon Institutes of Health. Bourbon Corporation.; [5]PhD. Professor. Faculty of Agriculture, Niigata University.

Background and objectives: Rice noodles are good foods for allergy patients of wheat flour, because of the absence of gluten in rice flour. However, it is difficult to make the rice noodles without gluten. In our previous study, adding Funori (Gloiopeltis furcata), a kind of seaweed, to the rice flour as a liaison was able to make the noodles using 100% rice flour. Recently, several studies have reported that the high-amylose rice inhibits early postprandial increment of blood glucose and insulin levels. In this study, we investigated the effect of different amylose content in the rice flour on the quality of rice noodles.

Methods: Two types of rice flour, an intermediate-amylose rice "Koshihikari" (KH; the most prevalent rice in Japan) and a high-amylose rice "Koshinokaori" (KK), were used to make rice noodles. Rice noodles were prepared with 250g of rice flour, 10g of Funori, and water using automatic noodle maker (PHILIPS HR2365/01). Physical properties, color (L*, a*, b*), and sensory attributes were measured after making and boiling of noodles.

Results: In the noodle making process, the optimum quality of rice noodles were obtained at 90mL (76%) of adding water for KH and at 110mL (84%) for KK. Difference of amylose content and particle diameter of rice flour may influence for the water absorption of rice flour during noodle making. Both noodles showed a light green color derived from Funori heated by copper pan. In case of physical properties of raw noodles, KK noodles showed higher value for hardness and elasticity than KH noodles. After boiling of noodles, lower values for hardness were observed in both of noodles. KK noodles were preferred at elasticity to KH noodles in the sensory evaluation of the noodles.

Conclusions: The high-amylose rice is generally unsuitable to Japanese taste as cooked rice. However, these findings showed that the adequacy of high-amylose rice as rice noodles. More investigation of human study is necessary to evaluate high-amylose rice noodles as the effective food for glycemic control.

Keywords: Rice flour, Rice noodles, High-amylose rice, Funori.

IN VIVO STUDY OF ANTIOXIDANT CAPACITY OF CHIA (SALVIA HISPANICA L.) IN SACCHAROMYCES CEREVISIAE

[1]Fernández-Espinar, María Teresa; [2]Molina, Itziar; [1]Gil, José Vicente; [3]Haros, Claudia Monika.

[1]Ph.D. in Biology. Biological Activity Group of Food Compounds. Institute of Agrochemistry and Food Technology (IATA-CSIC). Valencia. Spain.; [2]M.S. in Food Technology.Biological Activity Group of Food Compounds. Institute of Agrochemistry and Food Technology (IATA-CSIC). Valencia. Spain.; [3]Ph.D in Chemistry. Cereal Group. . Institute of Agrochemistry and Food Technology (IATA-CSIC). Valencia. Spain.

Background and objectives: Chia is an edible oil seed of the plant Salvia hispanica L. Its consumption is recommended because of its high oil content (25-38%) rich in omega-3 (50-67% α-linolenic acid), proteins of High biological value, natural antioxidants, vitamins, minerals, dietary fiber (30-54%) and bioactive compounds such as phytosterols. The present study has focused on aspects related to the antioxidant potential of chia. It is known that oxidative stress is associated with various human pathologies. The WHO recommends the daily consumption of antioxidants through diet to prevent or attenuate these pathologies. The antioxidant power of chia seeds has been studied in vitro by several authors, however there is a great lack of knowledge about its antioxidant promoter capacity in whole organisms.

The general objective of the present investigation is to study the protective antioxidant capacity of chia polyphenolic extracts at different concentrations using the yeast Saccharomyces cerevisiae as model organism.

Methods: A method adapted to microtiter plates is used to monitor yeast growth after culture pre-incubation with food ingredients and exposure to oxidative stress by hydrogen peroxide. Polyphenolic extracts of chia at different concentrations range from 10 mg/L to 1200 mg/L were tested.

Results: As a result, the polyphenolic extracts showed a significant protective effect against oxidative stress. This effect was more evident in moderate stress conditions and increased with polyphenol concentration, the greatest effect were obtained at the concentration of 1200 mg/L.

Conclusions: In conclusion, the present work completes the information regarding the polyphenol content of chia when showing their ability to promote the antioxidant protective effect in a complete model such as yeast.

Keywords: Oxidative stress, Yeast, Chia, Polyphenols, Antioxidant capacity.

EFFECTS OF BRAN PARTICLE SIZE ON GLYCEMIC RESPONSES. A RANDOMIZED CLINICAL TRIAL IN HEALTHY HUMANS

[1]Emilia Aimilia Papakonstantinou; [2]Mandala, Ioanna; [3]Papalexi, Katerina; [4]Chaloulos, Panagiotis.

[1]PhD. Lecturer in Nutrition and Metabolism. Department of Food Science and Human Nutrition. Agricultural University of Athens. Greece; [2]PhD. Associate Professor. Department of Food Science and Human Nutrition. Agricultural University of Athens. Greece.; [3]MS. Nutritionist. Department of Food Science and Human Nutrition. Agricultural University of Athens. Greece.; [4]BS. Nutritionist. Department of Food Science and Human Nutrition. Agricultural University of Athens. Greece.

Background and objectives: Diets characterized by low glycemic index (GI) and/or glycemic load (GL) have been associated with decreased risk of chronic diseases. Breads' grain particle size may affect glycemic response, possibly due to the altered starch surface, hence its susceptibility to enzymatic hydrolysis. However, the role of bran's particle size alone has not been studied. The aims of this study were a) to determine the GI and GL of three breads and b) to investigate the effects of bran's particle size on postprandial glycemic response.

Methods: Ten healthy, normal-weight subjects participated in GI investigation following International Standard Organization's protocol. Participants, in this double blind, crossover trial, consumed in random order 50g available carbohydrate portions as glucose (Glu, reference food, tested three-times) and white bread (WB), bread enriched with coarse wheat bran (CB), bread enriched with fine wheat bran (obtained by milling of the coarse bran) (FB) and the FB in which 10% of the flour was substituted with carob seed flour (CSFB), tested once, on separate occasions. Capillary blood glucose and salivary insulin samples were taken at 0,15,30,45,60,90 and 120min.

Results: CB was a high GI (70), low GL (10) bread; FB was a high GI (82), medium GL (12) bread; and CSFB was a high GI (70), low GL (8) bread. There was a significant glucoseXtime interaction (p<0.001), a glucoseXbread interaction (p=0.03) and a glucoseXtimeXbread interaction (p<0.001). There was a significant main effect of bread type on iAUC for glucose (p=0.01). Compared to the reference food, blood glucose concentrations were significantly lower: for CB at 120min (p=0.02); for FB at 15, 30, and 120min (p=0.049, p=0.004 and p=0.008, respectively); for CSFB at 15 and 30min and marginally at 45min (p=0.0008, p=0.008, p=0.06, respectively). Peak glucose rise was significantly lower only for CSFB compared to the reference food (p=0.03). No differences were observed for fasting glucose, fasting salivary insulin, iAUC for salivary insulin, time to peak rise for glucose or insulin.

Conclusions: Breads differed in GI/GL. Bran particle size and flour substitution by carob seed flour attenuated postprandial glycemic response, which may offer advantages to glycemic control.

Keywords: Bran, Particle size, Glycemic response, Carob.

NIGAICHIGOSIDE F1 FROM LANBUZHENG (GEUM JAPONICUM THUNB.) INHIBITS OLEIC ACID-INDUCED HEPATIC STEATOSIS IN HEPG2 CELLS

[1]Cheng, Xiangrong; [2]Xia, Shufang; [3]Sun, Jing; [3]Tang, Xue; [3]Le, Guowei; [3]Shi, Yonghui.

[1]Associate professor. School of Food Science and Technology. Jiangnan University. People's Republic of China; [2]Wuxi School of Medicine. Jiangnan University. People's Republic of China; [3]School of Food Science and Technology. Jiangnan University. People's Republic of China.

Background and objectives: Lanbuzheng (Geum japonicum Thunb.) is a wild vegetable in Guizhou province, China, which has also been used as traditional herbs as diuretics and astringents. Nigaichigoside F1 (NF1), the major triterpenoids in Lanbuzheng, has been report for its potent hypolipidemic and hypoglycemic activities. Thus, we hypothesized that NF1 would attenuate events leading to non-alcoholic fatty liver disease (NAFLD).

Methods: The culture media of HepG2 cells were added 1.0 mM oleic acid to induce hepatic steatosis. After 24 h, siginificant accumulation of lipid droplets were observed by Oil-Red-O based colorimetric assay, together with increased triacylglycerol (TAG) and malondialdehyde (MDA).

Results: The oxidative stress of HepG2 cells was significantly increased, which characterized by the content of reactive oxygen species (ROS), total antioxidant capacity (T-AOC), superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (Gpx), and the ratio of reduced and oxidized glutathione (GSH/GSSG). NF1 was purified from Lanbuzheng extract by Diaion HP-20 resin (60% ethanol elution, 3 BV/h) and characterized by ESI-MS, 1H-NMR, and 13C NMR. NF1 (10 uM) increased cell proliferation by 2.35 folds with decreased TG (43%), MDA (62%), and ROS (78%) content. The content of T-AOC, SOD, CAT, Gpx, and the ratio of GSH/GSSG were increased by 2.3, 1.27, 2.15, 1.05, and 1.72 folds, respectively. Moreover, RT-PCR results confirmed NF1 (10 uM) inhibited SREBP-1c gene expression while promoted HSL and Nrf2 gene expression.

Conclusions: In conclusion, NF1 effectively ameliorated NAFLD symptoms by decreased TAG accumulation and increased antioxidant capacity in oleic acid-induced hepatic steatosis in HepG2 cells.

Keywords: Geum japonicum Thunb., Nigaichigoside F1, Non-alcoholic fatty liver disease, Antioxidant.

THE TIME COURSE OF ACUTE EFFECTS OF THREE DOSES OF CAFFEINE ON ATTENTION, MOTOR SPEED AND MOOD

[1]Haskell-Ramsay, Crystal; [1]Jackson, Philippa; [2]Forster, Joanne; [3]Robertson, Bernadette; [1]Kennedy, David.

[1]PhD. Psychologist. Brain, Performance and Nutrition Research Centre. Northumbria University. United Kingdom.; [2]Psychologist. Brain, Performance and Nutrition Research Centre. Northumbria University. United Kingdom.; [3]PhD candidate. Psychologist. Brain, Performance and Nutrition Research Centre. Northumbria University. United Kingdom.

Background and objectives: Moderate doses of 75–200mg caffeine have well established effects on measures of alertness and reaction time. However, less is known of the impact of lower doses that are more reflective of levels found in a cup of tea. Similarly, studies of behavioural effects of caffeine have focused on a 30–120 minute window, despite the demonstration that salivary caffeine levels remain elevated at 5 hours post-consumption. The aim of the current study was to explore effects of 40, 80 and 120mg caffeine over an 8-hour period.

Methods: A randomised, placebo-controlled, double-blind, parallel groups design was employed to explore the effects of caffeine (40, 80 and 120mg) on choice reaction time (CRT), tapping, 'alertness' and 'sleepiness'. Participants (n=40 per group) were healthy adult caffeine consumers (mean intake 287mg/d) required to abstain from consuming caffeine overnight prior to morning testing. Following baseline, post-drink assessments commenced at 2, 40, 100, 190, 280, 370 and 460 minutes.

Results: Significantly faster CRT was observed following all doses of caffeine compared to placebo. A trend towards a treatment x session interaction indicated beneficial effects of 40mg on CRT were still evident at 460 minutes post-drink, whilst effects of 80 and 120mg dissipated at 280 minutes. Increased 'alertness' and/or decreased 'sleepiness' was evident up until 190 minutes post-drink following 80 and 120mg but decreased 'alertness' and increased 'sleepiness' was observed later in the day. Conversely, 40mg decreased 'sleepiness' from 280-460 minutes, with no effects on 'alertness'. Interestingly, effects on CRT and mood were observed during the 2 minutes post-drink session.

Conclusions: These findings demonstrate that 40mg caffeine can modulate CRT and subjective ratings of alertness and sleepiness. Effects on CRT were observed over a time period spanning from 2 minutes to 8 hours post-drink. These findings are important due to an increasing desire to limit caffeine intake. They indicate that 40mg caffeine can improve reaction time without any initial subjective 'arousing' effect, which may be preferable to some consumers. Further research should explore individual differences in responses to caffeine, to ascertain factors which may impact upon its dose and time-course effects.

Keywords: Cognition, Alertness, Caffeine, Low-dose, Time-course.

PROTECTIVE EFFECTS OF HYDROLYZED NUCLEOPROTEINS FROM SALMON MILT AGAINST ETHANOL-INDUCED LIVER INJURY IN RATS

[1]Matsui-Yuasa, Isao; [2]Goto, Mayu; [2]Yoshikawa, Eri; [3]Morita, Yuri; [4]Sekiguchi, Hirotaka; [4]Sutoh, Keita; [5]Usumi, Koji; [6]Kojima-Yuasa, Akiko.

[1]Department of Food and Human Health Sciences. Graduate School of Human Life Science. Osaka City University.; [2]M.Sc. Graduate student. Department of Food and Human Health Sciences. Graduate School of Human Life Science. Osaka City University.; [3]B.Sc. Student. Department of Food and Human Health Sciences. Graduate School of Human Life Science. Osaka City University.; [4]Ph.D. Researcher. Life Science Institute Co. Ltd.; [5]Ph.D. President. Life Science Institute Co. Ltd.; [6]Ph.D. Associate professor. Department of Food and Human Health Sciences. Graduate School of Human Life Science. Osaka City University.

Background and objectives: Oral administration of nucleic acids from salmon milt have physiological functions in the cellular metabolism, proliferation, differentiation and apoptosis of human small intestinal epithelial cells. In this study, we examined the effects of DNA-rich nucleic acids prepared from salmon milt (DNSM) on the development of liver fibrosis in an in vivo ethanol-carbon tetrachloride (CCl4) cirrhosis model.

Methods: DNSM was water-solubilized using nuclease and protease. Male Wistar rats were divided into four groups. Group 1 was the control; Group 2 was treated with ethanol and CCl4; Group 3 was treated with CCl4 alone; Group 4 was treated with ethanol, CCl4 and 0.12% DNSM. CCl4 (0.1 ml/kg of body weight diluted with olive oil to 25%) was administered by intraperitoneal injection twice a week, and 5% ethanol was administered in the drinking water ad libitum. The rats were euthanized after three weeks.

Results: Plasma aspartate transaminase and alanine transaminase were significantly less active in the DNSM-treated group than in the ethanol plus CCl4-treated group. Collagen accumulation in the liver and hepatic necrosis were observed histologically in ethanol plus CCl4-treated rats; however, DNSM-treatment fully protected rats against ethanol plus CCl4-induced liver fibrosis and necrosis. Furthermore, we examined whether DNSM had a preventive effect against alcohol-induced liver injury by regulating the cytochrome p450 2E1 (CYP2E1)-mediated oxidative stress pathway in an in vivo model. In this model, CYP2E1 activity in ethanol plus CCl4-treated rats increased significantly, but DNSM-treatment suppressed the enzyme's activity and reduced intracellular thiobarbituric acid reactive substances levels. Furthermore, the hepatocytes treated with 100 mM ethanol induced increase in cell death and were not restored to the control levels when treated with DNSM, suggesting that digestive products of DNSM are effective for the prevention of alcohol-induced liver injury. Deoxyadenosine was suppressed the ethanol-induced increase in cell death and increased the activity of alcohol dehydrogenase.

Conclusions: These results suggest that DNSM treatment represents a novel tool for the prevention of alcohol-induced liver injury.

EFFECTS OF 6 MONTH RESVERATROL SUPPLE-MENTATION ON VERBAL MEMORY PERFOR-MANCE IN HEALTHY ELDERLY ADULTS - A RAN-DOMIZED CONTROLLED TRIAL

(1)*Huhn, Sebastian;* (2)*Beyer, Frauke;* (3)*Zhang, Rui;* (4)*Stumvoll, Michael;* (5)*Villringer, Arno;* (6)*Witte, A. Veronica.*

(1)MSc. Nutritional Sciences. Department of Neurology. Max Planck Institute for Human Cognitive and Brain Sciences Leipzig. Germany.; (2)MSc. Medical Radiation Sciences. Department of Neurology. Max Planck Institute for Human Cognitive and Brain Sciences Leipzig. Germany.; (3)MSc. Nutritionist. Department of Neurology. Max Planck Institute for Human Cognitive and Brain Sciences Leipzig. Germany.; (4)MD. Medicine. Faculty of Medicine. IFB Adiposity Diseases Leipzig. Germany.; (5)MD. Medicine. Department of Neurology. Max Planck Institute for Human Cognitive and Brain Sciences Leipzig. Germany.; (6)PhD. Biologist. Department of Neurology. Max Planck Institute for Human Cognitive and Brain Sciences Leipzig. Germany.

Background and objectives: Resveratrol (RSV) is assumed to have beneficial effects on cognitive performance and brain-structure in humans (Huhn et al.2015). RSV, a polyphenol, occurs naturally in blueberries, peanuts, red grapes and red wine (Smoliga et al.2011). Animal models suggest that RSV is antioxidative, anti-inflammatory and mimics caloric-restriction (Athar et al.2007;Dal-Pan et al.2011). These effects might contribute to the mechanisms underlying the benefits of RSV on the metabolism, cardiovascular system and nerve-tissue found in human studies (Huhn et al.2015).

More recently, research focused on the impact of RSV on cognition. In that line, this study's aim was to evaluate the effect of 26 weeks RSV supplementation on measures of the California Verbal Learning Task(CVLT).

Methods: Subjects: 60 healthy elderly subjects (age60-78, mean68.19±5.16SD, anthropometry: table1, Drop-outs=7, randomized to RSV (N=27; 200mg/day) or placebo-supplementation (N=26) for 26 weeks.

Exclusion: stroke, major brain-pathologies, central-nervous-medication.

Measures: Blood-parameters, anthropometry, neuropsychological-test-battery including California-Verbal-Learning-Task.

Statistical Analysis: repeated-measures ANOVA was performed in SPSS (IBM,Version24).

Within-Subject-Factor: time

Within-Subject-Variables: CVLT-measures(Learning-sum, forgetting-rate, delayed-recall, recognition).

Between-Subject-Factors: RSV/placebo.

Covariates: age, sex, education.

Results: The preliminary results of the repeated-measures ANOVA did not reveal any significant time by intervention-group interaction on measures of the CVLT (all p>0.14). Compliance according to pill-counts and pill-diaries was high. Continuing analyses incorporate blood-parameters and additional cognitive measures.

Conclusions: The preliminary results of our study did not indicate significant effects of 26 weeks RSV supplementation on performance in the CVLT in healthy elderly subjects. This might partly be explained by a healthy sample that performed well already at baseline and a small scope to improve cognitive performance. Additionally, duration and/or dosage of RSV might have been insufficient to induce changes.

These results are in line with previous studies that did not find effects of RSV on cognitive measures (Köbe et al.2017;Wightman et al.2015). However, Witte et al.(2014) found, besides a moderate effect on cognition, significant changes in functional connectivity of the hippocampus, which is involved in memory processes. With subsequent analysis of additional cognitive measures, blood-parameters and sensitive high-resolution magnetic-resonance-images, we aim to further characterize the effect of RSV on cognition and brain structure. This will help to clarify the potential of RSV to improve or maintain cognitive functions in healthy elderly adults.

Keywords: Resveratrol, Cognition, Memory, Longitudinal, Elderly.

THE ANTIOXIDANT PROPERTIES AND FATTY AC-IDS PROFILE IN ORGANIC SAMPLES OF LEEKS (ALLIUM AMPELOPRASUM VAR. PORRUM) AND GARLIC (ALLIUM SATIVUM L.) IN NATURA

(1)*Guizellini, Gloria Maria;* (2)*Rodrigues Sampaio, Geni;* (3)*Pereira da Silva, Cintia;* (3)*Manólio Soares Freitas, Rosana Aparecida;* (2)*Ferraz da Silva Torres, Elizabeth Aparecida.*

(1)Nutrition Student. Nutrition Department. School of Public Health. University of São Paulo .USP. São Paulo. Brazil.; (2)PhD. Nutrition Department. School of Public Health. University of São Paulo .USP. São Paulo. Brazil.; (3)MSc. Nutrition Department. School of Public Health. University of São Paulo .USP. São Paulo. Brazil.

Background and objectives: The primary goal of organic agriculture is to produce foods safer than conventional agricultural foods that are produced using synthetic fertilizers and pesticides forbidden in organic systems. Studies have shown that growing conditions may influence the nutritional composition of different types of vegetables. Leeks and Garlic are source of various biologically active phytomolecules, including organosulfur compounds and polyphenols. They have been playing an important role in the human diet and in medicine for centuries. The aim of this study was to determine the antioxidant activity, proximate composition and fatty acids content of organics leeks (Allium ampeloprasum var. porrum) and garlic (Allium sativum L.).

Methods: The organics leeks (L) were analyzed with different solvents, methanol (70:30,v.v) (LM) and water (LW), garlic also (G), methanol extract (GM) and water (GW). The samples were characterized for total phenolic compounds and antioxidant activity using three different methods: DPPH, β-carotene/linoleic acid system and the test of oxygen radicals absorbance capacity (ORAC).

Results: Methanol:water (70:30,v.v) extract produced the best results the samples of organics leek for total phenolic compounds(1.23 ± 0.4 mg/EAG g). The water extract of garlic in natura (3.04 ± 0.7 mg/EAG g) indicates the best results of samples in the same analysis. As predominant palmitic, linoleic and linolenic acids present in leeks samples and in garlic in natura were palmitic and linoleic acid. The inhibition of β-carotene/linoleic acid peroxidation (%IOL) is better in LM and with different solvents presents similar results between them GM and GW (57.15 ± 2.2% e 57.59 ±1.5 %). The ORAC value of LMA and LW (88.45 ± 8.6 ET μmol/g and 47.09 ± 1.2 ET μmol/g) reduce in compare the samples of GM e GW (112.52 ± 0.1 ET μmol/g e 65.68 ± 4.5 ET μmol/g).The LM, LW, GM and GW exhibited antioxidant activity by DPPH method.

Conclusions: These results suggested that organic leeks and garlic presented antioxidant activity and contained significantly levels of phenolics. The consumption of leeks and garlic in natura can be able to provide significant health protection in order to prevent chronic diseases.

EFFECTS OF DIETARY PHENOLIC COMPOUNDS FROM SOUTH AMERICAN PLANTS ON FATTY ACID-MEDIATED INTERLEUKIN-6 RELEASE FROM MAMMALIAN GLIAL CELLS

[1]Cittadini, María Cecilia; [2]García-Estéves, Ignacio; [2]Escribano-Bailón, María Teresa; [2]Rivas-Gonzalo., Julián C.; [3]Valentich., Mirta A.; [3]Repossi, Gastón; [3]Soria, Elio A.

[1]Nutricionist. Instituto de Investigaciones en Ciencias de la Salud (INICSA). Facultad de Ciencias Médicas (Universidad Nacional de Córdoba) and CONICET. Córdoba. Argentina. Instituto Nacional del Cáncer. Ministerio de Salud de la Nación. Argentina.; [2]PhD. Grupo de Investigación en Polifenoles. Facultad de Farmacia. Universidad de Salamanca. Salamanca. Spain.; [3]PhD. Instituto de Investigaciones en Ciencias de la Salud (INICSA). Facultad de Ciencias Médicas (Universidad Nacional de Córdoba). CONICET. Córdoba. Argentina.

Background and objectives: Phenolic compounds are secondary metabolites of plants, which can exert beneficial effects on the central nervous system after food intake. Thus, our aim was to identify anti-inflammatory phenolic compounds from South American plants on mammalian glial cells, which play a central role in the neuro-immune regulation.

Methods: Phenolic compounds were extracted from Lantana grisebachii (LG), Aspidosperma quebracho-blanco (AQB), and Ilex paraguariensis (IP) teas and identified by HPLC-DAD-MS. Different extract concentrations (0-200 μg/mL) were tested in human T98-G and rat C6 cell lines of glioma. Cellular viability (by the resazurin assay), fatty acid profile (by gas chromatography) and pro-inflammatory interleukin-6 release (IL-6 by ELISA) were determined. Data were analysed by partial least square regression, to discriminate bioactive phenolic compounds as predictor variables and to correlate cellular responses.

Results: Twenty-one compounds, which were mainly iridoids, were determined in LG. Their geniposidic derivatives (3.3%) were significantly linked to lipid polyunsaturation, but not to IL-6 release. Thirty-one compounds were found in AQB, mostly hydroxybenzoic derivatives, of which only isorhamnetin-3-O-rutinoside (0.9%) was positively related to IL-6 release. Twenty-three compounds were identified in IP, including several caffeoylquinic derivatives. Chlorogenic (24.4%) and 1-caffeoylquinic (15.0%) acids modified glial lipids increasing ω-7 palmitoleic fatty acid, which was related to IL-6 decrease.

Conclusions: This work enhances phytochemical knowledge of three widely distributed plants, which have not been thoroughly studied as sources of bioactive phenols. Our results suggest that the 1-caffeoylquinic and chlorogenic acids provided by I. paraguariensis tea can exert anti-inflammatory effects, which would be significant for human nutrition and health given its high intake by South American populations.

Keywords: Chlorogenic acid. 1-caffeoylquinic acid. Iridoid. Isorhamnetin. Neuroinflammation. Ilex paraguariensis.

Conflict of Interest Disclosure: We confirm that there are no known conflicts of interest associated with this presentation and there has been no significant financial support for this work that could have influenced its outcome.

Brazil.; [5]Biologist. Chemistry Laboratory. Federal Institute of Mato Grosso do Sul. Coxim. Brazil.

Background and objectives: The fruit of cupuaçu is used in Brazilian cuisine to prepare juices, ice creams, liquors, creams,

---

puddings, cakes, sweets and sweets, due to the aroma and the accentuated acidity, much appreciated by consumers. Through the feeding we obtain macro and micronutrients and also bioactive compounds, health promoters, as the antioxidant, anti-inflammatory and hypocholesterolemic action of some of these compounds. The antioxidant activity may be related to the presence of vitamins and phenolic compounds. The objectives of this work were to characterize cupuaçu almonds in relation to pH and total acidity and to quantify bioactive compounds, such as vitamin C determination, phenolic compounds and antioxidant activity for the preparation of food products.

Methods: The cupuaçu almonds were separated from the fruit pulp and dried in an oven with air circulation at 60°C for 48 hours. The pH values were determined by digital potentiometer, titratable total acidity, vitamin C by the titration method according to the Adolfo Lutz Institute's analytical standards (2005), phenolic compounds by the Follin Ciocauteau method (Bucic-Kojic et al., 2007) Of the curve performed with gallic acid (200, 400, 600, 1000 and 1400 mg/L), and antioxidant activities by the capture of free radical DPPH (2,2-Diphenyl-1-picryl-hydrazyl) (Mensor et al., 2001).

Results: The pH value of the dehydrated almond was 4.44. The total acidity resulted in 0.029 g/100g. The vitamin C content was 272.73 mg/100g. The content of phenolic compounds obtained was 364.50 mg equivalent of gallic acid/100 g, 60% higher than that reported in the literature for fresh almonds (Pugliese, 2010), difference due to the process of dehydration concentrate the nutrients. The antioxidant activity resulted in 95.86%. The results show that the cupuaçu almond presents high content of vitamin C, phenolic compounds with significant antioxidant activity.

Conclusions: From the cupuaçu almond can be elaborated several food products with high nutrient content with a health action of vitamin C and phenolic componds, such as antioxidant activity.

Keywords: Theobroma grandiflorum, Almonds, Vitamin C, Phenolic compounds, Antioxidant activity.

blood glucose levels by increasing muscle glucose uptake in an insulin-independent manner. Insulin stimulates glucose uptake in muscle via translocation of glucose transporter 4 (GLUT4) vesicles to the plasma membrane. GLUT4 translocation involves the PI3K/Akt pathway. There are a few reports that show that isoleucine promotes GLUT4 translocation, but the details of the mechanism by which isoleucine increases glucose uptake in skeletal muscle are not yet fully understood. The purpose of this study was to clarify the mechanism of glucose uptake into skeletal muscle by isoleucine.

Methods: Male Wistar rats were food deprived for 18 h and then administered 1.35 g L-isoleucine/kg body weight (prepared as 54.0 g/L of the L-amino acid in distilled water) by oral gavage. GLUT4 translocation in skeletal muscle (gastrocnemius, soleus and EDL) was detected by immunofluorescent staining. We also evaluated the phosphorylation status of Akt and AMPK involved in glucose uptake evoked by insulin using C2C12 myotubes treated with isoleucine. Prior to the experiments, differentiated C2C12 myotubes were starved for 3 h in a Krebs–Henseleit–Hepes buffer and then treated with 1–10mM isoleucine for 30 min.

Results: The administration of isoleucine stimulated translocation of GLUT4 vesicles to the plasma membrane in all examined skeletal muscles. At the site of the plasma membrane, GLUT4 was more abundantly expressed in EDL of isoleucine administered rats as compared to other muscles. The phosphorylation of Akt was increased by isoleucine in C2C12 myotubes. On the other hand, there was no change in phosphorylation of AMPK.

Conclusions: EDL (fast twitch muscle) is more sensitive to the effect of isoleucine as compared to other muscles. Isoleucine seems to stimulate translocation of GLUT4 in skeletal muscle through a mechanism distinct from that of insulin.

Keywords: Isoleucine, Skeletal muscle, Glucose uptake, GLUT4, PI3K.

Departamento de Nutricion. Facultad de Medicina. Universidad de Chile. Chile.; [3]Biochemist. Departamento de Nutricion. Facultad de Medicina. Universidad de Chile. Chile.; [4]Veterinary. Departamento de Nutricion. Facultad de Medicina. Universidad de Chile. Chile.; [5]Nutricionist. Departamento de Nutricion. Facultad de Medicina. Universidad de Chile. Chile.

Background and objectives: Insulin resistance is a worldwide high prevalent disease accompanied usually by a chronic

low-degree inflammatory state. Calafate is a Chilean native berry with a high polyphenol content. Polyphenols have been shown to possess anti-inflammatory properties. We aim to determine the effect of a Calafate extract on the development of insulin resistance in mice fed on cafeteria diet.

Methods: By using of an Amberlite XAD7HP column a purified and polyphenol-rich calafate extract was prepared. Total polyphenols, total anthocyanins and antioxidant activity were determined. Male C57BL/6 mice were fed on cafeteria or standard diet for 14 weeks. From week 10th, mice received the calafate extract in water (daily doses of 50mg [total polyphenols] /Kg). Body weight, food and water intake were registered. IPGTT were performed at 9 and 13 weeks and p-AKT was evaluated to determine insulin signaling pathway activity. Also, insulin concentration in serum samples was measured.

Results: The purified calafate extract presented a total polyphenol content, anthocyanin content and antioxidant capacity of 2242.3 mg GAE/100g DW, 66.1 mg C-3-G/100g DW and 38.43 mmol $Fe+2$/100g DW, respectively. No differences were observed in the insulin concentration between groups. The IPGTT performed at week 9th showed that mice fed on cafeteria diet developed insulin resistance. Interestingly, calafate extract improved the glucose tolerance at week 13th. Western blotting revealed that calafate extract increased p-AKT content, suggesting enhanced insulin signaling.

Conclusions: Our results show for the first time a beneficial effect of a calafate extract over insulin resistance in an in vivo model.

Keywords: Calafate. Polyphenols. Diabetes.

Departamento de Nutrición, Diabetes y Metabolismo, Escuela de Medicina. Pontificia Universidad Católica de Chile.

Background and objectives: Healthy eating is one of the pillars of a healthy lifestyle, leading to the prevention of chronic non-communicable diseases. Antioxidants and fiber are two bioactive components with proven beneficial health properties. Currently, in Chile and the world, fiber and antioxidants intake is less than that recommended by the WHO.

Our objective was to develop a functional food, enriching a high consumption meat-based food with wine grape pomace flour (WGPF), rich in fiber and antioxidants, and to study the effect of its consumption on oxidative damage markers in an intervention study.

Methods: A beef hamburger (100 g) was formulated with 7% of WGPF, containing 3.5% of fiber and 1.2 mg EAG/g of polyphenols (WGPF-hamburger). WGPF is a byproduct of vinification (Cabernet sauvignon). A 3-month controlled intervention study was completed in 27 male volunteers with at least one component of the metabolic syndrome. Volunteers daily consumed one WGPF-hamburger during the first month, interrupted by a month washout period, and followed by a control month period where they daily consumed a hamburger without WGPF (control-hamburger). At the beginning and at the end of each intervention period we evaluated oxidative damage markers: Advanced Oxidation Protein Products (AOPP), carbonyls in proteins, oxidized LDL y malondialdehyde (MDA).

Results: Intake of WGPF-hamburger significantly decreased AOPP (p=0.005) and oxidized LDL (p=0.048) compared with control-hamburger consumption. No significant effect was observed in carbonyl groups in proteins and MDA levels between WGPF-hamburger and control-hamburger periods.

Conclusions: The consumption of a beef hamburger elaborated with 7% WGPF protected from oxidative damage when comparing to control-hamburger, showing its potential to prevent chronic diseases, and its functional properties. Supported by FONDEF (grant #IT14I10011) and Agrosuper.

ANTI-OBESITY EFFECTS OF KAEMPFEROL BY INHIBITING EARLY ADIPOGENESIS IN 3T3-L1 CELLS

[1]*Torres Villarreal, Denys Armandina;* [2]*Ortíz López, Rocío;* [3]*De La Garza Hernández, Ana Laura.*

[1]Bs. Nutrition. Autonomous University of Nuevo Leon, Center for Research and Development in Health Sciences, Faculty of Public Health and Nutrition; [2]School of Medicine, Tecnologico de Monterrey, México; [3]Autonomous University of Nuevo Leon. University of Public Health and Nutrition.

Background and objectives: Obesity is a chronic metabolic disorder defined as an abnormal or excessive fat accumulation with a health risk. Several scientific investigations are focused on search and identify different bioactive compounds that may be used as a treatment for obesity. Kaempferol is a natural flavonoid, found in fruits, vegetables and teas. Recent studies have suggested that it has anti-oxidant, anti-inflammatory and anti-obesity effects. In this context, the present study aimed to assess the anti-obesity properties of kaempferol on the anti-adipogenic and lipolytic effects and the expression of genes involved in the metabolic pathways.

Methods: 3T3-L1 cells were cultured in DMEM supplemented with 10% FBS and 1% antibiotics (initiation medium). At 24 hours, the differentiation was induced (day 0) with DMEM + 1 μL/mL dexamethasone, IBMX and insulin (differentiation medium (DM)), and 2 days after, the medium was replaced for fresh medium containing DMEM + 1 μL/mL insulin (post-DM). This medium was switched every 2 days. Preadipocytes (day 0) and mature adipocytes (day 12) were treated with 60 μM of kaempferol until the finishing of the treatment (day 21). At this point, cells were stained with Oil Red O to measure the lipid accumulation. Furthermore, the expression of genes involved in the adipogenesis, lipolysis and inflammation processes was evaluated with RT-qPCR.

Results: Kaempferol has a potential effect on adipogenesis by reducing 62% of lipid accumulation in relation to the positive control (p < 0.001). Moreover, the intracellular lipid content were diminished (39%) after treatment with kaempferol in mature adipocytes (p = 0.256). Regarding the molecular mechanisms, the treatment with kaempferol downregulated the mRNA expression of C/EBPα (p < 0.05) in comparison with the control cells. On the other hand, the expression levels of PNPLA2 (p < 0.01) and LIPE (p < 0.05), which are associated with hydrolysis of tri- and diglycerides, significantly increased in the presence of kaempferol.

Conclusions: These data indicate that kaempferol has anti-adipogenic effects in 3T3-L1 cells by suppressing the mRNA expression of C/EBPα and stimulating the expression of genes involved in lipid metabolism.

Keywords: Kaempferol, Obesity, Adipogenesis, Lipolysis, Nutrigenomic.

EFFECT OF THE LYOPHILIZATION PROCESS ON THE CONTENT OF BIOACTIVE COMPOUNDS FROM FRUIT PULPS OF BRAZILIAN PANTANAL

[1]*Kwiatkowski, Angela;* [2]*de Oliveira Costa, Camila Cristina;* [3]*Santos de Minas, Ramon;* [2]*da Silva Coimbra, Paula;* [4]*dos Santos Souza, Giovani;* [2]*Pontes de Andrade, Fátima Eliana;* [2]*Marçal Chaves, Roseni.*

[1]Dra. Agronomy. Food Technologist. Food Technology Coordination. Federal Institute of Mato Grosso do Sul. Coxim. Brazil.; [2]Graduate student of Food Technology. Federal Institute of Mato Grosso do Sul. Coxim, Brazil.; [3]Dr. Vegetable Production. Professor. Federal Institute of Mato Grosso do Sul. Coxim, Brazil.; [4]Graduate student of Chemistry. Federal Institute of Mato Grosso do Sul. Coxim, Brazil.

Background and objectives: The Pantanal is a biome situated in the state of Mato Grosso and Mato Grosso do Sul, Brazil. The vegetation of the Pantanal presents diverse diversity due to the influences provinces located to its surroundings, like Forest Amazon, Cerrado and others. Fruits are plentiful, but recently they are in focus by the research community. Thus, cupuaçu (Theobroma grandiflorum), noni (Morinda citrifolia) and cajá-manga (Spondias dulcis) can be classified as food with potential use in nutrition, providing several nutrients and bioactive compounds that can Assist in the prevention of degenerative diseases. The drying process by freeze drying helps to increase shelf life. The objective of this work was to evaluate and compare the levels of organic acids present and bioactive compounds, antioxidant capacity of fruit pulps of cupuaçu, noni and cajá-manga.

Methods: The pulps of the fruits of cupuaçu, noni and cajá-manga were analyzed. The pulps were lyophilization the pulps were frozen, at -40 ° C for 24 hours in ultrafreezer, and left under lyophilization for 48 hours in the absence of light. The values of pH, total acidity, determination of phenolic compounds by the Follin-Ciocauteau method, total flavonoids and antioxidant activities were determined by the DPPH (2,2-Diphenyl-1-picryl-hydrazyl) free radical.

Results: For cupuaçu pulp the results were: pH of 3.26; Acidity of 0.182 g / 100g; Content of phenolic compounds obtained was 130.80 mg equivalent of gallic acid / 100 g; Flavonoid content was 14.06 mg / 100g, with antioxidant activity 96.50%. Noni: pH 3.95; Acidity of 0.119 g / 100g; Phenolic compounds was 43.30

mg equivalent of gallic acid/100 g; 9.38 mg / 100g of flavonoids; 97.14% antioxidant activity. For cajá-manga: pH of 3.44; Total acidity 0.068 g / 100g; Content of phenolic compounds obtained was 160 mg equivalent of gallic acid / 100 g; Flavonoids content was 2.35 mg / 100 g, with antioxidant activity 95.23%. For cajá-manga pulp presents a higher content of phenolic compounds, but the cupuaçu pulp had a higher content of flavonoids.

Conclusions: Fruit pulps were shown to have high levels of phenolic compounds, such as flavonoids and high potential for antioxidant activity.

Keywords: Cupuaçu, Noni, Cajá-manga, Lyophilization, Antioxidant.

EXPLORING THE FUNCTIONAL PROPERTIES OF ELEPHANT FOOT YAM (AMORPHOPHALLUS PAEONIIFOLIOUS) TO AMELIORATE PERIMENO-PAUSAL SYMPTOMS

[1]Dave, Dr. Mital; [2]Nair, Dr. Sirimavo.

[1]Ph.D. Nutritionist. Department of Foods and Nutrition.The Maharaja Sayajirao University of Barod. Vadodara. Gujarat. India.; [2]Ph.D. Associate Professor. Department of Foods and Nutrition. The Maharaja Sayajirao University of Baroda. Gujarat, India.

Background and objectives: Background: Phytoestrogens are natural compounds present in the food, with structural similarity to human estrogen. These compounds have been considered to compete effectively with endogenous estrogens which bind to the ER and stimulate estrogen like effects. They help in ameliorating the perimenopausal and menopausal symptoms in women. Elephant foot yam contains phytoestrogens – isoflavones, coumestans and lignans. A limited research has look at these functional properties of elephant foot yam.   It has both nutritional and medicinal value.

Objective: To evaluate and promote the functional properties of Elephant Foot Yam (Amorphophallus paeoniifolious) to ameliorate perimenopausal systems and improve the quality of life in middle age women.

Methods: Women (n=100; 50 for experimental group and 50 for control group) between age group of 35-60 years who fulfilled the inclusion and exclusion criteria and given their consent were enrolled. The experimental group (EG) was supplemented with fine powder of yam and control group (CG) was provided nutrition health education for 45 days. Anthropometric measurements and menopause related symptoms score (MRS - using a standard questionnaire from the Professor Heinemann from Center of Epidemiology and Health Studies, Berlin, Germany) of study subjects were obtained before and after supplementation.

Results: Mean±SD for weight in EG and CG were 62±7.4and 63.2±7.4 respectively before intervention; which were reduced significantly to 60.6±6.9 (p<0.001) in EG and non-significantly to 63.1±7.5 (p=0.6) in CG. Similarly for BMI, EG showed a sig-

nificant reduction from 25.9±3.4 to 25.3±3.2 (p<0.001) and no specific change was observed for BMI in control group. Waist circumference was significantly reduced in EG – from 89.67±4.7 to 88.65±5 (p<0.01).

Mean±SD of MRS in EG was 11.9±2.5, which reduced to 6.3±3 after supplementation (p<0.001). A reduction in mean±SD of MRS was also observed in CG group where 11.2±1.52 was reduced to 9.0±1.7. Mean value showed a marked reduction for all three dimensions in both groups as well.

Conclusions: The study supports acceptability and effectiveness of elephant foot yam to improve quality of life in women. Detailed studies on underutilized crops, such as yams, and their health benefits are needed if food security and nutrition security are to be assured.

Keywords: Elephant Foot Yam, Menopause Rating Scale (MRS), Phytoestrogen.

HYDROLYSED PEA PROTEINS MITIGATE IN VITRO WHEAT STARCH DIGESTIBILITY

[1]Lopez Baron, Nataly; [2]Sagnelli, Domenico; [3]Blenow, Andreas; [4]Holse, Mette; [5]Saaby, Lasse; [6]Gao, Jun; [7]Vasanthan, Thava.

[1]PhD. Food Chemist. Department of Agricultural, Food and Nutritional Science. University of Alberta . Canada.; [2]PhD. Biotechnologist. Department of Plant and Environmental Sciences. University of Copenhagen. Denmark; [3]PhD. Associate Professor. Department of Plant and Environmental Sciences. University of Copenhagen. Denmark.; [4]PhD. Food Scientist. Department of Food Science. University of Copenhagen. Denmark.; [5]PhD. Pharmacologist. Bioneer. Denmark.; [6]MSc. Senior Lab Tecnologist. Department of Agricultural, Food and Nutritional Science. University of Alberta. Canada; [7]PhD. Professor. Department of Agricultural, Food and Nutritional Science. University of Alberta. Canada.

Background and objectives: Isolated pea proteins and their hydrolysates show potential to reduce blood glucose levels. An in vitro amylase digestibility study of cooked wheat starch in the presence of pea protein isolate in their native, heat-denatured and protease-hydrolysed counterparts was conducted in our lab. The results revealed that protein denaturation and protein hydrolysis enhanced starch-protein interaction that may have reduced the rapidly digestible starch content. Nevertheless, prior to a clinical trial, a more realistic in vitro digestibility technique that simulates the human gastrointestinal tract was needed to better understand this effect.

Objectives: Determine amylolysis of cooked wheat starch in the presence of native and hydrolysed pea protein by measuring the glucose release, in an in vitro static digestion model.

Determine starch amylolysis of extruded snacks prepared with blends of wheat flour and native or protease hydrolysed proteins at 12%, by measuring glucose release in an in vitro gastrointestinal dynamic model.

Methods: In vitro static digestion: Cooked wheat starch (control) and blends with native or hydrolysed pea protein, were mixed with simulated salivary fluid at pH6.9 and incubated (37°C-5min-170rpm). Samples were mixed with simulated gastric fluid pH2 for 2h in the presence of pepsin. Then, simulated intestinal fluid pH7 was added in the presence of bile salts and pancreatin. Samples were collected for glucose determination every 20min for 2h.

In vitro dynamic digestion: Extruded samples of wheat flour+native/hydrolysed pea proteins were mixed with human saliva and poured in a fundus resembling the stomach. Acid and pepsin were added gradually. Samples were collected every 7min and mixed in a vessel containing intestinal fluid. After the addition of the last sample from the fundus to the static intestinal digestion, samples were collected every 20min for 2h for glucose release determination.

Results: Native and protease-hydrolysed proteins when cooked with starch showed significant reduction in glucose release compared to the control at 40, 60 and 120min.

The addition of hydrolysed-protein to a extruded wheat snack reduced significantly the glucose release at 5, 20, 40 and 90min.

Conclusions: The study suggests a possible novel natural protein ingredient to formulate low glycemic food products.

Keywords: Pea proteins, Protein-hydrolysis, Starch, In vitro digestibility.

AMARANTH PROTEIN ACTS AS A PROTECTIVE FACTOR IN LIVER OF HAMSTERS FED WITH HIGH CONCENTRATIONS OF SATURATED FATTY ACIDS AND CHOLESTEROL

[1]Manólio Soares Freitas, Rosana Aparecida; [1]Caliman Salvador, Bianka; [1]Pereira da Silva, Cintia; [2]Maria Guizellini, Gloria; [3]Rodrigues Sampaio, Geni; [3]Gomes Arêas, José Alfredo.

[1]MSc. Nutrition Department. School of Public Health. University of Sao Paulo – USP. São Paulo. Brazil.; [2]Nutrition student. Nutrition Department. School of Public Health. University of Sao Paulo – USP. São Paulo. Brazil; [3]PhD. Nutrition Department. School of Public Health. University of Sao Paulo – USP. São Paulo. Brazil.

Background and objectives: Incidence of cardiovascular disease (CVD) in Western countries is elevated and related to high cholesterol levels, and is evident the role of diet in the control of cholesterol and dyslipidemia. Although studies suggest amaranth protein has a hypocholesterolemic effect, the biological pathways by which the protein acts are still not fully known. Thus the objective of this study was to evaluate the effect of ingestion of amaranth protein over lipid profile in liver of hamsters fed with high concentrations of saturated fatty acids (SAFA) and cholesterol.

Methods: Amaranth protein was isolated according to the isoelectric precipitation method, obtaining 89% of purity. The assay was performed with twenty-four hamsters divided into three groups with diets distinguished by protein source and fat profile. Experimental group (I) were fed a diet with 23% amaranth protein, high in SAFA and with 0.1% cholesterol. The control groups received a diet with 23% casein and fat profile according to AIN-93 (N), or 23% casein, high in SAFA and with 0.1% cholesterol (H). The total lipid content of livers was measured by gravimetric method, cholesterol concentration was analyzed by HPLC-DAD and fatty acids profile was performed by GC.

Results: Group I presented lower total lipid concentration (24%) compared to group H and did not differ from N group. The same occurred to cholesterol concentration in liver (65% lower than H group and similar to N group). Fatty acids profile for I group presented about 53% SAFA, H group presented 52% and N group presented 41%. Monounsaturated fatty acids (MUFA) was 16% for I group, 24% for H group and 9% for N group, furthermore polyunsaturated fatty acids (PUFA) was 32% for I group, 24% for H group and 50% for N group.

Conclusions: The use of amaranth protein demonstrated positive changes in liver lipid profile even including high-saturated fat acids in diet. Possibly amaranth peptides are absorbed and achieve liver cells, and/or amaranth protein act in intestine by signaling pathways. Therefore, stimuli on the consumption of amaranth represent an alternative to diversify the diet and promote a reduction of the risk of CVD.

Keywords: Amaranth protein, Lipids metabolism, Hypocholesterolemic effect.

EFFECT OF ANTIOXIDANT DIETARY FIBER FROM SPENT COFFEE (COFFEA ARABICA L.) GROUNDS ON GASTROINTESTINAL HEALTH OF ADULTS

[1]Gómez Castrejón, Karen Lizzet; [2]Campos Vega, Rocio.

[1]1Universidad Autónoma de Querétaro, Facultad de Química, Departamento de Investigación y Posgrado de Alimentos (DIPA), Cerro de las Campanas s/n, C.P. 76010, Santiago de Querétaro, Qro. México.; [2]Universidad Autónoma de Querétaro, Facultad de Química, Departamento de Investigación y Posgrado de Alimentos (DIPA), Cerro de las Campanas s/n, C.P. 76010, Santiago de Querétaro, Qro. México.

Background and objectives: Spent coffee grounds (SCG), the residue obtained after brewing, is rich in dietary fiber, compound that imparts several health benefits such as prevention or reduction of bowel disorders, and decrease risk of coronary heart disease and type 2 diabetes. Previously a novelty antioxidant dietary fiber rich extract was obtainedfrom SCG (ADFSCG). Moreover, with higher dietary fiber intake stool weight tends to be higher and transit time enhances which may contribute to the prevention of large bowel disorders such as constipation, diverticulitis and large bowel cancers. Thus, the objective of this study was to evalu-

ate the effect of ADFSCG (5g/day) consumption (21 days), as part of a cookie, on gastrointestinal health (43 adults) in a randomized and parallel to a control group (cookie without fiber) trial.

Methods: The intestinal habits and stool consistency were determined by Bristol scale, and the severity and frequency of 18 gastrointestinal symptoms were also evaluated (FDA). The enzymatic activity of β-glucosidase, β-glucuronidase, tryptophanase and urease as well as the antioxidant capacity (DPPH) were determined in faeces.

Results: None of the cookies significantly modified the anthropometric parameters. After ADFSCG cookies intake, total cholesterol increased significantly (within normal values). This group showed a decrease in the general discomfort, with significantly impact on inflammation. On the other hand, allthe18 gastrointestinal evaluated symptoms were improved afterADFSCG cookiesintake,showing a significantlydecreasein the frequency of diarrhea; while, a lower retrosternal burningwas reported after-control cookie intake. A decrease in β-glucosidase and β-glucuronidase was observed in the ADFSCGgroup, with no statistical difference in feaces antioxidant capacity (DPPH).

Conclusions: The ADFSCGcan serve as a source of dietary fiber by improving the bowel's well-being.Additional studies are needed to extend the knowledge of ADFSCG effects on gastrointestinal health.

Keywords: Spent coffee grounds, Antioxidant dietary fiber, Gastrointestinal health.

ENDOSPERM OF TARA SEED (CAESALPINEA SPINOSA) AND AMERICAN AGAVE LEAVES POWDER REGULATE BODY WEIGHT GAIN AND INTESTINAL HEALTH IN HOLTZMAN RATS

[1]Vilcanqui Pérez Fulgencio; [2]Villanueva Espinoza, María Elena; [3]Vílchez Perales, Carlos.

[1]MSc. Departamento de Nutrición. Universidad Nacional Agraria la Molina. Perú; [2]Dra. Departamento de Nutrición. Universidad Nacional Agraria la Molina. Perú; [3]Dr. Departamento de Nutrición. Universidad Nacional Agraria la Molina. Perú.

Background and objectives: There is scientific evidence about dietary fiber intake in prevention and treatment of non-transmissible diseases, which effects depend on type and fiber proportion. On this basis, the present study aimed to investigate the effect of different proportions of endosperm of tara seed (ETS), powder of the Agave americana leafs (AAL) and cellulose (pattern) on the physiological properties related to body weight gain and intestinal health.

Methods: Holtzman rats were feed with different proportions of ETS:AAL (6:0, 3:3, 0:6, 10:0, 5:5, 0:10 % respectively) and measure of feed intake, gain body weight, fat apparent digestibility, volume and fecal pH.

Results: Lower feed intake, decreased body weight gains, fecal mass and pH were showed in ETS (soluble fiber) diets in comparison to control diet. Indeed, higher values in fecal fat content and lower fat apparent digestibility were found to ETS. On the other hand, an increase in fecal volume and decrease in gut transit time were showed in animals feed with AAL (insoluble fiber).

Conclusions: These findings demonstrated that ETS reduce body weight gain due to hydration capacity and to the formation of viscous solutions of soluble fiber (75%) in the intestinal lumen that avoid contact between the digestive enzymes and nutrients. AAL powder with higher fiber insoluble content (80%) may play a role in the prevention and treatment of constipation due to its water retention capacity, low viscous solution formation and increase fecal volume.

Keywords: Dietary fiber. Soluble fiber. Insoluble fiber. Physiological properties.

GPETAFLR, A PEPTIDE ISOLATED FROM LUPINUS ANGUSTIFOLIUS L. PROTEIN HYDROLYSATE, EXERTS ANTI-INFLAMMATORY EFFECTS IN HUMAN PRIMARY MONOCYTES

[1]Millán-Linares, Mª Carmen; [1]Montserrat de la Paz, Sergio; [1]Yust Escobar, Mª del Mar; [1]Pedroche Jiménez, Justo Javier; [2]Millán Rodríguez, Francisco.

[1]Research, Health and Nutrition Department, Instituto de la Grasa (CSIC), Sevilla, España; [2]Research Professor, Health and Nutrition Department, Instituto de la Grasa (CSIC), Sevilla, España.

Background and objectives: Recent studies have shown that lupine protein hydrolysates (LPH) could be an important source of bioactive peptides, especially showing anti-inflammatory activity. The present study aimed to test whether peptide GPETAFLR released from the enzymatic hydrolysis of lupine protein may modulate the inflammatory response in human primary monocytes.

Methods: Freshly human monocytes were used to analyze the effects of GPETAFLR, after 24 hours of treatment at 50-100 μg/mL, on LPS-induced inflammatory response using FACS analysis, RT-qPCR, and ELISA procedures.

Results: We report that GPETAFLR from LPH possesses anti-inflammatory properties in human monocytes. GPETAFLR skewed the monocyte plasticity towards the anti-inflammatory non-classical CD14+CD16++ monocytes and reduced the inflammatory competence of LPS-treated human monocytes diminishing IL-1β, IL-6, and TNF-α production and gene expression. Results: **Conclusions:** Taken together, our results show that

---

GPETAFLR has the potential to impair the activation of human primary monocytes and the derived inflammatory conditions, and suggest a new role for Lupinus angustifolius L. protein hydrolysate in the regulation of the pathogenesis of health disorders in which monocytes play a key role, including atherosclerosis and several chronic diseases.

Keywords: Lupine, Bioactive peptide, Protein hydrolysates, Monocyte, Inflammation.

THE ANTIOXIDANT DIETARY FIBER FROM SPENT COFFEE (COFFEA ARABICA L.) GROUNDS IMPROVE CIRCADIAN LOCOMOTOR ACTIVITY AND ANTHROPOMETRIC PARAMETERS IN ADULTS WITH NORMAL WEIGHT AND OVERWEIGHT

[1]Campos Vega, Rocio; [2]Oseguera Castro, Karla Yadhira; [3]García Obregón, Olga Patricia; [4]Loarca Piña, Guadalupe; [4]Mendoza Díaz, Sandra Olimpia.

[1]PhD. Programa en Alimentos del Centro de la Republica (PROPAC). Facultad de Química. Universidad Autónoma de Querétaro. México.; [2]BsC. Programa en Alimentos del Centro de la República (PROPAC). Facultad de Química. Universidad Autónoma de Querétaro. México.; [3]PhD. Programa de Nutrición. Facultad de Ciencias Naturales. Universidad Autónoma de Querétaro. México.; [4]PhD. Programa en Alimentos del Centro de la República (PROPAC). Facultad de Química. Universidad Autónoma de Querétaro. México.

Background and objectives: All organisms present processes in their physiological functions that occur in a periodic and predictable way called "biological rhythms", including circadian rhythms (CR). Disruption of these rhythms (chronodisruption) is associated with an increased risk to develop non-communicable diseases such cancer, overweight and obesity, specially in the evening chronotype, for which reason the establishment of appropriate circadian rhytms is a priority. Recently, foods have been proposed as a powerful modular of the CR, however there is no evidence of the effect of fiber consumption on chronodisruption parameters like locomotor activity. The aim of this study was to evaluate the effects of the consumption (21 days) of antioxidant dietary fiber (ADFSCG, 5g/day), extracted from spent coffee grounds (SCG), as part of a cookie (C-ADFSCG), on the circadian locomotor activity, plasma antioxidant capacity as well as biochemical parameters of adults with normal weight and overweight.

Methods: The study was randomized and parallel to a control group (cookie without fiber).

Results: Caloric intake decreased in subjects who consumed the C-ADFSCG, reflected on the decrease of waist circumference and body fat percentage, in relation to baseline values and to the control group (p <0.05). In addition, plasma antioxidant capacity increased significantly (p <0.05) after C-ADFSCG consumption. Normal weight subjects (36%, from both treatments) increased their sleep quality and physical activity. At the beginning of the study, morningness chronotypes in subjects with normal weight, and eveningness chronotype in subjects with overweight, were identified. Interestingly, a significant increase in morningness chronotypes was observed in the 62.5% of overweight subjects and 45.4% on the normal weight subjects (63% of this group population) after C-ADFSCF consumption.

Conclusions: This study informs, for the first time, the potential of antioxidant dietary fiber, particularly ADFSCG, to modulate circadian locomotor activity, plasma antioxidant capacity and body fat.

Keywords: Spent coffee grounds, Antioxidant dietary fiber, Circadian rhythms, Plasma antioxidant capacity.

NUTRITIONAL, BIOACTIVE, AND BOTANICAL CHARACTERIZATION OF BEE POLLEN HARVESTED IN THE COLORADO RIVER VALLEY, ARGENTINA

[1]García Paoloni, María Soledad; [2]Vallese, Federico Danilo; [3]Springer, Valeria; [4]Andrada, Ana Cristina; [3]Pistonesi, Marcelo Fabián.

[1]Biochemistry. Laboratorio de Apicultura. INTA Hilario Ascasubi. Argentina; [2]BSc. INQUISUR. Departamento de Química. Universidad Nacional del Sur (UNS)-CONICET. Argentina; [3]PhD. INQUISUR. Departamento de Química. Universidad Nacional del Sur (UNS)-CONICET. Argentina; [4]PhD. Dpto. Agronomía. Universidad Nacional del Sur (UNS). Argentina.

Background and objectives: Honey bees (Apis mellifera L.) collects pollen from flowers as pollen loads to get proteins for sustaining the colony. Due to its protein content (macronutrient) bee pollen is consumed as a nutritional supplement. Additionally the presence of bioactive compounds like polyphenols (micronutrients) provides biological function reason why this bee product is considered a natural functional food. Bee pollen composition depends strongly on the botanical and geographical origin (even though post-harvested processing). The aim of this study is to characterize bee pollen collected in the Buenos Aires Valley of Colorado River (BAVCR) zone.

Methods: During the beekeeping season 2013-2014, twelve samples were harvested to quantify total proteins and total polyphenols and to evaluate the botanical origin. Total protein content was estimated by Kjeldahl method with a conversion factor of 6.25 as the Argentine Food Code indicates (Chapter X, art.

785) and the mean value obtained was 22% ± 2%. Total polyphenols was determinate by the reference method of Folin-Ciocalteu and the average content was 13.1 ± 3.3 mg gallic acid/g pollen.

Results: The values obtained are comparable to those reported in the literature. The botanical origin was established by acetolysis method (Erdtman-1960) and subsequently the pollen grains were identified and counted using light microscope. Main represented taxa in the samples were Brassicaceae, Lotus and Eucalyptus.

Conclusions: Both protein and polyphenols obtained values allow us to conclude that bee pollen collected in the BAVCR can be considered an excellent dietary supplement as well as a natural functional food. The vegetation availability of mentioned botanical taxa will enable beekeepers of this geographical area to obtain very good quality bee pollen.

Keywords: Functional food, Dietary supplement, Total protein, Polyphenols, Botanical origin.

PROPOLIS ETHANOLIC EXTRACT AS NATURAL BEE POLLEN LOAD PRESERVATIVE

[1]*García Paoloni, María Soledad;* [2]*Krepper, Gabriela;* [3]*Cibanal, Irene;* [4]*Fernandez, Leticia;* [5]*Centurión, María Eugenia;* [5]*Di Nezio, María Susana;* [5]*Pistonesi, Marcelo Fabián.*

[1]Biochemistry. Laboratorio de Apicultura. INTA Hilario Ascasubi. Argentina; [2]Biochemistry. INQUISUR Departamento de Química. Universidad Nacional del Sur (UNS)-CONICET. Argentina.; [3]Agricultural engineer. Laboratorio de Estudios Apícolas (LabEA). Universidad Nacional del Sur (UNS)-CIC. Argentina; [4]PhD. Laboratorio de Estudios Apícolas (LabEA). Universidad Nacional del Sur (UNS)-CONICET. Argentina; [5]PhD. INQUISUR Departamento de Química. Universidad Nacional del Sur (UNS)-CONICET. Argentina.

Background and objectives: Bee-products are recognized worldwide as natural functional foods mainly owing to their polyphenols content. Additionally there are many scientific reports about the use of propolis ethanolic extracts (PEE) for food conservation. In Argentina bee pollen (BP) is used as a dietary supplement and quality parameters are regulated in the Argentine Alimentary Code (Chapter X, art. 785). The drying process prior to commercialization is critical to prevent microbiological development and therefore increase larger shelf life. However, the temperature of this step must be controlled to avoid the loss of the phenolic components. The aim of this work was to determine the antimicrobial activity of PEE application over BP loads.

Methods: The antimicrobial effect against bacteria and yeast/mould was tested separately using the percentage of contaminated pollen loads method. For this in vitro trial, 20 Petri plates (20 BP loads per plate) were divided in four treatments with five repetitions: one control with BP loads (T1); another control with BP loads soaked with 7.50 μL of ethanol (T2), and BP loads soaked with 5.00 μL (PEE5) and 7.50 μL (PEE7.5) of PEE respectively. The number of pollen loads with bacteria was studied at 35°C in Plate

Count agar + nistatina while the count of mould/yeast was done in Sabouraud dextrose agar at 26°C.

Results: Fifty percent of BP loads from both controls showed fungal growth after 48 hours of incubation while treatments with PEE developed growth after 168 hours (seven days). The same results were obtained when antibacterial activity was measured on BP loads from PEE treatments. The total of the BP loads from controls were contaminated by bacteria and fungus after 72 hs. In contrast, PEE5 and PEE7.5 never reached this percentage during the whole trial.

Conclusions: This study allowed us to conclude that PEE present antimicrobial activity against bacteria and mould/yeast from fresh BP loads. Thus, PEE becomes a new alternative that offers a preservation method for BP intended for human consumption. Further investigations may reveal extra nutritional power conferred by PEE.

Biochemist. Lipids and Atherosclerosis UNIT, IMIBIC, CIBEROBN.

Background and objectives: There is a relationship between Metabolic Syndrome (MetS), and expression of genes related to endoplasmic reticulum stress. This condition alter the homeostasis of the endoplasmic reticulum in a chronic manner, which affects normal cellular response. OBJECTIVE: to evaluate the expression of the XBP1, CALR, CANX, HSPA5 and GSTP1 genes after the consumption of a breakfast with virgin olive oil (VOO) rich in phenolic compounds (FC) in HUVEC cells as an in vitro model of vascular endothelium.

Methods: Two breakfasts were administered with VOO with high (398 ppm) and low (70 ppm) FC content to 20 patients with MetS in a double-blind, randomized and crossover design. The HUVEC were treated with serum obtained at 0,2 and 4 hours after the consumption of the breakfasts. Gene expression was performed with OpenArray (Applied Biosystem).

Results: In comparison to serum obtained in the fasting state, treatment of HUVEC with serum obtained after consumption of VOO low in FC, decreased expression of XBP1, HSPA5 and CANX genes (p= 0.03, p=0.02 and p=0.01 respectively) at 2 hours

post-breakfast intake and increased expression of CALR gene (p = 0.03) at 4 hours post-breakfast intake. The treatment of HUVEC with serum obtained after consumption of the VOO-prepared breakfast with high FC content, on the other hand, decreased the expression of XBP1, CALR and GSTP1 genes (p=0.02, p=0.01, and p=0.05 respectively) at 4 hours post-breakfast intake. The comparison between treatments showed a significantly lower expression of XBP1, CALR and GSTP1 genes (p <0.001, p<0.001 and p=0.03 respectively) after the intake of the breakfast prepared with VOO with high content of FC at 4 hours in the postprandial state.

Conclusions: VOO rich in FC intake, regulates the expression of genes related to endoplasmic reticulum stress in patients with MetS in the postprandial state, which contributes to a less activation of cellular stress signaling.

Keywords: Phenolic compounds, Metabolic syndrome, Vascular endothelium, Endoplasmic reticulum stress.

APPLICATION OF PEAR ORANGE CITRUS FOOD FIBER (CITRUS SINENSIS OSBECK) IN THE PRODUCTION OF PRODUCTS FUNCTIONAL FOODS

[1]*Van Boekel, Simone;* [2]*Rodrigues, Nicolly;* [3]*Jesus, Déborah;* [3]*Matheus, Larissa;* [4]*Buriti, Lais;* [4]*Pontes, Priscila.*

[1]PhD. Nutritionist. Teacher. Course of Nutrition. Federal University of Rio de Janeiro.Campus Macaé. Rio de Janeiro.; [2]Graduate Course Nutrition. Federal University of Rio de Janeiro. Campus Macaé. Brazil.; [3]Nutritionist. Rio de janeiro. Brazil.; [4]Teacher of Nucleous of Food Technology. Federal University of Rio de Janeiro.Campus Macaé.   Brazil.

Background and objectives: Consumers often despise parts of fibers of the vegetables. The use of by-products of fruits adds value to new food products. OBJECTIVE: Develop cakes with flour of flavedo, albedo and pear orange pulp (FAP) and characterize them sensorially.

Methods: At the Laboratory of Food of Plant Origin of the Federal University of Rio de Janeiro the pear orange was submitted to the hygiene and extraction of the juice. The residue was dehydrated and crushed to obtain the citric flour. Four cakes were prepared, 3 of which were added with 1.5; 3.0 and 5% of citrus flour, respectively, and 1 cake without citrus flour. Common ingredients of cakes: vegetable oil, demerara sugar, egg, baking powder, wheat flour and orange juice. The cakes were submitted to an Acceptance Test by Order of Preference in a scale of preference, preferably in level 4, and the least in level 1. The statistical test was based on Friedman's Order Sum Test at 1% probability. The research was submitted to the Research Ethics Committee and its approval protocol is 954,908 with application to the Free and Informed Consent Form.

Results: 49 volunteers between 18 and 53 years old accomplish the Preference Ordination Test. There was no significant difference between the cakes of 0; 1.5; 3.0 and 5% of citrus flour at the 1% probability level, demonstrating that the tasters did not measure

the distinction between these samples. Among the 0% and 5% samples, there was a statistical difference at the 1% probability level. The cake with 5% of citrus flour was the less preferred, which can be explained by the higher percentage of citric fiber, which may interfere with the taste and texture of food products.

Conclusions: Citrus flour in cakes seems to be good for the use of pear orange by-products due to their good acceptance, who did not present significant differences in the sensory acceptance test and can be consumed by the general population.

Brazil.; [5]PhD. Nutritionist. Department of Biological and Health Sciences. Tuiuti University of Parana. Brazil. andreatarzia@hotmail.com.

Background and objectives: Kale (Brassica oleracea L. var. Acephala) is a vegetable whose consumption has increased due to researchs on its nutraceutical properties. This vegetable is rich on natural antioxidant compounds and have high levels of carotenoids, ascorbic acid, flavonoids, tocopherols, phenolic compounds

---

and glycosinolates, substances that act as antioxidants and that protect the human body against reactive oxygen species. Most perishable foods can be preserved by refrigeration and freezing for a limited time, with the benefits of retarding microbial activities and retaining their nutrients. The objective of this research was to elaborate kale pulp and evaluate its antioxidant activity and sensory acceptability after different periods of freezing.

Methods: Samples (6 kg of organic kale leaves) were cleaned, sanitized and processed in order to obtain as final product the kale pulp. Samples were frozen (-18ºC) and analyses were performed after 5, 30, 60 and 75 days of storage under freezing. An affective (hedonic) sensory test was performed on each test day by untrained assessors. For the affective test the taste was investigated on a 5-point hedonic scale. Antioxidant capacity of the products were evaluated according to the method of Prieto et al. (1999). Antioxidant capacity of the pulps were expressed as relative antioxidant activity (RAA%) to ascorbic acid. Results were analyzed using analysis of variance (ANOVA), and mean values were compared using Tukey's test. Values of $p \leq 0.05$ were considered statistically significant. The data were analyzed using Statistica 8.0 (Statsoft Inc., Tulsa, OK, USA).

Results: Results indicated that freezing the kale pulp up to 30 days did not affect the product acceptability by assessors regarding the parameter analyzed (taste). No difference (p<0.05) was found on RAA% during the tested period, and values ranged from 9.37% (Day 5) to 8.87% (Day 75), showing a good retention of the original antioxidant activity at the end of storage time.

Conclusions: Freezing of kale pulp can be seen as a good alternative for preserving the vegetable quality for a period of 30 to 60 days, without significant losses in the antioxidant activity and sensory profile.

Keywords: Brassica oleracea L. var. acephala, Kale pulp, Hedonic scale, Antioxidant activity.

Conflict of Interest Disclosure: Brassica oleracea L. var. acephala, kale pulp, hedonic scale, antioxidant activity.

ANALYSIS OF BIOACTIVE COMPOUNDS OF NONI SEEDS (MORINDA CITRIFOLIA L.)

[1]Kwiatkowski, Angela; [2]Marçal Chaves, Roseni; [3]dos Santos Souza, Giovani; [2]de Oliveira Costa, Camila Cristina; [4]Dias Pereira, Queila; [4]da Silva Coimbra, Paula; [4]Pontes de Andrade, Fátima Eliana; [5]Santos de Minas, Ramon.

[1]Dra. Agronomy. Food Technology . Federal Institute of Mato Grosso do Sul. Coim. Brazil.; [2]Graduate student of Food Technology. Federal Institute of Mato Grosso do Sul. Coxim, Brazil.; [3]Graduate Student in Chemistry. Federal Institute of Mato Grosso do Sul. Coxim. Brazil.; [4]Graduate Student in Food Technology. Federal Institute of Mato Grosso do Sul. Coxim. Brazil.; [5]Dr. Vegetable Production. Federal Institute of Mato Grosso do Sul. Coxim. Brazil.

Background and objectives: The noni (Morinda citrifolia L.) is a plant that has a fruit that has aroused the interest of the researchers for its therapeutic and nutritional properties. Prepared as fruit pulp juice has great demand in alternative medicine for the treatment of diseases and there are many works that prove its pharmacological properties. However, there are few scientific studies on the seeds of the fruits (Barros, 2009). The most common bioactive compounds determined in all parts of plants are the phenolic substances, which are formed in the secondary metabolism of plants. These compounds can be found in free form or linked to sugars and proteins, having several functions (Liu, 2007). The objective of this work was to analyze the content of bioactive compounds, vitamin C, titratable acidity and antioxidant activity of noni seeds.

Methods: The noni seeds were separated from the fruit pulp and dried in an oven at 60 ° C for 12 hours. Vitamin C analysis by titration with 2,6-dichlorophenolindofenol sodium solution, determination of phenolic compounds by the Follin-Ciocauteau method, carotenoids, total flavonoids and antioxidant activities by free radical capture DPPH (2,2-Diphenyl-1 -pyryl-hydrazyl).

Results: The pH value of the dried seed was 4.97. The total acidity resulted in 0.006 g / 100g. The vitamin C content was 303.03 mg / 100g. The content of phenolic compounds obtained was 297.00 mg equivalent of gallic acid / 100 g. The flavonoid content was 25.04 mg / 100 g and carotenoids 15.16 mg / 100 g. The antioxidant activity resulted in 90.96%. With these results we can highlight the high content of vitamin C and great potential of antioxidant activity. According to Costa et al. (2013) noni is a representative fruit with significant amounts of vitamin C.

Conclusions: The noni seed presented low content of organic acids, content of phenolic compounds such as flavonoids and carotenoids, high content of vitamin C and with great potential of antioxidant action.

EFFECT OF LACTOBACILLUS FERMENTUM CRL1446 ON IMMUNE-METABOLIC PARAMETERS AND INTESTINAL MICROBIOTA COMPOSITION IN OBESITY IN HIGH-FAT DIET FED MICE

[1]Gauffin-Cano, María Paola; [2]Fabersani, Emanuel; [3]Marquez, Antonela; [4]Ross, Romina; [2]Abeijón-Mukdsi, Claudia; [1]Medina, Roxana.

[1]PhD. Biochemist. Centro de Referencia para Lactobacilos (CERELA). CONICET. Argentina; [2]PhD. Biotechnologist. Centro de Referencia para Lactobacilos (CERELA). CONICET. Argentina; [3]BSc. Biotechnologist. Centro de Referencia para Lactobacilos (CERELA). CONICET. Argentina; [4]PhD. Pharmacist. Centro de Referencia para Lactobacilos (CERELA). CONICET. Argentina.

Background and objectives: Dietary strategies, including the use of probiotics as preventive agents that handle the intestinal microbiota and/or modulate the function of adipose tissue, would be suitable tools for the prevention or treatment of different condi-

tions associated with obesity. In this context, our aim was to evaluate the effect of Lactobacillus fermentum CRL1446 (CRL1446) on metabolic and immunological parameters and on the composition of intestinal microbiota in a model of obesity induced by a high-fat diet (HFD).

Methods: Balb/c mice were separated into the following groups: 1) SD: Standard diet, 2) HFD: High-fat diet, 3) HFD+CRL1446: mice receiving a HFD and a daily dose of 1 x 108 CFU of L. fermentum CRL1446 (CRL1446) in the drinking water. The dietary intervention was maintained for 6 weeks. Weight and food intake were monitored daily. It were determined at 20 and 45 days of experimental period: fat tissue weight (histologic studies), metabolic parameters (triglyceride (TG), total cholesterol (TC), glucose (Glu) and leptin (Lep)), seric immunologic parameters (TNF-alpha, IL-6, IL10 and MCP-1), macrophage and adipocyte functionality (ex vivo studies) and the gut microbiota composition (evaluated by high-throughput sequencing of 16S rRNA gene amplicons).

Results: CRL1446 strain induces a decrease in body and adipose tissue weights and the size of adipocytes. A decrease in plasmatic glucose, cholesterol, triglycerides, leptin, TNF-alpha and IL-6 levels and an increase of IL-10 were observed. Ex vivo studies showed a minor secretion of leptin by adipocytes. In macrophages, CRL1446 induced lower levels of MCP-1, TNF-alpha, IL-6 and higher levels of IL-10. Regarding intestinal microbiota, an increase in Lactobacillus and a decrease in Firmicutes/Bacteroidetes (F/B) index were observed.

Conclusions: The supplementation with L. fermentum CRL1446 produce changes in intestinal microbiota structure and metabolic and immunologic parameters. CRL1446 could potentially be a probiotic strain useful to correct the immuno-metabolic alterations associated with obesity through its adipomodulatory capacity.

Keywords: Obesity, Lactobacillus fermentum, Probiotics, Intestinal microbiota.

INHIBITION OF ACTIVITY OF CARBOHY-DRATE-HYDROLYSING ENZYMES BY POLYPHE-NOLS OF JATOBÁ-DO-CERRADO (HYMENAEA STIGONOCARPA MART.)

[1]Pereira da Silva, Cintia; [2]Aparecida Manólio Soares Freitas, Rosana; [3]Rodrigues Sampaio, Geni; [4]Alfredo Gomes Arêas, José.

[1]MSc. Nutritionist. Nutrition Department. School of Public Health. University of Sao Paulo. São Paulo. Brazil; [2]MSc. Chemistry. Nutrition Department. School of Public Health. University of Sao Paulo. São Paulo.Brazil; [3]PhD. Biologist. Nutrition Department. School of Public Health. University of Sao Paulo. São Paulo. Brazil; [4]PhD. Professor. Nutrition Department. School of Public Health. University of Sao Paulo. São Paulo. Brazil.

Background and objectives: Nutritional management of blood glucose levels is a strategy for the prevention and control of diabetes. Inhibitors of the carbohydrate-hydrolysing enzymes such as acarbose decrease post-prandial hyperglycaemia. However, this drug has certain adverse effects such as diarrhoea and nausea. Therefore, natural inhibitors from foods could be a good strategy to control glycaemic. The Brazilian Savannah has an extensive biodiversity, but it is underexplored. The jatobá-do- cerrado (Hymenaea stigonocarpa Mart.) is a native legume of Brazilian Savannah with great potential for exploration because it's an excellent source of dietary fiber and polyphenols. The objective of this study was to evaluate the potential inhibitory activity of jatobá extracts after digestion in vitro on α-amylase and α-glucosidase enzymes.

Methods: The phenolic extract was obtained by sequential extraction with 80% acetone and 60% ethanol. The digested extract was done using enzyme solutions (α-amilase, pepsin and pancreatin) at physiological pH. The total phenolic content (TPC) was evaluated by Folin reagent. Different concentrations of extracts were tested.

Results: The extract of jatobá after digestion in vitro presents 10 mg GAE.g-1 of sample. Our study have showed that the phenolic extracts greatly inhibited the α-amylase in a positive dose-dependence way (76 and 91% for 9 and 15 mg. mL-1, respectively). On the other hand, the extract showed a high α-glucosidase inhibitory activity (77 and 53%) but this activity is not positively related to concentration of extract (3 and 6 mg. mL-1, respectively).

Conclusions: The results of this present study indicate that polyphenols from jatobá are effective α- amylase and α- glucosidase inhibitors, which may modulate the postprandial glucose levels. Thus, the jatobá can be helpful in the management of type 2 diabetes.

Keywords: Jatobá-do-cerrado, Type 2 diabetes, α-amylase, α-glucosidase.

EVALUATION OF THE ABILITY OF FERMENTED CACTUS PEAR JUICE TO IMPROVE OXIDATIVE STRESS TOLERANCE IN YEAST

[1]Torres, Sebastian; [2]Veron, Hernan; [3]Isla, Maria Ines; [4]Gauffin-Cano, María Paola; [5]Dantur, Karina; [6]Fernández-Espinar, María Teresa; [7]Gil-Ponce, Jose Vicente.

[1]PhD. Biochemist. Instituto de Bioprospección y Fisiología Vegetal (INBIOFIV). CONICET. Argentina; [2]BSc. Biotechnologist. Instituto de Bioprospección y Fisiología Vegetal. CONICET. Argentina.; [3]PhD. Biotechnologist. Instituto de Bioprospección y Fisiología Vegetal. CONICET. Argentina.; [4]PhD. Biochemist. Centro de Referencia para Lactobacilos (CERELA). CONICET. Argentina; [5]PhD. Biochemist. Instituto de Tecnología Agroindustrial del NOA. CONICET. Argentina.; [6]PhD. Biologist. Instituto de Agroquímica y Tecnología de Alimentos. CSIC. España.; [7]PhD. Instituto de Agroquímica y Tecnología de Alimentos. CSIC. España.

Background and objectives: Cactus pears from Opuntia ficus-indica are strongly recommended in the human diet since

---

their nutritional and health-promoting features. Scientific evidence has demonstrated the benefits from cactus pear ingestion with special consideration about potentially active antioxidant phytochemicals. However, long-term storage represents the main drawback to the commercialization of this fruit. Since in many places cactus pears are consumed as juice, different procedures were developed to prevent its spoilage. Lactic acid fermentation of cactus pear juice (CPJ) using autochthonous bacteria constitutes an important biotechnology for the exploitation of this fruit. The aim of this study was to evaluate the effect of fermented CPJ (F-CPJ) on oxidative stress tolerance of Saccharomyces cerevisiae.

Methods: Lactobacillus plantarum S-811, an autochthonous lactic acid bacteria strain isolated from O. ficus-indica fruits from Northwest Argentina was used to fermented the juice. To evaluate the antioxidant response induced by CPJ and F-CPJ, cultures of S. cerevisiae were incubated with the juices (amounts equivalent to 50, 250 and 500 mg/L of phenolics) during 18 h at 28 °C. Cells were then exposed to sub-lethal oxidative stress, using 0.5 or 4 mM H_2O_2. After stress treatments, cells were cultured in YPD medium and incubated for 18 h at 28 °C. To evaluate the oxidant effect in each culture, growth-ratio curves (GRC) and effect curves (EC) were constructed as follows: RC = quotient between the growth curve (GC) of the culture exposed to oxidant and the GC of the non-exposed culture; EC = GRC for the culture pre-incubated with the juice was divided by the GRC for the culture pre-incubated without juice.

Results: Against a final concentration of 0.5 mM H_2O_2 there was not observed a significant protective effect by any of the evaluated juices. However, against 4 mM H_2O_2, CPJ and F-CPJ showed a significant protective effect, that was much higher with the F-CPJ (up to 15 times protection) than CPJ (up to 4 times protection).

Conclusions: These results suggest that F-CPJ with L. plantarum S-811 could be a suitable choice for the development of a CPJ with improved functional properties.

Keywords: Opuntia ficus-indica, Lactobacillus plantarum, Cactus pear juice.

ELABORATION AND ACCEPTANCE OF CEREAL BAR WITH FLOUR OF FLAVEDO, ALBEDO AND ORANGE-PEAR PULP (CITRUS SINENSIS OSBECK): OPTIONS OF FOOD PRODUCTS SOURCES OF FOOD FIBER

[1]*Van Boekel, Simone;* [2]*Pimentel, Lorrene;* [2]*Dofini, Juliana;* [2]*Ferreira, Camila;* [2]*Chaves, Stefani;* [3]*Buriti, Lais;* [3]*Pontes, Priscila.*

[1]PhD. Nutritionist. Teacher. Course of Nutrition. Federal University of Rio de Janeiro.Campus Macaé. Rio de Janeiro.; [2]Graduate Course Nutrition. Federal University of Rio de Janeiro. Campus Macaé. Brazil.; [3]Teacher of Nucleous of Food Technology. Federal University of Rio de Janeiro.Campus Macaé. Brazil.

Background and objectives: Food fiber prevent chronic diseases and has therapeutic evidence. The parts of the orange pear with the highest concentrations of fiber are flavedo, albedo and pulp most despised. Avoiding waste is sustainability and it is necessary to encourage the full use of fruits, which benefits human beings and the environment. OBJECTIVE. The objective of the present work will be to elaborate cereal bars with flavedo flour, albedo and pulp of orange-pear (FAP) and to evaluate their acceptance through affective sensorial methods.

Methods: In the Laboratory of Food of UFRJ, the oranges were sanitized, and then the seeds and the juice were despised. The FAP residue was dehydrated and crushed to obtain the citrus flour. After, were preparation 2 cereal bars of which were added with 3.0 and 5% of citrus flour, respectively. The sensorial analysis of the elaborated bars, was through Acceptance and Preference Tests of 50 non-trained adults participated, after consent in the research that was approved by the Research Ethics Committee.

Results: For cereal bars at 3.0 and 5.0% with FAP flour, the note indicated by the non-trained adults in the appearance attributes (25%, respectively); Aroma (45 and 40%, respectively); Texture (20%, respectively); Sweet taste (30%, respectively) and orange flavour (30 and 35%, respectively) was 8.0 indicating a similarity of acceptance between the different attributes. It was stated that up from 30% of non-trained adults buy cereal bars. The t-test with p-value 5% indicated for all attributes, averages very close and p value above 0.05, demonstrating that there was no significant difference between acceptance of samples for all attributes.

Conclusions: The sensorial tests showed good acceptance and purchase intention for the two bars with 3 and 5% of FAP flour of orange-pear. In this way, cereal bars may be nutritionally suitable food product options, since they are made with the orange parts that concentrate the dietary fibers.

Keywords: Food fiber, Citric fiber, Orange residue, Flavedo, Albedo.

CYTOPROTECTIVE ACTION AGAINST OXIDATIVE STRESS IN ASTROCYTES BY BACTRIS GUINEENSIS-L.H.E. MOORE (ARECACEAE) AND POUROUMA CECROPIIFOLIA ANTHOCYANIN EXTRACTS

(1)Albarracín, Sonia Luz; (2)Velasco, José María; (3)Osorio, Coralia; (4)Sutachan, Jhon-Jairo.

(1)PhD. Chemistry. Department of Nutrition and Biochemistry. Faculty of Sciences. Pontificia Universidad Javeriana. Bogotá. Colombia; (2)BSc. Nutritionist. Department of Nutrition and Biochemistry. Faculty of Sciences. Pontificia Universidad Javeriana. Bogotá. Colombia; (3)PhD. Chemistry. Department of Chemistry. Faculty of Sciences. Universidad Nacional de Colombia. Bogotá. Colombia; (4)PhD. Physiology and Neuroscience. Department of Nutrition and Biochemistry. Faculty of Sciences. Pontificia Universidad Javeriana. Bogotá. Colombia.

Background and objectives: Neurodegenerative diseases such Alzheimer, Parkinson and Huntington are characterized by protein aggregates, mitochondrial impairment, and oxidative stress that can lead to neuronal and astrocytic cell death. Epidemiological studies suggest that consumption of fruits rich in anthocyanins may reduce the risk or delay the development of some neurodegenerative diseases. Bactris guineensis (Corozo) and Pourouma cecropiifolia (Uva caimarona) are endemic plants from the Caribbean and Amazon regions whose fruits are consumed in juices and jellies. Previous studies have reported that these fruits are rich in antioxidants molecules like anthocyanins that may have therapeutical potential. In this study, we investigated whether fruit extracts from Bactris guineensis and Pourouma cecropiifolia suppress the toxic effects of hydrogen peroxide on astrocytes.

Methods: Anthocyanins rich extracts [ARE] from Bactris guineensis and Pourouma cecropiifolia fruits were isolated by high-speed countercurrent chromatography (HSCCC) and preparative HPLC, and their chemical structures were elucidated by using spectroscopic methods.

Once the extracts were obtained, astrocytes were cultured in 96 plate-wells and then treated with different doses of Bactris guineensis and Pourouma cecropiifolia extracts to evaluate their toxicity. Afterwards, to evaluate the protective effect of ARE, astrocytes were pre-treated with non-toxic doses of extracts for 24 hours and then were exposed to hydrogen peroxide for 1 hour. Protective effect was assessed by evaluating changes in cell survival, mitochondrial membrane potential and free radical production by resarzurin test and flow cytometry.

Results: Our result showed that Bactris guineensis and Pourouma cecropiifolia extracts were not toxic to any of the concentrations evaluated, exhibited a great protective activity, and rescued astrocytes from oxidative peroxide-induced stress by maintaining the mitochondrial membrane potential .

Conclusions: These findings suggest that anthocyanins extracts rich in delphinidin-3-O-β-glucopyranoside, cyanidin-3-O-β- glucopyranoside, and cyanidin-3-O-(600-malonyl) glucopyranoside from Bactris guineensis and Pourouma cecropii-

folia can regulate reactive oxygen species via enhancement of mitochondrial function, protecting astrocytes from cell death.

Keywords: Antioxidants, Neurodegenerative diseases, Astrocytes, Bactris guineensis , Pourouma cecropiifolia.

ELABORATION OF AN ADDED DIETARY ICE CREAM WITH INULIN

(1)Eliana María, Rodriguez; (2)Eliana María, Rodriguez.

(1)210587; (2)Mg. Nutricionist. Facultad de Ciencias Ecáctas y Tecnología. Universidad Nacional de Tucumán. Argentina.

Background and objectives: Inulin is stored in many plant species. Research indicates that inulin would have positive effects on the treatment of diabetes. The objectives of this research were to elaborate a low calorie ice cream added with inulin, to determine its chemical composition, sensorial and acceptability, and to compare the variation of pre and post consumption levels of traditional and modified ice cream.

Methods: From an experimental study, an ice cream with 10% inulin and 40% of peach pulp, added with sucralose, was made. Its chemical composition was determined and its sensorial properties and acceptability were evaluated in 50 people between 40 and 60 years old of both sexes residing in Tucumán, through tasting and hedonic scale.

Results: The prepared ice cream has a caloric value of 49 Kcal / 204 KJ per serving, carbohydrate 3.8 g, protein 0.9 g, total fat 3.3 g, saturated fat 2.2 g, fiber 1 g, and sodium 24 mg. 82% (41) detected a strong, shiny orange hue. 18% (9) did not observe differences between the two ice creams. 90% (45) detected peach aroma and Chantilly cream. 90% (45) reported feeling sweet taste. 88% (44) said that the modified ice cream was creamier than the average. To 84% (42) he liked the modified ice cream. Of the remaining. Regarding the variation in blood glucose levels, people who consumed the common ice cream had 100% normal blood glucose levels (70-110), with a mean of 67.5 μ. While in the post-iced common ice creams 100% had values above 110 mg with a μ of 142.54. In all cases, the glycemia before the modified ice cream was normal (70-110) with a μ of 66.1 and the post-consumption blood glucose levels were 94% normal with a μ of 101.7 and 6% of Values above normal with a μ of 117.3.

Conclusions: According to previous scientific evidence, inulin has positive effects on chronic noncommunicable diseases, and according to the data provided by this research, it does not produce significant variations in post-consumption levels of glycemias, therefore, it is proposed to insert in the Market this ice cream to contribute to healthy eating strategies.

Keywords: Modified ice cream, Inulin, Low calories.

A SYSTEMATIC REVIEW EXAMINING THE RELATIONSHIP BETWEEN ANIMAL SOURCE FOOD INTAKE AND GROWTH IN CHILDREN 6 TO 60 MONTHS IN LOW- AND MIDDLE-INCOME COUNTRIES

[1]Shapiro, Myra; [2]Downs, Shauna; [3]Quelhas, Diana; [4]Kreis, Katharine; [5]Kraemer, Klaus; [6]West, Jr., Keith; [2]Fanzo, Jessica.

[1]Phd Candidate. Center for Human Nutrition. Department of International Health. Johns Hopkins Bloomberg School of Public Health. Baltimore. USA.; [2]Phd. Berman Institute of Bioethics. Johns Hopkins University. Baltimore. USA.; [3]PhD. PATH. Seattle. USA.; [4]MPH. Nutrition Innovation. PATH. Seattle. USA.; [5]Sight and Life Magazine; [6]DrPH. Center for Human Nutrition. Department of International Health. Johns Hopkins Bloomberg School of Public Health. Baltimore. USA.

Background and objectives: Adequate nutrition is a critical factor in reducing the burden of growth faltering that affects millions of children in low- and middle-income countries (LMIC). This systematic review aimed to examine the association between animal source food (ASF) intake and length/height outcomes in LMIC children aged 6 to 60 months. Secondary outcomes were weight, head circumference (HC), hemoglobin (Hb) concentration, and anemia prevalence.

Methods: Databases searched were CINAHL, Embase, Global Index Medicus, PubMed, and Web of Science. Grey literature was searched in International Food Policy Research Institute publications, New York Academy of Medicine Grey Literature Report, OpenGrey, and Proquest Dissertations. Randomized controlled trials (RCT) and longitudinal and cross-sectional observational studies that quantified ASF consumption by frequency, quantity, or both in children 6 to 60 months in LMIC were included.

Results: There were 13,431 titles, 205 abstracts, and 89 full texts reviewed. Fourteen articles were included: 4 RCTs, 4 observational cohorts, and 6 cross-sectional. Three RCTs used a plant-based food (PBF) as the comparator, the results showed no differences in height (n=3) or Hb (n=1), mixed positive and null associations for weight (n=1), and higher HC for PBF (n=1). One RCT with a usual diet control resulted in higher Hb, lower anemia prevalence, and no difference in height or weight. In observational cohorts, ASF intake and height had a positive association (n=1), mixed positive/null (n=1), and negative (n=1). ASF and HC had a positive association (n=1), mixed positive/null (n=1), and no association (n=1); Hb and anemia were not examined. For cross-sectional studies, ASF and height had positive associations (n=1), mixed positive/null (n=3), and no association (n=2). ASF and weight had mixed positive/null associations (n=3); HC, Hb, and anemia were not examined. Positive or mixed positive/null associations were found in 6 of 13 (6/13) studies for height, 4/9 for weight, 1/2 for HC, and 1/2 for Hb; 1/2 studies had a negative association for ASF and anemia prevalence.

Conclusions: The variation in associations may be explained by the heterogeneous quantification of ASF intake. Our results suggest that increased access to ASF in LMIC may support reducing the burden of growth faltering in early childhood.

TOTAL ANTIOXIDANT CAPACITY AND ITS DIETARY SOURCES IN DIETS OF STUDENTS WITH DIFFERENT PHYSICAL ACTIVITY LEVEL

[1]Czlapka-Matyasik, Magdalena; [2]Przeorska, Dorota; [3]Van Lieshout, Machteld.

[1]Poznan University of Life Sciences; [2]Msc. Food Technologist. Department of Human Nutrition and Hygiene. Poznan University of Life Sciences. Poland; [3]PhD. Food Technologist Nutrition Consultant. Foodwise Pro B.V. Netherlands.

Background and objectives: Introduction: Physical activity, determine dietary patterns. Information about dietary sources of antioxidants in daily diet of students is limited.

Objectives: The aim of this study was to compare antioxidant capacity of diets students with different physical activity level and their dietary sources of antioxidants.

Methods: Method/Design: The study involved 47 subjects aged 19-25 years. The quantitative FFQ questionnaire administered by reviewer was collected and analyzed. Dietary recalls regarding the consumption of dietary sources of antioxidants, socioeconomic data and physical activity were collected. The antioxidant density of daily diet (Q-ORAC; µmolTE/1000 kcal), the share of food groups in total ORAC was evaluated. Daily physical activity of studies group was evaluated according to subject's declaration.

Results: Total daily antioxidant density in studied group was 7 056 µmolTE/1000kcal. Sources of total antioxidant capacity in daily students diet come from fruits (52%), vegetables (22%) and spices (25%). Students who were less active consumed less dietary sources of antioxidants, presented lower levels of diet antioxidant capacity. Dietary sources of antioxidants were fruits (52%), vegetables (22%) and spices 25%).

Conclusions: We found correlation between dietary sources of antioxidants and physical activity level. Dietary sources of antioxidants should be included in epidemiologic studies and analysed in aspects of physical activity.

EVALUATION OF PHYSICO-CHEMICAL CHARACTERISTICS AND ANTIOXIDANT ACTIVITY OF FLOUR JABOTICABA (MYRCIARIA CAULIFLORA) RESIDUE

[1]Thais Resende Teixeira, Karla; [2]Azevedo dos Santos, Talita; [3]Pimentel de Abreu, Joel; [1]de Souza Gouveia Moreira, Laís; [4]Lima Torres, Taíssa.

[1]Nutritionist of Antonio Pedro University Hospital / Fluminense Federal University, Niterói/ RJ – Brazil.; [2]Nutritionist graduate of Federal University of the State of Rio de Janeiro, Rio de Janeiro / RJ – Brazil; [3]Master of Science in food science at Federal University of the State of Rio de Janeiro, Rio de Janeiro / RJ – Brazil.; [4]Professor of Federal University of the State of Rio de Janeiro, Applied nutrition department, Rio de Janeiro / RJ – Brazil.

Background and objectives: The jaboticaba Myrciaria cauliflora (Mart.) is a native Brazilian fruit with high antioxidant potential, but still has a low commercialization and consumption, because of its high perishability and waste generation. The physico-chemical characterization and analysis of the antioxidant activity of the jaboticaba residue provide subsidies to the development of by-products with healthy and sustainable value, to allow greater accessibility to this fruit. The objective of the present study was to evaluate the physical-chemical characteristics and antioxidant activity of jabuticaba flour residue (Myrciaria cauliflora) to be an alternative in food preparation or enrichment.

Methods: The jabuticabas were purchased from the Center of Supply of the City of Rio de Janeiro (CADEG) in November 2014, respecting the seasonality of the fruit. The jaboticaba flour residue was obtained by drying the residue resulting from the jaboticaba juice formulation. The physical and chemical characterization was performed through pH, fixed mineral residue, lipid extraction, protein analysis, total sugars, fiber determination and total titratable acidity. In vitro antioxidant activity studies were carried out, the antioxidant compounds and phenolic compounds were extracted, the TEAC assay and the FRAP assay. Quantification of phenolic compounds was determined by the Folin-Ciocalteau spectrophotometric method.

Results: The flour jaboticaba residue showed a yield of 18%. The moisture (11.29%), ash (3.5%) Acidity (1.8%) and pH (3.5) in accordance with legal standards and the percentage of total sugar (62.43%) , lipids (0.6%), protein (12.13%) and fibers (9.35%) were adequate. The total antioxidant activity and phenolic of the flour jaboticaba residue showed: 1419.8 micromole Fe 2+ / g (FRAP) and 2505.53 micromole Trolox / g (ABTS) and 5410,3mg GAE / 100g.

Conclusions: These results are expressed over various other fruit flour documented in the literature. Therefore the flour jaboticaba residue is a viable way to provide this fruit in a sustainable manner, and to present itself as an alternative source of antioxidants to be used in the preparation of healthy products.

THE COMBINATION OF MEAL IMPROVEMENT AND PROTEIN-ENRICHED FOOD FOR INCREASING MUSCLE MASS OF THE ATHLETE

[1]Suzuki, Aiyuu; [2]Masaki, Yuusuke; [2]Matsuzawa, Hiroki; [3]Koyama, Yuuzou; [3]Namba, Hideyuki; [1]Murakami, Yukifumi; [3]Matsumoto, Megumi.

[1]MSc; [2]BSc; [3]PhD.

Background and objectives: Most athletes aim to improve performance by increasing muscle mass without increasing body fat mass. In this study, in order to establish the ideal weight-increasing method, we examined a diet improvement method using protein-enriched foods and performed a 3-week intervention test.

Methods: The subjects were five male shot-put players and eight soccer players in the university students. The intervention period is 3 weeks, and the subjects daily took Lumilan 200 ml (Kewpie Co., Ltd.) containing 84 kcal of energy, 8 g of protein and 0 g of lipid, and took foods containing 2 g of protein per 1 kg body weight, which were based on the high protein food table. Measurements of body composition and meal survey were conducted for 1 week before and after the intervention, and changes in nutrient and amount of food intake were measured.

Results: In shot-put players the body composition did not change, but in soccer plyers the body fat mass significantly decreased. Regarding meal intake, the amounts of lipid and dairy products were significantly increased, and cereals intake was significantly decreased in shot-put players. Meanwhile in soccer plyers, the intake amounts of protein, vitamin C, beans, fish and shellfish, and milk were significantly increased. Compared among both athletes, the increments of muscle, fat and body weight were significantly higher in shot-put players than in soccer plyers. Furthermore, increase in intake of protein and lipid was significantly higher in shot-put players. Both players were unable to achieve intake of 2 g protein per 1 kg body weight, so it was thought to be difficult to voluntarily improve diet habit for college student athletes. In addition, it was suggested that 8 g of protein-enriched foods per day were insufficient to achieve increments in 3 weeks.

Conclusions: When comparing features of the competition, the shot-put players have to take higher amount of meal for increments than the soccer players, then shot-put players could not achieve necessary intake amount of protein because of the increase of lipid intake accompanied by increased meal intake.

Keywords: Soccer, Increment, Protein, Shot-put, Muscle mass

COMPLEX LIPID COMPOSITION IN HUMAN MILK SAMPLES FROM DIFFERENT ETHNIC GROUPS

[1]Rowan, Angela; [2]Ma, Kevin; [3]McJarrow, Paul; [4]McGibbon, Alastair; [5]Fong, Bertram.

[1]GM Nutrition, Fonterra Research & Development Centre, Palmerston North, New Zealand; [2]MSc, Research Scientist, Fonterra Research & Development Centre, Private Bag 11029, Palmerston North, New Zealand; [3]PhD, Senior Research Scientist, Fonterra Research & Development Centre, Private Bag 11029, Palmerston North, New Zealand; [4]PhD, Principal Research Scientist, Fonterra Research & Development Centre, Private Bag 11029, Palmerston North, New Zealand; [5]MSc, Senior Research Scientist, Fonterra Research & Development Centre, Private Bag 11029, Palmerston North, New Zealand.

Background and objectives: Complex lipids, such as gangliosides and phospholipids, play important roles in intra- and inter-cellular signalling, migration, proliferation, neurological development, and inflammatory and immune responses. These lipids are found in biological fluids, including human milk in the milk fat globule membrane.

Growing evidence shows that complex lipids play an important role in infant development, which has led to studies of human milk composition. Furthermore, it has been suggested that human milk composition may be influenced by diet and ethnicity.

The objective of this study was to use modern techniques to determine gangliosides and phospholipids in human milk throughout lactation from a cross section of women of different cultures and ethnicities including Chinese, Malay and the Middle East.

Methods: The human milk samples were analysed for gangliosides and phospholipids using a validated high-performance liquid chromatography-mass spectrometry (HPLC-MS) method to determine the ganglioside and phospholipid classes and concentrations.

Results: Human milk consisted of both GM3 and GD3. GD3 was the dominant ganglioside in colostrum and transitional milk, while GM3 was the major ganglioside class in mature milk. Total ganglioside concentration was highest in colostrum and transition milk before decreasing in mature milk. Over the mature milk period, there was a gradual increase in average total ganglioside (GD3 +GM3) concentration from around 14 mg/L to high of around 25 mg/L.

Total phospholipid (SM, PC, PE, PI and PS) concentrations were highest in colostrum, before dropping to lower levels at the start of the mature milk period. However the pattern of changes for total phospholipid concentrations over the lactational period differed between ethnic groups.

Conclusions: Using modern HPLC-MS techniques, we measured the ganglioside and phospholipid concentrations in breast milk from a number of different ethnic populations across the lactation periods. There were similarities in average total ganglioside and phospholipid concentrations in the mature milk.

These components may be important for normal growth and development of the infant immune system, visual performance and cognitive performance. Data from this study may support the development of human milk replacers for use in situations where mothers are unable to breastfeed.

Keywords: Human milk, Gangliosides, Phospholipids

COMPOSITION OF FATTY ACIDS AND CHARACTERIZATION OF BIOACTIVE COMPOUNDS IN THE TUCUMÃ FRUIT (ASTROCARYUM HUAIMI MART.)

[1]Marques Romeiro Santos, Mirelly; [2]Stéphanie Fernandes, Dayane; [2]Monteiro Santee, Cynthia; [3]Jordão Cândido, Camila; [4]Fontoura Cavalheiro, Leandro; [5]Fernandes da Silva, Anderson; [6]Aragão do Nascimento, Valter; [7]Aiko Hiane, Priscila; [7]Mendes Ramos Filho, Manoel; [8]Freitas dos Santos, Elisvânia.

Brazil.; [2]Nutritional Science Undergraduate Student. Federal University of Mato Grosso do Sul. Brazil.; [3]Pharmacist. Food Processing Technitian. Federal University of Mato Grosso do Sul. Brazil.; [4]Chemist. Institute of Chemistry. Federal University of Mato Grosso do Sul. Brazil.; [5]MSc. Biologist. Federal University of Mato Grosso do Sul. Brazil.; [6]PhD. Professor. Post Graduate Studies in Health and Development in the Brazilian Midwestern Region. Federal University of Mato Grosso do Sul. Brazil.; [7]PhD. Professor of Pharmacy. Federal University of Mato Grosso do Sul. Brazil.; [8]PhD. Professor of Nutritional Science. Federal University of Mato Grosso do Sul. Brazil.

Background and objectives: The Brazilian Cerrado has a large variation of fruits with different nutritional and physico-chemical properties that have not been studied. The purpose of this study is to analyze the antioxidant properties and quantify the fatty acids of the tucumã fruit (Astrocaryum huaimi Mart.) found in the Brazilian state of Minas Gerais.

Methods: Total phenols, tannin, and antioxidant activity were analyzed using the Folin-Ciocalteu, Folin-Denis and the DPPH (1,1-diphenyl-2-picryl hydrazyl) stable free radical assay methods, respectively, in the extracts: aqueous, acetone, and ethanolic. For determining fatty acids from tucumã oil Gas-liquid chromatography Varian (model CP-3800) was used. The data was analyzed using the Statistical Package for the Social Sciences (SPSS) software, version 22.0 and reported as average ± standard deviation. The comparisons were done using analysis of variance (ANOVA), followed by Tukey post hoc analysis. The values were statistically significant when $p < 0.05$.

Results: The present study indicated a significant difference (p<0.0001) in the concentration of bioactive compounds in the different extracts. The tannins in the acetone extract resulted in 90.77 ± 1.13 mg EAT.100g-1, greater than in the ethanolic (63.57 ± 1.52) and aqueous (31.10 ± 0.34) extracts. The phenolic compounds were best extracted in ethanol (101.78 ± 1.88 mg EAG.100g-1) when compared to acetone (87.80 ± 2.48) and aqueous (62.17 ± 0.96). Among the analyzed extracts, the aqueous presented the least antioxidant potential with a confidence interval (CI50) equal to 259.95 ± 0.75, followed by the ethanolic (138.49 ± 0.89) and acetone (115.76 ± 5.67). The nutritional composition of the tucumã oil presented 29.4% of saturated fatty acids, 12.56% of polyunsaturated fatty acids and 46.2% of unsaturated fatty acids, with emphasis on oleic acid.

Conclusions: In the analysis of bioactive compounds, the acetone extract followed by the ethanolic had the best antioxidant potential and more phenolic compounds and tannins. The quantification of the fatty acids in the fruit presented more unsaturated fatty acids. Based on the results, the inclusion of tucumã pulp in the diet can prevent chronic diseases, as well as nutritional deficiencies, thus promoting health benefits.

ESTIMATION OF THE CURRENT POLYAMINE INTAKE IN THE SPANISH POPULATION

[1]Vidal-Carou, M. Carmen; [2]Comas-Basté, Oriol; [3]Sánchez-Pérez, Sònia; [4]Hernández-Macias, Salvador; [5]Latorre-Moratalla, M. Luz; [1]Veciana-Nogués, M. Teresa; [6]Rivero Urgell, Montserrat.

[1]PharmD. PhD. Department of Nutrition, Food Sciences and Gastronomy. University of Barcelona. Spain.; [2]PharmD. MSc. Department of Nutrition, Food Sciences and Gastronomy. University of Barcelona. Spain.; [3]BSc. MSc. Department of Nutrition, Food Sciences and Gastronomy. University of Barcelona. Spain.; [4]BSc. Department of Nutrition, Food Sciences and Gastronomy. University of Barcelona. Spain.; [5]BSc. PhD. Department of Nutrition, Food Sciences and Gastronomy. University of Barcelona. Spain.; [6]PharmD. PhD. Associació Catalana de Ciències de l'Alimentació (ACCA). Spain.

Background and objectives: For many years, the interest of the study of polyamines (PA) content in foods has lied in the need to formulate low PA diets as part of the treatment of certain neoplastic processes. Currently, however, more attention has been paid on PA potential beneficial effects, both at intestinal and systemic levels. PA are involved in the maturation of the intestinal epithelium in new-borns and have also been postulated as potential protective agents in cardiovascular diseases and diabetes complications due to their anti-inflammatory and antioxidant properties. Moreover, PA have awakened a renewed interest after realising that its endogenous synthesis diminishes in the process of aging. It has been proven that the dietary enrichment in PA results in an increase of PA plasmatic levels.

The aim of this work was to estimate the PA intake of the Spanish population, mainly focusing in the comparison between elderly and young adult populations.

Methods: PA intake estimation was done taking into account the PA contents collected in the database of our research group and food consumption data from Spanish National dietary survey in adults, elderly and pregnant women (ENALIA 2, 2016).

Results: Mean PA intake was close to 170 μmol/day for the Spanish population, slightly lower than that estimated from previous surveys in Spain. In comparison with other countries, PA intake in Spain was lower than that previously reported in the United Kingdom and similar to that reported in Japan. The total estimated PA intake for the Spanish population aged 65-74 years (elderly) was higher than that estimated for young adults (18-39 years).

Conclusions: The eating habits of the elderly seem to guarantee a high PA intake, principally explained by a higher consumption of fruits and vegetables. This partially compensates the lower efficacy of the endogenous PA synthesis described in this population group.

Keywords: Polyamines, Bioactive compounds, Elderly.

KIMCHI AND ITS BIOACTIVE COMPOUNDS IMPROVED COGNITIVE DEFICITS IN MICE INDUCED BY AMYLOID BETA

[1]Song, Yeong Ok; [2]Woo, Minji; [3]Kim, Mijeong; [4]Noh, Jeong Sook.

[1]Department of Food Science and Nutrition. Kimchi Research Institute. Pusan National University. Busan 46241. Republic of Korea.; [2]MSc. Department of Food Science and Nutrition. Kimchi Research Institute. Pusan National University. Busan 46241. Republic of Korea.; [3]PhD. Department of Food Science and Nutrition. Kimchi Research Institute. Pusan National University. Busan 46241. Republic of Korea.; [4]PhD. Department of Food Science and Nutrition, Tongmyong University, Busan 48520, Republic of Korea.

Background and objectives: Malfunction of cognition is often noticed in the elderly person suffering the dementia wherein elevation in oxidative stress is recognized. Kimchi, Korean fermented vegetable dish, demonstrated numerous health benefits and bioactive compounds in kimchi with antioxidant activity are claimed for revealing these effects. In this study, effects of kimchi and its bioactive compounds on the improvement of cognitive deficits damaged by Aβ25-35 were examined in mice. For the study, permeability of blood-brain barrier (BBB) of kimchi and bioactive compounds were determined in vitro.

Methods: Kimchi was mixed with a brined cabbage and condiments prepared with red pepper, garlic, green onion, and ginger. Kimchi was fermented until pH was reached 4.3±0.1. Brain damage was induced by a single intracerebroventricular injection of

Aβ25-35. Following 14 days, mice were fed chow diet and a concomitant oral administration of kimchi methanol extract (KME, 200 mg/kg/day), 3-(4'-hydroxyl-3',5'-dimethoxyphenyl)propionic acid (HDMPPA, 50 mg/kg/day), quercetin (50 mg/kg/day), ascorbic acid (50 mg/kg/day), or capsaicin (10 mg/kg/day), respectively (n = 7 per group). PBS was injected to the mice as a vehicle. Behavior tests including water-maze test, T-maze test, and novel object recognition test were performed. BBB permeability was evaluated using PAMPA assay, in vitro.

Results: Compared with the control group, in the water-maze test, the latency time to reach the platform was shorter in the KME and bioactive compounds group (p<0.05). These groups showed a greater preference for the new route than old route in the T-maze test (p<0.05). In the novel object recognition test, KME and bioactive compounds groups spent more time around the novel object than familiar object (p<0.05). Plasma ROS and peroxynitrite level elevated by Aβ25-35 was decreased by KME or bioactive compounds (p<0.05). KME and other compounds except for ascorbic acid were successfully penetrated BBB. The permeability of BBB was high in capsaicin, quercetin, KME, and HDMPPA, in order.

Conclusions: Kimchi exerted a preventive effect against the cognitive deficits induced by Aβ25-35 via suppression of oxidative stress, suggesting that kimchi consumption might have benefits on dementia. Synergic effects of bioactive compounds in kimchi rather than a single compound would increase these effects.

Keywords: Amyloid beta protein; Blood-brain barrier; Cognitive deficits; Kimchi; Oxidative stress.

KIMCHI DECREASED APOPTOSIS IN THE BRAIN OF MICE FED HIGH-CHOLESTEROL DIET THROUGH DECREASING LIPID ACCUMULATION, INFLAMMATION, AND OXIDATIVE STRESS

[1]Song, Yeong Ok; [2]Kim, Serim; [3]Woo, Minji; [4]Kim, Mijeong; [5]Noh, Jeong Sook.

[1]Department of Food Science and Nutrition. Kimchi Research Institute. Pusan National University. Busan 46241. Republic of Korea.; [2]BSc. Department of Food Science and Nutrition. Kimchi Research Institute. Pusan National University. Busan 46241. Republic of Korea.; [3]MSc. Department of Food Science and Nutrition. Kimchi Research Institute. Pusan National University. Busan 46241. Republic of Korea.; [4]PhD. Department of Food Science and Nutrition. Kimchi Research Institute. Pusan National University. Busan 46241. Republic of Korea.; [5]PhD. Department of Food Science and Nutrition, Tongmyong University, Busan 48520, Republic of Korea.

Background and objectives: Oxidative stress in the brain might cause degenerative neuronal diseases by elevating apoptosis through lipid peroxidation. Hypercholesterolemia is one known fact to disturb the lipid metabolism in the brain. Kimchi, Korean fermented vegetable dish, has demonstrated antioxidative, lipid-lowering, anti-inflammation, and antiatherogenic activities where quercetin, capsaicin, vitamin, mineral, and lactic acid bacteria are present. In this study, beneficial effects of kimchi consumption on alleviating apoptosis mediated through lipid accumulation, oxidative stress, and inflammation in the brain were examined in HCD-fed mice.

Methods: Kimchi methanol extracts (KME) prepared from fermented kimchi (pH 4.3±0.1) was used. Animal groups were mice fed high-cholesterol diet (HCD having an oral administration of KME (200 mg/kg bw/day) or distilled water for 8 weeks. The level of oxidative stress and lipid peroxidation were determined in the brain tissue. Gene expressions were analysed by western blot assay to elucidate the related mechanisms.

Results: Compared with the control group, expression of lipogenic enzymes (SREBP-1, -2, ACCα, FAS, and HMGCR) in the kimchi group were downregulated with concomitant upregulation of genes involved in the fatty acid oxidation (PPAR-α, CPT1, and ACOX1) and cholesterol export (CYP7A1) (P < 0.05). Reactive oxygen species and lipid peroxidation levels in the brain were significantly reduced (P < 0.05) in the kimchi groups, in contrast, the glutathione level was increased (P < 0.05). Protein expressions such as SOD, CAT, and GPx regulated by Nrf2 were increased (P < 0.05). Moreover, NFκB and their related inflammatory gene expressions were significantly downregulated (P < 0.05). Additionally, expression for proapoptotic factors (Bax, caspase -3, and -9) was downregulated while those for anti-apoptotic factor (Bcl-2) were upregulated(P < 0.05).

Conclusions: Kimchi decreased apoptosis in the brain of mice fed HCD through decreasing lipid accumulation, inflammation, and oxidative stress, suggesting that kimchi consumption might improve the brain function.

Keywords: Brain; High-cholesterol diet; Kimchi; apoptosis; Oxidative stress; Inflammation.

Background and objectives: Rice is a staple food and an important food not only as an energy source but also as a protein source especially in Asian countries. There are some unknown areas as for the physiological functions, especially immune system, of rice endosperm protein (REP) although the effect of formulae based on rice protein has been reported in the treatment with milk protein allergy. In our preliminary study, REP affected intestinal gene expressions related to immune system and also REP enhanced cellular immunity and deflected the balance of type I helper T cell (Th1)/type II helper T cell (Th2) to Th1 side in Lewis rats. Therefore, we attempted to clarify the effect of REP on the Th1/Th2 balance and IgE production.

Methods: Female BALB/c mice at 3 weeks of age were employed and were fed on an egg white protein (EWP) diet as a control group and an REP diet for 4 weeks. To assess the Th1/Th2 balance and IgE production, blood samples were collected from tail vein at 4 weeks, and IgG2a, a marker for Th1 type immune response, IgG1, a marker for Th2 type immune response, and IgE concentrations were measured by the ELISA method.

Results: At 4 weeks, the serum IgG1 concentration was significantly suppressed and IgG2a/IgG1 ratio was significantly increased by REP consumption although IgG2a concentration was not altered between two groups. This result suggests that REP deflected the Th1/Th2 balance to Th1 side. In addition, the serum IgE concentration in the REP group was significantly suppressed at 4 weeks compared with the EWP group.

Conclusions: REP deflected the balance of Th1/Th2 to Th1 side and suppressed the IgE production compared with EWP.

Niigata University. Japan.

Background and objectives: The increase of chronic kidney disease (CKD) is a serious problem worldwide. In Japan, CKD patients are estimated 13.3 million, about 13% of adults, and diabetic patients are 9.5 million. Diabetes and CKD are directly related, and CKD including diabetic nephropathy leads to CKD-mineral and bone disorder (CKD-MBD). Moreover, CKD-MBD is one of the major risk factors for cardiovascular disease as well as bone fractures. We have reported that rice endosperm protein (REP) had preventive effects on obese diabetes, fatty liver and diabetic nephropathy, compared with casein (C). This study is the advanced experiment and the aim is to clarify the effects of REP on the bone metabolism in Zucker Diabetic Fatty (ZDF) rats.

Methods: Seven week old male ZDF rats were fed 20% C and REP diets for 10 weeks. Fasting blood glucose levels and urinary albumin excretion (UAE) were monitored. At the end of the experimental period, some blood parameters related to the mineral metabolism (Ca, P, parathyroid hormone (PTH), and fibroblast growth factor-23 (FGF-23)) and a blood parameter related to the bone formation (osteocalcin) were determined to evaluate the progression of CKD-MBD. The femur bones were used for histomorphometric observation by μCT, and the bone strength was measured. In addition, the urinary metabolome measurements were conducted.

Results: Fasting blood glucose levels and UAE in the REP group were significantly suppressed compared with those in the C group. In the REP group, blood FGF-23 concentrations was significantly decreased although blood Ca and P concentration had no abnormal alteration in ZDF rats. Moreover, the osteocalcin level significantly increased in the REP group. The REP had no significant effects on bone mineral density but suppressed deterioration of bone microstracture parameters, and the bone strength was improved in the REP group. PCA analysis showed clearly different urinary metabolic profiles in the two groups.

COLITIS IMPROVEMENT EFFECT OF PYRO-GLUTAMYL PEPTIDES-RICH FERMENTED RICE DRINK IN MICE

[1]Wada, Sayori; [2]Kasuno, Toko; [3]Kiyono, Tamami; [2]Aoi, Wataru; [4]Naito, Yuji; [5]Sato, Kenji; [2]Higashi, Akane.

[1]Kyoto Prefectural University; [2]Division of Applied Life Sciences, Graduate School of Life and Environmental Sciences, Kyoto Prefectural University, Kyoto, Japan; [3]Kyoto Municipal Institute of Industrial Technology and Culture, Kyoto, Japan; [4]Molecular Gastroenterology and Hepatology, Kyoto Prefectural University of Medicine, Kyoto, Japan; [5]Division of Applied Biosciences, Graduate School of Agriculture, Kyoto University, Kyoto, Japan.

Background and objectives: Three pyroglutamyl peptides with anti-colitic activity had been identified in Japanese rice wine, sake, by oral administration of a small dose (0.1–1.0 mg/kg body weight) in mice. Since the alcohol percentage of sake is approximately 15%, we developed a functional peptides-rich fermented rice drink with no alcohol, for human application. We also compared the anti-colitic activity of developed fermented rice drink with Japanese traditional drinks, including sake and amazake, a traditional sweet, low- or non-alcohol Japanese drink.

Methods: For preparation of fermented rice drink, steamed rice, koji, lactic acid, and water were fermented according as amazake, but at low temperter for 1 week. Acute colitis was induced by oral administration of dextran sulphate sodium dissolved in drinking water for 7 days in mice. 4 samples (fermented rice drink, amazake, 2 different types of sake) were dissolved in distilled water and administered by gavage in aliquots of 200 microL once a day during the entire induction. The mice were sacrificed on day 7 the entire colon was removed from the cecum to the anus. We evaluated the colitis severity on the basis of microscopic observations of stool consistency (0, normal; 1, mild loose; 2, loose; 3, mild diarrhea; and 4, diarrhea). The inner contents of the colon were collected for microbiota analysis. Population of Bacteroiditis and Firmicutes were quantified on the basis of amplification of genome DNA coding 16S rRNA by polymerase chain reaction by using group-specific primers.

Results: Fermented rice drink group had a tendency to improve diarrhea score (1.6 ± 0.2, p = 0.061) compared with colitis group (2.7 ± 0.4), while Japanese traditional drink (amazake and sake) did not improve. There were no significant difference in the population of Firmicutes/Bacteroidetes ratio between colitis and rice drink group.

Conclusions: We developed novel no-alcohol functional rice drink, and it suppressed diarrhea to a greater extent than did the Japanese traditional drinks in mice. Fermented rice drink might holds promise for human application.

Keywords: Pyroglutamyl peptides, Fermented foods, Gut microbiota, Colitis.

Argentina.

Background and objectives: Several studies have associated a moderate consumption of garlic with improvements in health. The evidence suggests that its medicinal activities are mainly due to the organosulfur compounds (OSCs) garlic content. Garlic compounds have exhibited antioxidant activities and cardiovascular disease-protective properties. The remodeling of small arteries by excessive proliferation and migration of vascular smooth muscle cells (SMCs) is a phenomenon to consider, since it contributes to the development and complications of hypertension, one leading cause of morbidity and mortality globally. It seems that the mystery of OSCs and hypertension would be easy to elucidate; nevertheless, OSCs have shown to have different biological actions, potency and mechanisms in different cell lines and organ tissues. Moreover, only the bioavailable compounds would have bioefficacy. In this regard, previous works have identified a few OSCs in blood. For this study three bioaccessible OSCs, allyl mercaptan (AM), S-allyl cysteine (SAC) and 2-vinyl-4H-1,3-dithiin (2VD), were selected to evaluate their in-vitro effects on cultured SMCs isolated from mesenteric arteries of male spontaneously hypertensive rats.

Methods: Cell proliferation, cell migration and intracellular oxidative stress were evaluated after cell exposure to OSCs expected quantities in plasma, 10 µg/L of AM and 2VD and 50 µg/L of SAC.

Results: The results of the proliferation test by MTT assay showed that 2VD reduced by 20% the proliferation compared to the control, conversely SAC enhanced the proliferation by 15%. Scrape-wound migration assay showed that 2VD and AM reduced the cell migration in similar ratios (30%), whereas SAC increased the migration by 30% compared to the control. Concerning to the intracellular ROS levels, the compounds showed different behaviors at the studied concentrations. While AM was an intracellular antioxidant, 2VD and SAC increased the oxidative stress.

Conclusions: In conclusion, expected quantities of 2VD and AM in plasma, provided by garlic intake, were able to inhibit the migration of SMCs of spontaneously hypertensive rats. These compounds could help to protect the cardiovascular system from vascular remodeling produced by hypertension. Further studies will be needed to elucidate the specific mechanism of action to

inhibit the SMCs migration and the role of its different antioxidant effects.

Keywords: Organosulfur compounds, Garlic, Hypertension, Vascular remodeling.

UTILITY OF DEWAXED BROWN RICE AS A FOOD STAPLE IN THE MAINTENANCE AND IMPROVEMENT OF NUTRITION AND HEALTH STATUS IN THE ELDERLY

[1]Uenobe, Maya; [2]Wakuaku, Natsumi; [3]Saika, Toshiyuki; [3]Nishiyama, Naoki; [4]Itou, Kazuhiro; [5]Inagawa, Hiroyuki.

[1]PhD. MD. Department of Health and Nutritional Science. Nagoya University of Economics. Aich Japan; [2]Course of Nutrition Management. Graduate School of Human Life Science. Nagoya University of Economics. Aich Japan; [3]Toyo Rice Corp.. Wakayama Japan; [4]Heiann no Sato. Special Nursing Home for the Elderly. Aich Japan; [5]PhD. Phar.D.. Deparatment of Research & Development. Control of Innate Immunity Technology Research Association, Kagawa Japan.

Background and objectives: A new type of brown rice with its wax layer removed (dewaxed brown rice) resulting quick-cooking and tasty product contains 100-times more LPS than polished white rice. It also improves weight loss and constipation in antibiotics administered mouse model. In this study, the health maintenance function of dewaxed brown rice was investigated its effects on physical and nutritional status, bowel movements, immune function, cognitive function and other factors in residents of special nursing homes for the elderly who continuously ingested dewaxed brown rice.

Methods: This study was a controlled crossover trial in 35 elderly men and women living in special nursing homes for the elderly who were sorted into two groups and ingested either dewaxed brown rice or polished white rice three times a day for six months. The subjects underwent body weight measurements once a month, were checked daily for any bowel movements, and underwent salivary sIgA and C-reactive protein (CRP) measurements once every three months and assessments of cognitive function (Hasegawa dementia scale) once every six months. (Ethics Committee of Nagoya University of Economics: receipt number 2016-1).

Results: An interim assessment was conducted six months after the study began. In terms of physical status, body weight and body mass index (BMI) tended to increase in emaciated subjects and were significantly greater (p<0.05) after three months of ingesting the test food compared with before the study began. The mean number of days per month without a bowel movement tended to decrease in the dewaxed brown rice group. Salivary sIgA levels in the dewaxed brown rice group showed an increasing trend compared with before the study began, while CRP levels showed a decreasing trend. Assessments of cognitive function in the de-

waxed brown rice group showed improvement compared with those in the polished white rice group.

Conclusions: The results of this study suggested that dewaxed brown rice improves constipation, weight loss and inflammation in the elderly, and if introduced as a food staple to residents of welfare facilities for the elderly, could help improve constipation and malnutrition and prevent infections and cognitive decline in the elderly.

Keywords: Dewaxed brown rice. Nutritional status. Constipation. Immune system. Elderly.

PURIFICATION OF BIOACTIVE ANTIOXIDANT AND ANTIHYPERTENSIVE QUINOA (CHENOPODIUM QUINOA WILLD.) PEPTIDES

[1]Cisneros, Miluska; [2]Campos, David; [3]Aguilar, Ana María.

[1]BSc. Food Engineering. Industrial Biotechnology Institute. National Agrarian University La Molina. Peru; [2]Dr. Agronomic Sciences. Industrial Biotechnology Institute. National Agrarian University La Molina. Peru; [3]Dra. Agronomic Sciences. Industrial Biotechnology Institute. National Agrarian University La Molina. Peru.

Background and objectives: Quinoa is a pseudo Andean cereal known for its protein quality. Also, there are studies that had shown antioxidant and antihypertensive capacity of quinoa peptides. Thus, the aim of this work was to purify bioactive peptides from quinoa protein concentrate through ultrafiltration (10 and 3 kDa cut off) and low pressure chromatographic techniques (adsorption and gel filtration chromatography), in order to improve their antioxidant and antihypertensive capacity.

Methods: -Determination of 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid) (ABTS) antioxidant capacity (umol Trolox equivalent/g protein)

-Determination of antihypertensive capacity through concentration of quinoa peptide to inhibit the angiotensin converting enzyme (ACE) by fifty percent (IC50)

-Adsorption chromatography with ethanol as eluent in steps of 0, 25, 50 and 75 % aqueous solution of ethanol

-Gel filtration chromatography with Milli-Q water as isocratic eluent

Results: -It was found an antioxidant capacity of 1,667.38±9.55 μmol trolox equivalent (TE)/g protein and 0.3007 mg/mL of IC50 value in quinoa hydrolyzate.

-The fraction obtained from a 3 kDa ultrafiltration cut off got higher both, antioxidant and antihypertensive capacity than the quinoa hydrolyzate.

-When both (adsorption and gel filtration chromatography, in that order) separation techniques were used after 3 kDa ultrafiltration cut off, the highest antioxidant (3,784.85±17.06 μmol TE/g protein) and antihypertensive capacity (IC50 = 0.0391±0.01

mg/mL) were obtained, in comparison to only apply gel filtration chromatography.

-It was found a 82.05 percent of correlation between antioxidant and antihypertensive capactiy, showing that both functional properties are related to each other

Conclusions: -The fraction that presented the highest antioxidant and antihypertensive capacity in the first purification stage, corresponded to the permeate obtained with the cut off membrane 3 kDa

-In the adsorption chromatography, the highest antioxidant and antihypertensive capacity were attributed to the peptides eluted with a 25% aqueous solution of ethanol, indicating the slight hydrophobicity of said peptide sequence

-During the gel filtration chromatography, better results were obtained in peptides previously subjected to adsorption chromatography, which represent those with lower molecular weight and hydrophobic character

-Purification achieved the increase of both, antioxidant and antihypertensive capacity in bioactive quinoa peptides, with a high correlation between each other

Keywords: Quinoa, Antioxidant peptides, Antihypertensive peptides, Purification.

A HEALTHY POSSIBILITY: MALTED FLOUR FROM RYE GROWN IN ARGENTINA

[1]Zuleta, Ángela; [2]Zuleta, Ángela; [2]Moreyra, Federico; [2]García, Pilar Teresa; [2]Gómez Castro, Maria Laura; [2]Larregain, Claudia Cecilia; [2]Coscarello, Ethel Noemi; [2]Weisstaub, Adriana Ruth.

[1]university of buenos aires; [2]BUENOS AIRES.

Background and objectives: Rye is the second most important winter forage cereal in Argentina. The flour made from rye has a greater proportion of dietay fiber than wheat flour.. Dietary fiber (DF) has beneficial physiological effects on the human organism. Increased intake of DF through foods is actually being recommended for good health because DF is likely to help reduce diabetes and intestinal diseases. Some components of soluble fiber called prebiotics, like beta glucans or aranbioxilans, are defined as non-digestible food ingredients that positively affect the host. The quality of DF varies according to the type of cereals and to the process that is carried out to obtain the flour. Rye grains for this work came from the INTA, Bordenave Púan. The production of flours, with functional properties implies the malting of the rye, and there are antecedents by which the malting process increases the amount of soluble fibers.

Methods: In the first instance, an evaluation of the quality of the seeds of the different varieties was carried out. The most efficient rye varietes after the malting process are Don Ewald and Camilo. In order to determinate their characteristics, we analyzed the composition of these varieties . The total, soluble and insoluble fiber content was determined by Method 991.43 AOAC, with flours obtained from the unmalted and malted cereal.

Results: The comparative results demonstrate a tendency to modify the amount of fiber in cereal flour after the malting process. Our results show a decrease in the insoluble fiber fraction and an increase in the soluble fiber fraction. The total fiber content of malted and unmalted rye flour was on average 18% . The insoluble fiber content of unmalted rye flour was 16% and malted rye flour was 14%, obtaining of soluble fiber content of 2 % in the unmalted flour and 4% in the malted flour. This functional property of bioactive ingredients is currently being evaluated in an animal model of Wistar rats.

Conclusions: Preliminary results are showing a functional activity of these ingredient.

Keywords: Rye flour, Malted rye, Dietary fiber.

SYNERGISTIC EFFECT OF WALNUT AND BLACK CHOKEBERRY MIXTURE ON ANTI-LIPID PEROXIDATION IN D-GALACTOSE INDUCED AGING MODEL

[1]Song, Eunkyung; [2]Choi, Yoon jeong; [2]song, Mijeong; [3]Kim, Hyun-Sook.

[1]MSc. Student. Food and Nutrition. Sookmyung Women's University. Seoul. Korea.; [2]BSc. Student. Food and Nutrition. Sookmyung Women's University. Seoul. Korea; [3]PhD. Professor. Food and Nutrition. Sookmyung Women's University. Seoul. Korea.

Background and objectives: Many studies mentioned the cellular damage caused by reactive oxygen species(ROS) could be aging. D-galactose causes aging-related changes and oxidative stress in the organism. Lipids are the first target of free radicals, and lipid peroxidation related the aging process. Walnut kernels (Juglans regia L.) contains antioxidant phenolic compounds. Many studies showed that walnut phenolics belong to ellagitannin, or hydrolyzable tannins related antioxidant activities. Chokeberry(Aronia melanocarpa) is one of the richest sources of polyphenols, especially anthocyanin among other fruits. Previous studies showed that polyphenols of chokeberry have antioxidant and anti-inflammatory activities. In this study, we mainly investigated that synergistic effect of walnut and chokeberry mixture on anti-lipid peroxidation of the serum and various tissues in D-galactose induced aging model.

Methods: Thirty-five Balb/c mice(8 weeks of age) were divided into five groups(n=7 for each group): the normal control group(NC), D-galactose control group(DC), D-galactose with chokeberry diet group(CHD), D-galactose with walnut diet(WD), and D-galactose with walnut and chokeberry mixture diet(WCH). All groups were intraperitoneally infected with D-galactose(120mg/kg) daily for eight weeks, except for NC group which was treated with saline. Levels of malondialdehyde(MDA) in serum, liver, brain, and kidney were determined by according assay kits in D-galactose treated mice.

Results: It was found that the serum, hepatic, and brain MDA level in DC groups were higher than the NC group(p<0.05). Compared to DC group, CHD, WD and WCH groups showed significantly decrease serum, hepatic, and kidney MDA level(p<0.05). Serum MDA level in WD group was the lowest concentration compared to other groups. Hepatic MDA level in CH group was the lowest concentration compared to other groups, and also hepatic MDA level in WCH group lower than WD group. There was the lowest MDA level in kidney than WD and CHD groups.

Conclusions: Walnut and chokeberry mixture had anti-lipid peroxidation and synergistic effect. Especially, walnut and chokeberry mixture had been decreased the lipid peroxidation product in kidney compared walnut and chokeberry, respectively. But results showed that walnut and chokeberry mixture had not anti-lipid peroxidation in serum, liver, and brain. Further studies are needed to the mechanism of the lipid peroxidation and synergistic effect of various tissues.

Keywords: Synergistic effect, Walnut, Chokeberry, Lipid peroxidation, Aging

Laboratory of Translational Immunology. Department of Internal Medicine. University of Campinas. São Paulo. Brazil.

Background and objectives: Type 1 Diabetes leads to the increase of reactive oxygen species, promoting oxidative stress in the organism. This study aimed to evaluate the effects of the treatments with aqueous leaves extract of P. alata or isolated compounds catechin, rutin, isoorientin and vitexin in the inhibition of proliferation of TCD4+ and TCD8+ cells of NOD mice in co-cul-

ture with MIN6 cells and also the antioxidant effects in the supernatants of these cultures.

Methods: T cells (2,5x105) were submitted to co-culture with MIN6 cells (8x104) to determine the concentrations of aqueous extract of P. alata and isolated compounds in inhibition of T cell proliferation. After that, the supernatants were collected for antioxidant activity analyses by FRAP and ABTS protocols and oxidative stress by TBARS protocol.

Results: The concentration that promoted inhibition in the cell proliferation in approximately 50% (ID50) was 500ug/mL of P.alata; 50uM of catechin; 300uM of rutin; 5uM of isoorientin and 200uM of vitexin. The FRAP analysis showed higher antioxidant activity in the treatment with rutin, catechin and P. alata while in the ABTS analysis it was verified higher antioxidant activity in the treatment with rutin and vitexin. These both techniques (FRAP and ABTS) demonstrated an increase in capacity to reduce pre-forms oxidized ions in the groups treated with P. alata, rutin, catechin and vitexin. This activity is associated to antioxidant and anti-inflammatory action, enhancing the protective action in experimental model diabetes type 1. In TBARS analyses, the compound rutin showed a tendency in decrease lipid peroxidation levels when compared to cells that were not submitted to treatment.

Conclusions: All the treatments presented inhibition in T cells proliferation, suggesting an anti-inflammatory effect and P. alata and the isolated compounds rutin, catechin and vitexin have showed an antioxidant effect when analyzed the supernatants. The oxidative stress verified by TBARS suggest that rutin is the main isolated compound that decrease the lipid peroxidation. These antioxidant properties from P. alata and compounds can indicate a protection against cell damage from oxidative stress observed in type 1 diabetes evolution.

Keywords: Oxidative stress, Lipid peroxidation, Passiflora alata Curtis, Anti-inflammatory effect; NOD mice.

NEUROPROTECTIVE EFFECT OF SALVIA HISPANICA I (CHIA) OIL AGAINST PESTICIDES IN RATS

[1]Oriondo Gates, Rosa Lorenza; [2]Valdivieso Izquierdo, Lazaro Ruben; [2]Delgado Pérez, Doris.

[1]Docente miembro investigador Instituto Centro de Investigaciones de Bioquímica y Nutrición. Peru; [2]Docente miembro investigador Instituto Centro de Investigaciones de Bioquímica y Nutrición"Alberto Guzmán Barrón" Facultad de Medicina - UNMSM.Peru

Background and objectives: Salvia hispanica (chia) oil has considerable amounts of polyunsaturated fatty acids (PUFAs), similar to linseed oil. The oil could be used as a potential source of high functional ingredients in omega-3 fatty acids. On the other hand toxicological studies on exposure to neurotoxic substances in humans have shown that the central nervous system (CNS) is

one of the main target organs for its toxicity. The objective of this research was to evaluate the neuroprotective effect of Salvia hispanica oil (chia) on the neurotoxicity induced by pesticides in rats.

Methods: G1: Control, G2: pesticide substance, G3: chia oil 4ml / Kg day, G4 pesticide substance + chia oil 2ml / kg day, G5: pesticide substance + chia oil 4ml / kg day, four animals per group randomly assigned. After six weeks of treatment the animals were sacrificed and the brain was removed from the occipital part of the skull, part of the cerebellum was fixed in formalin solution and the other part of the brain was washed with Sodium Chloride solution 0.9 %. A 10% homogenate of brain was prepared in 0.05M phosphate buffer solution pH 7.4, centrifuged and the supernatant was used for the biochemical assays: Levels of: Malonaldehyde by lipoperoxidation (TBARs) and quantification of protein. Ethics of animals was respected

Results: Variation of weight: G1: 30.45%, G2: 28.9%, G3: 40.2%, G4 31%, G5: 37.7%; TBAR umol / L, proteins mg%: G1: 14.6 ± 2.3, 193.1 ± 5.9; G2: 19.1 ± 1.9, 197.7 ± 14.9; G3: 17.0 ± 1.8, 197.5 ± 6.0; G4: 17.2 ± 1.0, 199.5 ± 16.3; G5: 15.2 ± 1.4, 200.6 ± 12.2. Histological: G2 group there was an effacement of nuclear and cytoplasmic membranes in the brain compared to G1 and G5, there was a slight recovery of the nuclear and cytoplasmic contours.

Conclusions: The weight gain was influenced by the pesticide substance; G2 presented greater oxidative stress than the other groups; G5 presented TBARS value very close to G1, which was corroborated in the histological section.

Keywords: Chia oil, Neuroprotection, Pesticides.

INFLUENCE OF REGULAR CONSUMPTION OF GREEN BANANA FLOUR ON THE INTESTINAL FUNCTIONING IN SERVERS OF A FEDERAL UNIVERSITY

[1]Basile, Lívia; [1]Lima, Cláudia; [2]Diniz, Ana Paula; [3]Jara, Audrei; [2]Grejianim, Jessica; [2]Vicente, Renata.

[1]PhD. Nutritionist. Nutrition Course. Federal University of Grande Douradas. Brazil.; [2]Nutritionist. Nutrition Course. Federal University of Grande Douradas. Brazil.; [3]Student. Nutrition Course. Federal University of Grande Douradas. Brazil.

Background and objectives: Green banana flour, considered a food with functional properties, stands out as a source of resistant starch and fibers, providing energy for intestinal cells and homeostasis of the gastrointestinal tract. The objective of the presente study was to evaluate the influence of regular consumption of green banana flour on the intestinal functioning of healthy adults.

Methods: The group studied was composed of 44 servers from a federal university, of which 23 are components of the Green Banana Flour Group and 21 of the Control Group. The volunteers from the Green Banana Flour Group consumed two tablespoons of green banana flour per day, and those from the Control Group consumed two tablespoons of cassava flour per day in the main meals, for eight weeks. Fecal consistency was assessed by the Bristol scale ranging from hard feces or cymbals (type 1) to totally aqueous and without solid pieces (type 7). The participants' diet was evaluated through the fat and fiber score. Both the Bristol scale and the fat and fiber score were applied before and after the consumption of the flours. Statistical analysis was performed using Student's t-test and paired t-test, with a significance level of 5%. The project was approved by the Research Ethics Committee of the Federal University of Grande Douradas, protocol number 1.074.863, 06/11/2015.

Results: After the consumption of green banana flour, it was observed that there was a significant change in feces consistency, verified by the Bristol scale. After the consumption of the flours, the individuals of the Green Banana Flour Group had a higher fiber score than the individuals of the Control Group. It was verified that 70% of the individuals who consumed the green banana flour reported improvement in intestinal functioning.

Conclusions: Green banana flour may have helped increase fiber intake and improved feces consistency and intestinal functioning of individuals who participated in the research, making a contribution to prevent intestinal diseases.

Keywords: Green banana flour, Intestinal functioning, Feces consistency, Fiber.

THE EFFECT OF GREEN BANANA BIOMASS IN THE LIPID AND GLYCEMIC PROFILE IN SWISS MICE ON HYPERCALORIC DIET

[1]Rocha Simonin De Souza, Vagner; [2]Sardella, Julia; [2]Demetrio-Mérida, Lyris.

[1]PhD. Nutritionist. Departament of Nutrition. Redentor University; [2]Nutritionist. Redentor University.

Background and objectives: The green banana is rich in resistant starch, which has the similar effect of fiber in the prevention of chronic diseases. This study aimed to analyze the effects of the biomass of green bananas in the lipid profile and glucose in Swiss mice.

Methods: Twelve male Swiss mice were followed for 60 days, divided into three groups: (1) control (DC) normocaloric commercial diet, (2) DHC, cafeteria diet and (3) DHCB, cafeteria diet supplemented with biomass. The animals were heart puncture blood for measurement of plasma lipids and glucose. The assessment of total body fat was performed by summing the individual deposits. The lipids present in the fecal mass and liver were determined by the method of Bligh-Dyer.

Results: The group presented DHCB BMI values lower than those in DC and CLD. The content of liver fat group was higher than DHC DHCB. In addition, the DHC group also had more total body fat compared with DHCB. Plasma levels of total cholesterol, LDL-C, triglycerides and glucose, the DHC group presented

higher levels than the group DHCB. In addition, the DHC group presented a higher glucose intolerance compared with DHCB and control. The fecal lipid excretion was higher in group DHCB.

Conclusions: The biomass of green bananas to a high calorie diet supplemented gives a protection to changes caused by this diet on lipid profile and glucose Swiss mice, probably by increasing the fecal excretion of lipids.

Keywords: Green Banana, Resistant starch, Swiss mice, Hypercaloric diet.

Chile.; [6]Biologist, Ph.D. Departamento de Nutrición, Diabetes y Metabolismo. Facultad de Medicina. Pontificia Universidad Católica. Chile.; [7]M.D., Ph.D. Departamento de Nutrición, Diabetes y Metabolismo and Centro de Nutrición Molecular y Enfermedades Crónicas. Facultad de Medicina. Pontificia Universidad Católica. Chile.

Background and objectives: In recent years, new antiatherogenic mechanisms have been attributed to high density lipoproteins (HDL), including their ability to prevent lipid peroxidation, a key pathogenic process underlying a wide variety of chronic diseases. Natural antioxidant components present in certain foods are able to prevent this oxidative process. Thus, the food industry is leading a major effort to develop and increase consumption of antioxidant-enriched products for improving health and preventing disease in the general population. In Chile, approximately 10 mill. hectoliters of wine are produced per year, a process by which 20% of the total grape weight is lost as pomace waste. Red wine grape pomace (RWGP), a by-product derived from winemaking, is composed mainly of grape skin and seeds. This pomace is a valuable resource for production of fiber and antioxidant-rich flour that can be used as ingredient in the development of functional foods.

To evaluate the effect of RWGP flour consumption on the antioxidant capacity of HDL in humans.

Methods: While one group of subjects added 20 g RWGP flour/day to their usual diet for 4 months (treated group, n=12), another group consumed their usual diet during the same time (control group, n=12). Blood samples were taken from all volunteers, before and after the intervention. Plasma was used to evaluate total cholesterol content and lipoprotein cholesterol profile. In addition, antioxidant capacity of total plasma and gel filtration-purified HDL particles was determined through an in vitro fluorescence-based assay.

Results: Compared with controls, subjects who consumed a diet supplemented with RWGP flour during 4 months showed an increase in the antioxidant capacity of total plasma and purified HDL, without significant changes in total cholesterol or lipoprotein cholesterol levels.

Conclusions: Intake of RWGP flour -presumably due to its content of biologically active components- exhibits a favorable effect in vivo by improving the antioxidative functionality of HDL in humans. Thus, widespread use of this functional ingredient may be beneficial in the prevention and treatment of atherosclerotic cardiovascular disease.

EFFECT OF THE CONSUMPTION OF MORINGA OLEIFERA IN DIABETIC RATS

[1]*Piña Cruz, Rubén;* [2]*Villarruel-López, Angélica;* [2]*Vázquez-Paulino, Olga Deli;* [3]*Guerrero-Quiroz, Luis Alfonso;* [4]*López-Dela Mora, David Alejandro;* [4]*Nuño-Anguiano, Karla Janette.*

[1]Student of Nutrition Degree. University Center of Tonala. Guadalajara University. Mexico.; [2]PhD. Department of Pharmacobiology. University Center of Exact Sciences and Engineering. University of Guadalajara. Mexico.; [3]PhD. University Center of Agricultural Biological Sciences. University of Guadalajara. Mexico.; [4]PhD. Department of Health Sciences. University Center of Tonala. University of Guadalajara. México.

Background and objectives: The use of Moringa oleifera (Mo) has been evaluated in diseases such as Diabetes mellitus for its possible ability to lower glucose concentration as it contains

polyphenols (quercetin, kaempferol, glucosides). However, most studies have been done with the extract of the plant, which does not reflect the actual way of consumption as the population consumes it in powder.

Evaluate Mo powder to study the effects on glucose, triglycerides, Cholesterol, body weight, toxicity, genotoxicity and predominance of microbiota in diabetic rats.

Methods: Four groups were established for the toxicity test: control and Mo with doses of 100, 200 and 500 mg/kg (Milligrams per kilogram of weight) respectively, which were used for the micronucleus count in erythrocytes. Another 5 groups were used for the diabetic model. In addition, glucose, body weight, triglycerides, cholesterol, HDL and LDL were measured. Histological sections of the liver, intestine and kidney were performed to observe any abnormalities. Finally, the number of enterobacteria before and after Mo consumption was monitored.

Results: No significant difference was found between the amount of micronucleus on control group with groups administered with Mo. There were no adverse effects at any of the doses, so no signs of toxicity were found. A slight tendency to decrease glucose was observed with the Mo groups. As well we observed weight gain in diabetic groups that were not treated with Mo. Similar results were obtained for measurements of triglycerides, cholesterol, LDL and HDL. In intestinal microbiota no differences were observed between the Mo groups and control group. Histologically, no abnormal change was observed in the administered groups with Mo in comparison with control group.

Conclusions: The consumption of Mo powder at high or low doses did not represent a risk in the experimental model. Previous studies have shown that consuming of Mo helps lower blood glucose. However, in the present study the decrease was not significant. The consumption of Mo powder could function as an adjuvant in lowering cholesterol and triglycerides. It is required to compare the consumption of Mo powder and the Mo extract to evaluate the hypoglycaemic properties.

EFFECT OF REGULAR INGESTION OF GREEN BANANA FLOUR IN RISK FACTORS FOR METABOLIC SYNDROME IN SERVERS OF A FEDERAL UNIVERSITY

[1]Basile, Lívia; [1]Lima, Cláudia; [2]Oliveira, Karoline; [3]Cassuya, Candida; [4]Cruz, Analia.

[1]PhD. Nutritionist. Nutrition Course. Federal University of Grande Dourados. Brazil.; [2]Student. Nutrition Course. Federal University of Grande Dourados. Brazil.; [3]PhD. Pharmaceutical. Nutrition Course. Federal University of Grande Dourados. Brazil.; [4]Technique in nursing. Nutrition Course. Federal University of Grande Dourados. Brazil.

Background and objectives: Some studies have reported the beneficial effects of green banana on diseases such as diabetes, dyslipidemia and cardiovascular disease. The objective of the present study was to evaluate the influence of regular consumption of green banana flour on risk factors associated with the metabolic syndrome.

Methods: The study group consisted of 44 servers from a federal university, of which 23 were from the Green Banana Flour Group and 21 from the Control Group. The individuals in the Green Banana Flour Group consumed two tablespoons per day of green banana flour, and those in the Control Group consumed two tablespoons per day of cassava flour in the main meals, for eight weeks. Nutritional assessment was performed with measures of weight, height and waist circumference, three 24-hour recalls, and biochemical tests of total cholesterol and fractions, triglycerides, fasting glucose, insulin, homocysteine and C-reactive protein, before and after consumption of flours. Systemic blood pressure was also measured. Statistical analysis was performed using Student's t-test and paired t-test, with a significance level of 5%. The research was approved by the Ethics Committee in Research of the Federal University of Grande Dourados, for the protocol nº 1.074.863, 06/11/2015.

Results: There was no significant difference between the baseline clinical characteristics of subjects in both groups. It was observed that after the consumption of green banana flour, individuals had a significant reduction of total cholesterol (-6.8%) and LDL cholesterol (-10.4%), and increased fiber intake (33.1%). There was no significant difference in the anthropometric variables and in the systemic blood pressure in both groups, after the consumption of the flours.

Conclusions: It was concluded that although green banana flour did not collaborate to reduce risk factors associated with the metabolic syndrome, it presented important contributions to the health of the individuals, such as reduction of plasma levels of total cholesterol and LDL cholesterol and increased consumption of fibers, and may play an important role in disease prevention, especially dyslipidemias and cardiovascular diseases.

RESEARCH IN ANALYTICAL CHEMISTRY APPLIED TO NUTRITION AS A TOOL IN TEACHING

[1]López-Donado, Lorena; [2]Saldaña, Dulce; [2]Vargas, Rodrigo.

[1]MSc. Nutritionist. School of Nutrition. Faculty of Medicine and Health Sciences. Mariano Galvez University. Guatemala.; [2]MSc. Pharmaceutical chemist. Professor. Faculty of Medicine and Health Sciences. Mariano Galvez University. Guatemala.

Background and objectives: The Faculty of Medical Sciences and Health of the Mariano Gálvez University of Guatemala provides the student with high quality laboratories with state-of-the-art technology that enables productive teaching and research development. Research provides the opportunity to develop competencies for the execution of research projects that seek the resolution of health and nutrition problems of the country.

The objective was to promote creativity as well as motivate the development of applied research in the field of nutrition.

Methods: The research developed during the course of Analytical Chemistry applied to Nutrition, are carried out with the equipment, reagents and supplies provided by the university. The laboratories have equipment to perform the following procedures: potentiometry, gas chromatography and high performance liquid chromatography, among others. Minor laboratory equipment and a variety of glassware including Soxhlet equipment are also used to develop these processes. The research is carried out in 3 stages, generating a preliminary project, followed by a protocol, and finally, the student has at his disposal the laboratory to develop the experimental part and final report.

Results: Six research projects were developed to determine important analytes in the selected foods taking care of the technical quality of the processes.

The students who have taken part in the Analytical Chemistry applied to Nutrition have excelled in different areas: 3 students have presented their results by means of posters at the scientific fair of the Faculty of Medical Sciences and Health of the university; a student has been involved as part of the scientific team of a co-financing project of the National Secretariat of Science and Technology and a student has been inclined to develop his ad gradum thesis on analytical chemistry topics.

Conclusions: The experiences in the course of Analytical Chemistry applied to Nutrition demonstrate the importance of promoting curiosity, as well as encouraging students to formulate research proposals, from the formulation of questions related to the subjects of the regular courses, which are taught in undergraduate medical science and health care.

Biochemistry & Molecular Biology II, School of Pharmacy, and Institute of Nutrition and Food Technology "José Mataix", Biomedical Research Center, University of Granada, Spain.

Background and objectives: Intestinal microbiota (IM) plays a central role in the host's health and, consequently, control of the IM is a priority to prevent a plethora of health issues. Probiotics are used in the treatment of diverse pathologies. However, evidences of their capacity to influence the IM is scarce. The aim of this work was to investigate the effects of Lactobacillus paracasei CNCM I-4034, Lactobacillus rhamnosus CNCM I-4036 and Bifidobacterium breve CNCM I-4035 on the IM of genetically obese rats.

Methods: Forty-eight obese Zucker-Leprfa/fa rats and 16 Zucker-lean+/fa rats were used. Eight obese and 8 lean rats were

sacrificed as baseline. The remaining 40 obese rats were randomly assigned to receive one of the 3 probiotic strains, a mixture of L. paracasei and B. breve, or a placebo by oral administration each day for 30 days. An additional group of 8 lean rats received placebo for 30 days. Fecal samples were taken to perform fluorescence in situ hybridization (FISH) and 16S rRNA gene pyrosequencing.

Results: FISH analysis showed significant increases in the Bacteroides genus in the rats treated with the mixture of B. breve and L. rhamnosus, and the Atopobium cluster in the B. breve group. Pyrosequencing analysis showed: 1) an increase in the Marinilabiaceae and Streptococcaceae families in the rats fed the mixture; 2) a decrease in the Lactobacillales order in the B. breve group; 3) a decrease in the Anaerostipes genus in the L. paracasei group; 4) a decrease in the Parabacteroides genus in the L. rhamnosus group. An increase in the relative abundance of the Parabacteroides and Lactobacillus genera together with a decrease in the Prevotella and Lactococcus genera were found in the obese rats fed the placebo.

Conclusions: These probiotic strains are capable of modifying the IM of genetically obese rats.

Keywords: Obesity, Probiotics, Intestinal microbiota

Costa Rica Institute of Technology. Cartago. Costa Rica.; [2]School of Biology. Costa Rica Institute of Technology. Cartago. Costa Rica.; [3]BTA. Division of Biofunctionality and Safety of Food. Institute of Biological Chemistry and Nutrition. University of Hohenheim. D-70599. Stuttgart. Germany.; [4]MSc. Division of Biofunctionality and Safety of Food. Institute of Biological Chemistry and Nutrition. University of Hohenheim. D-70599. Stuttgart. Germany.; [5]PhD. MD. Institute of Physiology. Department of Vegetative and Clinical Physiology. Medical University Hospital. Tuebingen. Germany.; [6]PhD. Division of Biofunctionality and Safety of Food. Institute of Biological Chemistry and Nutrition. University of Hohenheim. D-70599. Stuttgart. Germany.

Background and objectives: 6-Prenylnaringenin (6-PN) and 8-prenylnaringenin (8-PN) are prenylflavonoids predominantly found in hops (Humulus lupulus L.) and beer, with potential health-promoting properties. Their oral bioavailability in humans is low and limits their development for clinical applications. The aim of this study was to compare the apparent permeability coefficient (Papp) of both 6-PN and 8-PN using the transepithelial transport experiment with Caco-2 cells, a well described in vitro model of intestinal absorption, which can be correlated to in vivo absorption in humans.

Methods: Caco-2 cells were grown in permeable membrane inserts until enterocytic differentiation. The integrity of the epithelium was confirmed by testing the transepithelial electrical resistance and Lucifer Yellow permeability. The monolayers were incubated with 100 μmol/L 6-PN or 8-PN in the apical chamber, and the apical (lumen) to basolateral (systemic) transport of 6-PN and 8-PN was determined by HPLC. Prenylflavonoid concentrations in the apical chamber and inside the cells were also measured at the end of the experiment. Papp was calculated for both free and total (after deconjugation with β-glucuronidase/sulfatase) prenylflavonoid concentrations.

Results: The Papp of 8-PN was significantly higher than for 6-PN, but only when comparing the concentrations after enzymatic de-conjugation and not when comparing the free compound alone. Moreover, Papp of total 6-PN ($8.4\pm0.7\times10^{-6}$ cm/s) and total 8-PN ($2.4\pm0.4\times10^{-5}$ cm/s) were 12.7 and 38.7-fold higher than Papp of the free compound, respectively. Of the initial dose, only up to 8% total 6-PN and 25% total 8-PN were recovered in the basolateral chamber. Both compounds displayed evidence of considerable efflux of metabolites towards the apical chamber and abundant accumulation of the free substance in the enterocytes.

Conclusions: The prenylflavonoids 6-PN and 8-PN exhibited low intestinal permeability in vitro, with less than 1% transepithelial transport of the compounds in the free form. In addition, the significantly lower Papp for 6-PN suggests that prenylation at carbon-6 may result in decreased bioavailability of this compound in comparison to its positional isomer 8-PN. Further research should focus on the search for alternatives to improve the bioavailability of these bioactive prenylflavonoids.

Keywords: 6-prenylnaringenin, 8-prenylnaringenin, Humulus lupulus, Caco-2 cells, Apparent permeability.

INFLUENCE OF THE CONSUMPTION OF THREE VARIETIES OF QUINOA (CHENOPODIUM QUINOA WILLD.) ON ADIPOSO TISSUE AND INTESTINAL HISTOMORPHOMETRY IN OBESES RATS

[1]*Bernuy Osorio, Nataly Dolores;* [2]*Vílchez Perales, Carlos.*

[1]MSc. Nutrition. Department of Nutrition. Universidad Nacional Agraria La Molina. Peru.; [2]PhD. Professor. Department of Nutrition. Universidad Nacional Agraria La Molina. Peru.

Background and objectives: The presence of bioactive compounds in fruits and vegetables has been demonstrated and their effects in the treatment and prevention of diseases such as cancer, stroke, etc, has also been demonstrated. Compounds such as flavonoids and phenolic acids have been found in quinoa, however, its effects have not yet been studied in vivo tests. The aim of this study was to determine the effect of the inclusion of three varieties of quinoa (Chenopodium quinoa Willd.) in an obesogenic diets on the accumulation of adipose tissue and intestinal histomorphometry in obese rats.

Methods: 42 adult obese Holtzman male rats divided into seven groups, of six animals each, were used. With the exception of one group (Control), the others were fed - during 23 days – one of the six diets containing 20% of Altiplano, Pasankalla and Negra Collana quinoas, either boiled or roasted. At the end of the feeding period all the animals were sacrificed and the visceral (VF) and abdominal (AF) fats were weighed. Samples of liver and small intestine (SI) were taken and stored (-20°C) for further analysis of thiobarbituric acid reactive substances (TBARS), and histomorphometry of SI (height, width, area, crypt depth and goblet cells). Data were submitted to ANOVA using MLG under a completely randomized design with 2x2 factorial arrangement + Control; and comparison of means by Fisher test using the MINITAB statistical program.

Results: Visceral and abdominal fats, lipid peroxidation and histomorphometry of SI were not affected significantly (P>0.05) by dietary treatments; however, lipid peroxidation in liver tissues of rats that consumed quinoa-containing diets were significantly lower (P<0.05) than those of the control diet.

Conclusions: Feeding obese rats with diets containing different varieties of processed quinoa do not affect VF or AF accumulation and histomorphometry of SI; however, it affects lipid peroxidation (TBARS values), particularly in liver tissues.

Keywords: Quinoa, Lipid peroxidation, Adipose tissue, Histomorphometry.

Conflict of Interest Disclosure: The authors of this communication declare that they have no conflict of interest.

INFLUENCE OF THE INCLUSION OF PEEL OR FLESH OF TWO VARIETIES OF POTATO (SOLANUM TUBEROSUM SSP) ON FAT TISSUE AND OXIDATIVE STRESS IN OBESE RATS

[1]*Ortiz, Viviana;* [2]*Vilchez, Carlos.*

[1]MSc. Nutritionist. Department of Nutrition.Universidad Agraria La Molina. Peru; [2]PhD. Professor Department of Nutrition. Universidad Agraria La Molina. Peru.

Background and objectives: Obesity is a chronic inflammatory disease trigger the release of non-esterified fatty acids and increases oxidative stress (OE), with the risk of developing cardiovascular diseases and atherosclerosis, among others, and to reduce the damage it is suggested to increase the consumption of antioxidants from functional foods, which possess bioactive compounds (BC) that exert protective effect against EO. The potato has BC and its content differs among varieties and part of the tubercle, with a higher concentration in the peel than in flesh. These findings show the need for studies using experimental animals. The aim was to determine the effect of the inclusion of peel or flesh of two varieties of potato, Yungay (Y) and Canchan (C) on the accumulation of adipose tissue and oxidative stress in obese rats.

Methods: 24 obese Holtzman male rats were divided into four groups of six rats each. Each group was fed - during 28 days - one of the four diets that contained 10% of peel or flesh of the Y or C variety. At the end of the feeding period, all the animals were sacrificed. The weights of visceral and abdominal fat were recorded; liver samples were taken to measure the antioxidant status by the SOD (superoxide dismutase) and CAT (catalase) activities. The data were subjected to ANOVA under a Completely Randomized Design with 2x2 factorial arrangements and the comparison of means by the Fisher Test using the MINITAB statistical program.

Results: Dietary treatments did not affect (P>0.05) visceral and abdominal fat tissue weights. The Yungay variety had a highly significant effect (P<0.01) on the enzymatic activity of CAT and it showed significant interaction (P<0.05) for the diet with flesh of Yungay. Also, the SOD variable presents a very significant interaction (P<0.01) between variety and part of potato, being higher in the diet with flesh of the variety Yungay.

Conclusions: Diets with peel or flesh of potato varieties do not decrease the accumulation of visceral or abdominal fat tissue in experimental animals. The flesh of the Yungay variety promotes better enzymatic activities of catalase and superoxide dismutase in the liver.

Keywords: Potatoes, Rats, Oxidative stress, Adipose tissue.

FAST HISTAMINE QUANTIFICATION IN TILAPIA FILLETS USING INFRARED SPECTROSCOPY

[1]Caso Vargas, Luis Ramiro; [2]Delgado Macuil, Raúl; [3]Leslie Susana, Arcila Lozano.

[1]PhD. Biotechnologist. Tecnologías Emergentes y Sustentabilidad-Complejo Mixteca. Benemérita Universidad Autónoma de Puebla.; [2]PhD. Optoelectronic. Centro de Investigación en Biotecnología Aplicada. Instituto Politécnico Nacional; [3]PhD. Biotechnologist. Centro de Investigación en Biotecnología Aplicada. Instituto Politécnico Nacional.

Background and objectives: Histamine is a biogenic amine synthetized by food spoiling bacteria that exhibit L-histamine decarboxylase activity. Within biogenic amines it is the one with the highest toxicity level, followed by: tyramine, tryptamine, phenethylamine and cadaverine, respectively. Its major incidence it's in fish and food with high contents of the amino acid histidine. It is known that when ingested in doses greater than 50mg/100g, it causes scombroid poisoning, a food borne illness with severe allergic-like symptoms. In order to detect it, chromatographic methods have been used but most of them are time consuming. In this work, we develop a fast method to detect and quantify histamine in tilapia fillets without sample extraction, derivatization nor chromatographic runs, using infrared spectroscopy (FT-IR).

Methods: The frozen tilapia fillets were purchased in the supermarket and immediately transferred to the laboratory in a cooler. They were thawed and washed using deionized water. The initial histamine concentration was determined by HPLC using a calibration curve from 1 to 1,000ppm (7 points, each point by triplicate). For the FT-IR analysis, 45 grams of fillet were doped with Histamine·2HCl as free base at: 1, 5, 10, 50, 100, 200, 500, 1000ppm and homogenized. The doped tilapia samples were deposited then on the ATR crystal and measured in the IR-medium region five times each. The quantification model was performed by partial least squares (PLS) using the 1484 to 1054 cm^{-1} and 909 cm^{-1} region which showed spectral variation according to histamine concentration.

Results: The most accurate model was the one that obtained a RMSEC = 2.17 and a r^2= 0.994, as well as a RMSEP = 4.89 and r^2 = 0.9983 (10 factors). The optimal range for histamine quantification was determined to be between 10 and 200 ppm, which is desirable because international regulations often allow a maximum of 100ppm for unprocessed fish and 200ppm for processed fish, respectively; excepting the US (50ppm). Using this technique, it is also possible to reduce the analysis time from several hours to only 10 minutes.

Conclusions: Infrared spectroscopy can be a fast and reliable technique to detect and quantify histamine in tilapia fillets.

Keywords: Histamine, Tilapia, Infrared spectroscopy, Partial-Least Squares regression.

Federal University of Rio Grande do Norte. Brazil.

Background and objectives: Modern society food habits have caused an increase in the incidence of non communicable chronic diseases (NCD). Although these food habits present diversity, they are mostly associated with obesiogenic metabolic disorders. Growing consumption of industrialized foods with high glycemic index and caloric density has increased the incidence of obesity-related diseases, commonly a result of metabolic disorders induced by diet. Thus, the objective of this study is to investigate the effect of diet on the parameters involved in the genesis of these complex sets of metabolic alterations. In this study an experimental diet was produced and analyzed, evaluating its effect on markers of metabolic disorders.

Methods: Two groups of adult male Wistar rats (n = 5 for each group) were feed with a standard or experimental diet for 17 weeks. Centesimal composition, glycemic index and glycemic load were determined for the experimental diet. Animals were evaluated during the experiment using abdominal perimeter and Lee index. At the end of the experiment, biochemical metabolic analysis and PPARγ mRNA expression in retroperitoenal and gonadal adipose tissue were performed.

Results: The experimental diet group presented a high glycemic index and glycemic load, increasing Lee index and abdominal perimeter of animals from the 6th week of experiment. Fasting glycaemia, triglycerides, VLDL-C, retroperitoenal and gonadal adipose tissue PPARγ expression were significantly increased in the experimental diet group in comparison to standard diet group (p < 0.05).

Conclusions: Thus, the results indicate that this diet represents a new model to induce obesity and metabolic disorders and might contribute for further studies in the field.

Keywords: Metabolic disorders. Cafeteria diet. PPARγ.

Background and objectives: Metabolic syndrome (MetS) is an obesity-based condition characterized by the presence of insulin resistance (IR), high blood pressure and dyslipidemia. MetS clinical features include endothelial dysfunction and a pro-oxidant, pro-thrombotic, inflammatory condition. Trypsin inhibitors are studied in a variety of models for their anti-obesity and anti-inflammatory bioactive properties. Our group has previously demonstrated the satietogenic effect of tamarind seed trypsin inhibitors (TTI) in eutrophic rat models and anti-inflammatory effects of other trypsin inhibitors. In this study, the objective was to evaluate the effect of TTI on satiety and inflammatory parameters in an experimental model of metabolic syndrome (MetS).

Methods: Three groups of n=5 male Wistar rats with obesity-based MetS received for 10 days one of the following: 1) Cafeteria diet; 2) Cafeteria diet + TTI (25 mg/Kg); 3) Standard diet.

Results: TTI reduced food intake in animals with MetS. Nevertheless, weight gain was not different between studied groups. IL-6 production did not differ between groups. Interestingly, TNF-α was lower in animals receiving TTI.

Conclusions: Our results corroborate the satietogenic effect of TTI in a MetS model. Furthermore, we showed that TTI added to a cafeteria diet may decrease inflammation regardless of weight loss. This puts TTI as a candidate for studies to test its effectiveness as an adjuvant in MetS treatment.

Keywords: Obesity. Cafeteria diet. TNF-α. Glycemia.

FORMULATION OF A MEAT ALTERNATIVE PRODUCT: VIENNA SAUSAGE, SOURCE OF FIBER AND HEALTHY FATS

[1]Ugarte, Mariana; [2]Landriel, Martín; [2]Bossio, Javier.

[1]Msc. Nutritionist. Bachelor's Degree on Science and Food Technology. Lanus National University. Argentina.; [2]BSc. Bachelor's degree on Science and Food Technology. Lanús National University. Argentina.

Background and objectives: There is a big demand of process foods rich in critical nutrients, just as saturated and trans fats, sodium, which is associated to the development of cardiovascular diseases, 90 % of meat food are composed by a big amount of these nutrients. The formulation of meat products can be modified by replacing traditional ingredients with healthy ones, without losing competitive or modifying organoleptic properties.

Our objective is to formulate a Viena sausage source of fiber, reduce in fats and replace saturated fats with fats rich in oleic acid. The Lanus National University is been developing several types of functional foods, with fats substitution and fortified in fiber.

Methods: Several fibers were evaluated (from carrot, wheat, citrics and inulin) regarding water retention and gelling. Afterwards two Viena saussages formulations were developed: A) "Standard": based on standard market formulation B) "Healthy alternative": with high oleic oil, and inulin with wheat fiber mix.

Pork and cow lean meat, pork fat, soybean isolate, starch, allowed stabilizers, preservatives, flavorings and colorings were used. In the second formula a mix of inulin and wheat fiber was added. The pork fat was replaced by high oleic sunflower oil.

The procedure was emulsifying the ingredients by chopping and mixing with a colloid mill, stuffed in cellulosic gut, cooking and pasteurized up to 72ºC, fast cooling, saussages peeling and vaccum packing in bags.

The bags were preserved at 8ºC during 8 weeks, every 15 days microbiological and stability tests were carried on. Finally a sensory evaluation took place with 25 judges

Results: The elaborated saussages were microbiologically suitable, with 6% of healthy fiber, 12 % of protein, 7% of total fat (5% were monounsaturated fats), the packaging did not pour, their organoleptic features were suitable and were accepted by the 90% of the judges.

Conclusions: It is suitable to use mix of vegetable fibers and specific oils for formuling healthy and competitive Viena saussages, without rising manufacturing costs too high, just $1,5 per each 6 units pack.

Keywords: Meat healthy products, Fatty acids, Saussages, Fiber.

A QUERCETIN OXIDATION PRODUCT WITH EXTREMELY POTENT ANTIOXIDANT AND CYTOPROTECTIVE PROPERTIES

[1]Fuentes, Jocelyn; [2]Atala, Elias; [2]Speisky, Hernan.

[1]PhD student. Instituto de Nutrición y Tecnología de los Alimentos (inta). Universidad de Chile; [2]Phd. Pharmacist. Nutrition and Food Technology Institute (inta). Universidad de Chile. Chile.

Background and objectives: Within the frame of our studies on the redox consequences associated with the oxidation of polyphenols, we recently reported that the oxidation of quercetin leads to the formation of a mixture of metabolites whose ROS-scavenging properties are similar to those displayed by the non-oxidized flavonoid (Food Chem. 234:479–485, 2017). In the present work we established the identity of such metabolites, isolated them and investigated their antioxidant and cytoprotective properties in cultured cells.

Methods: The identification and isolation of the metabolites was done chromatographically by means of HPLC-DAD and HPLC-ESI-MS/MS. Each metabolite was added to Hs-68 and Caco2 cells that were exposed to indomethacin or to hydrogen peroxide as ROS-generating agents. The antioxidant and cytoprotective effects of these compounds were evaluated through their dichlorodihydrofluorescin oxidation-inhibiting and LDH leakage-preventing activities, respectively.

Results: Under the chromatographic conditions employed by us, twelve major metabolites were evident. Of these, only one, identified as 2,5,7,3',4'-pentahydroxy-3,4-flavandione (FD), was able to account for the antioxidant and cytoprotective effects afforded by the whole oxidized quercetin mixture. Notably, FD exerted such effects at low nanomolar concentrations (1-10 nM), revealing that its antioxidant and cytoprotective potency is three-to-four orders of magnitude greater than that of quercetin (which was effective only at near 10 μM concentrations). Almost identical results were seen in Hs-68 or Caco2 cells. The effects of the flavandione (5 nM) were equally seen regardless of whether this compound was added to the cells 40 min before the ROS-generating agents (namely, pre-incubated and washed-off after) or together with the latter (i.e., co-incubated during 40 min); thus, suggesting that the FD is able to early trigger antioxidant responses intracellularlly.

Conclusions: The present results demonstrate for first time that a product of quercetin oxidation is not only active in preventing cells from oxidation and lytic damage, but also reveal that in the case of the FD formed, this metabolite is three-to-four orders of magnitude more potent than quercetin. The present results strongly suggest that when it comes to the antioxidant actions of quercetin, our attention should be increasingly extended towards some of its oxidation products.

MSc.Endocrine and Metabolic Diseases Research Center. School of Medicine. University of Zulia. Maracaibo. Venezuela; [7]MD, PhD.Faculty of Medicine. University of Cordoba. Spain.

Background and objectives: There is a great interest of the industry on food components physiologically active in flaxseed, besides the hypoglycemic effect of soluble fiber. Most cereals contain a large amount of carbohydrates, among them wheat, wich is characterized by its massive consumption in many countries. With the aim of incorporating healthier consumption strategies, different technological processes have been used in order to reduce the glycemic index of these products, however, there is still controversy about the action of dietary fiber in the reduction of this indicator. In this study the glycemic index and glycemic load of three commercial wheat products were determined in healthy individuals

Methods: The glycemic index and glycemic load of three commercial wheat products were determined in 21 healthy individuals who randomly consumed 4 types of foods of 50 g of carbohydrates each: white bread (PH), whole wheat bread with flax fiber (PF), wheat tortilla without fiber (TS) and glucosed solution as reference product (SG). Fasting and post-prandial glycemia was measured at times 15, 30, 45, 60, 90 and 120 min. Insulin was measured at 0 minute and 120 min

Results: The area under the glycemia curve was lower for the three product types (PB) 13491 ± 1426 (PF) 12136 ± 1322 (TS) 13002 ± 1248 than for the reference product (SG) 14162 ± 1245. The glycemic index values PB 67.41 ± 1.2 (PF) 61.19 ± 1.4 and (TS) 66.99 ± 1.1 and glycemic load (PB) 16.31 ± 1.6; (TS) 15.11 ± 2.1 were lower for the product with fiber (PF)10.91 ± 1.1, with no difference in insulin concentration

Conclusions: This study suggests that the amount of carbohydrates and type of fiber contained in these products can be considered as intrinsic factors In their nutritional composition, capable of affecting post-ingestion glycemic response in healthy individuals.

Keywords: Glycemic index, Flax, Fiber, Wheat.

DIETARY PATTERNS, SOCIO-DEMOGRAPHIC FACTORS AND ANTHROPOMETRIC MEASUREMENTS IN ADULT NEW ZEALANDERS

[1]Beck, Kathryn; [2]Jones, Beatrix; [3]Ulah, Insha; [4]McNaughton, Sarah A; [5]Haslett, Stephen J; [6]Stonehouse, Welma.

[1]PhD. Dietitian. College of Health. Massey University. New Zealand.; [2]PhD. College of Sciences. Massey University. New Zealand.; [3]PhD. Science and Engineering Faculty. QUT. Australia.; [4]School of Exercise and Nutrition Sciences. Deakin University. Australia; [5]PhD. Statistical Consulting Unit. The Australian National University. Australia.; [6]PhD. Food and Nutrition Business Unit. CSIRO. Australia.

Background and objectives: No studies have investigated the dietary patterns of a representative sample of NZ adults. This study investigated associations between dietary patterns, socio-demographic factors and anthropometric measurements in adult New Zealanders.

Methods: Dietary patterns were identified using factor analysis in adults 15 years plus (n=4657) using 24-hour diet recall data from the 2008/09 NZ Adult Nutrition Survey. Multivariate regression was used to investigate associations between dietary patterns and age, gender and ethnicity. After controlling for demographic factors, associations between dietary patterns and food insecurity, deprivation, education, and smoking were investigated. Associations between dietary patterns and BMI and waist circumference were examined adjusting for demographic factors, smoking and energy intake.

Results: Two dietary patterns were identified. Pattern one ('healthy') was characterised by breakfast cereal, low fat milk, soy and rice milk, soup and stock, yoghurt, bananas, apples, other fruit and tea, and low intakes of pies and pastries, potato chips, white bread, takeaway foods, soft drinks, beer and wine. Pattern two ('traditional') was characterised by beef, starchy vegetables, green vegetables, carrots, tomatoes, savoury sauces, regular milk, cream, sugar, tea and coffee, and was low in takeaway foods. The 'healthy' pattern was positively associated with age, female gender, NZ European or other ethnicity, and having a secondary school qualification, and inversely associated with smoking, food insecurity, area deprivation, BMI and waist circumference. The 'traditional' pattern was positively associated with age, male gender, smoking, food insecurity and inversely associated with having a secondary school qualification.

Conclusions: 'Healthy' and 'traditional' dietary patterns were associated with socio-demographic factors and anthropometric measurements. These findings could be used to inform future nutrition interventions in adult New Zealanders

Keywords: Dietary patterns, Factor analysis, Obesity, Socio-Economic Status.

KNOWLEDGE ON NUTRITION COMPONENT OF SAFE MOTHERHOOD INITIATIVE AMONG PRIMARY HEALTH CARE WORKERS IN IBADAN NIGERIA

[1]Ahmadu, Abraham Ajigasokoa; [2]Okekunle, Akinkunmi Paul; [3]Oyewole, Oyediran; [4]Atinmo, Tola.

[1]BSc. MPH. Nutrition and Public Health Expert. Save the Children International. Nigeria.; [2]Department of Human Nutrition. University of Ibadan. Nigeria. Department of Nutrition and Food Hygiene. Harbin Medical University. PRC.; [3]Senior Lecturer. Department of Health Promotion and Education. University of Ibadan. Nigeria.; [4]Professor of Nutrition. Department of Human Nutrition. University of Ibadan. Nigeria.

Background and objectives: Maternal and child health is frequently under threat due to multifaceted challenges. The safe motherhood initiative (SMI) was designed to lessen the burden of maternal and child mortality with the primary health care workers (PHCW) as important stakeholders. We hypothesise that PHCW in Nigeria has sufficient knowledge about the nutrition component (NC) of SMI. This study aims to evaluate the knowledge on NC of SMI among PHCW in Nigeria.

Methods: 153 PHCW (from 21 Primary Health Centres across 2 local government areas) in Ibadan Nigeria identified through multi-stage sampling completed validated semi-structured questionnaires on socio-demographic characteristics, and knowledge of PHCW was assessed using a validated 101-question knowledge scale (designed based on the NC of SMI by nutrition experts) measured on a 4-point Likert scale. Knowledge score (KS) was categories as poor (≤mean KS) and good (>mean KS) and χ2 test was used to evaluate the association between level education, years of experience and level of knowledge of PHCW at p<0.05.

Results: Most PHCW (98.5%) were females, 16.9% were trained certified nurse, 18.9% had a minimum of bachelor's degree education and 22.8% had over 20 years of experience. About 27.4% of PHCW were unable to adequately define the NC of SFI, 45.7% were unable to cite the benefits of breastfeeding, 29.4% was unable to provide at least four nutritionally-related information necessary for pre-natal care. Overall mean KS of PHCW was 58.8±5.9. While 38% of certified nurses and 37.9% with a minimum of bachelor's degree education had poor knowledge, percentage of PHCW with good knowledge of NC of SMI was significantly higher (p=0.025) among PHCW with > 20 years of experience (77.1%) compared with PHCW with <20 years of experience (36.4%)

Conclusions: Knowledge on NC of SMI among PHCW is low and the year of experience is likely to influence the level of knowledge of PHCW on NC of SMI. Continous nutrition education with an emphasis on NC of SMI is necessary for PHCW in this setting.

BASELINE KNOWLEDGE OF ANAEMIA AMONG IN-SCHOOL ADOLESCENTS IN DELTA STATE, NIGERIA

[1]Ibiyeye, Eyovwerhi; [2]Okekunle, Akinkunmi Paul; [3]Sanusi, Rasaki Ajani.

[1]BSc. MPH. Graduate Student. Department of Human Nutrition. University of Ibadan. Nigeria.; [2]BSc. MPH. Graduate Student. Department of Nutrition and Food Hygiene. Harbin Medical University. China.; [3]MBBS. MSc. PhD. Reader. Department of Human Nutrition. University of Ibadan. Nigeria.

Background and objectives: Anaemia is ubiquitous yet imperceptible among adolescents, especially in developing countries. It is associated with poor cognitive and learning ability and likely risk of morbidity and mortality. Furthermore, knowledge of anaemia among adolescent in sub-Saharan African countries especially Nigeria is often under-reported in literature. In this study, we assessed the knowledge of anaemia among in-school adolescents in Delta state, South-south Nigeria.

Methods: Using a multi-stage sampling technique, 498 in-school adolescents; selected after duly informed consent from secondary schools across Delta state, Nigeria completed validated semi-structured questionnaires on socio-demographic characteristics and knowledge of anaemia was evaluated using a validated 15-point knowledge scale. Respondents were categorised as early adolescent (EA) or late adolescent (LA) by their age; 10-14years and 15-19years respectively. Also, knowledge score (KS) was categories as poor (≤mean KS) and good (>mean KS). Independent sample t and χ^2 tests at $p<0.05$ was applied to assess the relationship between age, sex and KS of respondents

Results: Mean age of respondents was 15.4±2.0 years, 44.4% were females, and mean KS was 1.8±1.1. Though KS insignificantly differed (t=-0.8, p=0.430) between males (1.8±1.1) and females (1.9±1.1), 59.2% and 40.8% of males and females respectively had poor KS (χ^2= p=0.105). In addition, KS was significantly higher (t=-2.4 p=0.012) among LA (1.9±1.2) compared to EA (1.6±1.1).

Conclusions: Most adolescents had poor knowledge of anaemia, and a nutrition education intervention would be necessary to improve the poor knowledge about anaemia among adolescents in this setting.

Keywords: Adolescent. Nutrition knowledge. Anaemia. Delta state. Nigeria.

PREDILECTION IN SELECTION OF GRUELS AS A GUIDE FOR THEIR POTENTIAL ROLE AS VEHICLES FOR NUTRIENT-SUPPLEMENTATION DURING PREGNANCY AND LACTATION IN THE WESTERN HIGHLANDS OF GUATEMALA

[1]Fuentes, Deborah; [2]Arriaga, Claudia Lorena; [3]Diaz-Ruiz, Elena; [4]Garcia-Meza, Rosario; [5]Solomons, Noel W.; [6]Hirst, Daniel; [7]Bonorden, Melissa.

[1]BSc. Nutritionist.Center for Studies of Sensory Impairment, Aging and Metabolism; [2]BSc. Chemist. Center for Studies of Sensory Impairment, Aging and Metabolism; [3]BSc. Nutritionist. Center for Studies of Sensory Impairment, Aging and Metabolism; [4]MA. Nutritionist. Center for Studies of Sensory Impairment, Aging and Metabolism.; [5]Center for Studies of Sensory Impairment, Aging and Metabolism (CeSSIAM). Guatemala City. Guatemala.; [6]MSc. Food Scientist - Product Development Hormel Foods Corporation; [7]MSc. Senior Food Scientist - Product Development Hormel Foods Corporation.

Background and objectives: Previous studies on pregnant and lactating women's diets have shown deficits in protein and micronutrient intakes, raising the question of what dietary vehicle might be appropriate for nutrient-supplementation. Thin gruels have been shown to be the hot beverage of preference in pregnancy and lactation to increase energy intake and ostensibly improve human milk production. Our objective was to identify the most frequently-selected gruels in three demographic areas of Guatemala, as possible vehicles for supplementation.

Methods: We invited women between 17-70 years of age from rural, semi-urban and urban Quetzaltenango Province to participate by bringing gruels of their choice to a sensory-testing exercise. Study procedures and objectives were explained and participation was voluntary. Women provided oral consent and were gifted with thermos-bottles to bring a gruel sample of their spontaneous selection to the test site.

Results: 13 different gruel varieties were brought by 127 women: 52 rural; 33 semi-urban; and 42 urban. Gruels prepared were (in descending order): Incaparina® (27.6%), cracked-corn (15.7%), oatmeal (15.7%), wheat germ (9.4%), pinol (8.7%), corn-dough (5.5%), rice (3.9%), corn-soy blend (CBS) (3.9%), plantain (3.1%), cornstarch (3.1%), 13-Cereals® (1.6%), sweet corn (0.9%), and Bienestarina® (0.9%). Predominant gruels by area were: cracked-corn gruel in rural area (28.8%) and Incaparina® in semi-urban (30.3%) and urban (42.9%).

Conclusions: Local culture, as well as access to ingredients, may be a factor determining the type of gruel selected, meaning they were the "available" ones, but not strictly the "favorites". A predilection for unprocessed ingredients for gruels was noted in rural settings, whereas industrially-processed gruels tended to be preferred in urban and semi-urban areas.

Keywords: Gruels, Food preference, Variety, Guatemala.

HOMESTYLES: A RANDOMIZED CONTROLLED TRIAL

Byrd-Bredbenner, Carol; Quick, Virginia; Martin-Biggers, Jennifer.

PhD. Professor. Rutgers University. New Brunswick. NJ. USA.

Background and objectives: Few interventions have aimed to enable and motivate parents to gain the skills and self-confidence needed to shape home environments and lifestyles to be protective against childhood obesity. Thus, HomeStyles, a parent-directed online intervention, was created to help parents better control factors associated with increased risk of obesity in their homes and lifestyles.

Methods: Parents completed the baseline survey and were randomly assigned to the experimental or attention control group. Both groups received instructional guides in a mini-magazine format. Guide content for the experimental group focused on diet, physical activity, and sleep. Content was home safety for the control group. After receiving 8 different guides (~1/month), parents completed the post survey. Surveys included an array of valid, reliable scales assessing cognitions and behaviors associated with childhood obesity prevention.

Results: The 172 participants (n=83 experimental; n=89 control) all had >1 child 2 to <6 years and most were female (93%), white (58%), had at least some post-secondary education (87%), and had middle-high family affluence (84%). Within group comparisons showed that between baseline and post surveys, parents and children in both study groups significantly (P<.01) increased physical activity; parents improved meal planning behaviors, meal preparation self-efficacy, healthy weight-related behaviors modeling; and decreased household availability of salty/fatty snacks. However, comparisons of baseline and post surveys revealed that only the experimental group significantly reduced total screen-time, increased family meal frequency, reduced frequency of eating meals in front of the television, increased frequency of eating meals at a dining table, reduced use of media devices and television while eating, improved self-efficacy for nearly all childhood obesity-protective behaviors, increased encouragement of children to be physically active, increased self-efficacy for getting children to be physically active, and improved values associated with modeling physical activity behaviors. ANCOVA revealed that the experimental group had better improvements in physical activity, screentime, family mealtime behaviors, self-efficacy for childhood obesity-protective behaviors, and values placed on not modeling sedentary behavior for children at post-survey than the control group.

Conclusions: The HomeStyles program for families with preschool children was effective in promoting improvements in an array of obesity-preventive cognitions and behaviors.

COMPARISON OF LIFESTYLE PATTERNS AND BODY WEIGHT MANAGEMENT PRACTICES BETWEEN NORMAL WEIGHT AND OBESE FEMALE UNIVERSITY STUDENTS (RIYADH – SAUDI ARABIA)

[1]*Alqahtani, Amera;* [1]*Alsubaie, Areej;* [2]*Alateq, Arwa;* [1]*Alsagabi, Beshair;* [1]*Aloraini, Munirah;* [1]*Benajiba, Nada.*

[1]Clinical Nutrition Program. Department of Health Sciences. College of Health and Rehabilitation Sciences, Princess Nourah Bint Abdulrahman University. Riyadh. KSA.; [2]5-Clinical Nutrition Program, Department of Health Sciences, College of Health and Rehabilitation Sciences, Princess Nourah Bint Abdulrahman University, Riyadh, KSA.

Background and objectives: Introduction: The prevalence of overweight and obesity among Saudi women is reaching 44%. Instead of adopting healthy lifestyle, this population may adopt some weight management practices (WMP) which may be unhealthy and some may lead to serious health problem

Objectives: To compare lifestyle patterns and WMP adopted by obese and normal weight Saudi females by assessing the difference in energy and macronutrients intake, dietary habits, level of physical activity and WMP.

Methods: Cross sectional study among female students at Princess Nourah Bint Abdulrahman University (PNU) (Riyadh – KSA.), 200 participants were randomly selected, assigned in two groups in obese and normal weight (each group have 100 students) depending on BMI. Data collected through questionnaire and analysis was performed using SPSS program, Chi2 and T-test were used to assess the difference between the two groups.

Results: Uunhealthy WMP were high among obese students. Total calorie intake was not different, however fat intake was significantly higher in obese group (p<0.01). Level of moderate active was significantly higher in normal group than obese group (33% versus 19%, respectively). Food frequency consumption showed that fruit, date and dressing were higher in obese group compared to normal weight group (p-value = 0.02, 0.01 and 0.03).

Conclusions: Obese PNU female students adopt unhealthy WMP besides their nutritional intake and dietary habits are not healthy. Increasing awareness about the healthy lifestyle to manage weitht is urgently needed.

THE EFFECT OF NUTRITION EDUCATION PROGRAM ON DIET QUALITY SCORES IN POLISH ADOLESCENTS: 3- AND 9-MONTH FOLLOW-UP. ABC OF HEALTHY EATING PROJECT

[1]Kowalkowska, Joanna; [2]Wadolowska, Lidia; [3]Hamulka, Jadwiga; [1]Danielewicz, Anna; [4]Kostecka, Malgorzata; [5]Jeruszka-Bielak, Marta.

[1]MSc. Nutritionist. Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland.; [2]Full Professor. Nutritionist. Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland.; [3]Professor. Nutritionist. Faculty of Human Nutrition and Consumer Sciences. Warsaw University of Life Sciences. Poland.; [4]PhD. Nutritionist. Faculty of Food Science and Biotechnology. University of Life Sciences in Lublin. Poland.; [5]PhD. Nutritionist. Faculty of Human Nutrition and Consumer Sciences. Warsaw University of Life Sciences. Poland.

Background and objectives: The impact of nutrition education programs on adolescents' dietary patterns in short- and long-time perspective is weak known [1, 2]. Objective: Assessment of the effect of nutrition education program on diet quality scores after 3- and 9-moth follow-up in Polish adolescents.

Methods: The prospective study involved 464 adolescents aged 11-13 years at baseline. Based on frequency food consumption two diet quality scores (range: 0-100 points) were established: pro-Healthy Diet Index (pHDI) included dairy products, fish, vegetables and fruit; non-Healthy Diet Index (nHDI) included fast foods, sweetened beverages, energy drinks and sweets. After 3- and 9-month follow-up changes in pHDI and nHDI were compared between 'control' group (n=145) and 'educated' group (n=319) in which one-time nutrition education program was implemented.

Results: The mean pHDI was insignificantly higher in 'educated' than 'control' group after 3-month (28.0 vs 27.3 points) and 9-month follow-up (28.9 vs 26.4 points). The mean changes in pHDI were insignificant. The mean nHDI was significantly lower in 'educated' than 'control' group after 3 months (12.4 vs 15.7 points) and 9 months (14.0 vs 16.7 points). The mean changes in nHDI were significant. After 3 months nHDI was lower by 1.8 points in 'educated' but higher by 1.1 points in 'control' group, after 9 months lower by 0.2 points and higher by 2.1 points respectively.

Conclusions: One-time nutrition education episode can reduce unhealthy dietary habits in Polish adolescents but not improve pro-healthy dietary patterns, both in short- and long-time perspective.

MATERNAL NUTRITION EDUCATION OFFERED DURING ANTENATAL, SELF-EFFICACY AND NEEDS OF MIDWIVES IN MULAGO HOSPITAL, KAMPALA, UGANDA

[1]Nankumbi, Joyce; [2]Nankumbi, Joyce; [3]Nalwadda, Gorrette.

[1]MSc. MSN. Midwife and Nutritionist. Department of Nursing, College of Health Sciences, Makerere University.Kampala. Uganda; [2]MSc.MSN. Midwife-Nutritionist.Department of Nursing, School of Health science. Makerere University.Kampala Uganda; [3]PhD. Senior Lecturer. Department of Nursing. School of Health science. Makerere University. Kampala Uganda.

Background and objectives: An adequate nutrition during gestation is an important environmental factor influencing pregnancy outcome. Maternal malnutrition during pregnancy affects the health of the mother and baby. Midwives are preferably well placed to offer nutrition education to pregnant women; however they may not be equipped with the knowledge, skills and confidence to deliver nutrition education. The aim of this study was to explore the maternal nutrition education (MNE) in a hospital setting, determine the perceived self-efficacy and identify the nutrition education needs of midwives in Mulago hospital antenatal care clinic.

Methods: The study employed an exploratory qualitative design. Six in depth interviews, 6 direct observations for group education, and 12 one on one observations of midwives and pregnant women interaction were conducted. The transcribed interviews and field observation notes were analyzed using the latent content analysis.

Results: Maternal nutrition education characteristics, self-efficacy and maternal nutrition education needs of the midwives were the emerging themes. The delivery of MNE was inadequate in scope and depth. Surprisingly, the MNE was offered to only preg-

nant women attending the first ANC visit. The routine antenatal education session lasts 45 minutes to 1 hour, covering a variety of topics but MNE is allotted minimal time (5-15 minutes). The MNE organization, mode of delivery, guidelines, materials/ resources and service environment were grossly deficient. The midwives demonstrated good communication/facilitation skills during the sessions, and highlighted the nutrient rich dietary sources, increased nutrient demand, as well as food safety and hygiene requirements. Overall midwives' MNE competences were limited and had moderate perceived nutrition education self-efficacy. Midwives were ignorant about the maternal nutrition guidelines. Relevance of appropriate weight gain during pregnancy, guidelines for healthy habits, avoidance of substance abuse and nutrition precautions in special circumstances were missing in MNE. Information, MNE resources, infrastructural, and health systems gaps were identified.

Conclusions: The scope and depth of MNE is inadequate. There are midwives, health systems related gaps for successful MNE conduct. There is need for alternative innovative MNE delivery models, and strengthening capacity of midwives in MNE.

Keywords: Maternal nutrition education, Midwives, Self-efficacy, Education needs.

IMPACT OF AWARENESS CAMPAIGNS IN LOWERING SODIUM LEVELS IN COMMERCIAL WHITE BREAD IN MOROCCO

[1]Derouiche, Abdelfettah; [2]El-Kardi, Younes; [3]Farhloul, Fatima-Zahra; [4]Mokhantar, Khaoula; [5]Jafri, Ali.

[1]PhD. Professor. Ben M'Sik Faculty of Science. University Hassan II of Casablanca. Morocco.; [2]MSc. PhD Researcher. Ben M'Sik Faculty of Science. University Hassan II of Casablanca. Morocco.; [3]BSc. Master Student. Ben M'Sik Faculty of Science. University Hassan II of Casablanca. Morocco.; [4]MSc. Master Delegate. Ben M'Sik Faculty of Science. University Hassan II of Casablanca. Morocco.; [5]PhD. Post-Doctoral Fellow. Ben M'Sik Faculty of Science. University Hassan II of Casablanca. Morocco.

Background and objectives: Sodium over-consumption is closely linked to hypertension, stroke and other cardiovascular diseases (CVD). According to the World Heath Organization's estimates, hypertension prevalence Morocco exceeds 30%, and could be responsible, with other CVD, of 34% mortalities in the country. Bread is one of the most important sources of sodium in several countries, including Morocco. This study aims to assess the impact of 5 years of awareness campaigns (2011 – 2016) in reducing the quantity of sodium chloride used in preparing commercial white bread, and in improving nutritional knowledge and practices related to sodium.

Methods: Nutritional knowledge, attitudes and practices (KAP) about sodium were assessed using a questionnaire in interviews with 418 bakeries in Casablanca, Morocco. The questionnaire covered topics on the consequences of sodium over-consumption and recommended daily intake. The quantity of sodium chloride in commercial white bread was measured using Mohr's titration method. Bread samples were collected and analyzed from 160 bakeries in 2011 and 2016.

Results: The KAP survey revealed that most professional bakers are not familiar with the campaign (73%) of salt reduction and do not have sufficient information about the recommendations (78%). Still, 72.8% were committed to start reducing added sodium during the preparation of bread. Among the bakers who are familiar with the campaign (27%), up to 14.5% reduced sodium chloride by 33% (from 15 to 10 grams of sodium chloride per kilogram of flour). Analysis of white bread revealed that added sodium chloride decreased from 17.8 g/kg in 2011 to 13.1 g/kg in 2016, which is equivalent to a decrease of more than 25% over five years (0.94 g per year). Still, sodium chloride levels are very different between bakeries (10.5 to 19.6 g/kg).

Conclusions: This study highlights the effectiveness of awareness campaigns and the importance of involving the targeted stakeholders and industry professionals. Although the campaign did not reach all the targeted audience, results show that it was effective among those it reached. More efforts should be invested in involving as much as possible in order to have a more balanced sodium intake.

TO DESIGN AND TEST EFFICACY OF SCIENTIFICALLY AND CULTURALLY APPROPRIATE, COMPREHENSIVE NUTRITION AND HEALTH COMMUNICATION PACKAGE FOR RURAL NULLIPAROUS MARRIED WOMEN OF NORTHERN INDIA TO ADDRESS A W

[1]Misra, Puneet; [2]Kant, Shashi; [2]Anand, Krishnan; [2]rai, sanjay.

[1]MD. MPH. Professor. CCM. AIIMS. New Delhi. India; [2]MD. Professor. CCM. AIIMS. New Delhi. India.

Background and objectives: Lot of work has been done to reduce LBW and IMR by giving nutritional supplements to pregnant females, but almost no work has been done to address the pre pregnancy issues to deal with this problem, which is more important from health point of view. The study is designed with objective to test an innovative evidence-based package to break the cycle of low birth weight, and high infant mortality. This study

is also innovative in being directed at a population sub-group that has not been targeted

Methods: Study was done at rural field practice area of AIIMS, New Delhi, India. All newly married nulliparous females in selected area were included. More than 700 hundred females were recruited for the study. Intervention and Control area was selected randomly. Intervention was given in form of health education, nutritional education, demonstration of preparation of low cost culturally appropriate food, involvement of grass root level workers, health functionaries, local volunteers etc. Data was collected after one year of follow up

Results: The results after intervention were found to be significant and there was increase in the overall knowledge of females of intervention group. There was observed difference in the knowledge attitude and practices of the females before and after intervention.

Conclusions: Such interventions will lead to better maternal and child health. It will help in breaking the cycle of poor maternal health and thus low birth weight which is a major cause for high infant mortality. We expect to have positive effect of this intervention on women itself and their babies. This is going to influence and will help mothers form a basis for good nutrition to be followed in later years.

Keywords: Low birth weight, nutrition package

A STUDY OF CHANGES IN FOOD PREFERENCES

Ueda, Reiko.

PhD. R.D. Professor. Department of Early Childhood Education and Nursing. Faculty of Education and Human Sciences. Teikyo University of Science. Japan.

Background and objectives: To identify effective nutrition education ("shokuiku" in Japanese) strategies for preventing picky eating, a survey was conducted to determine changes in food preferences.

Methods: A questionnaire survey to assess changes in food preferences was administered to 1,192 university students living in Tokyo between April and July 2016.

Results: The students' favorite foods were as follows: chicken, strawberries, eggs, beef, white rice and pork. The students' least favorite foods were as follows: tomatoes, green peppers, celery, carrots and liver. The foods that the students disliked as children but grew to like as they got older are as follows: green peppers, eggplants, tomatoes, natto (fermented soybeans) and carrots. The reasons for growing to like these disliked foods were as follows: i) natural with age (aging); ii) refused to eat it because they disliked the appearance (visual aversion); iii) enjoyed the taste once they tried (aversion without even trying); iv) disliked the texture but grew to like it once they forced themselves to eat it; and v) learned of the health and beauty benefits. The foods that the students liked as children but grew to dislike as they got older are as follows (in order of least preference): natto, tomatoes, carrots, raw fish and shrimp. The reasons for growing to dislike these foods were as follows: i) overeating; ii) unpleasant experiences such as diarrhea and vomiting after eating; and iii) decreased appreciation for fatty foods due to aging.

Conclusions: The results of the present study suggest that the following methods could effectively eliminate food dislikes: i) sit back and wait for growth; ii) prepare visually appealing and appetizing foods; iii) provide health information, and iv) encourage eating even if it is only a small amount (for continued consumption). In addition, to prevent people from developing aversions to foods they once liked, overeating should be avoided.

Keywords: Food Preferences, Aging, Overeating, Shokuiku.

Further collaborators: Special thanks to the students who answered to the questionnaires.

CONSUMPTION OF FOOD NOT SUPPLIED BY HOSPITAL IN A PEDIATRIC ONCOLOGY UNIT

[1]*Behling, Estela;* [2]*Martins de Lima, Thaiane.*

[1]PhD. Professor. Departament of Nutrition. Faculdade de Medicina. Universidade Federal do Rio Grande do Sul. Porto Alegre. Brazil.; [2]Nutricionist. Residência Integrada Multiprofissional em Saúde. Hospital das Clínicas de Porto Alegre. Porto Alegre. Brazil.

Background and objectives: The impact of a good or bad nutrition, allowing appropriate physical and cognitive development is already widely described in the literature. In the specific case of pediatric cancer patients, it is important not only for adequate physiological development but also for nutrition as a means of assisting in the maintenance of appropriate physical conditions to transcend the various phases of chemotherapy, surgery and/ or radiotherapy., As well as supply the demands of the disease itself. Based on this, the hospital diet is elaborated, not only with the purpose of providing the necessary nutrients to these patients, but also, an adequate microbiological condition, emphasizing hygienic-sanitary food quality. In view of the current lack of research on the subject, specifically with immunosuppressed patients, the present study aimed to evaluate the consumption of foods not provided by the hospital for patients of a Pediatric Oncology Unit.

Methods: It was an observational, cross-sectional study whose data collection instrument was applied between March and October 2016. This study included legal guardians of patients treated in this Pediatric Oncology Unit for at least seven days and with the oral feeding as the main route of feeding. Those legal guardians of patients receiving an exclusive palliative care or of patients in an exclusive breastfeeding were excluded from the study.

Results: Thirty-two responsible were interviewed, 26 (81.25%) of those reported that they had been advised about the risks of offering non hospital food to the patient; however, 31 (96.87%) reported that the patient for whom they were responsible had already consumed some food not provided by the hospital. Also, when asked

about the types of food offered to these patients, the category encompassing candies and/or snacks was the most cited (32.4%).

Conclusions: Thus, it is suggested that although they had receive guidance, there was not necessarily an appropriation and understanding, showing the necessity to implement effective practices of continued nutritional education, aiming the co-responsibility of patients and their families.

ANALYSIS OF THE PRESENCE OF TERMS SUCH AS HOMEMADE, TRADITIONAL AND SIMILAR TERMS IN LABELS OF INDUSTRIALIZED FOOD PRODUCTS COMMERCIALIZED IN BRAZIL

[1]*Uggioni, Paula;* [2]*Muller, Jessica;* [2]*Machado, Priscila Pereira;* [2]*Santos, Andreia Martins dos.*

[1]PhD. Assistente Professor. Dept. of Nutrition. Nutrition Postgraduate Programme of Federal University of Santa Catarina; [2]Nutritionist.

Background and objectives: Contemporary Western nutrition has been characterized, at the same time, by the increase in the consumption of industrialized food products and the increase in the consumers' interest in traditional food products. The presence of terms such as homemade, traditional, and others in food labels are not foreseen in the Brazilian legislation on food labeling, since such terms may mislead consumers in relation to the real nature or origin of the product. The present study aimed at identifying the use of terms such as homemade, traditional, original, and others in the labels of industrialized food products in Brazil.

Methods: For this purpose, food labels (front panel) of all the industrialized products available for purchase in a supermarket that belongs to one of the ten greatest supermarket chains in Brazil were analyzed. The total frequency of the terms by food groups according to the Collegiate Directive Resolution (RDC 359/2003) was observed.

Results: From the total of food products, 14.1% (N=778) presented terms in the labels. Terms related to brand age or product age, in different languages, were found with a frequency of 58.1% of labels (N=495), followed by the terms traditional with 20.1% (N=175) and original with 11.0% (N=94) of the labels analyzed. In relation to food groups, group I (bakery products) and II (vegetables and bottled vegetables) presented a higher relative frequency, both with 21.4%.

Conclusions: Findings indicate the frequent commercialization of industrialized products with terms that refer to a more traditional or homemade manufacturing method with local ingredients. In this respect, results highlight that the information contained in food labels ought to be clear and correct, so that the consumer is able to make his own conscious choice on food.

SURVEY ON FOOD AND HEALTH OF JAPANESE BRAZILIAN (NIKKEIJIN)

[1]*Ishii, Satomi;* [2]*Kajita, Rutsuko;* [3]*Otani, Shizue;* [4]*Masumoto, Simone;* [4]*Okamoto, Carmen;* [4]*Ucida Watanabe, Erica.*

Affiliation: [1]PhD; [2]Rakuno Gakuen University Graduate Student; [3]Rakuno Gakuen University JICA Trainee; [4]Hospital Nipo-Brasileiro Nutritionist.

Background and objectives: It is generally known that the content of daily meal is greatly affect the human health. Today, the average life expectancy of the Japanese people is 83.7 years, which is the world's longest longevity. Those for Brazilian peoples are 75 years. Japanese migration to Brazil began in 1908. The main objective of this study is to determine the relationship between food and health in people of Japanese ancestry living in Brazil.

Methods: For this reason, 30 Nikkeijin living in Sao Paulo and 28 workers of Japanese descent that came from Brazil to Japan, residents of Ibaraki Prefecture, were interviewed, using questionnaire and surveyed for the content of daily meal.

Results: The average age of Nikkeijin residing in Brazil was 50 years, and the average age of Nikkei residents living in Japan was 33 years. There were many elderly Nikkeijin living alone in Brazil, and those who live in Japan were also lived alone.

For the both groups of Nikkeijin the rice was most commonly eating Japanese food.

Eating habit of the Nikkeijin living in Japan was the Brazilian style, but drinking miso soup was also high. The favorite Japanese food was Sushi and Ramen (Chinese noodles) for those living in Japan. It was characteristic that in comparison with Japanese, the diet of Japanese Brazilian people was that they eat more meat, use more oil and have less intake of fresh vegetables. Salt was mostly used for seasoning.

The amount of sugar ingested from sweets and drinks was high, and accordingly energy intake was also high. Residents in both regions had higher blood pressure and obesity.

Conclusions: There is a possibility that illnesses of Nikkeijin who migrated to Brazil and assimilated into a Brazilian style eating with fatty and meat-rich diet may indicate the future disease trend of Japanese.

FOOD CONSUMPTION PATTERNS IN ADULT WORKERS OF AN ELECTRONIC COMPANY IN ZAPOPAN, MEXICO

[1]López-Uriarte, Patricia Josefina; [2]Vazquez-Aguilar, Laura Alejandra; [3]Márquez Sandoval, Yolanda Fabiola; [4]Magaña Gonzalez, Claudia Rocio.

[1]PhD. Nutritionist. Centre of Research in Food Behavior and Nutrition. University of Guadalajara. Zapotlán el Grande, Jalisco. Mexico; [2]MD. Nutritionist. University of Specialties. Guadalajara, Mexico.; [3]PhD. Nutritionist. Department of Human Reproduction, Growth and Child Development. Center of Health Sciences. University of Guadalajara. Mexico; [4]PhD. Anthropologist. Centre of Research in Food Behavior and Nutrition. University of Guadalajara. Zapotlán el Grande, Jalisco. Mexico.

Background and objectives: The study of food consumption patterns has advantages over the conventional dietary studies, since it allows a global evaluation of consumption of different type of diets and its effect on health. The objective was to describe the food consumption patterns identified in a group of adult workers of an electronic company.

Methods: A cross-sectional study was realized in 165 workers. Sociodemographic and clinical data were obtained through personal interviews. Weight, height and body mass index were measured. A food consumption frequency questionnaire was applied and blood samples were collected. Data were grouped by sex and BMI to obtain descriptive and analytical statistics. Principal component analysis was used to determine patterns of food consumption.

Results: 74.5% of the sample were women (25.5%, men) averaged on 39.9 years. 78.2% of participants were overweight or obese. Significant differences were observed between BMI (normal weight, overweight, obesity) and consumption of: ethanol (p=0.02); iron(p=0.01); very low-fat animal food (p=0.04); total sugars and fat-free sugars (p=<0.01) and alcoholic beverages (p=0.009). Four main patterns of food consumption were identified through principal component analysis: 1) healthy, 2) heterogeneous, 3) whole dairy food/sweet pastry, and 4) red meat/processed foods.

Conclusions: The diversity of patterns of food consumption identified shows different ways of eating and drinking of this group of workers, as they eat a wide variety of foods and beverages, sometimes healthier or less healthy, which would contribute to explain in part, their food behavior, which could have an impact on health.

Keywords: Food patterns, Workers, Food consumption.

IMPROVED COMPLEMENTARY FEEDING PRACTICES IN THE SELECTED AREA OF DHAKA CITY

[1]Akter, Ferdausy; [2]Hossain, Mariam; [2]Roy, Medha; [2]Khatun, Mahfuza; [3]Sultana, Moffashara; [4]Jahan, Khurshid; [5]Akter, Syeda Mahsina; [6]Roy, Swapan Kumar.

[1]BSc. Food & Nutrition. College of Home Economics. University of Dhaka. Bangladesh; [2]BSc. Food & Nutrition. College of Home Economics. University of Dhaka. Bangladesh.; [3]MSc. Assistant Professor. Dept. of Food & Nutrition. College of Home Economics. University of Dhaka. Bangladesh.; [4]MSc. Director. Bangladesh Breastfeeding Foundation. Bangladesh.; [5]MSc. Assistant Director. Bangladesh Breastfeeding Foundation. Bangladesh.; [6]MBBS, MSc, Dip in Biotech, PhD, FRCP, Senior Scientist, Chairperson, Board of Trustees Bangladesh Breastfeeding Foundation. Chairperson Nutrition Foundation. Bangladesh.

Background and objectives: According to Bangladesh DHS 2014, 23% children of 6-23 months properly feed complimentary food (minimum acceptable diet). The main objective of the study was to improve the complementary feeding (CF) practice through nutrition education and to see the effect of five selected improved homemade CF recipes on behavioral practice of CF.

Methods: A community based randomized controlled trial was conducted for 3 months among 130 children aged 6-23 months in two areas (Mirpur and Mohammadpur) of Dhaka city. Intervention group (n= 56) received 2 months nutrition education together with recipe trials demonstrating 5 recipes selected from the nationally approved manual titled 'Improved recipes for complementary feeding of children aged 6-23 month, 2013' and followed up for next one month. The control group (n=57) were only observed. Information on infant feeding practice including frequency, quantity, quality, diversity, hygiene practice and anthropometry were collected at baseline and endline in both groups but infant feeding practice and anthropometric data were collected two times more in intervention group.

Results: The feeding frequency had significantly increased 33% higher (4 Vs. 3 times) in the intervention group than the control group through nutrition education during the observation period (p<0.001). Weight gain of the children had increased 7% in intervention group (9.02 Vs. 8.42 Kg) compared to the control group after the intervention (p <0.001). The quantity of feeding items had increased 16% (17g vs. 9g) in the intervention group than control group. Feeding of commercially prepared infant food was decreased by 60% in the intervention group. At the end of the follow-up, the highest to lowest consumed recipes were khichuri (32.1%), fruit firni (23.2%), small fish chop (16.1%), chirar polao (14.3%) and Egg-Suzi (14.3%) in intervention group. Percentage of hand washing before feeding and cooking had increased from 33.9 to 80.4 in intervention group and 47.4 to 52.6 in control group.

Conclusions: Nutrition education together with introduction of improved recipes can effect positively towards behavioral changes and feeding practices on Complementary Feeding.

Keywords: Complementary feeding, Nutrition education, Recipe trial, Behavioral change.

SHORT-TERM SCHOOL BASED ORIENTATION PROGRAM CAN IMPACT TO CREATE AWARENESS ON NUTRITION AMONG ADOLESCENTS

[1]Roy, Swapan Kumar; [2]Jahan, Khurshid; [3]Israt, Samina; [4]Islam, Sayeda Sumaiya.

[1]MBBS, MSc, Dip in Biotech, PhD, FRCP, Senior Scientist, Chairperson, Board of Trustees Bangladesh Breastfeeding Foundation. Chairperson Nutrition Foundation. Bangladesh.; [2]MSc. Director. Bangladesh Breastfeeding Foundation (BBF). Bangladesh; [3]MSc. Program Manager. Bangladesh Breastfeeding Foundation (BBF), Bangladesh; [4]MSc. Assistant Program Officer. Bangladesh Breastfeeding Foundation (BBF). Bangladesh.

Background and objectives: Intervention on adolescent nutrition is recognized as a key intervention to break the intergenerational cycle of malnutrition. Although, The Government of Bangladesh has adopted supportive policies and operational plans, the nutrition scenario of adolescents are still far from optimal.

The aim of the project was to increase knowledge and awareness on nutrition among the adolescent girls through an extensive orientation program.

Methods: This orientation program aimed to cover importance of adolescent's growth and nutrition, physical and mental changes, healthy food choice, nutritional requirement, advantages and deficiency disorder of different food/food groups, personal hygiene and sanitation, discourage child marriage and early child bearing.

2-hours long orientation session including video, demonstration of an innovative IEC tool on adolescent's nutrition was conducted through interactive multimedia projection among the adolescent girls' who are studying between VI-XII grade of school/college/madrasa. The rounded double sided paper disk IEC tool contained information on ideal body weight, height, BMI, and recommended nutrient intake by age group (10-19 yrs). Other side of the tool included best nutrient sources, nutrient composition, benefits and deficiency disorders of 9 food/ food groups and food pyramid of Bangladesh. Demonstration to easily define age wise ideal body weight, height, BMI, energy and nutrient requirements and best food sources was performed as a part of the orientation session.

Results: More than 75,000 adolescent school girls aged between 10-19 years were oriented from 350 orientation seminars at the District level. Out of 10, over 95% of the adolescent girls scored full marks in the post test. 100% adolescent girls were able to answer the question about number of nutrient, symptoms of malnutrition and nutrition & hygiene that should maintain during adolescent. Little difference was found in scores by Division.

Conclusions: Highest interest and active participation was observed among the adolescent girls. Such orientation program on nutrition targeting adolescent girls should be held regularly as part of school health program of Bangladesh.

Keywords: Adolescent, Adolescent Nutrition, School health program, Nutrition, Nutrition education.

ENVIRONMENTAL EDUCATION AND NUTRITIONAL BEHAVIOR BASED ON TRADITIONAL MEDICINE: CASE OF INTERNALLY DISPLACED WOMEN IN THE 2010 POST-ELECTORAL CRISIS IN IVORY COAST

Djane, Kabran Aristide.

PhD.Sociologist. Sociology department. Peleforo Gon Coulibaly University of Korhogo. Ivory Coast.

Background and objectives: During the Ivorian crisis, population displacement has been observed across the country with a peak after the post-election crisis of November 2010; Thus, food system have been destroyed. In this case, green nutrition based on their pre-acquired environmental knowledge (Environmental education) was adopted, especially in their feeding behavior, in order to avoid a decline of calories and to allow food cure in such a difficult period. The objective of this scientific production is to understand the determinants and logics that underpin the appropriation of Green nutrition method derived from traditional medicine, based on knowledge of the environment, plants, by internally displaced women due to war from the region of Aboisso, near the border of Ghana, in Ivory Coast.

Methods: The data are collected from the International Organization for Migration (IOM) (2009) and from the town hall of Aboisso (2010) in Ivory coast on 213 internally displaced women. Non-probabilistic sampling was used . A questionnaire, an interview guide and the observation grid were also used to allow triangulation of information . Content analysis and statistical processing were carried out on Excel and the Sphinx Lexica V5 software.

Results: 73% of displaced women surveyed use traditional food practices due to the military crisis situation. On these, only 13% seek the advice of their spouse. The most used method at 86% is broth of crushed tree pods. The rest in leaf tea, they drink. 37% of women use the advice of a traditional practitioner (specialist in plant medicine), the rest is self-medication (55%) or advice from friends (8%) with a good knowledge of the contribution of Nature to diet and gain in calories. The choice of the traditional method, based on knowledge of environment, stems from the lack of money at 15%, the behavior of the family at 52% and the living conditions at 33%.

Conclusions: In times of crisis, traditional medicine based on a good knowledge of the environment (environmental education beforehand) nevertheless supports modern nutritional practices. These methods need to be examined in the different aid programs for displaced persons in order to support psychologically displaced women.

Keywords: Environmental education, Nutritional behavior, Traditional medicine, Internally Displaced Women, Ivory coast

USE OF JOB AIDS TO IMPROVE MATERNAL KNOWLEDGE OF NUTRITION RELATED ANTENATAL MESSAGES IN MOTHER AND CHILD HOSPITALS, ONDO STATE

[1]Ariyo, Oluwaseun; [2]Babatope, Similoluwa.

[1]BSc. MSc. PhD. Nutritionist. Department of Human Nutrition. University of Ibadan. Nigeria; [2]BSc. MSc. Nutritionist. Department of Human Nutrition. University of Ibadan. Nigeria.

Background and objectives: Nutrition education is essential to improve nutritional status of pregnant women, yet its delivery is often ineffective in Nigeria's antenatal clinics. Although job aids have been shown to improve delivery of education in health programmes, its use is limited in nutrition education. This study was designed to evaluate the effect of the use of job aids on nutrition knowledge of pregnant women in Ondo State, Nigeria.

Methods: This quasi-experimental study involved 200 pregnant mothers attending antenatal services at Mother/Child Hospitals in Akure (experimental-100) and Ondo (control-100). A semi-structured, interviewer-administered questionnaire was used to collect information on socio-demographic characteristics. Knowledge on general health, nutrition content of antenatal messages and nutrient-food association were assessed using a 40-point scale categorized as good ($\geq$23) or poor (<23) knowledge. Job aids was developed from nutrition component of antenatal booklet to support nutrition education in experimental group while control group used conventional nutrition education. Baseline and endline knowledge were assessed and compared using paired t-tests at $p<0.05$.

Results: Age of mothers in experimental (29.0 ± 3.9years) and control group (28.1 ± 4.5years) was similar while 93.0% (experimental) and 86.0% (control) groups had at least secondary education. At baseline, more experimental (34.0%) than control (30.0%) mothers considered colostrum 'poor' for a baby and more control (55.0%) than experimental mothers (47.0%) knew breastfeeding should be initiated within one-hour of birth. More control (44.0%) than experimental (37.0%) knew appropriate attachment during breastfeeding. At endline, fewer experimental (11.8%) than control (37.0%) mothers considered colostrum 'poor' and more experimental (92.9%) than control mothers (60.0%) knew breastfeeding should be initiated within one-hour of birth. More experimental (85.9%) than control (48.0%) knew appropriate attachment during breastfeeding. Knowledge score of control (23.1 ± 3.6) and experimental group (23.6 ± 4.9) was similar at baseline with 60.0% (control) and 57.0% (experimental) mothers having good knowledge. At endline, knowledge score was significantly higher in experimental (27.9 ± 4.3) than control group (23.0 ± 5.2) with 91.8% (experimental) and 61.0% (control) having good knowledge.

Conclusions: The use of job aids enhanced nutrition knowledge among pregnant mothers attending mother and child hospitals in Ondo State. The use of job aids for nutrition education during antenatal care visits is hereby recommended.

Keywords: Antenatal care, Intervention, Nutrition knowledge, Nutrition education.

THE FOOD-HEALTH-CULTURE INTERFACE: DIETARY PRACTICES OF SOUTH INDIAN MIGRANTS IN BRISBANE, AUSTRALIA

[1]Thomas, Preetha; [2]Schubert, Lisa; [3]Whittaker, Andrea.

[1]PhD. Nutritionist. School of Public Health. The University of Queensland.Brisbane. Australia; [2]PhD. Nutritionist. School of Public Health. The University of Queensland. Brisbane. Australia.; [3]PhD. Medical Anthropologist. School of Social Sciences. Monash University. Melbourne. Australia.

Background and objectives: This paper discusses the relevance of considering the food-health nexus in the dietary practices of South Indian migrants in Brisbane, Australia. Studies of migrant health in Australia, as elsewhere, have shown an increased risk of diet-related non-communicable disease (NCD). Indian migrants in particular have a higher risk of developing conditions such as Type 2 diabetes. Food practices among migrant communities are shaped by many forces, as they seek to retain cultural practices while adopting food influences of the host-country.

Indian food traditions are rooted in medicinal discourses, which comprise food-based prescriptions and proscriptions for health. The aim of this paper is to examine the impact of culture-driven patterns of food choice in the food-health interface for this migrant community.

Methods: The findings presented in this paper are part of a larger study, a focused ethnographic exploration of dietary practices among South Indians in Brisbane. Qualitative methods, including in-depth semi-structured interviews, participant observation and photo-elicitation were used to collect data from 21 Indian families originating from the southern Indian states of Kerala and Tamil Nadu, representing diversity in terms of religious background, family size, and life-stages.

Results: Dietary practices and food-based remedies are an integral part of ethno-medicinal systems among this migrant community. The paper identifies that the community's understandings of the food-health nexus is strongly underpinned by culture; this in turn informs dietary practices. It describes how these understandings are interpreted and used in today's global food contexts, the use of traditional food-based techniques to ensure good nutrition, and remedies to prevent and treat common ailments and health conditions.

Conclusions: The paper provides insights into desirable healthful dietary practices that need to be encouraged, and misconceptions about practices that need to be addressed. The findings present an opportunity to develop culturally-tailored recommendations to promote dietary practices compatible with cultural practices and consistent with food-based dietary guidelines. This could in turn assist in the prevention and/or delay of the onset of diet-related NCDs among South Indian migrants.More broadly, the study identifies aspects to be considered while communicating culturally sensitive, context-based healthy eating messages to minority populations.

Keywords: Food, Health, Culture-specific dietary guidelines.

IS THAT 'KHAJA'? DEFINING SNACKS FOR YOUNG CHILDREN IN KATHMANDU VALLEY, NEPAL

(1)Pries, Alissa; (2)Filteau, Suzanne; (3)Sharma, Nisha; (4)Upadhyay, Atul; (5)Adhikari, Babita; (6)Niraula, Pratik; (6)Thapa, Anushka; (7)Thebe, Sonia; (2)Ferguson, Elaine.

(1)MPH. Technical Advisor. Helen Keller International. USA.; (2)PhD. London School of Hygiene and Tropical Medicine. UK.; (3)MPH. Helen Keller International. Nepal.; (4)PhD. Helen Keller International. Nepal.; (5)MRD. Helen Keller International. Nepal.; (6)BND. Helen Keller International. Nepal.; (7)Helen Keller International. Nepal.

Background and objectives: Healthy snacks can be an important source of energy/nutrients and are recommended in most guidelines for young child feeding. While WHO/PAHO defines snacks as 'foods eaten between meals', recent reviews show a range of definitions for snacks, including: time of consumption, portion size, or food type. This qualitative study assessed how snacks are defined among caregivers of young children in Nepal.

Methods: Seven focus-group discussion (FGDs) among 32 primary caregivers of children 12-23 months and 10 structured-observations of children were conducted in Kathmandu Valley. FGDs included a guided discussion on caregivers' definitions of snacks (khaja) and participatory exercises based on behavior-centered design. For structured observations, children were observed for a 12-hour period, with details noted for feeding episodes.

Results: FGD participants defined khaja in comparison to main meals (khana), with caregivers describing snacks for young children as food/beverages given to 'keep something in the belly'. While khaja portion sizes for adults are smaller/lighter than meals, participants reported that portion sizes for children were often similar to meals. Observations of child feeding found that snacks were served in similar or larger portions than meals. Caregivers fed snacks frequently throughout the day, and not necessarily in accordance with typical Nepali meal patterns. Foods that were commonly identified as snack foods, including biscuits and instant noodles, were sometimes fed during khana, while other foods typical for meals, including rice/lentil porridges, were fed in-between meals.

Conclusions: While Nepali caregivers define snacks as foods/beverages fed between meals, this definition was inconsistent in practice and snack foods were fed during meals. Snack definitions commonly used in guidelines and research are not necessarily appropriate when considering diet quality for young children in Nepal, and possibly other contexts as well. Focusing on types of foods eaten by young children may be more appropriate than consideration of portion size or consumption time. Recommendations for snacks should consider child- and context-specific definitions, and further research is needed to understand how varying snack definitions relate to children's overall dietary adequacy.

Keywords: Snacks, IYCF, Nepal, Nutrition, Dietary assessment.

THE EFFECT OF EDUCATION PROGRAM ON NUTRITIONAL KNOWLEDGE IN POLISH ADOLESCENTS: 3- AND 9-MONTH FOLLOW-UP. ABC OF HEALTHY EATING PROJECT

(1)Hamulka, Jadwiga; (2)Kowalkowska, Joanna; (2)Wadolowska, Lidia; (3)Gornicka, Magdalena; (4)Biezanowska-Kopec, Renata; (5)BRONKOWSKA, MONIKA.

(1)Faculty of Human Nutrition and Consumer Sciences. Warsaw University of Life Sciences. Poland; (2)Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland.; (3)Faculty of Human Nutrition and Consumer Sciences. Warsaw University of Life Sciences. Poland.; (4)Faculty of Food Technology. University of Agriculture in Krakow. Poland.; (5)Faculty of Food Science. Wroclaw University of Environmental and Life Science. Poland.

Background and objectives: Educators are still working to design nutrition education programs to improve health outcomes [1, 2]. Effect of nutrition education may decrease through time-span after one-time education episode. Objectives: Assessment of short- and long-term effect of education program on nutritional knowledge in Polish adolescents.

Methods: The prospective study involved 464 adolescents aged 11-13 years at baseline. Nutritional knowledge was expressed in points (range: 0-18) and compared between 'educated' group (n=319) and 'control' group (n=145) after 3 and 9 months. In 'educated' group one-time education program was implemented.

Results: At baseline the mean nutritional knowledge in 'educated' group was 6.1 points and in 'control' group 5.5 points. The mean nutritional knowledge in 'educated' group was 8.5 points after 3-month and 8.3 points after 9-month follow-up, in 'control' group 6.2 and 7.2 points, respectively. The mean increase in nutritional knowledge was higher in 'educated' than 'control' group: after 3-month follow-up by 1.8 points (p<0.0001), after 9-month by 0.4 points (p<0.05); after 3 and 9 months in rural subsample was higher by: 2.5 points (p<0.0001) and 2.2 points (p<0.0001), in urban subsample was higher by 1.4 points (p<0.0001) and lower by 0.5 poitns (p≥0.05), in boys higher by: 1.7 points (p<0.0001) and 0.6 points (p≥0.05), in girls higher by: 1.8 points (p<0.0001) and 0.3 points (p≥0.05).

Conclusions: One-time education episode improved the nutritional knowledge of adolescents, and the effect was still existing after 3 and 9 months. The strongest long-term effect of education was found in adolescents from rural area. References: [1] Dominguez Rodriguez AD et al. BUILDING ON CULTURE: A GRANDMOTHER-INCLUSIVE STRATEGY YIELDS SIGNIFICANT RESULTS ON MATERNAL CHILD HEALTH AND NUTRITION (MCHN) OUTCOMES IN SOUTHERN SIERRA LEONE

[1]Aidam, Bridget; [2]Webb Girard, Aimee; [3]MacDonald, Carolyn; [4]Wee, Rebecca; [5]Aubel, Judi; [6]Simba, Joseph; [7]Gruenewald, Christina; [8]Bangura, Allieu.

[1]PhD. Nutritionist. Evidence and Learning Unit. World Vision International; [2]PhD. Nutritionist. Rollins School of Public Health. Emory University. USA.; [3]PhD. Nutritionist. Nutrition Centre of Expertise. World Vision International. Canada.; [4]MPH. Public Health Specialist. Rollins School of Public Health. Emory University. USA; [5]PhD. Anthropologist. Grandmother Project – Change through Culture. Italy; [6]BA. Development Program Effectiveness. World Vision. Sierra Leone.; [7]MSc. Nutritionist. Technical Advisory Unit. World Vision. Germany; [8]MPH. Public Health Specialist. Program Effectiveness Unit. World Vision. Sierra Leone.

Background and objectives: In many African and Asian communities, grandmothers provide care for pregnant and lactating women (PLW), including influencing nutritional practices of PLWs and young children. To date they represent an untapped resource largely overlooked by MCHN programs. World Vision (WV) piloted an innovative grandmother-inclusive approach (GMA) to actively involve grandmothers to promote optimal maternal infant and young child nutrition (MIYCN) practices.

Methods: Mixed methods were used to understand family members' roles and establish baseline levels for MIYCN knowledge, attitudes and practices (KAP). The study conducted April 2013 - May 2016, assigned 15 communities to intervention and 7 to comparison groups. Comparison areas received standard Ministry of Health and WV nutrition interventions. In addition to standard interventions, the intervention communities received the GMA, which uses adult education methods to engage grandmothers, including praise sessions, participatory learning activities and intergenerational discussions. The end-line evaluation (May–June 2016), surveyed 291 mothers of children under two years of age, 101 PW and 219 grandmothers on MIYCN KAP, self-efficacy and birth weight. Analyses compared differences in MIYCN KAP between groups at baseline and end-line.

Results: Self-efficacy scores were much higher for grandmothers in intervention (19.6; max=20) than in comparison sites (14.8), paralleling higher nutritional attitudes and knowledge (Max=16 points; 12.0 + 1.7 vs. 9.8 + 3.1), better adequate maternal diet diversity (>5 food groups 95% vs. 65%) and greater meal frequency (2.6 ± 1.4 vs. 1.6 ± 1.3) in intervention versus comparison sites, respectively, at end-line (p<0.001 for all).

Significantly more children in intervention communities were exclusively breastfed in the first week of life (90% vs. 79%, p=0.01), achieved minimum dietary diversity (77% vs. 52%, p<0.001) and minimum acceptable diet at 6-23 months (52% vs. 23%, p<0.001). Pregnant women in intervention groups had better antenatal care attendance and improved food intake, contributing to higher mean birth weights (3.34 ± 0.47 kg vs. 3.08± 0.43 kg, p<0.001).

Conclusions: These overwhelmingly positive results support the conclusion that the grandmother-inclusive approach can contribute to substantive, community-wide improvements in MCHN. Collaboration with grandmothers, influential in their communities, appears to be key in bringing about optimal cultural changes.

ELEVATING THE QUALITY OF NUTRITION CARE IN VIP INTERNATIONAL MEDICAL PATIENTS

[1]Lin, Shu-Chi; [1]Chen, Jiyuen-Tieng; [2]Tsai, Hsiao-Jung; [2]Jen, Kai-Lin; [1]Chao, Tzu-Ching.

[1]MSc. Dietitian. Department of nutrition. Taiwan Adventist Hospital. Taiwan.; [2]BSc. Dietitian. Department of nutrition. Taiwan Adventist Hospital. Taiwan.

Background and objectives: With the well-developed medical technology and rational price, Taiwan's medical service quality is above par, indicating that Taiwan has advantages in developing health care tourism. Taiwan Adventist Hospital constantly pushes itself to achieve Joint Commission International (JCI) accreditation, which is publicly known as the highest standard in healthcare quality and patient safety, and has been certified by the official institutions in the United States, Canada, Australia, New Zealand, Japan and Singapore nowadays; therefore, Taiwan Adventist Hospital has been recognized for international medical quality. However, with the increasing number of international medical patient, different dietary preference due to regional and cultural differences has become a great challenge, and thus we keep improving the quality of meals, hoping to elevate the VIP international medical patients' satisfaction with the meal to 90%.

Methods: Since the VIP ward was established in August 2015, there'd been twice as the satisfaction with the meal is only 66%

according to the survey by Quality Control Center. In order to improve the hospital stays of patients in VIP ward, Department of Nutrition has designed the Food Satisfaction Questionnaire, served the food with five-star tableware, implemented the nutrition consultation in 24 hours, and provided the customized meals according to personal preferences from May to December in 2016.

Results: 1.	Department of Nutrition designed the Food Satisfaction Questionnaire in both English and Japanese version.

2.	Results: **Conclusions:** The food supply can be personalized adjusted by the special dietitian according to patients' condition and eating habits based on food culture differences, therefore elevating international medical patients' satisfaction, improving the quality of nutrition care, and further bringing the patients back to health as soon as possible.

Keywords: Quality of nutrition care; International medical patients.

DESIGN OF WESTERN-STYLE VEGETARIAN DISHES FOR INTERNATIONAL MEDICAL PATIENTS

(1)Lin, Shu-Chi; (1)Chen, Jiyuen-Tieng; (2)Tsai, Hsiao-Jung; (2)Jen, Kai-Lin; (1)Chao, Tzu-Ching.

(1)MSc. Dietitian. Department of nutrition. Taiwan Adventist Hospital. Taiwan.; (2)BSc. Dietitian. Department of nutrition. Taiwan Adventist Hospital. Taiwan.

Background and objectives: With the advancement of transportation technology, cross-border travel has become widespread. However, attaining medical treatment while abroad remains a challenge, especially for those who are unable to find suitable or familiar foods during hospitalization. Thus, expanding menu options to include Western vegetarian dishes would be optimal in order to improve the hospital stays of international patients.

Methods: Dietitians would collect and analyze western recipes, and review production methods with the chef. Part of the recipes that include animal products should then be replaced by vegetarian ingredients such as tofu, and any sauce in Western vegetarian dishes can be made with nuts, like almonds and cashews, in order to increase the flavor. Dietitians should visit the affected international patients during their hospitalization, introduce the meal, and provide health and diet advice. Depending on the patient's status and eating habits, the food content can be adjusted. Finally, the Food Satisfaction Questionnaire is designed for measuring satisfaction of the international medical patients with Western vegetarian dishes. Questionnaires will be scored by percentage numerically for each item; the higher the score, the more satisfied patients are.

Results: From July 2016 to March 2017, 40 food satisfaction questionnaires for the international meals were collected. We designed the 7-day Western Vegetarian Cycle menu. The food supply was adjusted according to eating habits based on food culture differences. For instance, we provided more fruit or salad for European and American patients, and soy sauce or miso for Japanese

patients. Results: **Conclusions:** Provide Western-style vegetarian food to international medical patients in order to improve satisfaction with food and with overall hospital care.

Keywords: Vegetarian dishes; International medical patients; Food Satisfaction Questionnaire.

DEVELOPMENTAL TRIAL OF NUTRITIONAL EDUCATION PROGRAM ON CALCIUM INTAKE FOR JUNIOR HIGH SCHOOL STUDENTS

(1)Nakanishi, Yukiko; (2)Kojima, Asako; (3)Ikeda, Takako.

(1)PhD. Nutritionist. Department of Heath Food Sciences. University of Human Arts and Sciences; (2)Msc. RD. Department of Health and Welfare. Abiko City Office. Japan; (3)PhD. RD. Department of Health Design. Showa Women's University. Japan.

Background and objectives: School lunches are required to give consideration to actively ingest calcium, which is particularly needed during the growth period. However, the method of evaluating food education activities at present educational site has not been established. In this research, we aimed to develop and evaluate a food education program on calcium for junior high school students incorporating PDCA cycle.

Methods: Survey was conducted in July and December 2016, targeting all 251 students enrolled in F junior high school. Actual condition survey on food, questionnaire survey on dietary habits, mental health survey, and BDHQ 15y (Simple self-registered diet history questionnaire: brief-type self-administered diet history questionnaire) for junior high school students were examined. The effect of grade level on each item and the impact assessment by comparing before and after educational activities were examined using $\chi2$ test (effective response rate 94.8%). The intake of normal milk, low fat milk, yoghurt and cheese was divided into quartiles and a one-way analysis of variance was conducted on the mental health score and micronutrient deficiency score (effective response rate 88.4%).

Results: The micronutrient deficiency score and the mental health score both gained higher scores than adults. Significant correlation was found between mental health score and micronutrient deficiency score in yoghurt ingestion and dairy product intake, and in the group with low yoghurt intake, the score of mental health and micronutrient deficiency tends to be high in all students. In the group with low dairy intake, mental health scores in female students and mental health and micronutrient deficiency scores in all students tended to be higher. Students who can correctly select 5 kinds of calcium-rich foods which are particularly necessary for junior high school students was 39.1% before food education, but significantly increased after food education.

Conclusions: Development of nutritional education program on calcium accompanied with evaluation based on the concept of health promotion using the PDCA cycle is effective for improving the school's dietary education activity and motivation for student's

CAREGIVERS' PERCEPTIONS OF SNACKS AND FACTORS INFLUENCING THEIR USE FOR YOUNG CHILD FEEDING IN URBAN NEPAL

[1]Sharma, Nisha; [2]Pries, Alissa; [3]Upadhyay, Atul; [4]Thapa, Anushka; [5]Thebe, Sonia; [6]Filteau, Suzanne; [6]Ferguson, Elaine.

[1]MPH. research Coordinator. Helen Keller International. Nepal; [2]MPH. Helen Keller International. USA.; [3]PhD. Helen Keller International. Nepal.; [4]BND. Helen Keller International. Nepal.; [5]Helen Keller International. Nepal.; [6]PhD. London School of Hygiene and Tropical Medicine. UK.

Background and objectives: Ensuring a nutritious diet during the complementary feeding period is vital for preventing childhood malnutrition. Prior research in Kathmandu Valley found high consumption rates of nutrient-poor snack foods among children 12-23 months of age. This qualitative study was conducted to elicit Nepali caregivers' perceptions of snack foods and beverages and factors influencing their feeding decisions to help understand why caregivers chose to feed their toddlers these foods.

Methods: Seven facilitated discussions and participatory exercises were conducted with 32 primary caregivers of children 12-23 months of age in purposively sampled areas of Kathmandu Valley. Focus groups were stratified by caregiver type (mother or grandmother) and socio-economic status (SES) (low or middle/high). Discussions were guided by a facilitator, and participatory exercises included: 1) free-listing of foods and beverages consumed by children as snacks, 2) categorization into similar food groups, and 3) ranking of snacks according to perceived healthiness, convenience, cost, and child preference.

Results: Perceived health and nutritional benefits of foods/beverages were the most common reasons for caregivers' choices of snacks for their young children. Fruits, eggs and milk were considered nutritious while 'market foods', such as instant noodles and chips, were considered 'junk foods' and not healthy for children. Despite this distinction, caregivers reported feeding these less healthy foods if their child demanded them. Certain commercial foods, such as chocolate and fruit drinks, were considered healthy by some caregivers; and biscuits/cookies were often categorized as healthy commercial foods. Commercial snack foods were consistently ranked high on convenience both because of minimal preparation and ease of feeding, as children 'gobbled them up'. Caregivers of lower SES reported that their financial situation influenced the choice of certain snacks for their children, while caregivers of higher SES reported feeding 'whatever the child wants'.

Conclusions: While caregivers reported health/nutrition benefits influencing their choices of snacks, a child's preferences and caregiver's economic status also guided their decisions. These findings suggest future research is needed to develop snack options that are nutrient-rich, inexpensive, and appealing to young children.

ADHERENCE TO THE MEDITERRANEAN DIET OF NUTRITION AND DIETETICS STUDENTS IN CYPRUS

[1]Yücecan, Sevinç; [2]Madencioğlu, Servet.

[1]PhD. Nutritionist.Department of Nutrition and Dietetics.Faculty of Health Sciences.Near East University.; [2]MSc. Nutritionist. Department of Nutrition and Dietetics. Faculty of Health Sciences. Near East University. Cyprus.

Background and objectives: Adherence to the Mediterranean diet is associated with significant improvements in health status. This study aimed to determine the adherence to Mediterranean diet in Nutrition and Dietetics students at Near East University in Cyprus.

Methods: The study was conducted on 174 Nutrition and Dietetics students, aged 18 to 31 years. The nutritional status and Mediterranean Diet Score (MDS) of individuals were determined by food-frequency questionnaire, and a 72-h dietary record. MDS focuses on the consumption of non-refined cereals, fruits, vegetables, legumes, potatoes, fish, red meat and meat products, poultry, full fat dairy products, olive oil and alcoholic beverages. MDS was calculated, and then classified into three groups: good (between 36-55 points), moderate (between 21-35 points), and poor (0-20 points). General characteristics, anthropometrical measurements and physical activity levels (International physical activity questionnaire (IPAQ) short form) of participants were also determined. The study protocol was approved by the Ethics Committee at Near East University.

Results: According to study results 30.8% of students were found out to have low adherence, while 67.7% of students had moderate adherence and 1.5% of students had high adherence to Mediterranean diet. The results showed that MDS decreased as the students were approaching to senior year. There was significant difference between the first year and the senior year students. There was no significant difference (p=0.609) between the male and female students in terms of adherence to Mediterranean diet. Physical activity evaluation results showed that most of the students (40.2%) were minimally active. Male students were significantly more active than female students (p=0.007).

Conclusions: The Mediterranean diet is considered as a dietary pattern that contributes to better health and quality of life. The findings indicate that the eating habits of the Nutrition and Dietetics students, even those studying nutrition, are in need of improvement.

Keywords: Mediterranean diet, Mediterranean Diet Score, Nutrition and Dietetics Students.

MAJOR DIETARY PATTERNS OF TWO ETHNIC GROUPS LIVING IN NORTH-WEST OF IRAN BASED ON AGE, GENDER AND ECONOMIC STATUS

Rezazadeh, Arezoo; Omidvar, Nasrin; Eini-Zinab, Hassan.

Department of Community Nutrition. National Nutrition and Food Technology Research Institute. Faculty of Nutrition and Food Technology. Shahid Beheshti University of Medical Sciences and Health Services. Iran.

Background and objectives: The aim of this study was to determine major dietary patterns of two major(Azeri) and minor(Kurd) ethnicities living in Urmia, West Azerbaijan, Iran based on age, gender and economic status

Methods: In this cross-sectional study, 723participants (427 women and 296 men) aged 20–64 year old, from two ethnic groups (445 Azeri and 278Kurd) were selected through a multi stage cluster systematic sampling. Economic status (ES) was collected by questionnaire and dietary information was collected by a valid semi-quantitative F.F.Q through interviews. Dietary patterns (DPs) were determined using principal component analysis. Data was analyzed by one-way ANOVA and Chi-square analysis.

Results: Three major DPs were extracted including "Traditional High SES (THS)" (high in fruit and vegetables, dairy products, olives, nuts, herbal infusions, traditional Pancake, dolma, thick soup and pickles); "Transitional" (high in fast foods, red and visceral meat, kebab, salty snacks, sauces, sweetened drinks, sweets, poultry, fish, seeds and coffee); and "Traditional Low SES (TLS)" (high in tea, refined grains, potatoes, whole grains, vegetable& hydrogenated oils and animal fat, traditional stew, salt, eggs and legumes). THS and TLS was highly consumed in Azeris and Kurds, respectively. There weren't any significant differences between two groups in consumption of Transitional DP. A greater percentage of Azeri women and those living in middle &high ES households were at the highest tertile of the THS DP. In Kurds, those categorized in the highest tertile of THS had higher per capita income and expenses than those in lower tertiles. Azeris and Kurds who were in the highest tertile of the transitional DP, were younger and kurds had higher income/capita and cost of living / capita. Among Azeri Turks, more men and among Kurds higher percentage of those with lower per capita income and costs were at the highest tertile of TLS DP.

Conclusions: Findings suggest that ethnic background, gender and economic status associated with extracted dietary patterns in the studied ethnic groups. Also, age was an important determinant in adhering to a modern or traditional pattern. Therefore, such characteristics should be considered in planning and formulating diet related policies and programs.

Keywords: Dietary patterns, Economic status, Gender, Ethnicity, Iran.

ADVERTISING, MARKETING, SCHOOL AND FAMILY: CO-RESPONSIBLES OF NUTRITIONAL STATUS, FOOD PRACTICES AND HABITS OF CHILDREN AND ADOLESCENTS OF COSTA RICA

[1]*Holst Schumacher, Ileana;* [2]*Nuñez-Rivas, Hilda Patricia;* [3]*Campos Saborío, Natalia;* [4]*Chacón Ruiz, Betty;* [5]*Alfaro Mora, Flory Virginia.*

[1]MSc. Microbiologist. Faculty of Microbiology. University of Costa Rica. Costa Rica.; [2]PhD. Nutritionist. Costa Rican Institute for Research and Education on Nutrition and Health. Costa Rica.; [3]PhD. Educator. Vice-Rector of Research, Distance State University of Costa Rica. Costa Rica.; [4]BSc. Nutritionist. Vice-Rector of Research, Distance State University of Costa Rica. Costa Rica.; [5]BSc. Social Worker. Costa Rican Institute for Research and Education on Nutrition and Health. Costa Rica.

Background and objectives: Health promotion is a systematic, continuous, integrated and complex strategy for the development of articulated and sustainable procedures that are in permanent transformation. This strategy contributes to the construction of welfare and quality of life of the educational community, especially students, by coordinating different settings (family, community and school) who are called to protect their overall health. This study aims to know if schools and high schools are good or not health promoters in Costa Rica.

Methods: A two-stage mixed multimethod (quantitative and qualitative) design was used. A total of 2667 students of both genders from 40 schools and 24 high schools in the seven provinces of Costa Rica was studied. Weight and height were used to obtain BMI (kg / m2). Social determinants related to food and nutritional security of students in their homes, schools and high schools were explored using a validated questionnaire. All children over 12 years old read and signed the Informed Consent Form to participate in the study. Children under the age of 12 signed the Informed Assent Formula and also had parental permission to participate.

Results: In the student population prevails the excess and the deficit weight (26.4% and 8.7%, respectively). The availability of sweets and soft drinks in homes and schools is greater than the intake of fruits. A 57.7% of young people are not happy with their body image and 38.1% are "on diet". The 42.2% of parents do not control the consumption of unhealthy food in their children; such as, fast foods and processed and prepared products with high content of salt/sodium, sugar and fat.

Conclusions: There is an upward trend in the malnutrition (excess and deficit weight) in the student population. Risk feeding practices were detected in youth that could enhance the development of eating behavior disorders (anorexia and bulimia). Advertising, marketing, school and family are co-responsible environments for customs, practices and habits of children and young people, related to availability, access, consumption and biological utilization of food.

FOOD CONSUMPTION AND PHYSICAL ACTIVITY IN RESIDENTS OF INTEGRAL GENERAL MEDICINE OF THE MUNICIPALITY PLAZA DE LA REVOLUTION. 2017

Domínguez Ayllón, Yarisa.

MSc. Pediatric Medical.National Institute of Higieny , Epidemiology and Microbiology. Cuba.

Background and objectives: Introduction: The eating habits of a population are a decisive factor in their level of health. Inadequate food consumption and low physical activity are directly or indirectly associated with diseases of high prevalence and mortality in developed and developing countries.

Objectives: To identify the food consumption and physical activity in residents of integral general medicine of the Municipality Plaza de la Revolution. 2017

Methods: Material and Methods: **Results:** The 5.3% never ate breakfast, 36.8% ate fruits less than 1 time per day, 26.3% reported consuming ½ portions of vegetables per day, 47.4% reported consuming 3 or more servings of legumes a week, 36.8% Reported consuming 2 servings of legumes a week, 15.8% reported not consuming fish, 31.6% reported consuming 2 servings per day of sugary drinks, 57.9% reported not consuming alcoholic beverages, 47.4% consumed fried foods occasionally, 68.4% Does not add salt to food, 36.8% perform physical exercises and 79.1% have an acceptable Body Mass Index.

Conclusions: Food consumption shows an acceptable behavior, but not physical activity; Taking into account that the study groups are health professionals.

Keywords: Food consumption, Physical activity, Health professionals.

INTERNET AS A TOOL FOR DISSEMINATION RELIABLE INFORMATION ABOUT NUTRITION

[1]*Zając, Joanna;* [2]*Bała, Małgorzata;* [3]*Koperny, Magdalena.*

[1]MSc. Nutritionist. Biologist. Department of Hygiene and Dietetics. Jagiellonian University. Medical College. Krakow. Poland.; [2]Prof. MD. Department of Hygiene and Dietetics. Systematic Reviews Unit – Polish Cochrane Branch. Jagiellonian University. Medical College. Krakow. Poland.; [3]MSc. Systematic Reviews Unit – Polish Cochrane Branch. Jagiellonian University. Medical College. Krakow. Poland.

Background and objectives: Internet, different forums, social media have become a source of information on health, prevention or even treatments. Massive amounts of information about nutrition, dietetics, diets or supplements can be found easily, but this amount of information is not correlated with its quality. That is why it is especially crucial to disseminate dietetic information of high quality in social media. Cochrane reviews are high quality source of reliable information on the effects of healthcare intervention. The aim of presented work is to present results and concerns about dissemination of high quality information about nutrition in social media.

Methods: Using data from Cochrane Poland Facebook fanpage and Cochrane Poland Tweeter account we analyzed results of dissemination of information about nutrition. On each social media profile posts based on plain language summaries of Cochrane reviews are published in Polish regularly 3 times a week, since March 2016 (Facebook) and November 2016 (Tweeter).

Results: 55 posts being connected with dietetics, supplements and lifestyle were published on Facebook fanpage. 25% were focused solely on vitamins supplementation: on average those posts reached more than 500 individuals, while those focusing on pro-healthy influence of particular food products were more popular (more than 700). The most popular were post about coffee and its properties and interventions to reduce cholesterol level. In comparison to Facebook fanpage, Tweeter posts connected with lifestyle and supplements were the most often displayed topics. Since both profiles were launched the popularity is slowly but constantly growing. The largest groups of the receivers of our information represent young adults (25-34 years old).

Conclusions: Raising number of fans and followers shows the need for reliable information, especially among young people. Diversification of dissemination ways allow to reach different people with different interests as it is depicted by different top-topics on both social media profiles.

Keywords: Information, Dissemination, Social media, Plain language summaries.

ASSESSMENT OF CONSUMER'S AWARENESS OF FOOD FORTIFICATION IN TANZANIA

[1]*Theobald, Hannah;* [2]*Surati, Julius;* [3]*Tench, Jonathan;* [4]*Musinguzi, Enock.*

[1]BSc. PhD. Scaling Up Nutrition Business Network & Global Alliance for Improved Nutrition. London. United Kingdom; [2]BAcc. Scaling Up Nutrition Business Network & Global Alliance for Improved Nutrition. Dar es Salaam. Tanzania,; [3]BSc. MSc. Scaling Up Nutrition Business Network & Global Alliance for Improved Nutrition. London. United Kingdom.; [4]Scaling Up Nutrition Business Network & Global Alliance for Improved Nutrition. Dar es Salaam. Tanzania.

Background and objectives: The Government of Tanzania recognises that food fortification is a cost-effective mechanism for preventing and alleviating micronutrient deficiencies and its effects, particularly anaemia (prevalence of 39.6% among adult

Tanzanian women). Fortification of salt, wheat flour, maize flour and oil is currently mandatory in Tanzania, with voluntary fortification also permitted. To help increase consumer demand for fortified foods, the government introduced a fortification logo in 2013, which was supported by a public awareness campaign. Little is known about public awareness and understanding of food fortification, which are both direct demand drivers for fortified foods.

The objective of this research was to understand the level of consumer awareness and knowledge of food fortification in Tanzania.

Methods: A quantitative market research survey, consisting of 23 questions relating to participant's demographic characteristics, food purchasing behaviours, and awareness of and attitudes towards nutrition and food fortification, including awareness of the national food fortification logo. 1087 participants, (18-55 years, 57% female, 80% low socio-economic class) took part in the survey.

Results: 53% of survey participants reported a level of awareness of food fortification. Of these 19% correctly defined food fortification, while 34% incorrectly believed that food fortification was the combining of various foods. 217 survey participants (20%) reported prior awareness of the fortification logo rising to 34% (n=371) when shown the logo. For those who were aware of the logo, 70% felt it positively influenced food purchase decisions and 51% trusted the logo. Once provided with a definition of food fortification, 34% agreed that fortification increased the nutritional value of a food; however, 30% believed that fortified foods were for the rich and are expensive.

Conclusions: Despite low awareness of fortification and the logo, consumers understood the nutritional benefits of food fortification when provided with a definition. Reported spontaneous awareness of Tanzania's food fortification was consistent with findings of a larger national survey, where 13.3% of respondents reported ever seeing the logo. Further awareness raising campaigns on the role of food fortification and of the national logo are warranted, in order to support increased consumer demand for fortified foods and consequently nutrient intakes.

Keywords: Food fortification, Consumer awareness, Logo.

Conflict of Interest Disclosure: Conflict of interest disclosure: HT, JS, JT, EM work for the SUN Business Network, one of the four support networks of the Scaling Up Nutrition Movement. The SUN Business Network works to encourage private sector action on nutrition and is made up of more than 350 business members. EVALUATING USUAL SERVING SIZES OF COMMONLY CONSUMED STAPLE FOODS IN RELATION TO OBESITY: A CASE STUDY OF ADULT WOMEN IN KAWEMPE DIVISION, KAMPALA DISTRICT, UGANDA

Ahumuza, Gracious; Nyakake, Lynn; Ainomugisha, Prudence; Ssenyondo, Muzafaru.

Bachelor of Science in Human Nutrition. Department of Food technology and Nutrition. Makerere University. Uganda.

Background and objectives: The prevalence of obesity and overweight among women in Uganda is rapidly increasing. Worldwide, one of the major causes of obesity is consumption of excess food servings. In Uganda little research has been conducted in regards to factors associated with obesity hence less knowledge is known. This study was conducted to fill this gap and to chiefly determine if excess staple servings are consumed, knowledge and attitudes toward food servings and to quantify the carbohydrate content in these servings.

Methods: A survey of 118 women (15-45 yrs) living in the suburbs of Kampala, Uganda. Semi-structured questionnaire was used to collect dietary and socio-cultural data. Data for nutritional status was collected by taking weight, height, Waist Circumference, Hip Circumference and MUAC using standard WHO procedures. The number of food servings consumed was derived by measuring the usual amounts of staple foods each woman considered a serving and then comparing these amounts to standard serving sizes. Harvest Plus Food Composition tables for Uganda was used to determine the carbohydrate composition of these servings.

Results: Based on the WHR, 38.2% were overweight and 32.7% obese. Using BMI, 47.3% had normal body weight while 32.7% were overweight and 20% obese.

Only 17.3% of the women had heard about the term food serving before. Of these 3.6% knew what a food serving is.

Regarding attitude, even after respondents were explained to what a food serving is, 33% insisted it was not important to count food servings due to cultural reasons such as bad food habit to measure food and beliefs like only money should limit food serving size.

The food servings for all the staples usually consumed and considered to be one serving size by the respondents was at least two times higher than the standard serving size.

The highest average carbohydrate content consumed was 439.64 grams found in the presumed one serving of maize porridge.

Conclusions: Excess servings of the staple foods were consumed which were the likely cause of overweight individuals. The knowledge and attitudes about food servings were poor. Thus educating individuals about what counts as a serving can be of great strategy in reducing obesity.

Keywords: Food serving, Staple foods, Carbohydrate content, Obesity, Standard serving size.

EFFECT OF SHORT-TERM NUTRITION EDUCATION ON PERCEIVED KNOWLEDGE OF URBAN ADOLESCENT GIRLS UTILIZING 'BBF'S ADOLESCENT NUTRITION CYCLE & DIETARY ADVICE TOOL'

[1]Roy, Swapan Kumar; [2]Urmee, Farhana Jubaida; [2]Khatun, Farhana; [2]Jahan, Hasnat; [2]Tamim, Abida; [2]Nupur, Umme Salma; [3]Islam, Sayeda Sumaiya; [4]Ratna, Moffashara Sultana; [5]Israt, Samina; [6]Jahan, Khurshid.

[1]MBBS, MSc, Dip in Biotech, PhD, FRCP, Senior Scientist, Chairperson, Board of Trustees Bangladesh Breastfeeding Foundation. Chairperson Nutrition Foundation. Bangladesh.; [2]BSc. Nutritionist. College of Home Economics. University of Dhaka. Bangladesh; [3]MSc. Assistant Program Officer. Bangladesh Breastfeeding Foundation. Bangladesh; [4]MSc. Assistant Professor. Dept. of Food & Nutrition. College of Home Economics. University of Dhaka. Bangladesh; [5]MSc. Program Manager. Bangladesh Breastfeeding Foundation. Bangladesh; [6]MSc. Director. Bangladesh Breastfeeding Foundation. Bangladesh.

Background and objectives: There is significant malnutrition among adolescent girls in Bangladesh. A program to improve nutrition is not in place.

The aim of the study was to determine how much short-term nutrition education can increases level of perceived knowledge of urban adolescent girls on health & nutrition.

Methods: It was an intervention study with a control group. This study was conducted among adolescent girls aged (11-19) years. The study areas were Azimpur, Mirpur, Dhanmondi & Shaheedbag. Investigators were trained by BBF. Total 384 adolescent girls were selected. Nutrition education was given utilizing 'Bangladesh Breastfeeding Foundation's Adolescent Nutrition Cycle & Dietary Advice Tool'.

Results: This study shows that at baseline the knowledge about the definition of nutrition was found 24% in intervention and 23.8% in controls. After education 70.8% increased in intervention group and 24.9% in control group. This study also shows that, among intervention group 44.8% adolescent knows about balanced diet whether from control group it was 30.2%. Knowledge about sources of protein was increased from 29.1% to 66.7% in intervention group & 26.5% to 34.2% in control group. At baseline both fast food and beverage in intervention and control group was 19.3% & 17.9% but after nutrition education it increases up to 45.8% & 18.5% respectively. About 10.4% & 10.3 adolescent knew about prevention of anemia in baseline where as in end line it was 28.1% & 10.8% respectively. Significant (P<0.001) improvement were seen in nutritional knowledge after intervention.

Conclusions: BBF's Adolescent Nutrition Cycle & Dietary Advice Tool' which was used in nutrition education was fruitful to improve the knowledge of adolescent girl's nutrition and health.

PATRIMONIALISATION OF THE QUEBRADA DE HUAMAHUACA: EFFECTS ON HEALTH AND DIET OF TILCARA NATIVES

[1]Arrachea, Maria Jose; [2]Navarrete, Monica Beatriz; [1]Sordini, Natalia.

[1]Nutritionist. Sciences of Health School. FASTA University. Argentina; [2]MD.Nutritionist. Sciences of Health School. FASTA University. Argentina.

Background and objectives: Background:Tilcara, a town located in the Quebrada de Humahuaca, Jujuy, Argentina, was named in 2003 as a World Heritage Site. The pattern of food consumption of the local population may have been affected as a result of the patrimonialisation of the region.

Objective: To assess the prevalence of cardiovascular risk factors, dietary pattern, nutritional status and social representation on the addition of new foods and forms of preparation into the traditional diet of adults aged 35 to 65 living in Tilcara in 2015.

Methods: Quali-quantitative, descriptive cross-sectional study. The data collection was done through interviews and surveys. A non-probability convenience sampling was used based on 31 Tilcara natives aged 35 to 65.

Results: The gender ratio is 55 percent female and 45 percent male. More than half of the individuals have cardiovascular risk factors. The main ones are overweight, obesity and higher-than-normal cholesterol levels. There was a high frequency of consumption of legumes, green leafy vegetables, tomatoes and carrots, rice, noodles, bread, sugar, artificial juices and soda. It is worth mentioning that the consumption of quinoa and amaranth was close to none. The sample has knowledge about a large number of regional dishes although they are not frequently prepared. With regard to non-traditional foods awareness rice was not identified as a food belonging to them although it is not a traditional food. As far as beliefs are concerned, most of the sample associates the consumption of foods and preparations outside their traditional diet with negative effects on health. Finally, it was possible to identify that the sample considers the regional meals as important.

Conclusions: Foods outside the Andean diet and traditional preparations coexist in the diet of individuals. In this way, they gradually move away from ancestral food mandates and approach the diet of populations living in urban centers. However, they are not completely identified with any of them. Instead, they form a new group characterized by a mix of both having own food identity.

IMPACT OF NUTRITION EDUCATION ON REDUCING OF OVERWEIGHT IN 6-12 YEARS OLD CHILDREN OF AFFLUENT SOCIETY IN DHAKA CITY

[1]Luna, Saimon Farhana; [2]Sultana, Syeda Saliha Saliheen; [3]Roy, Swapan Kumar.

[1]1MSc. Food and Nutrition. College of Home economics, University of Dhaka. Research Associate. Committee of Action for Research. Extension and Service (CARES) & Consultant Nutritionist. Ashik Multispeciality Hospital. Shaymoli. Dhaka; [2]2MSc. Food and Nutrition. University of Dhaka. Associate Professor. Dept. of Food & Nutrition. College of Home Economics. University of Dhaka. Bangladesh; [3]3PhD. Nutrition. University of London. Senior Scientist. Chairperson. Bangladesh Breastfeeding Foundation (BBF).

Background and objectives: Nowadays childhood obesity is an emerging problem worldwide, even it is a serious paucity of developing countries. In Bangladesh childhood obesity is rising rapidly in recent age and has emerged as a major public health threat. To the author's knowledge there was no intervention study was done on this issue in this country among this 6-12 years old children. The aim was to see the impact of nutrition education aimed at improving dietary practice to reduce overweight in children at affluent society.

Methods: A longitudinal intervention study consisting of an intervention (n=150) and a control group (n=150) was carried out among the children aged between 6-12 years in selected affluent areas of Dhaka city during June-Dec 2012. Intervention group received 3 months nutrition education on avoiding fast food and watching TV while eating (which tends to much more eating), emphasizing on appropriate dietary guideline, physical exercise, participating school sports, eating diversified food and hygiene practice. Education was provided to the parents from intervention group about fortnightly for the 1st month and once for the next 2 months. We collected data from the children and their parents of both groups including both Anthropometric (Height, weight, MUAC of the children) and Dietary intake (using 24 hours recall method) records of the children. Control group was observed only. The results were compared between two groups using student's paired t-test and Chisquired test using SPSS/Window's version 11.5.

Results: Background characteristics of both groups were comparable. 6-12 years school going overweight children's mean body weight reduction was 1.51kg in intervention group while in control group, body weight was increased to 3.05 kg (p < 0.01) after nutrition intervention. Respondent's mean BMI reduction was 1.49 in intervention group while in control group BMI raised up to 0.58 in control group (p < 0.01). After intervention, the total calorie intake was reduced to 1823 from 2265 kcal in intervention group while in control group total calorie intake elevated from 2143 to 2160 kcal in control group.

Conclusions: Comprehensive nutrition education was effective for reducing overweight. This education should be scaled up for all affluent society of Bangladesh.

Keywords: Overweight, Improved dietary practice, Affluent society

EVIDENCE-BASE LEARNING ALTERNATIVE EDUCATION COLLABORATION SYNERGY EDUCATION-POLICY-IMPLEMENTING PROGRAM (CASE STUDY IN DEPARTMENT OF NUTRITION SCIENCE, HASANUDDIN OF UNIVERSITY, INDONESIA)

[1]Machdar Dachlan, Djunaidi; [2]Thaha, Abdul Razak; [3]Sugihantono, Anung; [4]Izwardy, Doddy.

[1]Dr, MS Nutritionist. Hasanuddin University. Indonesia; [2]Dr. MD. MSc. Prof. Nutritionist. Hasanuddin University. Indonesia; [3]MD. MKes. Health Planning. Ministry of Health Indonesia; [4]Ir. MA. Nutritionist. Minirtry of Health Indonesia.

Background and objectives: Evidence-based learning model is a learning process that was developed to encourage the contribution of synergistic collaboration between education, policies and implementing programs as learning outcomes. Purpose: To develop evidence-based learning model in Department of Nutrition Science, Hasanuddin of University

Methods: Through the process of review, evaluation, workshops, and a review panel of experts, be continued round table task force, formulated the graduate profile, learning outcomes, matrix courses and great SCU, the structure of the curriculum and learning strategies for competence of undergraduate science of nutrition through a learning process based on evidence in Department of Nutrition Science, Hasanuddin of University.

Results: It has been in repositioning and restructuring the curriculum based on problem-solving cycle into evidence-based learning curriculum where family-based sentinel surveillance is used as a reference proof Accelerate learning and scaling-up nutrition is used as a learning theme. In the learning process of each student H will assist and learn at 40-50 HH for 6 semesters learning phase. Each course was served eight classroom sessions, 2 sessions of discussions 10 cases, 4 family field study sessions, 2 sessions of the seminar. Teaching materials have been prepared and 10 cases for discussion on all subjects. This model has been applied since 2016

Conclusions: Evidence-based learning will gain convergence and connectivity between educational institutions and stakeholders who will use the results of their students, and ensure the quality of graduates

Keywords: Evidence Base Learning; H-H Surveillance; Collaboration–Synergy; Scaling-up Nutrition

CHILDREN'S INDUSTRIALIZED FOOD CONSUMPTION AND THE FACTORS THAT LEADS TO THEIR ACQUISITION

(1)Haddad Caleiro Pereira, Cláudia; (1)Bagatini Saud Ferro, Élen Lúcia; (2)Moreto, Pryscila Grazielle Silva; (1)Rossi, Camila Manfredi dos Santos.

(1)MD. Nutritionist. Curso de Nutrição. Universidade de Franca. Brasil.; (2)Bel. Nutricionist. Curso de Nutrição. Universidade de Franca. Brasil.

Background and objectives: Nowadays, the daily routine favors the consumption of processed food due his practicality. The Media is one of the elements that incite his consumption, reaching, mostly the children. Therefore, the present study aims to identify the main factors that may be leading to the acquisition of processed food, and the media influence on the child's nutritional state.

Methods: The main audience were 18 students, aged 6 to 10 years, in a private school, located in Franca, São Paulo. To the parents, a questionnaire with questions about the children's eating habit, and how the Television may be influencing the purchasing of processed food. For the Nutritional state evaluation, the Body mass index (BMI) was calculated, and analyzed according to the 2007 growth curves. And was classified according to the Health Ministry (2009), based on the growth curves of the World Health Organization (WHO).

Results: As a result of this research, 22,2% of the childrens who go along with their parents at the supermarket were overweight. 75% of the parents said that they bought what the child wanted, just to avoid tantrums. The offering of gifts is one of the elements that influence the acquisition of processed food, this variant was verified in 38,8 % of the cases. The parents must know how to identify this kind of strategies, in order to avoid them, ensuring to their kids a proper nutrition. 94,4% of the parents affirmed that practicity is the main factor to buy this kind of food. 44,4% of the researched childrens watched 1-2 hours per day, 5,5% were overweight. 17% watched 3-4 per day, 11% were overweight and 5,5%, 5-6 hours per day, all of them were overweight.

Conclusions: The media know of the vulnerabilities of their target audience and in the case of children, the gift offerings are one of the trickery that influence the purchase. Parents should realize these artifacts and avoid them, guiding children early on about such stratagems and the importance of healthy eating. Often these parents, to avoid tantrums and crying, fulfill all the wishes of their children, regardless of the fact that they may be damaging the child's health in the future.

Background and objectives: In Central and West Africa, approximately 50% of women of reproductive age have anaemia. This study assessed whether a theory-based, branded school- and community-based behaviour change programme called "Follow in My Green Food Steps" increased intake of green leafy vegetables and Knorr iron-fortified bouillon cubes in South-West Nigeria in order to improve iron intake.

Methods: 603 pairs of mothers and daughters (aged 12-18 years) participated in a field experiment in Ile-Ife (intervention) and Osogbo (control), of which 519 participated in the post-intervention assessment. Determinants were measured based on the Theory of Planned Behaviour and use of iron-fortified cubes and green leafy vegetables were measured as part of an adapted Food Frequency Questionnaire focusing on stews and soups.

Results: The intervention positively influenced awareness of anaemia and the determinants of behaviour. It also resulted in a 41% increase in respondents adding the recommended bunch of green leafy vegetables to their stews compared to a 5% increase in the control group. There was also a significant increase of 0.5 cube per soup on average in the amount of iron-fortified cubes added to soups vs. the control group (0.1 cube per stew).

Conclusions: The intervention had a positive impact on awareness of anaemia, determinants of behaviour, self-reported intake of Knorr iron-fortified bouillon cubes and intake of green leafy vegetables.

Keywords: Behaviour change, dietary intake, iron fortification
Conflict of Interest Disclosure: RL, BG, MS, DS, KvhH and AJ are employees and OA and TM received funding of Unilever, a manufacturer of Food and Beverages products (including Knorr bouillon cubes).

SOCIODEMOGRAPHIC CONTEXT AND THE EFFECT OF NUTRITION EDUCATION PROGRAM ON UNHEALTHY DIETARY PATTERN IN POLISH ADOLESCENTS: 9-MONTH FOLLOW-UP. ABC OF HEALTHY EATING PROJECT

(1)Hamulka, Jadwiga; (2)Kowalkowska, Joanna; (2)Wadolowska, Lidia; (3)Wawrzyniak, Agata; (4)Figurska-Ciura, Danuta; (5)Groszczyk, Barbara; (6)Kozirok, Witold.

(1)Faculty of Human Nutrition and Consumer Sciences. Warsaw University of Life Sciences. Poland; (2)Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland; (3)Faculty of Human Nutrition and Consumer Sciences. Warsaw University of Life Sciences. Poland; (4)Faculty of Food Science. Wroclaw University of Environmental and Life Science. Poland; (5)Faculty of Food Sciences and Nutrition. Poznan University of Life Science. Poland; (6)Department of Trade and Services. Gdynia Maritime University. Poland.

Background and objectives: Sociodemographic characteristics influence on effectiveness of adolescents' nutrition education [1]. It is weak known how sociodemographic characteristics act on unhealthy dietary patterns in long-time perspective. Objective: Assessment of the effect of nutrition education program on unhealthy dietary pattern in sociodemographic context after 9-month follow-up in Polish adolescents.

Methods: The prospective study involved 464 adolescents aged 11-13 years at baseline. Eating habits were assessed based on frequency food consumption. A non-healthy diet quality index (nHDI) including 4 foods (fast foods, sweetened beverages, energy drinks, sweets) was analysed (range: 0-100 points). After 9-month follow-up changes in nHDI were compared between 'educated' (n=319) and 'control' (n=145) groups and analysed in subgroups: boys/girls, rural/urban residence, bottom/middle/upper tertile of family affluence scale (FAS) [2].

Results: After 9 months the mean changes in nHDI between 'educated' and 'control' groups were significant in boys and urban subsample. In boys the mean nHDI was lower by 0.9 points in 'educated' and higher by 2.0 points in 'control' group. In girls the mean increase in nHDI was insignificantly lower in 'educated' than 'control' group (by 0.4 and 2.3 points, respectively); in rural subsample the mean decrease was insignificantly higher (by 0.9 and 0.5 points, respectively); in urban subsample the mean increase in nHDI was significantly lower in 'educated' than 'control' group (by 0.2 and 4.0 points, respectively); in bottom FAS tertile the mean increase in nHDI was insignificantly lower in 'educated' than 'control' group (by 2.1 and 4.6 points, respectively); in upper FAS tertile the mean decrease in nHDI was insignificantly higher in 'educated' than 'control' group (by 2.1 and 0.1 points, respectively).

Conclusions: The strong effect of one-time nutrition education episode in reducing unhealthy dietary pattern in Polish adolescents in long-time perspective was shown in boys. For girls a special attention should be paid in designing nutrition education.

CULTIVATING NUTRITION-SENSITIVE CROPS TO IMPROVE NUTRITIONAL PRACTICES OF WOMEN AND CHILDREN IN NORTHERN GHANA

(1)Osman Mohammed, Shaibu; (2)Kappos, Kristen; (3)LeMay, Philippe; (3)Abdulai, Yunus; (3)Abu, Seidu.

(1)John Snow Inc. (JSI); (2)JSI Ghana; (3)Global Community Ghana.

Background and objectives: Dietary diversity is a challenge for improving nutrition outcomes of women and children in Northern Ghana. According to the 2014 Demographic and Health Survey, only 14.1 percent of children ages 6 – 23 months in Northern Ghana were fed the minimal acceptable diet. The United States Agency for International Development (USAID)-funded Resiliency in Northern Ghana (RING) Project works with local women farmers to promote the cultivation and utilization of nutrition-sensitive crops such as soybeans, green leafy vegetables, and orange-fleshed sweet potatoes to improve nutritional practices through food production and income generation pathways. Training on food utilization is done through engagement of community groups with participatory cooking demonstrations as a key component of the activity. The RING Project conducted a household survey to identify the consumption and sale patterns of the three crops post-harvest.

Methods: Multi-stage sampling method was employed to select beneficiaries for the survey at the interventions levels. The sample size was weighted by district. A total of 2,517 participants' households benefitting from at least one of the agricultural interventions were interviewed. Data analysis was done using SPSS

software version 20 and Microsoft Excel 2013 for cleaning the data prior to analyses. Categorical variables were summarized into frequencies and percentages whereas continuous variables were summarized into ratios, means, minimum, maximum and standard deviations to infer themes and meanings.

Results: Participants reported setting aside portions for household consumption, and reported high level of consumption for all three crops by pregnant and lactating women and children 6 – 59 months. The non-consumed foods were sold by women in local markets and provided additional incomes for the families. Using their new knowledge gained in good agricultural and nutrition practices, most of the farmers reported their intention to continue to cultivate and consume the nutrition-sensitive crops without project support

Conclusions: Farmers are incorporating nutrient-dense crops into their local dishes. We will show evidence on how training on crop utilization and cooking demonstrations enabled households to enrich local dishes with nutrient-dense products for complementary feeding and women's diet. We will also discuss the household consumption and sale patterns of the three crops.

Keywords: Dietary diversity, nutrition-sensitive agriculture, household consumption, first 1,000 days period

IMPACT OF NUTRITION EDUCATION ON OVERWEIGHT ADOLESCENT GIRLS (10-19YEARS) IN THE SELECTED SCHOOLS OF DHAKA CITY

[1]Khatun, Mahfuza; [1]Sonia, Nazmun Nahar; [1]Mou, Mashuda Kabir; [1]Anjum, Rifat; [1]Akter, Sonia; [1]Naharin, Kashfia; [2]Ratna, Moffashara Sultana; [3]Israt, Samina; [4]Akter, Syeda Mahsina; [5]Roy, Swapan Kumar.

[1]BSc. Food & Nutrition. College of Home Economics. University of Dhaka. Bangladesh.; [2]MSc. Assistant Professor. Dept. of Food & Nutrition. College of Home Economics. University of Dhaka. Bangladesh.; [3]MSc. Program Manager. Bangladesh Breastfeeding Foundation. Bangladesh.; [4]MSc. Assistant Director. Bangladesh Breastfeeding Foundation. Bangladesh.; [5]MBBS, MSc, Dip in Biotech, PhD, FRCP, Senior Scientist, Chairperson, Board of Trustees Bangladesh Breastfeeding Foundation. Chairperson Nutrition Foundation. Bangladesh.

Background and objectives: Overweight among adolescents (10-19 years) is an emerging public health concern alongside under-nutrition in developing countries, like Bangladesh. Overweight adolescents are more likely to become obese in adulthood as well as the consequences associated risk for cardiovascular disease, hypertension, diabetes mellitus type II, osteoarthritis, some types of cancer (colon, breast, kidney) and complication during pregnancy. So it is essential to develop public policies aimed at preventing overweight and reducing overweight rates in the pediatric population. The aim of the study was to see the impact of nutrition education on reducing body weight of the adolescents.

Methods: An experimental randomized study containing an intervention (n= 35) and a control group (n=35) was conducted for 4 months among 70 adolescent girls aged 10-19 years in two schools of Dhaka city. At first, screening was carried out through anthropometry (height, weight) to identify 'overweight' following standards of BMI cutoff and enrolled as subjects in both groups. The intervention group received nutrition education of 40-45 minutes long sessions fortnightly for 2 months following a leaflet containing information on healthy life style including food based dietary guidelines, foods to avoid, healthy food choice, demonstration of physical activity, personal hygiene, ideal growth chart, risks and consequence of overweight. The control group was only observed. Data on anthropometry, knowledge, physical activities and food frequency were collected at baseline and end line in both groups.

Results: The mean body weight significantly reduced by 910 g in the intervention group while an increase of 160 g was found in the control group (p< 0.05).The percentage of subjects doing physical activities increased almost by 3 fold at the end of intervention compared to baseline.

Conclusions: Nutrition education on healthy food habit and life style has a positive impact on overweight prevention among the adolescent girls.

Keywords: Overweight, nutrition education, healthy food habit, Physical activities.

The Josef Pilsudski University of Physical Education in Warsaw. Poland.

Background and objectives: Adolescents have various expectations regarding the quality of food products and their preferences are mainly based on family patterns raised from childhood. The preferences can be also modified by education programme increasing willingness to taste unfamiliar foods. Exploring factors determining perception of food products by adolescent is important for better preparing such programme.

To gain insights into factors determining perception of food products by adolescents using quantitative approach combined with practical task during sensory workshop. Furthermore, ex-

perience and familiarity with various fruits and vegetables were examined together with willingness to consume.

Methods: 765 adolescents aged 11-13 years from Poland participated in the study. The questionnaire covered aspects such as perception of food packaging including practical task with 15 s exposure; the desire to learn new flavours; preparing meals with parents/grandparents; preferences and familiarities of fruits/vegetables and the importance of senses in fruits/vegetables choice and consumption.

Results: Adolescents declared that the most important information for them on the product packaging was the expiry date and then ingredients, nutritional value, storage conditions. The least important were: brand and appearance. Practical task provided additional information on the relevance of the other attributes. About 80% of all adolescent declared that they are interested in getting to know new tastes/flavours by consuming products and they stated participate in preparing meals at home. Nevertheless many adolescents had a problem with giving examples of spices used in the process of seasoning. Among the listed, most popular spices were salt and pepper. A high share of participants claimed to be familiar with domestic and exotic fruits and they declared the desire to consume some unknown fruit (e.g. carambola, figs, avocados) but were far more reluctant to try unknown vegetables (e.g. chicory, asparagus, patison).

Conclusions: The most important information for adolescents on the product's packaging was the expiry date. The variety of spices known and used by participants was relatively low. Adolescents declared less familiarity of some vegetables compared to fruit and less interest in their consumption.

Keywords: Adolescent, perception, experience, familiarity, food consumption

Conflict of Interest Disclosure: Project was funded by Carrefour Foundation. Scientists Team was responsible for all stages of project

HEALTHILY, COLOURFULLY, TASTY - BE IN TOUCH WITH YOUR SENSES AND ENJOY CONSUMPTION. SENSORY WORKSHOP WITH ADOLESCENTS: ABC OF HEALTHY EATING PROJECT

[1]Gutkowska, Krystyna; [1]Kostyra, Eliza; [1]Piotrowska, Anna; [1]Hoffmann, Monika; [1]Czarniecka-Skubina, Ewa; [1]Wasiak-Zys, Grazyna; [2]Baczkowicz, Malgorzata; [3]Kurp, Lidia; [1]Hamulka, Jadwiga.

[1]Faculty of Human Nutrition and Consumer Sciences. Warsaw University of Life Sciences. Poland; [2]Faculty of Food Technology. University of Agriculture in Krakow. Poland; [3]Faculty of Food Science. University of Warmia and Mazury in Olsztyn. Poland.

Background and objectives: Sensory experience as a multi-modal perception, memory aspect, expectations and context of consumption influence the formation of eating habits and food choices. Involving children in various tasks related to food preparation could be an opportunity to increase healthy eating behaviour and reduce the formation of neophobia.

Objectives: 1) Introduce adolescents to the role of the senses in food selection, eating and acceptance of products, 2) Increase the ability to recognize the sensory properties in products, 3) Enrich experiences of adolescents in relation to less known/unknown products (fruits, vegetables).

Methods: 765 adolescents aged 11-13 years from Poland took part in the sensory workshops. The workshop consisted of a lecture and a practical tasks. The lecture referred to the role of the senses in the evaluation of product qualities. At practical activities, adolescents described the product's (yoghurt) packaging after 15s of exposure, identified the smell of various herbs/fruits and their acceptability using 5-point facial hedonic scale. They also determined sensory properties of yoghurt took part in preparing the canapes (integration of different senses) and evaluated their eating habits as consumers (now and in the future).

Results: Adolescents noticed and remembered various information on the packaging (e.g. storage conditions). They prepared a map of the most important food label cues from the consumers point of view. During olfactory task, it was revealed that the ability of identification and acceptance of odour by participants depended on the type of stimulus. Adolescents showed great creativity when describing their impressions related to the sensory quality of strawberry yoghurt. While preparing canapes, adolescents willingly included in their composition less known fruits and vegetables. They created visually attractive, tasty and acoustic products and enjoyed their consumption. A large group of children declared willingness to change their eating habits (e.g. reduce consumption of sweets).

Conclusions: Adolescents willingly participated in the workshops and were absorbed by the tasks. They also declared that the workshop made them more open to the preparation and consumption of new, healthy food products and dishes, including fruits and vegetables.

Keywords: Adolescent, senses, impressions, enjoyable consumption

MY HEALTHY SCHOOL PROGRAM

María, Escasany; Casagrande Soria, María Laura; Antún, María Cecilia; Gonzalez, Veronica; Ferrari, María Florencia; Eisenberg, María Paula; Saidman, Natalia; Liguero, María Eugenia; Di Paola, Melina; Icicson, Mariela.

Affiliation: Directorate-General of Health Development. Deputy Mayor's Office. Buenos Aires City Government. Argentina.

Background and objectives: The My Healthy School Program (MHS) of the Directorate-General of Health Development of the Deputy Mayor's Office of the Buenos Aires City Government, is an educational program which promotes healthy habits in the entire educational community. It has been in place since 2012 in Buenos Aires City kindergarten and elementary public schools, with a duration of 2 years in each establishment.

Methods: Indicators of the Program's scope, as well as the main findings of the general assessment are described.

Results: Since its initiation MHS has been implemented in 130 kindergarten schools and 167 elementary schools (one third of all city establishments). This represents a scope of approximately 61 000 children and 6 700 teachers. To date, the Program has carried out 3 236 workshops for children, 662 for teachers and 628 workshops for families. The Recess in Movement component had the participation of 22 342 children, and over 200 articulations with other Government programs were carried out. Furthermore, My Healthy Magazine, a bimonthly publication on MHS key issues, has reached 14 editions and has been distributed to all students of participating schools.

The Program assessment has taken into account the feedback of children, families and teachers. Sixty percent of children who participated in MHS considered they adopted healthier eating habits after the Program, and 55% said they were doing more physical exercise. Among changes in eating habits, children mentioned increase in vegetable (41%), fruit (55%) and water (65%) intake.

In regards to teachers, over 90% expressed being satisfied or very satisfied with the Program, 51% considered MHS generated positive changes in the educational community's habits and 47% said MHS trained and provided them with tools for addressing the issues in the classroom. The qualitative component of the assessment showed the presence of nutritionists in the establishments stands out as a key advantage.

Conclusions: The scope and acceptance of MHS make it a very useful strategy for creating heathier school environments.

FOSTERING PHYSICAL ACTIVITY DURING CHILDHOOD: A GOVERNMENT SECTOR EXPERIENCE

Antún, María Cecilia; Escasany, María; Casagrande Soria, María Laura; Ferrari, María Florencia; Gonzalez, Veronica; De Ruggiero, Marina; Di Paola, Melina; Eisenberg, María Paula; Mirri, María Eugenia.

BSc in Nutrition. Directorate-General of Health Development. Deputy Mayor's Office. Buenos Aires City Government. Argentina.

Background and objectives: Physical activity (PA) has multiple benefits for physical and mental health in children, as well as a positive impact during adult life. Childhood is a critical period for the development of healthy habits; therefore, promotion of PA in this stage is essential.

Since 2012, the Directorate-General of Health Development of the Deputy Mayor's Office of the Buenos Aires City Government has implemented, as part of its Health Stations (HS) and My Healthy School (MHS) programs, diverse strategies for fostering PA in child population. The object of this work is to describe those strategies.

Methods: Cross-sectional study.

Results: The Recess In Movement Project (RIM) is an initiative of the MHS program, its goal being the promotion of PA during school recesses. For this purpose, a team of PA professors assist the establishment in the implementation of a series of actions. Furthermore, recreational equipment is provided, and older students and teachers are trained as for the continuity of the project. This strategy has had the participation of 100 schools and 22 342 children, and 2 694 children and 179 teachers were trained.

Moreover, Game Zones have been implemented within the HS setting. They consist of an educational recreational space where PA is fostered and bonds with other children and their families are encouraged. Individual and collective active games are offered, and child population healthy eating issues are tackled. PA professors specially trained in healthy eating notions are in charge of the activities. To date, 26 017 children have participated.

Conclusions: Both strategies attempt to encourage the acquisition of healthy lifestyles commencing in childhood, in the hope that this behavior will endure in adult life and contribute to improving the quality of life and health of the population.

Keywords: Physical activity – health promotion – healthy lifestyles

PROJECT JA: A NOVEL APPROACH TO STIMU-LATE POSITIVE ATTITUDE FROM CHILDREN TO FRUITS AND VEGETABLES CONSUMPTION AND TO THE MOVEMENT

[1]Cormillot, Adrian; [2]Verón, Sergio; [3]Pereiro, Romina; [4]Klimovsky, Ezequiel; [4]Olaya Rojas, Angela; [5]Viard, Mónica; [6]Federico, Andrea.

[1]Fundación ALCO; [2]Profesor. Fundación ALCO, CABA. Argentina; [3]Nutritionist. Fundación ALCO. CABA. Argentina; [4]MD.Quid Consulting. CABA. Argentina; [5]Pharmacyst. Quid Consulting. CABA. Argentina; [6]BSS. Quid Consulting. CABA. Argentina.

Background and objectives: Consumption of fruit and vegetables among children is generally below recommended levels. In addition it has been shown that only 1/3 of high school students get the recommended levels of physical activity. Different interventions have been demonstrated to be of help in stimulating fruit and vegetables consumption and movement in children. The objective of this presentation is to show the methodology, design and participation results of a recreational intervention developed in Argentina during 2016: Project JA

Methods: A pilot program was developed during 2015, through 7 presentations in 6 schools. Following this pilot program a definitive interactive workshop has been developed by a team conformed by physician, nutritionist, physical education teacher with the collaboration of a scriptwriter. The workshop includes a performance with dances and interactive games with the children's participation lasted 45 minutes, following by 20 minutes exchange of professionals and children and photographs. Fruits colors and movement games and activities were emphasized

Results: From March 2016 to January 2017, 200 workshops were performed in 71 schools and other places (hospitals and sciences expo) at 29 cities in the 24 Argentinean provinces, with participation of around 25000 children aged 6-12. Twenty six thousand brochures and 30000 fruit units were brought to the participants and teachers. A brief video will be shown, including the most popular moments of the workshop and participant's interviews regarding the workshop

Conclusions: The methodology chosen for the workshop had a great acceptance by the participant children and the teachers and a positive approach to fruits and vegetables consumption and to movement has been perceived.

Keywords: Fruits, vegetables, movement, children

PORTRAIT OF CONTEMPORARY MOROCCAN LIVES IN CASABLANCA BETWEEN THE ORIGINAL FOOD CULTURE AND MODERNITY

[1]Hibbi, Nadia; [2]Saile, Rachid; [2]Abdelfattah, Derouiche.

[1]PhD. Nutritionist. Laboratory of Biology and Health-URAC 34- Faculty of Sciences Ben M'Sik. Hassan II University. Casablanca, Morocco.; [2]Professor Laboratory of Biology and Health- URAC 34- Faculty of Sciences Ben M'Sik. Hassan II University. Casablanca, Morocco.

Background and objectives: Developing countries, including Morocco, experiencing significant discrepancy in dietary practices between the city and rural area. The objective of this study is to compare between certain eating practices of Casablancan (urban) and people from Souss (rural) due to urbanization.

Methods: Our sample includes 149 women and 155 men from Casablanca and 157 women and 152 men from Souss Région . This sample was stratified according to ethnicity (urbans, Casablancan Soussi [CS], and Casablancan not Soussi [CNS]), gender and age.

Results: The food consumed varies according to the meal: As for lunch, we note that 35.5% ate traditional dishes (couscous, tagines) and 47.7% consumed fruits and vegetables (salad, sautéed vegetables). We also note a low consumption of fast food during that meal (0.5%). For the dinner, the typology is more diversified, in fact, during the meal, our study population tended to consume more fast food (19.7%) and dairy products (12.4%), in addition to meat and fish grilled (13.2%), fruits and vegetables (13.7 %). Also, our data indicated an association between the change in the type of food taken at lunch, and ethnicity (p <0.0001) : there is a frequent consumption of fruits and vegetables (51.0%) in rural Soussis at lunch compared to Casablanca (44.2%), relatively the same frequency in both CS and CNS ethnic groups (41.8% and 46.6% respectively) . In addition, Casablanca are more likely (48.3%) to eat couscous and tagines (41.8% in CS and 45.9% in CNS) that Soussis 27.1%. The meal / food category consumed at breakfast is different from that consumed at other meals. Therefore, for this meal, our population prefer taking soup (42.3%), bread with garnish (31.4%) and milk / dairy products (20.7%). Similarly, for this meal, the change in the type of food consumed is associated with ethnicity (p <0.05). Indeed, 48.8% of Soussis took dairy products for breakfast; this prevalence is higher than that observed in Casablanca (24.3%) [Higher in CNS (39.7%) than CS (9.0%)].

Conclusions: Food style of our urban population has a pendulisme between the Western-style food and that of the original Moroccan culture, particularly the typology of food consumed.

Keywords: Food culture. Pendalisme.

SCHOOL TEACHER'S KNOWLEDGE AND SCHOOL PRACTICES RELATED TO FRUIT CONSUMPTION AND THEIR PERCEPTIONS ABOUT STUDENT'S ATTITUDES TOWARD THE SAME ISSUE

[1]Cormillot, Adrian; [2]Verón, Sergio; [3]Pereiro, Romina; [4]Klimovsky, Ezequiel; [4]Olaya Rojas, Angela; [5]Viard, Mónica; [6]Federico, Andrea.

[1]MD Fundación ALCO. CABA. Argentina.; [2]Profesor. Fundación ALCO, CABA. Argentina; [3]Nutritionist. Fundación ALCO. CABA. Argentina; [4]MD.Quid Consulting. CABA. Argentina; [5]Pharmacyst. Quid Consulting. CABA. Argentina; [6]BSS. Quid Consulting. CABA. Argentina.

Background and objectives: Nutritional education policies in schools have a positive impact increasing the consumption of fruits and vegetables by children. Teachers play an important role in this goal. The purpose of this study is to establish the degree of school teachers' knowledge and their perception about student's attitudes regarding fruit and vegetables consumption

Methods: A study was conducted in 22 schools of different provinces of Argentina, during 2016. A survey was carried out on teachers of children between 6 and 12 years of age to collect information regarding knowledge, school practices and perception related to fruits and vegetable consumption in their students. Argentinean region and public/private school were studied as independent variables.

Results: 155 from 20 provinces teachers answered the survey.

Knowledge: 47.7% of them knew that at least 3 portions of fruit are recommended per day. 94.8% totally agree that is good to eat fruit and 93.5% totally agreed that it should be eaten every day.

Practices: only 3.9% reported that the school usually offers fruits to children and 3.2% that children usually take fruits to school.

Perceptions: 98.1% think that kids do not consume the adequate portion of fruits. 71.6% think that they consume fewer amounts of fruits than kids of the same age. 93.5% of teachers totally agree that for kids is hard to eat fruit every day.

Evaluating the region as independent variable, it was found that the proportion of teachers who knew that at least 3 portions of fruit is recommended per day, is major in NEA (North East Argentina)-Mesopotamia and Patagonia

Conclusions: Teacher's knowledge regarding fruit consumption recommendations should be improved, as well as school strategies to stimulate children's fruit intake.

Keywords: Knowledge – Fruits consumption - School teachers

IMPACT OF A PROMOTIONAL PROGRAM REGARDING HEALTHY EATING IN BMI AND FEEDING HABITS IN HIGH SCHOOL STUDENTS

[1]Ponce y Ponce de León, Gisela; [2]Arizona Amador, María Betzabé; [2]Rieke Campoy, Ulises; [2]Camargo Bravo, Adriana; [3]Mayagoitia Witrón, José de Jesús; [2]Pimentel Jaimes, José Alfredo; [2]Higuera Sainz, José Luis; [4]Tizoc Márquez, Arodi.

[1]Facultad de Enfermería Universidad Autónoma de Baja California; [2]Facultad de Enfermería UABC; [3]Hospital General, Mexicali; [4]Facultad de Enfermería, UABC.

Background and objectives: Introduction: obesity has increased in an epidemic way in the last two decades, presenting itself at earlier ages. Environmental factors like sedentary lifestyle and bad eating habits have become main culprits. Educational interventions focused at providing solutions for feeding and nutritional problems that affect alumni are being recognized as an essential complement to actions aimed at improving feeding security of students.

Objective: analyze the impact of a promotional program of healthy eating regarding BMI and feeding habits in high school students.

Methods: longitudinal and correlation experimental study, it was performed in 415 high school students in two phases. First phase (preintervention) consisted of weight, waist line and height measuring and a questionnaire regarding eating habits and nutrients knowledge was applied, a promotional program of healthy eating (PPHE) was implemented on the experimental (EG) and the control group (CG). An informative flyer on the subject was handed and informative banners were placed at school. The second phase (intervention) was performed in which weight, height and waistline measuring was done, the previous questionnaire was once again applied on both groups. Data analysis was done using SPSS 20 software.

Results: decrease in weight in EG and increase in CG (X2 .001). Better eating habits were observed in the EG after PPHE but no so regarding the consume of fast food and sweets (p=<0.05). Both groups (E&C) showed good knowledge of food and nutrients post intervention, 93% and 94.5% respectively. Regarding good eating habits E showed a good response post intervention in 91.4% (p=<0.05).

Conclusions: there was a positive effect over BMI and change of eating habits in EG. The effects on BMI and eating habits were evaluated on the short term but we cannot conclude if these will remain on the long term.

Keywords: Program, BMI, feeding habits, high school students

FUNKY FOODS TO REDUCE MALNUTRITION AMONG YOUNG CHILDREN IN SOTNIKUM OPERATION DISTRICT, SIEM REAP, CAMBODIA

[1]Blaney, Sonia; [2]Main, Barbara; [3]Chhorvann, Chhea; [4]Vong, Lenin; [5]Menasria, Lylia; [6]Hun, Vannary; [7]Leblanc, Caroline.

[1]Professor or nutrition, Moncton University; [2]Senior Health advisor, World Vision Canada, Mississauga, Ontario, Canada; [3]Director of National Institute of Public Health of Cambodia,; [4]Consultant, World Vision Cambodia; [5]Graduate student enrolled in the programme of Master in Nutrition, Moncton University; [6]Technical Health and Nutrition specialist, World Vision Cambodia; [7]Professor of nutrition, Moncton University.

Background and objectives: In Cambodia, stunting and wasting affect 32% and 10% of children below five years of age respectively. In Siem Reap province, these proportions are even higher, 36% and 10%. Poor infant and young child feeding (IYCF) practices have constantly been reported as the cornerstone of young child nutritional status and development. In Siem Reap, breastfeeding practices are encouraging as 65% of children 0-5 months are exclusively breastfed. Nevertheless, only 36% of children 6-23 months do benefit from the three recommended IYCF practices. The objective of our research was to assess the impact of a higher consumption and promotion of micronutrient-rich local foods on child nutritional status, dietary intake and practices.

Methods: The research is currently ongoing in Sotnikum district area, Southern part of the country. This is a cluster-randomized controlled trial among children 6-23 months old living in 14 villages (cluster) randomly selected and assigned to each treatment group namely: cricket + nutrition education (NE), Moringa oleifera + NE and NE only. The number of villages intends to get a sample size of 120 per group in order to detect a mean improvement of 1 g/ dl of hemoglobin level between baseline and after 6 months of implementation and to take into account a 10% drop-out. Cricket and Moringa are given daily to children. Quantities of each food aimed to add at least 2 mg of iron to their daily diet. Data on nutritional (anthropometry, haemoglobin and ferritin) and health status (c-protein, presence of intestinal parasites in faeces, occurrence of illnesses), dietary intake, food and health practices, household food security and socioeconomics have been collected at baseline and will be collected at endline. On a weekly basis, data on dietary intake, health status, food and health practices including food compliance and responsive feeding are gathered.

Results: At the end of July 2017, the endline study will assess the impact of the consumption and promotion of local foods on child nutrition outcomes.

Conclusions: To come.

Keywords: Complementary feeding, nutrition, Cambodia, young children, local foods

ANTHROPOMETRIC AND LUNCHBOXES COMPOSITION OF PRIVATE SCHOOL STUDENTS OF THE CITY OF INTERIOR OF SÃO PAULO

[1]Haddad Caleiro Pereira, Cláudia; [1]Bagatini Saud Ferro, Élen Lúcia; [2]Pacheco, Keroly de Araújo; [2]Gomides, Natália Bertulucci; [3]Manochio Pina, Marina Garcia.

[1]MD. Nutritionist. Curso de Nutrição. Universidade de Franca. Brasil.; [2]Bel. Nutricionist. Curso de Nutrição. Universidade de Franca. Brasil.; [3]PhD. Nutricionist. Curso de Nutrição. Universidade de Franca. Brasil.

Background and objectives: In the most cases are the parents who make the acquisition of food that will be part of school lunchboxes and not always care with the nutritional question acquiring less healthy food. The purpose of the work is evaluate the lunchboxes composition of children 6-8 years of a private school municipality of São Paulo and compare the results with nutritional status.

Methods: For nutritional assessment of students was used the Growth curves for BMI/Age for children 5-19 years of the WHO 2007 and the classification of Ministry of Health (2009). The lunchboxes evaluate was realized through by observation at playtime for two days a week randomly chosen.

Results: Detected a high number of overweight children (overweight and obesity), corresponding to 29% of the total, and no cases of underweight, it was also observed that the incidence of girl´s overweight and obesity was higher than boys, which was not detected in any case of obesity, just overweight. The kids who participated of this study presented caloric intake of 522,6 kcal in a just meal, with minimum varying of 125.85kcal and maximum of 1350kcal. It was found a low consumption of fruits (12,9%) and high consumption of artificial juices (71%).

Conclusions: The Statistic analysis detects that the snack taken by the students didn´t interfere in their status nutritional, however parentes could opt for healthier foods for prevent children eutrophic leave this condition due to inadequate choices in the composition of lunchboxes

Keywords: Lunchbox, school, nutritional status

THE IMPORTANCE OF NUTRITIONIST IN THE PREPARATION AND MONITORING THE MENU IN SCHOOL KINDERGARTEN

[1]Rossi, Camila Manfredi dos Santos; [1]Haddad Caleiro Pereira, Cláudia; [1]Bagatini Saud Ferro, Élen Lúcia; [2]Rodrigues, Talita de Paula Alves; [3]Manochio Pina, Marina Garcia.

[1]MD. Nutritionist. Curso de Nutrição. Universidade de Franca. Brasil.; [2]Bel. Nutricionist. Curso de Nutrição. Universidade de Franca. Brasil.; [3]PhD. Nutricionist. Curso de Nutrição. Universidade de Franca. Brasil.

Background and objectives: In Brazil, surveys reveal that the prevalence of overweight children more than tripled, showing the importance of developing school practices that promote healthy eating habits. Consequently, this study aimed to: assess whether the monitoring of school lunches by nutritionist at the institution exerts some influence on the nutritional status of preschool children from 2 to 5 years, check qualitatively the distribution of macro and micro nutrients in your daily diet during their stay at school and parents ' opinions about the presence of the nutritionist.

Methods: Through calculation BMI/age assessed the nutritional status of each child. The data obtained with the anthropometric assessment have been classified according to the curves of the World Health Organization (WHO) and the related data results from analysis gathered through the menu prepared by a nutritionist in two early childhood institutions.

Results: It was found that 95% of preschoolers were eutrophic and 5% with thinness in school with nutritionist. The institution without nutritionist 66.6% of preschoolers were eutrophic and 33.3% overweight. Through examining the menu it was observed in both schools, low intake of carbohydrates and proteins and in the institution without the consumption of nutritional lipids and sodium was superior to another school. The intake of calcium, vitamin A and iron was lower than recommended. All parents of two institutions stated that the presence of the nutritionist in daily monitoring was essential, but there have been doubts about the professional presence in the institution, because at school with nutritionist, 83% confirmed the monitoring already in school without professional nutritionist 53. 3% say existed and 46. 6% were unsure, no parent replied that there was no nutritional monitoring.

Conclusions: The results obtained show that the presence of the nutritionist in the daily assistance influences on children's eating habits and anthropometric profile, being essential for adequate nutritional status.

Keywords: Importance of nutrition, food consumption and nutritional status.

HOUSEHOLD POND-FISH PRODUCTION IN SOUTHERN ETHIOPIA INCREASES FISH CONSUMPTION FREQUENCY AND DIETARY DIVERSITY IN WOMEN OF REPRODUCTIVE AGE

[1]Zello, Gordon; [2]Tamiru, Darasa; [3]Reta, Fikadu; [4]Kefyalew, Tafesse; [5]Zatti, Kyla; [6]Drew, Murray.

[1]PhD. Professor. College of Pharmacy & Nutrition. University of Saskatchewan. Saskatoon Canada.; [2]MSc. Lecturer. School of Nutrition, Food Science and Technology. Hawassa University. Hawassa Ethiopia.; [3]MSc. Head. School of Nutrition, Food Science and Technology. Hawassa University. Hawassa Ethiopia.; [4]MSc. Assistant Professor. Dept of Biology. College of Natural and Computational Science. Hawassa University. Hawassa Ethiopia.; [5]PhD. Research Associate. Dept of Animal & Poultry Science. College of Agriculture & Bioresources. University of Saskatchewan. Canada.; [6]PhD. Professor. Dept of Animal & Poultry Science. College of Agriculture & Bioresources. University of Saskatchewan. Canada.

Background and objectives: The National Nutrition Program in Ethiopia focuses on food and nutrition security especially in vulnerable populations (e.g. women and children). In southern Ethiopia, government and university partners have recently (within 5 years) introduced aquaculture in farming practices (i.e. fish ponds) as means to address these security concerns. Evaluation of the aquaculture initiative in improving nutrition security is required. Our objective was to determine the association of household pond-fish production with fish consumption, dietary diversity and nutrition status of women of reproductive age.

Methods: Women, 19-49y of age, from fish producing (FP) [n=61] and non-fish producing (NFP) [n=117] households residing in Dila Zuria and Wensho Woredas (i.e. districts) participated. Fish consumption frequency was measured using three consumption patterns (i.e. frequent, occasional and non-fish eaters). Women's dietary diversity score (DDS) was determined by intake of 9 food groups within a 24h period. Nutrition status of the women was crudely assessed by measuring body mass index (BMI). In addition, focus group discussions were performed to obtain in depth information about pond fish production, consumption and usage.

Results: Nile tilapia (Oreochromis niloticus) was the most common pond species and species preferred for sale (i.e. income). Respondents from NFP households were less likely to consume fish frequently (OR=0.044, p<0.001) than those FP households. The mean (±SD) DDS in women from FP households (5.50±2.16) was significantly higher than their NFP counterpart (4.09±1.98, p<0.001). No differences (p>0.05) in mean height, weight and BMI were found between women in FP and NFP households.

Conclusions: The short period of time (<5 years) since the introduction of fish-ponds in the Woredas and the simple measure used to assess nutrition status (i.e. BMI) may explain the lack of difference observed in the nutrition status of the women. However, aquaculture has great potential in improving the food and nutrition security (e.g. nutrients, income) and our results illustrate some of the benefits of pond-fish production in southern Ethiopia

(i.e. more fish consumption and improved DDS). Further research is necessary to determine the longer-term impact of fish production on the nutrition status of both women and children.

Keywords: Dietary diversity, Nutrition status, Aquaculture, Food security, Ethiopian women

PARECE ALFACE, MAS NÃO É. (IT LOOKS LIKE LETTUCE, BUT IT IS NOT)

[1]Barata, Mayra; [1]Capezzuto Fernandes Dias, Manuela; [2]Figueiredo Barata, Mayra; [1]Slater Villar, Betzabeth.

[1]Nutritionist. Public Health Faculty. Sao Paulo's University. Brazil.; [2]São Paulo.

Background and objectives: The school plays a mediating and crucial role in the formation of students' eating habits. In this sense, it is possible to affirm that in the school environment the importance of the autonomy of the educating ones for their own alimentary choices, being responsible for the other social actors, members of the school community in the territory, for the control of the health, for the reduction of the risk factors and favoring healthy eating environments. The present intervention work intended to awaken children's curiosity and the social and cultural importance of food. With the educators, it helps them in building a pleasant ambiance of the meal and instigates them to work alimentation subjects in class.

Methods: In order for the objectives to be achieved, the intervention focused on two distinct groups: students and educators. After the initial observation period, the authors elaborated 4 dynamics for the 255 students enrolled in the Municipal School of Infant Teaching - Santos Dumont (Magic Box, dance and massage with food, ceramic Continents, food stamps and finalization) and two dynamics for the 24 school educators.

Results: The results were obtained through observation after the intervention and application of initial and final questionnaires with the educators. The data obtained in the questionnaires show that the educators felt more encouraged and confident to work with their students in the classroom. At the observed lunches, the teachers sat at the table with their students and the rule of absolute silence was not present. Some students demonstrated knowledge of the vegetables worked in the dynamics and were not afraid, nor disgusted to try new foods.

Conclusions: The intervention work inserted this school community within a ludic perspective of learning and improvement. It presents ways and new ideas for food to be worked in classrooms. The study becomes an example of how basic health care can be applied in schools, especially under a vision of health promoting and protecting.

Background and objectives: Sedentary lifestyle and unhealthy eating behaviors during pregnancy are highly prevalent in the world and have great negative impact on maternal and child outcomes. Interventions in prenatal care can change this situation. The present study aims to evaluate the effectiveness of an intervention promoting healthy eating and leisure-time walking in antenatal care.

Methods: A controlled, non-randomized, intervention study in primary health care in a midsize city in southeastern Brazil. Trial Registration: RBR-6kf7wc. Obstetric low-risk adult pregnant women included in the first trimester and followed through the third trimester, divided into two groups: intervention (n=181), pregnant women receiving care from professionals participating in the educational intervention, and control (n=172), pregnant women receiving usual antenatal care. The intervention was conducted by doctors and nurses who participated in an educational training to promote leisure-time walking and healthy eating during antenatal care visits. The impact on pregnant women's behaviors was evaluated by multilevel logistic regression, with the main outcome of being reached the recommended 150 minutes per week of leisure-time walking (yes/no).

Results: There were positive impacts on the percentage of women in intervention group who walked at least 150 minutes per week (OR 3.1; 95%CI: 1.24, 7.75) compared to controled group. The practice of leisure-time walking in the second trimester (OR 2.59; 95%CI: 1.04, 6.42) and third trimester of pregnancy (OR 3.33; 95%CI: 1.69, 6.55) was higher in intervention group. Furthermore, there were protective effects against high consumption of soft drinks and/or industrially processed cookies in the third trimester (OR 0.49; 95%CI: 0.24, 0.98) in the same group. There was no impact on the other eating behaviors (vegetables, fruits and beans).

Conclusions: These lifestyle intervention was effective, tripling the proportion of pregnant women who achieve the recommended walking time and reducing the proportion with a high consumption of soft drinks and industrially processed cookies by half.

NUTRITION EDUCATION AND YOUTH: A TRAINING AN INTERVENTION INITIATIVE TO PROMOTE SOCIAL CHANGE WITHIN YOUNG WOMEN IN SAN MARCOS, GUATEMALA

[1]Barragán Wug, Zandy Mariela; [2]Garcia-Meza, Rosario.

[1]Nutrition Student. Paz Joven Guatemala. Rafael Landivar University.; [2]Nutricionist. Master proofreader. Rafael Landivar. University.

Background and objectives: According to the National Institute of Statistics in Guatemala (INE) youth represents the majority among national population. Social context for young women in Guatemala faced challenges in access to education, health and the guarantee of their human rights in general. Poverty and exclusion sum additional stressors to young women nutrition and health wellbeing and access to processes for social change can contribute to improve their opportunities to a better life

Methods: This reports from a bigger training and intervention initiative aimed to reduce anemia and nutritional vulnerability through capacity building processes. Training was developed through a guide which took into account the Food and Nutritional Guidelines content developed for Guatemala by the Ministry of Health. This guide was also adapted based on local context using the "Vulnerability and Capacity analysis" proposed by the Red Cross International and UNICEF. 6 participatory workshops with 1,300 young women were implemented and 600 young women were supplement with Iron and folic acid. Pre-post qualitative assessment was performed to identified impact changes. A follow up with young women who received supplements is still in need to perform.

Results: Improvement in the importance of nutrition perception was identified among participants. Leadership roles in food security commissions were performed by young women in 6 communities after completed training processes. Youth groups were conformed after having the training processes implemented, including initiatives at the municipal level

Conclusions: Training processes for social change, in the case of nutrition and youth, needs to take into account the context to develop and perform them better. Including decision making figures into training and intervention initiatives can support young women health, nutrition and leadership.

PROGRAM FOR HEALTHY EATING PRACTICES IN A RURAL COMMUNITY OF NORTH INDIA

Rai, Sanjay; Misra, Puneet; Kant, Shashi.

MD. Professor. CCM. AIIMS. New Delhi. India.

Background and objectives: Women are the main person in the family preparing and managing food for the family and should understand the best dietary practices which fit in their budget and can be available locally, so it is very important that female understand the healthy eating practices with low cost locally available food.

Methods: This was part of another study, where we collected data for nutrition related health problem in females in Ballbagarh area of Haryana state in northern part of India. During study we found that most of the females have very poor knowledge about nutrition So we planned an intervention, where live demonstration was given by trained dietician in their own community near their homes about foods which are locally available and part of their food. Self help groups were made and help of grass route level health workers, volunteers were taken to make it sustainable

Results: Most of the females were not aware about healthy eating practices, there was high salt intake and fat intake as they were adding lot of extra salt and fat in most of items. Consumption of green leafy vegetables and sprouts was low in the area. After demonstration we have found that most of the females stopped using extra salt and fat in diet and started using sprouts. This program continued for one

Conclusions: Due to our efforts during study, the awareness and the overall improvement in the nutrition and health status of the postmenopausal women has increased in the area. We involved ASHA, ANM, AW worker and most importantly volunteers from their community to promote healthy eating practices even after completion of study for long term sustainability and bringing it into day to day practice.

IMPACT ON BODY WEIGHT AND BODY COMPOSITION OF A NUTRITIONAL INTERVENTION PROGRAM PERFORMED AT THE WORKSITE: DATA FROM SI. MEDITERRANEO PROJECT

[1]Vitale, Marilena; [2]Melegari, Camilla; [2]Rapetti, Valeria; [3]Grasso, Annamaria; [4]Cecchini, Chiara; [5]Riccardi, Gabriele.

[1]PhD. Nutritionist. Department of Clinical Medicine and Surgery.; [2]MSc. Nutritionist. Barilla F.lli S.p.A. Parma. Italy.; [3]MSc. Nutritionist. Department of Clinical Medicine and Surgery. "Federico II" University of Naples. Italy.; [4]MSc. FEAT SrL. Bologna. Italy.; [5]Professor. Endocrinology. Department of Clinical Medicine and Surgery. "Federico II" University of Naples. Italy.

Background and objectives: Overweight and obesity are the major risk factors for non-communicable diseases. Worksites have

the potential to become a central element in national efforts to reduce obesity because the majority of adults spend most of their time at work; therefore, worksites provide opportunities for group interventions that could facilitate weight control. Accordingly, the purpose of this study was to investigate the effects on body weight and body composition of a nutritional intervention program based on the promotion of the Mediterranean diet and regular physical exercise at worksite.

Methods: Overweight and obese employees (n=58) enrolled in this worksite trial with a 0-6-month nutritional intervention program and a follow-up after six-month. The intervention, collected by a nutritionist, was based on recommendations to reduce energy intake and saturated fat, and increase fiber consumption, according to the features of the Mediterranean diet. An increase of daily physical activity was also promoted. Outcome measurements included changes in body weight, waist circumference and body composition. Dietary habits were investigated by self-administered-24-hour-recall. Physical activity was assessed by a validated questionnaire.

Results: Significant decreases in body weight were observed during the intervention compared to baseline. The same findings were observed after 6-month of follow-up, even if the majority of the participants showed a tendency to resume their initial weight. A lower body fat and waist circumference was also observed during the intervention compared to baseline (p<.05). However, after 6-month of follow-up, a significant increase of fat mass was observed. The analysis of the habitual diet showed several beneficial dietary changes: fiber and polyunsaturated-fatty-acids intake were increased, while saturated-fatty-acids and added sugar consumption were decreased. The analysis of the physical activity questionnaire showed a significant increase of time spent walking during the intervention. On the contrary, a significant decrease was observed at 6-month of follow-up.

Conclusions: A nutritional education program is an effective tool to improve anthropometric measures and body composition in people at work. Unfortunately, most of the benefits tend to disappear when the intervention is discontinued. Systematic nutritional management programs should be developed and implemented at the worksites to help people to control their body weight and improve their food choices.

FACILITATORS AND BARRIERS INFLUENCING OPTIMAL NUTRITION PRACTICES AMONG PREGNANT WOMEN

[1]Sanghvi, Tina; [2]Ghosh, Sebanti; [3]Dasgupta, Paramita; [1]Ghosh, Archna; [4]Roy, Sumitro.

[1]Alive & Thrive - FHI 360; [2]Alive & Thrive - FHI360; [3]CMS Communication; [4]Independent Consultant.

Background and objectives: From May - October 2015, Alive & Thrive conducted formative research in the states of Bihar and Uttar Pradesh (UP), India to understand the determinants, barriers and facilitators for adopting optimal maternal, infant, and young child nutrition (MIYCN) practices and behaviors at the household level. This poster focuses on two maternal nutrition behaviors: consumption of iron and folic acid (IFA) and calcium tablets, and dietary diversity (intake of specific nutrient-rich food) in pregnant women.

Methods: Qualitative and quantitative methods were used including in-depth interviews with pregnant women, husbands of pregnant women, and frontline workers. We also conducted small group discussions, observations, and a set of rapid household trials to test recommended 'small do-able actions' for more than 200 pregnant women.

Results: Social norms, affordability, availability, cultural preferences, food habits and support from family members determined actual practice of dietary diversity among pregnant women. Inadequate supply, lack of specific knowledge regarding benefits (e.g. IFA prevents serious risk of death from postpartum hemorrhage) and ways to manage IFA side effects, among pregnant women, husbands, and mothers-in-law were determining factors for low IFA and calcium consumption.

Rapid household trials showed that women were willing to try new nutrition practices with support from family members in procuring necessary food items from the market and reminding them to eat recommended foods in required quantities. An important aspect of the trials which led to uptake in the recommended practice of ensuring IFA and calcium consumption was counselling of women and influencers on its health benefits and specific mortality reducing effects.

Conclusions: The capacity of frontline workers needs to be strengthened to provide timely counseling and demonstrate dietary diversity to pregnant women and mothers. Support and engagement of husbands and mothers-in-law can play an important role in motivating and building confidence of pregnant women to improve their nutrition practices and uptake of IFA and calcium consumption.

SYSTEMATIC REVIEW COMPARING COMPLEMENTARY FEEDING PRACTICES IN URBAN AND RURAL AREAS IN KENYA

[1]Orado, Thalma; [2]Keino, Susan.

[1]BSc. MPH Candidate. School of Public health. Moi University. Kenya; [2]PhD. Lecturer. Department of Human Nutrition School of Public Health. Moi University. Eldoret. Kenya.

Background and objectives: Breastfeeding is crucial during the first six months of an infant's life as it provides optimal nutrition to enhance child survival, growth and development. At 6 months of age, breast milk alone is no longer

sufficient to meet the nutritional requirements of infants necessitating the introduction of other foods and liquids alongside the breast milk. The WHO recommends that the process continues from 6 months up to 24 months of age; although breastfeeding may continue beyond 2 years. This is a critical growth phase for children whereby if appropriate care is not given nutrient deficiencies and frequent illnesses contribute to a vicious cycle of under-nutrition and disease. Poor complimentary feeding practices also contribute to negative growth outcomes such as stunting, underweight and obesity among children below five years of age; which can be risk factors for ill health during early childhood, adolescence and adulthood.

The objective of this study is to review published literature on the complementary feeding practices; comparing those practiced in rural areas with those practiced in urban areas in order to enhance knowledge that can help promote best practice when it comes to complementary feeding in Kenya.

Methods: This study adopts a systematic literature review approach. A search for literature published from 2007 to 2017 was carried out on PubMed and Google Scholar. Search results were screened for eligibility in a multi-stage process. Inclusion criteria included year of publication, location of study (Kenya), age group studied (children between 6 and 24 months) and outcome of interest (complimentary feeding).

Results: Out of 593 search results, only 46 studies were reviewed. This paper outlines complementary feeding strategies practiced in Kenya both in rural and urban settings. Sorghum and millet porridge, mashed potatoes, plantain and pumpkin are the most common foods introduced. Juices, fruits, milk and water are also given additionally. Diets of children in rural areas is more rich in natural foods compared to diets of those in urban areas. However it less diverse.

Conclusions: Kenya being a middle-income country, certain barriers both in rural and urban areas limit practical adherence to optimal complementary feeding guidelines.

Keywords: Some of the key words used included: "complementary feeding practices", "rural and urban" "early childhood feeding" and "Kenya"

Conflict of Interest Disclosure: No financial or non-monetary support has been received from any organization for the conduct of this study. Therefore I wish to declare no conflict of interests.

THE KITCHEN IS OURS: DEVELOPING COOKINGS KILLS IN THE COMMUNITY

(1)Gines Geraldo, Ana Paula; (2)Rabello Chechi, Larissa Isabele; (2)Sousa, Julia Favaretto de; (2)Mello, Arthur Thives de; (3)Vieira, Francilene Gracieli Kunradi; (3)Assis, Maria Alice Altenburg de; (3)Di Pietro, Patricia Faria; (3)Boaventura, Brunna Cristina Bremer; (4)Pinto-e-Silva, Maria Elisabeth Machado.

(1)PhD. Nutritionist. Federal University of Santa Catarina. Department of Nutrition.; (2)Undergraduate student. Department of Nutrition. Federal University of Santa Catarina. Florianópolis. Brazil.; (3)PhD. Nutritionist. Department of Nutrition. Federal University of Santa Catarina. Florianópolis. Brazil.; (4)PhD. Nutritionist. Department of Nutrition. University of Sao Paulo. São Paulo, Brazil.

Background and objectives: The ability to prepare food can impact on people's food choices. Cooking skills have been devised, developed and perfected in all societies, and improved from generation to generation. However, it is of concern that young people are not acquiring the basic skills of cooking that enable them to have autonomy over the foods they choose. Given this scenario, it is necessary to develop strategies aimed at sensitizing people on the importance of cooking and improving culinary skills. The objective of the present study was to show a food and nutritional education program developed with audio-visual resources, to encourage the development of cooking skills in the community.

Methods: The selection of themes to compound the program was based on a review of cooking techniques (cutting, chopping, peeling, tempering, and cooking methods like roasting, grilling, frying, steam cooking) involved in pre-preparation and preparation of foods. The elaboration of theoretical content used in the videos was based on books of gastronomy and scientific articles. The videos were recorded by three students of the undergraduate nutrition course of the Federal University of Santa Catarina, Brazil, supervised by teachers of disciplines related to food preparation. All videos were developed in the Dietetic Technique Laboratory of the university, using a semiprofessional camera and the program Final Cut Pro for Windows to edict the videos.

Results: Twenty-five videos were developed on the following topics: cleaning fruits and vegetables, measuring techniques and ingredients weighing, types of knives, mise en place, use and functions of utensils in the kitchen (sieve, vegetables peeler, kitchen brush, sharpening steel, cutting board, fouet, spatula) use and functions of stand mixer, food processor, blender and oven. Up to now 15 videos have been posted weekly in a youtube channel developed for this purpose and they were shared in social networking's Facebook and Instagram for the dissemination of the activities developed in the program. The average video views on Facebook and Instagram were 259.27 and 103.42, respectively.

Conclusions: The activities developed allowed the development of materials on topics of culinary practice that are fundamental for the development and improvement of the culinary skills of the community.

Keywords: Cooking skills, healthy eating, culinary confidence, food preparation

DO "EMPOWERED" WOMEN AND THEIR CHILDREN HAVE BETTER NUTRITION OUTCOMES THAN THEIR LESS-EMPOWERED PEERS?

[1]Nordhagen, Stella; [1]Nordhagen, Stella; [2]Klemm, Rolf.

[1]PhD. Africa Regional Monitoring and Evaluation Advisor. Helen Keller International. Senegal.; [2]Vice President Nutrition. Helen Keller International. & Senior Associate. JHU School of Public Health. USA.

Background and objectives: Women's empowerment is considered key to improving women's and children's nutrition, but issues of measurement and complexity mean that direct evidence of a link is limited. This research examines the association between different domains of empowerment and dietary and nutrition status outcomes among women and their young children in Burkina Faso.

Methods: We examine cross-sectional data on married women and their young children from a 2014 household survey (designed by the International Food Policy Research Institute, n=2468) across 60 villages in rural Eastern Burkina Faso. Based on a set of questions about women's status, a set of "empowerment scores" were created covering seven domains (1) spousal communication, (2) purchasing decisions, (3) healthcare decisions, (4) family planning decisions, (5) infant and young child feeding decisions, (5) meeting with other women, and (6) social support, as well as an aggregate women's empowerment score. Using simple and multivariate regression analysis, we examine unadjusted and adjusted associations between each empowerment domain and the aggregate score and woman-based outcomes including dietary diversity, consumption of key nutrient-rich foods, anemia prevalence, hemoglobin concentrations, BMI, and underweight status. We repeat similar analyses to examine associations with child-based outcomes, including exclusive breastfeeding through 6 mo of age, consuming nutrient-rich foods, dietary diversity, and HAZ, WAZ, and WHZ scores. Multivariate regressions control for potential confounding variables, such as educational attainment and wealth, as well as clustering of results by village.

Results: The results show moderate but not systematically positive associations between women's empowerment and child/maternal nutrition outcomes. For example, women's hemoglobin levels, BMI, and likelihood of early breastfeeding are found to be positively associated with the empowerment scores, whereas children's growth outcomes are uncorrelated with empowerment. Certain domains of empowerment were more commonly positively associated with outcomes: interaction with women in community, social support, and healthcare decisions.

Conclusions: While women's status is associated with nutrition outcomes, the relationships found here are not clear-cut. This may be due to the cross-sectional nature of the data or the way in which empowerment was measured in this study.

Keywords: Gender, empowerment, women's nutrition

DOES ENHANCED HOMESTEAD FOOD PRODUCTION (EHFP) AND NUTRITION EDUCATION HAVE AN IMPACT ON WOMEN'S DIETARY DIVERSITY AND NUTRITIOUS FOOD AVAILABILITY? A CASE FROM PROJECT LEASER BEAM (PLB) IN BANGLADESH

[1]Afroz, Shirin; [2]Asif, Chowdhury Abdullah Al; [3]Waid, Jillian; [4]Stormer, Ame; [5]Mundy, Gary; [6]Hannan, Abu; [7]Talukder, Aminuzzaman.

[1]Shirin Afroz. MSC. MPH. Director Nutrition. Chowdhury Abdullah Al Asif. MDS. Research and Evaluation Manager. Jillian L. Waid. Director Research Learning and Evaluation. Ame Stormer. PhD. Regional Director for Programs. Gary Mundy. MA. Regional Monitorin; [2]MDS. Research and Evaluation Manager. Helen Keller International. Dhaka. Bangladesh.; [3]MSW. Director Research Learning and Evaluation. Helen Keller International. Dhaka. Bangladesh.; [4]PhD. Regional Director for Programs. Regional Office. Helen Keller International. Phnom Penh. Cambodia.; [5]MA. Regional Monitoring and Evaluation Advisor. Regional Office. Phnom Penh. Cambodia; [6]B. Sc. Ag. (Hons.). Helen Kellen International. Dhaka. Bangladesh.; [7]MPH. Country Director. Helen Keller International. Dhaka. Bangladesh.

Background and objectives: Micronutrient inadequacy is a major challenge faced by individuals in resource-poor countries such as Bangladesh where the diet is predominantly plant and rice based. Women and children face higher levels of malnutrition than men. In partnership with the Mondelez Foundation, Helen Keller International (HKI) implemented Project Laser Bean (PLB) from 2012 to 2016 in four upazilas of Satkhira District, in the southwestern coastal area. PLB provided training to households to increase the amount and diversity of garden production. We introduced poultry-rearing practices for egg production, formed marketing committees with links to market actors, built business skills to market agricultural products, and educated mothers through nutrition education.

Methods: Data were collected from project participants as a panel survey at baseline (n=207) during 2012 and end line (n=197) at 2016. A pre-post comparison was done to analyze the changes in key outcome measures among beneficiary households.

Results: We observed a significant reduction in inadequate dietary diversity from 76% at baseline to 23 % at end line (p<0.001). We also saw an increase in the knowledge of vitamin A rich foods from 14% at baseline to 93% at the end line (p<0.001). While knowledge of anemia symptoms was high in the beginning of the project, it also increased from 85% to 99% (p<0.001). We observed a reduction in the average number of months in the year that households reported having an insufficient amount of food to eat as well from 1.24 months at baseline to 0.47 months at endline.

Conclusions: We observed positive changes in both food security and dietary diversity among mothers over the program period, with substantial improvements in knowledge. As change in knowledge did not act as a mediator in the increase in dietary diversity, future research should investigate other pathways to dietary improvement. Moreover, since we had no comparison pop-

ulation, we cannot attribute these changes to the program alone, but the program was likely a contributor. Further research should explore these issues utilizing a control group to be able to determine program impact and attribution.

DIET SODA CONSUMPTION AND ITS RELATIONSHIP WITH OVERWEIGH IN ADULTS AND ELDERLY IN BRAZIL

[1]Gines Geraldo, Ana Paula; [2]Pinto-e-Silva, Maria Elisabeth Machado.

[1]PhD. Nutritionist. Federal University of Santa Catarina. Department of Nutrition.; [2]PhD. Nutritionist. Departament of Nutrition. University of Sao Paulo. Brazil.

Background and objectives: Recent studies suggested that diet soda consumption may also be associated with health consequences, particularly type 2 diabetes and the metabolic syndrome. The objective of this study was to analyze the relationship between DS consumption and overweight in adults and elderly.

Methods: A cross-sectional study involving adult employees of two public universities in São Paulo state, Brazil. An online questionnaire was applied containing questions on the diet soda consumption and information about demographic, socioeconomic, anthropometric and health characteristics. The statistical analyses performed included: the chi-square test to determine association between explanatory and dependent variables, adopting a level of significance of $p < 0.05$.

Results: A total of 1323 individuals took part in the study. The prevalence of DS consumption was 36.8%. 64.2% were women, 83.3% were aged between 30 and 40 years old, with ≥16 years of schooling (76.6%) and income above $ 11900.00 (83.7%). 59.4% of the DS consumers had some degree of overweight and 63.6% reported having difficulty maintaining body weight. Among the obese, the prevalence of consumers was 45.6 times higher than those who did not consume. The frequency of difficulty in maintaining body weight was higher in consumers (63.6%) than in non-consumers (46.5%). In the evaluation of DS consumption and overweight, consumers were divided into three groups according to the amount and frequency of DS consumption frequency: "low" (mean frequency of consumption less than once per week and average amount of less than a glass), "moderate" (mean frequency of consumption once a week and average amount of one glass) and "intense" (mean frequency of consumption 2 to 3 times a week and average amount of consumption of two glasses). There was a statistically significant association between DS intake and nutritional status ($p = 0.004$). 41.8% of the obese individuals were present in the "intense" group while 23.8% of the eutrophic subjects were in this group, while on the other hand, the situation is reversed in the group "low", since the eutrophic individuals were the most present in this group.

Conclusions: The majority of DC consumers presented some degree of overweight and DS consumption was associated with overweight.

Keywords: Diet soda, overweight, consumption, artificial sweeteners, beverages

FACTORS OF RELEVANCE FOR HEALTHY EATING FROM THE PERSPECTIVE OF NUTRITION COLLEGE STUDENTS OF STATE OF SAO PAULO

[1]Koritar, Priscila; [2]Alvarenga, Marle.

[1]MSc. Nutrition Professor. UNIP. Brazil. PhD fellow. Public Health School. University of São Paulo. Brazil; [2]PhD. Professor. Nutrition Department. Public Health School of University of São Paulo. Brazil.

Background and objectives: Alimentation is an important determinant of health. The concept of healthy eating, however, is variable and suffers multiple influences nowadays. In the case of experts in nutrition, the perception of what is healthy eating can influence their professional conduct. The purpose was to evaluate factors considered relevant for healthy eating between nutrition college students of state of Sao Paulo participants of the Brazilian cohort Nutritionist Health Study - NutriHS

Methods: A sample of 412 nutrition college students (18 and 30 years) of 34 public and private institutions in 22 cities of the state of São Paulo answered online questionnaires indicating the importance of 14 factors for healthy eating and eating disorders (ED) risk behavior. They related age, weight, height, type of institution and graduation year. The nutritional status were assessed by means of Body Mass Index. Factors of importance for healthy eating were evaluated with respect to type of institution, nutritional status and ED risk behavior by weighted frequency.

Results: Students were on average 22.7 years (SD 2.9), 70.1% had normal range weight, 48.8% were in the first two years of graduation and 28.4% presented ED risk. The main factors of relevance to healthy eating - the consumption of natural or minimally processed foods, pleasure and respect for signals of hunger and satiety - are in line with the Guideline for the Brazilian population, independent of type of institution, year of graduation, nutritional status and ED risk behavior. Some differences were observed in others factors of relevance to healthy eating. Caloric restriction was considered less important among students in the fifth year and more important among students with obesity caloric restriction. Have contact with food, cook and eat in appropriate environments were considered more important among public institutions students.

Conclusions: Characteristics strongly defended by the Guideline for the Brazilian Population as consumption of natural or minimally processed foods and pleasure have been incorporated as important by nutrition college students. Despite this, several

other characteristics related to healthy eating are different among students and need to be better worked during the college.

DESIGNING CULTURALLY APPROPRIATE MESSAGES AND APPROACHES FOR MATERNAL, INFANT, AND YOUNG CHILD NUTRITION IN MOZAMBIQUE: USE AND ADAPTATION OF TRIALS OF IMPROVED PRACTICES

[1]Barros, Iracema; [2]Picolo, Melanie; [3]Victor, Leonor; [4]Kavle, Justine.

[1]BSc. Nutrition Advisor. Maternal, Newborn, and Child Health and Nutrition Division. Maternal and Child Survival Program/PATH. Mozambique.; [2]BSc. Senior Nutrition Advisor. Maternal, Newborn, and Child Health and Nutrition Division. Maternal and Child Survival Program/PATH. Mozambique.; [3]BSc. Nutrition Officer. Maternal, Newborn, and Child Health and Nutrition Division. Maternal and Child Survival Program/PATH. Mozambique.; [4]PhD, MPH. Senior Nutrition Advisor. Maternal, Newborn, and Child Health and Nutrition Division. Maternal and Child Survival Program/PATH. USA.

Background and objectives: The United States Agency for International Development-funded Maternal and Child Survival Program (MCSP) is implementing an integrated reproductive, maternal, newborn, and child health and nutrition project in Northern Mozambique. The nutrition component focuses on preventive and curative interventions, both at facility and community level, with the goal of improving maternal, infant, and young child nutrition (MIYCN) practices. Despite the breadth of nutrition programs in Mozambique, little is known about behaviors, cultural beliefs, and perceptions that influence MIYCN, yet the Mozambique Ministry of Health recommends locally contextualized nutrition messages. We conducted a formative assessment to ascertain: 1) cultural beliefs, perceptions, and challenges related to infant and young child feeding (IYCF) for children 0-23 months of age using the Trials of Improved Practices (TIPs) methodology; 2) the role of fathers and grandmothers in influencing IYCF; and 3) cultural beliefs and perceptions related to maternal food consumption.

Methods: TIPs consists of 3 home visits to mothers of children 6-23 months of age. The first visit is to understand current feeding practices and ascertain challenges, the second is to counsel the mother on the feasible IYCF practices to try in a 7-day period, and the third visit is to discuss their experiences with the trial period. In-depth interviews (IDIs) and food frequency questionnaires were conducted with 26 mothers of children 6-23 months of age. IDIs were also conducted with mothers of children 0-5 months of age, pregnant women, and key influencers, including husbands and grandmothers. IDIs were recorded, transcribed, and coded by theme.

Results: A counseling guide was rolled out by MCSP in Mozambique. Targeted approaches and messages were aimed at ad-

dressing challenges to exclusive breastfeeding, increasing quality and quantity of food intake, increasing adherence to maternal iron and folic acid supplementation, and using local foods for recipes in cooking demonstrations.

Conclusions: TIPs is an innovative approach that allows mothers to test feasible practices at home and can inform program design and implementation to improve IYCF practices.

Keywords: Trials of Improved Practices, behavior change, infant and young child feeding, counseling messages, Mozambique

STUDY OF THE REASONS OF THE LOW CONSUMPTION OF VEGETABLES IN A POPULATION OF URUGUAYAN CHILDREN OF SCHOOL AGE

Raggio Aonso, Laura Maria; Raggio Alonso, Laura María.

Affiliation: Student PdD Chemistry, Food engineering, Food Department, School of Nutrition, UDELAR, Uruguay.

Background and objectives: The low intake of fruits and vegetables that children eat is becoming a cause of growing concern around the world. A low intake has been linked to a higher risk of developing noncommunicable diseases. Uruguay does not escape this world situation.

The objective of the present study is to explore the reasons and barriers of low consumption of vegetables in Uruguayan children of school age, in order to find strategies to promote the consumption of these foods.

Methods: A database of children from 6 to 12 years old interested in participating in the research was generated.

From the first study with the group of parents, we categorize the main reasons for the low consumption of vegetables that were obtained, which were grouped in 14 sentences.

With the sentences obtained in study 1, we sent a second survey, along with the list of the 20 most consumed vegetables in our market. For each sentence, they selected the vegetables that responded to the same one.

The frequency of mention of each vegetables was calculated for each sentence, followed by a Correspondence Analysis (CA) to visualize the relationship between the sentences and vegetables and a Hierarchical Agromerative Clustering of the vegetables.

Results: Factors 1 and 2 of the CA explained 81.63% of the variance of the results obtained from 260 parents.

Of the 20 listed vegetables, they were categorizate into 5 groups, each associated with different sentences.

For Example:

Cauliflower was considered a vegetable that many children do not consume because their parents never offered it, because someone in the family does not like it or because they do not know how to prepare it, so that vegetable is not usually part of the family diet.

Peas, spinach, chard, and zucchini are vegetables that children used to consume when they were young, but not today, and most parents do not know why they do not like them now and therefore must "force" them to consume them.

Conclusions: The results obtained allowed us to obtain a first approximation aimed at proposing future working hypotheses, with the aim of increasing the consumption of vegetables among children of school age.

Keywords: Children, low cosumption, vegetables

ROLE-MODELING CULTURALLY APPROPRIATE NURTURING CARE PRACTICES TO IMPROVE INFANT AND YOUNG CHILD NUTRITION

[1]Granger, Kristina; [2]Moreaux, Marjolein; [3]Koniz-Booher, Peggy.

(1) MPH. SBCC Technical Manager. Strengthening Partnerships,

Results: **Background and objectives:** The 2016 Lancet early childhood development series highlighted the importance of nurturing care (combining health, nutrition, and caregiving), indicating that improper nutrition and lack of stimulation can lead to irreversible developmental and health outcomes. The period from birth to three years is a critical time for brain development, and caregivers often interact most with children this age during mealtime. Based on this evidence, SPRING promotes nurturing care practices that help improve caloric intake and diversify young children's diets during this critical window of opportunity.

Methods: SPRING uses a community-led video model to promote nutrition, hygiene, and nurturing care through videos starring local early adopters who role-model positive behaviors. This approach begins with qualitative formative research, which is used to prioritize culturally-specific nurturing care practices to improve maternal, infant, and young child nutrition (MIYCN). Community members are then trained in production and early adopters star in locally produced videos that demonstrate positive nutrition practices, including responsive feeding and nurturing caregiving interactions by both men and women. The local videos are screened during community group meetings and always involve facilitated discussions. This model was first implemented in India and then adapted for Niger.

Results: In India, the complementary feeding videos highlighted feeding young children patiently, not force-feeding, and encouraging the child to self-feed with finger foods, along with messages on food consistency and dietary diversity. In Niger, the videos focused on promoting a responsive caregiver feeding style and using a separate plate because formative research showed children ate from a family plate, with little interaction with a caregiver. Monitoring data has shown an increase in nurturing care behaviors in both countries, and qualitative research findings indicate that seeing the practices modeled in the videos helps caregivers to adopt them.

Conclusions: These results indicate that community video is an effective approach for improving responsive feeding behaviors that contribute to improved nutrition through the concept of nurturing care. This work provides an opportunity to strengthen linkages between nutrition and early childhood development by highlighting nutrition and care behaviors that can potentially help to enhance child development and positive parenting skills.

Keywords: Nutrition, IYCF, responsive feeding, SBCC, nurturing care

PREVALENCE OF FOOD AND NUTRITION SECURITY IN VULNERABLE GROUPS (MOTHERS AND THEIR CHILDREN (7-36 MONTHS)) FROM URBAN SLUMS OF VADODARA, GUJARAT, INDIA

[1]Chandorkar, Suneeta; [2]Chandorkar, Suneeta.

[1]PhD. Nutritionist. Department of Foods and Nutrition. The Maharaja Sayjirao University of Baroda. Vadodara, India; [2]PhD. Nutritionist. Department of Foods and Nutrition. The maharaja Sayajirao University of Baroda. Vadodara, India.

Background and objectives: Urban poor, dwelling in slums, are at higher risk of Food and Nutrition insecurity and women and children are the most vulnerable group. Hence, the present investigation aimed at mapping the prevalence of food and nutrition insecurity among vulnerable individuals (mothers and their children (7-36 months)) living in urban slums of Vadodara city.

Methods: Two Hundred Ninety Seven slum households from two out of five zones of Vadodara city were assessed for Food and Nutrition Security (FNS). Four dimensions of Food and Nutrition Security namely, accessibility, availability, utilization and stability were assessed for mothers and children 7-36 months of age by WFP VAM method (2010).

Results: Mothers were found to be moderately secure using 1890 Kcal energy/consumer unit/day as the indicator for availability. Using optimal breastfeeding practices as indicator of availability the children were categorised as having low FNS. Presence and availing of safety net programs namely food through public distribution system and take home ration through government feeding programs for mothers and children indicated high FNS while the marginal to poor utilisation of same threatened the FNS in the vulnerable groups. Accessibility as studied using Individual Dietary Diversity Score (IDDS) of mothers showed that 91%, 9.1%, and 0.3% were moderately secure, secure and insecure, respectively while 82%, 6% and 12% of children were moderately secure, secure and insecure respectively. Although 89% of the mothers were literate no significant correlation was found between IDDS of mother and child with the education level of mother. FNS measured by utilization namely presence of chronic energy deficiency (CED) indicated that 29% of the mothers had CED, 43% were nor-

mal and 28% were overweight. About 54% were stunted, 25% were wasted and 45% were underweight.

Presence of safety net programmes indicated stability of FNS. The composite index for overall FNS in study households indicated moderate security.

Conclusions: Though the presence of safety net program ensured availability of food and stability, the mothers and children from the urban slum households experienced moderate to low FNS due to poor utilization of the same.

APTITUDES AND STYLES OF LIVING, IN TYPE II DIABETES ADULT PATIENTS ADMITTED IN THE MEDICAL CLINIC I WARD OF THE SOCIAL SECURITY CENTRAL HOSPITAL IN ASUNCIÓN

Guggiari, Johanna.

MSc.MD. Nutricionist. Instituto de Previsión Social. Paraguay.

Background and objectives: Therapeutic compliance of patients suffering from chronic diseases requires a multidisciplinary approach. Health professionals should develop awareness son the problem in patients and their families. Not only the family, but the community and also patient organizations are key factors for the success of treatment.

To describe aptitudes and styles of living, in Type II Diabetes adult patients admitted in the Medical Clinic I ward of the Social Security Central Hospital in Asunción.

Methods: Descriptive design and transversal analysis. One hundred patients withType II Diabetes Mellitus were part of the study. The IMEVID questionnaire was applied to all of them. Variables studied were. Age, sex, lifestyles, level of Glycated Hemoglobin. Statistics: Parametric and non Parametric Measurements. Pearson Correlation Test. Significance: $p < 0,05$.

Results: 100 patients were admitted. Female subjects: 66 %. An inappropriate lifestyle was confirmed in 58 % of the patients admitted with Type II Diabetes Mellitus. Female subjects were predominan treaching 66% of the total. 47 % of the patients had Glycated Hemoglobin above 7%. Pearson correlaction reached 0.03207 ($p<0,05$).

Conclusions: A high percentage of the patients admitted to the Hospital withType II Diabetes Mellitus leadanin appropriate lifestyle and present a high value of Glycated Hemoglobin.

Keywords: Diabetes Mellitus, lifestyle, glycated hemoglobin.

STUDY OF FOOD PATTERN, BY USING GROUP DISCUSSION METHOD, IN MOROCCAN RURAL POPULATION

[1]Barouaca, Hassan; [2]El Hassouny, El Hassan; [3]Bour, Abdellatif.

[1]PhD. Nutritionist. Higher Institute of Nursing Professions and Techniques of Health of Errachidia. Morocco; [2]PhD. Nutritionist. Equipe de Transition Alimentaire et Nutritionnelle (ETAN). Laboratoire des Essais Biologiques. Université Ibn Tofaïl. Kenitra. Maroc; [3]Prf. Nutritionist. Equipe de Transition Alimentaire et Nutritionnelle (ETAN). Laboratoire des Essais Biologiques. Université Ibn Tofaïl. Kenitra. Maroc.

Background and objectives: It is now well established that nutritional factors are the major determinants of food behavior and the emergence of chronic diseases. In Morocco, there is no data on food behavior in rural population as Moroccan population now is in epidemiological transition.

This research aims to study the food pattern in rural population (Bani Zeroual) of Taounate region.

Methods: We used a well-known analysis method: Focus Groups (FG) to determine all items that may be characteristics of this population. Also we have assessed the diet over a period of three to five days during which the respondent is asked to recall and describe all food and drinks consumed in the 24 hour prior to the interview

Results: The data obtained showed that the Mediterranean diet was not the diet commonly followed by the whole population studied. Moreover, the phenomenon of nutritional transition whose specificity in Bani Zeroual population is the maintenance of certain traditional foods such as cereals and vegetables in addition to the introduction of westernized foods such as dairy products. These profiles were associated with the socio-demographic characteristics of individuals

Conclusions: It becomes clear that the use of focus groups is an effective tool for studying the behavior of food and health status of a population. Therefore, focus groups can be used not only for Behavioral Study Food and health status of a population, but also in other areas.

At the end of this study, this method of idea generation: FG can be an "indicative" diagnostic tool for the behavior of food and the health status of a population that can act as a "smoke detector ". Subsequently, the obstacles and problems detected are to be verified and confirmed by conventional diagnostic methods of 24 recall and frequency questionnaire.

Keywords: Focus groups, dietary pattern, health status of a rural population

PILOT STUDY TO ASSESS PREFERENCE AND AC-CEPTABILITY OF RECIPES USING BIOFORTIFIED SWEET POTATOES AMONG WOMEN IN PANA-MANIAN RURAL COMMUNITIES

[1]Britton, Adela; [2]Chu, Jenny; [3]Barría, Maika; [4]Rios- Castillo, Israel; [5]Vergara, Eira.

[1]BSc,Nutritionist, Nutrition and Dietetic Department, Medicine School, University of Panama, Panama City, Panama.; [2]Nutritionist, Nutrition and Dietetic Department, Medicine School, University of Panama, Panama City, Panama.; [3]Nutritionists, Research and Innovation Division in Genetic and Biodiversity Resources, The Institute of Agricultural and Livestock Research of Panama (IDIAP), Panama City, Panama; [4]MSc, Nutritionists, Nutrition and Dietetic Department, Medicine School, University of Panama, Panama City, Panam; [5]MPH, Nutritionists, Nutrition and Dietetic Department, Medicine School, University of Panama, Panama City, Panama.

Background and objectives: Undernutrition and micronutrient deficiencies among rural indigenous and non-indigenous communities remain as a public health problem in Panama. The present study is aimed to determine the preference and acceptability of recipes with biofortified sweet potatoes with housewives from the communities of Chichica and El Copé, two rural Panamanian communities.

Methods: A descriptive cross-sectional observational pilot study was conducted through a survey of acceptability, using a hedonic scale, and one of preference. This study is part of a muti sectoral nutrition- sensitive agriculture project leaded by IDIAP in Panama (AgroNutre). Four recipes based on usual consumption patterns were selected, two with a salty taste and two with a sweet taste. The sample had a total of 50 housewives from Chichica and El Copé. Data on dietary diversity and frequency of consumption of vitamin A source foods were also obtained through the USAID Home Dietary Diversity Indicator (HDDS).

Results: The four recipes evaluated in this study were accepted by both communities. In addition, the most preferred salty recipe was sweetpotato tamale in both communities. As for the sweet recipe, the most preferred in Chichica was sweet potato soda; and in El Cope, it was the sweet potato weevil

Conclusions: Biofortified sweet potato was well accepted in both communities, which supports the use of this biofortified item as a strategy to combat vitamin A deficiency.

Keywords: Panama, indigenous, biofortified crops, nutrition, food security.

MEDITERRANEAN DIETARY MODEL FOR PRE-VENTION OF FOOD-RELATED DISEASES AND FREQUENCY OF CONSUMPTION SELECTED PRODUCTS IN ITALIAN AND POLISH STUDENTS

[1]Bronkowska, Monika; [2]Piotrowska, Ewa; [2]Lozna, Karolina; [2]Figurska-Ciura, Danuta; [3]Habanova, Marta; [4]Del Core, Guseppina.

[1]associate professor, Department Of Human Nutrition, Wrocław University of Environmental and Life Sciences; [2]Dr. Department Of Human Nutrition, Wrocław University of Environmental and Life Sciences; [3]associate professor, Department of Human Nutrition, Slovak University of Agriculture in Nitra; [4]Pontificia Facoltà di Scienze dell'Educazione delle Figlie di Maria Ausiliatrice.

Background and objectives: Traditional Mediterranean diet was characterized by an abundance of vegetable, fruit, cereals and legumes, dairy products consumed in moderate amounts, olive oil as the principal source of fat, red meat consumed in low amounts, fish consumed in moderate amounts, and wine consumed in moderate amount, normally with meals.

Currently, there is a growing interest in the possibility of overall dietary patterns' complex influence on the risk of ischemic heart disease, arterial hypertension, diabetes cancers, biomarkers of obesity, and cardiovascular disease because some food items and nutrients could have synergistic or antagonistic effects when they are consumed in combination.

Methods: The study was conducted between 2015 and 2016 at three Roman universities. 454 students aged 20-25 from Italy and Poland participated in the study. The QEB Questionnaire was developed by the Behavioral Nutrition Behavioral Team, the Committee on the Science of Human Nutrition, the Polish Academy of Sciences. Students answered questions in the questionnaire designed to study nutritional behaviors and opinions on food and nutrition placed on the g mail platform.

Results: 47% from of students Italy and Poland consumed 3 meals a day, and over 48% consumed them irregularly. Approximately 43% of the respondents dripped fish once a week and 24% several times a week. In this group was the majority of Italian students. Only 42% consumed fruit and 44% vegetables a few times a day, the majority of them were Italian students (34%). Students from Poland (36% of the respondents) were more likely to eat white bread than the Italian ones. Italian students (45% of the respondents) consumed whole wheat pasta more often than students from Poland. 61% of students do not use any fat to spread the bread, mainly Italian students. Students from Poland (43% respondents) more often eat red meat several times a week than Italian students.

Conclusions: Polish students although they are studying and currently live in Italy do not apply the rules of the Mediterranean diet. There is a large group of Italian students who also do not follow the rules recommended in this diet.

ATTITUDES TOWARD BEEF AMONG NUTRITION COLLEGE STUDENTS

[1]Koritar, Priscila; [2]Alvarenga, Marle.

[1]MSc. Nutrition Professor. UNIP. Brazil. PhD Fellow. Nutrition Department. Public Health Schol of University of São Paulo. Brazil.; [2]PhD. Professor. Nutrition Department. Public Health Schol of University of São Paulo. Brasil.

Background and objectives: Although meat consumption be indicated as part of healthy eating, attitudes toward meat are diverse in society. Eating attitudes - beliefs, thoughts, feelings, behavior and relationships with food - of nutrition college students will guide professional practice. The purpose was to evaluate attitudes toward beef among nutrition college students of state of São Paulo participants of the Brazilian cohort Nutritionist Health Study – NutriHS.

Methods: A sample of 613 nutrition college students (from 18 to 30 years) of 34 public and private institutions in 22 cities of the state of São Paulo answered online, in free association, the first word that comes to mind when they think in the word "beef" and a questionnaire about eating disorders (ED) risk behavior. They related age, weight, height, type of institution and graduation year. The nutritional status was assessed by means of Body Mass Index. The frequency of the words that came to mind when students were prompted to free associate to the word "beef" was evaluated and compared according to ED risk behavior, type of institution and graduation year.

Results: Students were on average 22.9 years (SD 3.0), 70.5% had normal range weight, 50.9% were in the first two years of graduation and 28.4% presented ED risk. Of the ten most frequent associations 34.4% reported some nutrient, 23.9% some type of meat, 20.9% culinary association, 7.9% appreciation, 3.1% meal, 2.5% animal, 2.5% disapproval, 1.6% blood, 1.3% death and 1.0% frequency of consumption. Some differences between groups were observed as associations with type of meat were more frequent among students of fifth year and culinary associations were more frequent between students with low weight.

Conclusions: Attitudes toward beef are varied among nutrition college students. Although this variation is expected, the results indicate that attitudes toward food should be better discussed during the college, since they can directly influence professional practices.

Keywords: Attitudes, beef, nutritional sciences, students

EFFECT OF NUTRITION EDUCATION TO MOTHERS ON IMPROVED PULSE CONSUMPTION BY YOUNG CHILDREN AGED 6-24 MONTHS IN RURAL SIDAMA, SOUTH ETHIOPIA

[1]Whiting, Susan; [2]Berhanu, Getenesh; [3]Henry, Carol; [4]Green, Timothy J.

[1]PhD. College of Pharmacy and Nutrition. University of Saskatchewan. Canada; [2]MSc. University of Saskatchewan. College of Pharmacy and Nutrition. Canada; [3]PhD. University of Saskatchewan. College of Pharmacy and Nutrition. Canada,; [4]PhD. Healthy Mothers Babies and Children Theme. South Australia Health and Medical Research Institute. Australia.

Background and objectives: Poor feeding practice is not always lack of food but lack of knowledge of caregivers on appropriate feeding practices. Households with low income consume large amounts of starchy staples and little protein in low income countries. Pulse crops are rich in protein and key micronutrients yet pulse consumption is very low in Ethiopia, especially in SNNPR. The aim of the current study was to evaluate the effect of nutrition education for mothers on the consumption of pulse among their children aged 6-24 months.

Methods: 771 mothers-child pair (386 intervention, 385 control) randomly selected from 12 villages were participated in the educational intervention study from Sidama Zone, South Ethiopia. Nutrition education given for mothers for 9 months on key messages about pulse benefits, household pulse processing techniques and incorporating pulse in the complementary food (CF). Health Extension Workers (HEWs) were trained on the key messages, and then provided group education and house-to-house counseling for mothers for 9 months. In control sites HEWs gave usual lessons. Frequency of pulse consumption as well as mothers' practice of incorporating pulse in complementary food was assessed using a standard pre-tested questionnaire at baseline, midline and endline.

Results: Using pulse for CF improved at midline and endline compared to baseline. At baseline 49.9% of mothers from intervention group reported that they have used pulse for CF and this increased at midline (94%) and endline (98.4%). Used haricot bean was most common: 46.4% at baseline of which 73% give once or twice a week; 96.3% at midline of which 37% give more than one per day and 94.6% at endline of which 57% give more than one per day. At endline nearly 3% of mothers from the intervention group also started using faba bean in CF. At baseline 64.2% mothers from control group reported that they have used pulse for CF which did not increase midline (67%) or endline (67.7%).

Conclusions: Nutrition education intervention improved pulse consumption among children in rural communities of Ethiopia. Thus, promoting of pulse crops for incorporating in complementary food should be encouraged.

TRANSFORMATIONS AND SOCIO-CULTURAL ASPECTS OF THE MEDELLIN SCHOOL DINING PROGRAM FROM 1961 TO 2010

[1]Arboleda, Luz Marina; [2]Velasquez, John Edinson.

[1]Nutritionist dietitian, PhD in social Sciences Coordinator of the Socio-anthropology on Food Research Group School of Nutrition and Dietetics - University of Antioquia; [2]Nutritionist dietitian school of nutrition and dietetics, University of Antioquia, Medellin Colombia.

Background and objectives: Diet is a complex sociocultural act providing biological, nutritional, political and social dimensions. Interlocking them creates inequalities such as food shortages and access to food through social programs. The aim of this study is to identify the changes in the program of school restaurants in Medellin (Colombia), and to interpret the perception of the program's beneficiaries.

Methods: Qualitative and historical perspectives; ethnography and history of the present time. Ethnography was conducted with school beneficiaries and their parents, councilors, program coordinators, food handlers and nutritionists. Historical Archives of Medellin and Minutes Archive Medellin Municipal Council were reviewed to collect the historical information, reports and correspondence.

Results: The program has different models of service provision and different coverage; it has retained the sympathy of the mayors and officials of the various secretariats. This was set up at the beginning, in 1935, from a perspective of charity school by elite women, and then it had a hygienist and nutritional vision of right to food; and finally, a food and nutrition safety vision. In the supplied speeches and preparations, the absence of cultural references is identified.

Conclusions: School Restaurants programs help to reduce the suffering caused by hunger, but they are not always designed thinking about the cultural aspects that involves food.

Keywords: School restaurants, hunger, food, Medellín

EFFECT OF THE SCHOOL-BASED HEALTH PROMOTION INTERVENTION ACTIVITAL ON DIETARY INTAKE AND WAIST CIRCUMFERENCE: A CLUSTER RANDOMIZED CONTROLLED TRIAL

[1]Ochoa, Angelica; [2]Ochoa Avilés, Angelica; [3]Andrade Tenesaca, Dolores Susana; [4]Verstraeten, Roosmarijn; [5]Huybregts, Lieven; [6]Lachat, Carl; [7]Ramírez Jimbo, Patricia Liliana; [7]Andrade Muñoz, Diana Jesús; [8]Donoso Moscoso, Silvana Patricia.

[1]Universidad de Cuenca; [2]MD. PhD. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Ecuador.; [3]MSc. PhD. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Ecuador.; [4]MSc. PhD. Consultant. Ghent-Belgium; [5]MSc. PhD. Poverty Health and Nutrition Division. International Food Policy Research Institute. Washington DC-USA; [6]MSc. PhD. Department of Food Safety and Food Quality. Ghent University-Belgium.; [7]Eng. MSc. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Ecuador.; [8]Bioq. MSc. Department of Biosciences. Faculty of Chemistry Sciences. Cuenca University. Ecuador.

Background and objectives: Unhealthy diet and abdominal obesity during childhood are important risk factors for chronic diseases at adulthood. We report the effect of a school-based intervention on the nutritional value of dietary intake and waist circumference after 28 months; and explore if the effect varied within important subgroups (weight and socioeconomic status).

Methods: A cluster randomized controlled trial (10 intervention/10 control schools) including 1430 adolescents (12-14 years old) was conducted in Ecuador. The intervention aimed to decrease adolescents sugar intake and unhealthy competitive food (rich in sodium, fat or added sugar) intake, as well as to promote fruit and vegetable intake (primary outcomes). Waist circumference was a secondary outcome. Primary outcomes were estimated by means of two twenty-four-hour recall. All outcomes were measured before and after the intervention. The interventions consisted of healthy eating classes with adolescents, healthy eating workshops with parents and canteen staff, and social events. The effect of the intervention was assessed using linear mixed effects models. A subgroup analysis by weight and socioeconomic status was performed including all the outcomes with a significant intervention effect.

Results: The analysis involved data from 1046 adolescents. Students from the intervention group consumed less unhealthy competitive food during snacks (-23.32 g; 95% CI: -45.25,-1.37) and less added sugar (-5.66g; 95% CI: -9.63,-1.65). Daily fruit and vegetable intake decreased compared to baseline, albeit significantly less in the intervention group (23.88 g; 95% CI: 7.36, 40.40). Waist circumference (-0.84 cm; 95% CI: -1.68, 0.28) was lower in the intervention group. The intervention effect on fruit, vegetables, added sugar, and, competitive food was independent of the weight and socioeconomic status of the participants. The effect on waist circumference, was larger among overweight-obese (-1.35 cm; 95% CI: -2.25, -0.45) but similar for different socioeconomic backgrounds.

EARLY INFANT AND CHILD FEEDING PRACTICES AND THEIR ASSOCIATION WITH CHILD GROWTH IN THE RURAL KALALÉ DISTRICT OF NORTHERN BENIN

[(1)]*Mpody, Christian;* [(2)]*Alaofe, Halimatou;* [(2)]*Taren, Douglas.*

[(1)]MD. Research Assistant. Epidemiology and Biostatistics. University of Arizona. USA.; [(2)]PhD. Professor. Health Promotion Sciences. University of Arizona. USA.

Background and objectives: An understanding of feeding practices can help develop appropriate nutrition education messages. The objective for this study was to determine what were the early infant and child feeding practices in Northern Benin and their relationship with child growth.

Methods: Baseline data from a village-level irrigation program on food production was used for this study. Dietary and anthropometric data were collected from 559 children < 24 months of age. 24-hour recall was used to determine what foods were currently consumed by the children and if they were currently breastfeeding. Mothers were asked to recall when specific food items were first given to their children. 24-hour recall data were used to create a modified Infant and Child Feeding Score (ICFS) as described by Arimond and Ruel. Correlations and general linear models were used to determine the relationship between the ICFS and growth of children, controlling for education, employment, marital status, and SES. Results were also stratified by 4 age groups: 6-8 months, 9-11 months, 12-17 months and 17-24 months of age.

Results: Greater than 90% of infants were breastfeed through 17 months of age and 53.8% were breastfeed between 17 and 24 months. 13.1% were stunted and 20.7% were underweight. The most common order for introduction of foods to the children followed a pattern of liquids first then porridge, cow's milk, soft food, fish, vegetables. Meat was usually the last food introduced with less than 30% consuming meat at 10 months of age. The diet was also low in oil with < 20% consuming oil before 12 months of age. The ICFS was positively related with weigh-for-age for 6-8 month old children and with lengh-for-age for all children and for the age groups 12-17 months and 17-24 months. These relationships remained significant in a fully adjusted model. There was no significant association between the ICFS and weight-for-length.

Conclusions: The ICFS was associated with child growth. Additionally the results suggest that the pattern of introducing complementary foods could be modified to improve child growth.

Keywords: Infant, Breastfeeding Diet, Growth

THE RELATIONSHIP BETWEEN THE SUBJECTIVE EVALUATION OF MEAL IN FEMALE UNIVERSITY STUDENTS AND THEIR LIFE STYLE

[(1)]*Koizumi, Kayo;* [(2)]*Okubo, Mion;* [(3)]*Omori, Akane;* [(4)]*Cho, Chuhwa;* [(5)]*Nakajima, Sanae.*

[(1)]Ph.D. Japan Woman's College of Physical Education. Japan; [(2)]Japan Woman's College of Physical Education. Japan; [(3)]M.S. Abiko Nikaido High School. Japan; [(4)]Japan Woman's College Of Physical Education Graduate school . Japan; [(5)]Ph.D. Kyoritsu Women's Junior College. Japan.

Background and objectives: The nutritional environment in Japan has been changing rapidly. Environmental, social, and individual factors influence eating patterns, which in turn affect maintaining an appropriate bodyweight. It is important to eat three meals daily, breakfast, lunch, dinner, and to choose meals of appropriate quantity and quality. However, it is difficult for female university students to effectively choose in the manner. The aim of this study was to uncover the level of recognition of desired meal characteristics for female university students, and examine the reason why they are not able to choose appropriate quantity or quality in their meals.

Methods: A self-administered questionnaire was distributed to Japanese female university students attending Women's' University (F: n=185) or Physical Education University (PE: n=70). The questionnaire contained questions on lifestyle, physical characteristics, food intake frequency, and included a comment section regarding photographs of two kinds of meals. We classified their comments as "dietary behavior", "quantity", "nutrient", "food group", "dish division", "quantity/nutrient/food group unidentified", and "other" according to Healthy Japan 21 (second term), counted the number of comments in each category. The subjects were also divided into two groups based on "quantity". The data was analyzed by t-test. Difference with $p<0.05$ was considered significant.

Results: The results showed no significant difference in the number of the comments between F (4.4 ± 2.4) and PE (4.9 ± 2.4). Also the number of the comments of "quantity of meal" showed no significant difference between the two groups (0.78 ± 0.92).

Conclusions: The results indicated that exercise habits, food intake frequency and dietary habits in Japanese young females did not influence dietary behavior.

Keywords: Quantity of meal, female university students, life style, physical characteristics

Conflict of Interest Disclosure: No potential conflicts of interest were disclosed.

PROMOTING FACTORS OF NUTRITIONAL CULTURE IN ADOLESCENTS AND YOUNG ADULTS OF THE UNIVERSITY OF LA SABANA

[1]*Rodríguez, Sandra;* [1]*Segnini, Franco;* [1]*Martínez, Mariagracia;* [1]*Cajiao, Valentina;* [2]*Celis, Luis.*

[1]Student of Medicine. Universidad de La Sabana, Bogotá. Colombia; [2]Egresado en Biología y Educación. Especialista en Prospectiva y Estrategia Organizacional. Especialista en Bioética. Maestría en Biología, Colombia.

Background and objectives: The adolescents of our country, have become a group for the study of the development of chronic non communicable deseases as diabetes and obesity through the study of some risk factors evaluated.

The purpose of our work is to evaluate the body composition, lifestyles and nutricional habits of young adults of the Universidad de La Sabana, Bogotá with the purpose of implement programs to promote a nutricional culture.

Methods: This study was descriptive cross-section with random sampling of the University population of the Universidad de La Sabana. It was done through the measurement of body composition through the use of an impedanciometre, anthropometric measures, measures of perimeter, diameters and taking of fasting blood samples for the determination of total cholesterol, triglycerides and lipoproteins in a population of 165 students between the ages of 16 and 21 years.

Results: The results obtained show that among the 165 students, 10.3% were underweight, 13.93% were overweight and 0.6% showed obesity. As to gender, 4.8% of the men and 9% of the women were overweight, 3% of the men and 7.2% of the women were underweight and 0.6% of the women showed obesity. Blood chemistry: 30% suffered hypercholesterolemia, 18% suffered hypertriglyceridemia, 17% had low levels of HDL and 67% had high levels of LDL. Also 2% had pre-diabetes levels, this in a population that ranged from 16 to 21 years can be related with genetical factors or also due to bad nutritional habits. 7% of the population whose homocysteine values were higher than the normal parameter have an increased risk of thromboembolism, heart disease, stroke and complications of diabetes such as neuropathy. The elevation of this aminoacid can be caused by bad eating habits. From all cases studied, 40% showed risk factors for a metabolic syndrome. 60% did not perform any physical activity, 44.70% of them were women

Conclusions: These results allowed us to implement in the institution a culture of healthy habits, reason why we worked with the University Welfare Department to adjust the menu that offers the campus encouraging the students to a higher consumption of fruits and vegetables, low-salt food and low carb foods.

Keywords: Nutritional culture, obesity, cardiovascular risk, body composition, body mass index.

Conflict of Interest Disclosure: These results show Diabetes Mellitus and metabolic syndrome are not diseases of older adults, as we found it among the population of ages between 16 and 21 years old; which are individuals that suffer from high cardiovascular risk factors as hemocisteinemia, hypertriglyceridemia, hyper-cholesterolemia, obesity and even 2% of them have pre-diabetes. This results are really important because if not corrected on time, the damage could be irreversible.

Universidade Federal Fluminense. Brasil.; [5]PhD. Nutritionist. Universidade Estadual do Rio de Janeiro. Brasil.

Background and objectives: Introduction: Food choice is influenced by several factors, including sensory, economic, social, cultural, and psychological aspects, and is related to social environment and personal history and values.

Objective: To describe the factors that influence food choice in adolescents according to sex, weight, and physical activity level.

Methods: The study investigated 405 6th and 7th graders from two public schools in Niterói, Rio de Janeiro, Brazil. Data were collected in 2014 using a multidimensional questionnaire. Adolescents were asked to select, among 15 options, the 3 most important reasons for their food choice, which were categorized as: sensory aspects ("taste", "color", "smell", "appearance"), socio-cultural aspects ("habit", "my family usually eat", "my friends like", "low-calorie foods", "religion"), economic/access aspects ("have in my house", "price", "easy to buy", "easy to prepare"), and "healthy eating". The chi-square test ($p < 0.05$) was used to verify the homogeneity of proportions of factors according to categories of gender, weight status, and physical activity level.

Results: Among the analyzed adolescents mean age was 12,05 years old, 53,6% were male, 34,4 % overweight, 58% physically active. The top factors influencing food choice by the studied adolescents were "taste" (72%), "smell" (45%), "appearance" (32%), "texture" (22%), and "color" (20%), followed by "having a healthy diet" (19%) and "my family usually eat" (16%). Compared to insufficiently active adolescents, a higher proportion of active adolescents cited "having a healthy diet" as an important factor in food

choice; the same was observed for females compared to males. Overweight adolescents showed greater interest in low-calorie foods, compared to non-overweight adolescents. These differences presented statistical significance.

Conclusions: The study indicated that sensory aspects appear to be the most important factors took into consideration when choosing foods. Physically active adolescents and female showed more concern about healthy eating. These findings can help in the design of healthy eating promotion actions aiming adolescents.

Keywords: Adolescents. Food choice. Motives to choose food. Food consumption.

EVALUATION OF CLASSROOM FOOD EDUCATION (SHOKUIKU) COMBINED WITH VEGETABLE TASTE TESTING FOR COLLEGIATE FEMALE ATHLETES

[1]Nakajima, Saori; [2]Omori, Akane; [1]Cho, Chuhwa; [3]Koizumi, Kayo.

[1]Japan Woman's College of Physical Education Graduate school . Japan.; [2]M.S. Abiko Nikaido High School. Japan.; [3]Ph.D. Japan Woman's College of Physical Education. Japan.

Background and objectives: There are comprehensive food education programs, namely Shokuiku, that aim to improve dietary practices and reduce lifestyle-related diseases. This study aims to assess the effectiveness of the shokuiku combined with vegetable taste testing of bean sprouts, which aims to improve attitudes toward healthy eating vegetables.

Methods: The shokuiku was delivered to long distance runners (n=6) and naginata athletes (n=9) aged 18-22 years, within 90 minutes post-training. We prepared two kinds of bean sprouts cooking (boiled and fried) for the shokuiku. The content of the shokuiku included preparing two types of bean sprouts (boiled and fried) and recording the participants' feedback on appearance and taste. Afterward, they attended a lecture on vegetable preparation and nutritional value, and again recorded feedback. The feedback was divided and recorded into three categories, those being interest and motivation, knowledge and understanding, thinking and judgment. The questionnaire contained questions on knowledge of vegetable dishes and dietary habits.

Results: The long distance runners (83.3%) had more focus nutritional balance than the naginata athletes (22.2%) and were selective in their meals. The naginata athletes focused more on quantity of the meal. Furthermore, the naginata athletes showed a higher price ceiling than long distance runners, having a higher intake of vegetable dishes with potatoes and starches, green and yellow vegetable, white vegetable, fungi and algae. In their assessments, long distance runners had more feedback on the "knowledge and understanding", where naginata athletes had a higher feedback percentage in "interest, and motivation,"

Conclusions: For cases such as the long-distance runners, we should undertake Shokuiku focused on "knowledge and understanding". For naginata athletes who prioritized quantity, it is likely that Shokuiku regarding "interest and motivation" would have an affect on their day-to-day dietary habits.

Keywords: Food Education, vegetable dishes , collegiate female athletes

FOOD AND BEAUTY CONDUCT ADVERTISEMENTS: AN ANALYSIS OF THE MAGAZINE ANUÁRIO DAS SENHORAS' CONTENTS

[1]da Silva Gomes Ribeiro, Cilene; [2]Silveira, Juliana; [3]Caroline dos Santos, Leticia; [4]Auler, Flavia.

[1]PhD in History, Collaborating Professor of the Postgraduate Program in Bioethics of the Pontifical Catholic University of Paraná. Brazil; [2]Graduated in Nutrition in Pontifical Catholic University of Paraná. Brazil; [3]Graduated in Nutrition in Pontifical Catholic University of Paraná. Brazil.; [4]PhD in Health Science, Professor and Coordinator Undergraduate Program in Nutrition of the Pontifical Catholic University of Paraná. Brazil.

Background and objectives: In Brazil, during the 30s there was a noticeable industrial development along with increased consumption of goods and culture both imported from other countries, especially the United States. It was in this context that several magazines aimed at women were created, like "Yearbook of Ladies" an example of publication of this time, directed for this genre, that suggested ways of living, dressing, consuming and especially ways of how women should behave toward society and when taking care of their houses. The aim of this study was therefore to identify food advertising intended to women, information on health, beauty, nourishment and body image present in magazines and how they were passed on to the readers of these reports by approaching ads and materials linked to the magazine.

Methods: The study was developed from observation and content analysis of seven (7) volumes of this magazine published between the years of 1941 and 1957.

Results: Thus, it was found over that the number of publications intended for food increased along the years, mainly about the called ultra processed one in addition to a large representativeness of women with tuned silhouettes and a strong focus on thinness in almost all content intended to beauty and women's health presented in magazines.

Conclusions: The way society is transformed and changes its relationship to the way of living, consuming, dressing, eating, relating to each other, and even getting sick is closely linked with the media, with the technical scientific development process, along with socioeconomic interests.

Keywords: Media, advertising, food, beauty, women.

CONSUMPTION OF HABITUAL CULINARY PREPARATIONS IN NEIGHBORHOODS OF MONTEVIDEO ACCORDING TO PERCENTAGE OF HOUSEHOLDS AT POVERTY

[1]Simoncelli, Mariana; [2]Sena, Geraldine; [3]Defféminis, Mónica; [3]Martinez, Joseline; [4]Britz, Monica.

[1]Licenciada en Nutrición. Departamento de Nutrición Poblacional. Escuela de Nutrición.Universidad de la República.; [2]Licenciada en Nutrición. Departamento de Nutrición Poblacional. Escuela de Nutrición.Universidad de la República. Uruguay; [3]Licenciada en Nutrición. Departamento de Nutrición Poblacional. Escuela de Nutrición.Universidad de la República. Uruguay; [4]Magister. Licenciada en Nutrición. Departamento de Nutrición Poblacional. Escuela de Nutrición.Universidad de la República. Uruguay.

Background and objectives: Information on culinary preparations habitually consumed by the population taking into account poverty status is relevant for the understanding of cultural eating practices and for providing the basis of educational strategies on food and nutrition.

To study the culinary preparations habitually consumed in different neighborhoods of Montevideo during May 2016 according to percentage of households at poverty.

Methods: Observational, non-probabilistic, descriptive study of 756 households distributed in different neighborhoods of Montevideo. The person in charge of the home culinary preparations was interviewed using a structured questionnaire. Neighborhoods were classified according to the percentage of households with income at poverty level (Encuesta Continua de Hogares- Instituto Nacional de Estadística, 2014).

Results: 52% of households were composed by 2 to 3 members, and 75% of those interviewed were female indicating that women have a leading role in family feeding. Preparations more frequently consumed at lunch time were pot meals (47%), in neighborhoods with highest poverty, and fried breaded beef (33.9%) in neighborhoods with lowest poverty. At dinner time, pot meals were outstanding (19.8%) in all neighborhoods, probably due to the season of the interview. In those neighborhoods with lowest poverty, taste (42%) was the main reason for consumption, whereas price (25.6%) was the main reason in those with highest percentage of low income consistent with this resilient practice at poverty. During the week-end, more than half of all households selected barbecued or baked meats (28.5%) and simple or stuffed pasta (28.4%), the latter preparation more present in neighborhoods with highest percentage of poverty. These selections could be due to cultural factors and tradition, as a result of the influence of immigration during the first half of the XX century, as well as native culinary practices.

Conclusions: During week days, differences found in habitual culinary preparations in neighborhoods according to presence of poverty indicate the importance of efficiency, satiety and price as factors influencing selection, whereas on week-ends multiple cultural influences appear to be present, especially Spanish and Italian.

Keywords: Culinary preparations- Neighborhoods- Poor households

"MISUSE OF FOOD DURING GRADUATION CELEBRATIONS ON SCHOOL OF NUTRITION STUDENTS OF UNIVERSITY OF BUENOS AIRES (UBA), ARGENTINA: CAN ONLINE SOCIAL NETWORKS DISCOURAGE WASTE OF FOOD?"

[1]Santoro, Martina; [2]Marassich, Ivana; [2]Monferolli, Regina; [2]Nanni, Jesica; [2]Kosiorek, Eliana; [2]Dominguez, Analia; [3]Lema, Silvia.

[1]BSc. Nutritionist. Escuela de Nutrición. Universidad de Buenos Aires. Argentina.; [2]BSc. Nutritionist. Escuela de Nutrición. Universidad de Buenos Aires. Argentina; [3]PhD. Nutritionist. Escuela de Nutrición. Universidad de Buenos Aires. Argentina.

Background and objectives: Throwing food at recent university graduates is an Argentine tradition, wasting food that should be used for nourishment.

To help fix this problem, the School of Nutrition (UBA) in partnership with national organizations signed a Letter of Adherence to the "Save Food" FAO-led Initiative.

Objectives: 1) collecting UBA Nutrition students' opinions about this use of food; 2) developing a Social Marketing Program ("Festejo NutriConsciente") to propose alternative forms of celebration via social networks; 3) doing a Program's short-term evaluation.

Methods: This study was conducted between April 2016 and March 2017. For the first aim, a semi-structured survey on a sample of UBA Nutrition students was applied. For aims 2 and 3, "Festejo NutriConsciente" through Instagram, Facebook, and Twitter was developed. In a short-term evaluation, number of "Likes" in social networks were accounted and an online survey among 69 Nutrition students graduated in November 2016 was conducted.

Results: On 202 initially surveyed students 68.3% considered this celebration "bad" /"very bad" mainly due to the waste of food; 12% considered this kind of celebration "good" / "very good" for being a tradition. 53.5% believed that achieving a behavioral change would be "difficult" / "very difficult"; 64.4% never questioned the wasting of food during graduation celebrations. When assessing social networks, 5,465 Likes were obtained in Instagram, 4,732 in Facebook, and 789 in Twitter. Among 69 Nutritionists graduated in November 2016, 30 reported having celebrated without food. 26 of them reported that they had been influenced by Festejo NutriConsciente Program; the rest argued being against

throwing food during celebrations before the Program was implemented. Those who did use food claimed it was their families' and friends' decision to do so. All of surveyed subjects claimed to have heard about the Festejo NutriConsciente Program.

Conclusions: Given the impact of the Festejo NutriConsciente Program, it should be continued to propagate behavioral changes and should be extended to other undergraduate degree programs in UBA.

ROLE OF FOOD DEMONSTRATION WITH INTENSIVE COUNSELLING IN INCREASING DIETARY DIVERSITY AMONG PREGNANT WOMEN: RURAL BANGLADESH PERSPECTIVE

[1]*Islam, Nazia;* [2]*Kazi Mohammed, Mahmood;* [3]*Shabnam, Sadia;* [4]*Rifat, Mahfuza;* [5]*Afsana, Kaosar.*

[1]B. Pharm. M. Pharm. Senior Sector Specialist. Health Nutrition and Population Programme. BRAC. Bangladesh; [2]MBBS. MPH. Senior Medical Officer. Health Nutrition and Population Programme. BRAC. Bangladesh; [3]MBBS. MPH. Manager. Health Nutrition and Population Programme. BRAC. Bangladesh.; [4]MBBS. MSc. PhD. Programme Head. Health Nutrition and Population Programme. BRAC. Bangladesh; [5]MD. MPH. PhD. Director. Health Nutrition and Population Programme. BRAC. Bangladesh.

Background and objectives: 'Alive & Thrive's integration of Maternal Nutrition Interventions (MNI) into BRAC Maternal, Neonatal and Child Health (MNCH) programme of BRAC Bangladesh aimed to test the operational feasibility to deliver a package of maternal nutrition interventions through behaviour change communication as part of a large scale rural MNCH programme. The purpose of this project is to reduce maternal malnutrition through promoting dietary diversity, increased energy intake, and iron-folic acid and calcium intakes. This initiative cover almost 3.3 million (3,368,312) people from 10 sub-districts of 4 districts. One of the key activities of this project is demonstration of the daily required amount of 5 highly recommended varieties of food i.e. fish or meat, egg, milk or milk product, dark green leafy vegetables and yellow/orange fruits and vegetables beside rice and pulses by community health workers with intensive counselling about the importance of these food in each trimester to the pregnant women. Therefore this abstract intends to reveal the achievement of the programme activities from September, 2015 to February, 2017.

Methods: This paper used secondary data source that is the management and information system (MIS) of the MNI project. All intervention sub-districts under this project is considered as study area.

Results: From September, 2015 to February, 2017, data revealed that, a total of 128,914 pregnant women were registered and 284,395 number of demonstration sessions were conducted.

Within this period, consumption of all 5 recommended variety of foods by pregnant women dramatically increased from 20% in 2015 (September) to 84% in 2017 (February) which may resulted from the extensive demonstration with counselling. In February 2017, percentage of women who consume all 5 groups of foods increased to almost 80% whereas in September 2015 this percentage was 55% for fish/meat consumption, 30% for egg, 26% for milk, 31% for dark green leafy vegetables and 25% for yellow/orange fruits and vegetables.

Conclusions: The results provide clear evidence and indication that practical demonstration of food with intensive counselling can increase diversified food consumption among pregnant women and thus it can be used as powerful tool to improve maternal dietary diversity as well as to reduce the malnutrition during pregnancy.

Keywords: Food demonstration, counselling, dietary diversity, maternal malnutrition, behaviour change communication

(C) School of Nutrition and Dietetics, University of Santo Tomas, Chile; [4]Nutricionist. School of Nutrition and Dietetics, University of Santo Tomas, Chile; [5]MSc. School of Nutrition and Dietetics, Pharmacy Faculty. University of Valparaiso, Chile.

Background and objectives: Background:

Purchase decisions of a household relate to quantity and quality of food needed to lead an active and healthy life is an important indicator for the assessment of food and nutrition security, to identify and characterize the nature of food insecurity, the severity of food deficits, predict who are at greater risk of future hunger, detect changes and evaluate the impact of interventions.

Evaluating purchase decisions in our population provides evidence on food availability that the population has access to.

Objective:

To determine the factors that influence the purchase decisions of those in charge of household purchases

Methods: The population of the present study included families with preschool and school-age children of both sexes in daycare or primary school vulnerable in the 5th region of Chile. A focus group was held and 8 household representatives in charge of food purchases at home participated. Participant ages ranged between 32 and 50 years old.

Results: Participants indicated that they buy food weekly (5/8), 2 daily and 1 monthly. Vegetables and fruits were reported

to be purchased at the farmers market. Factors influencing food choice for the home were: cost, taste and, as less important, nutritional quality. Participants indicated that they did not mind traveling farther distances to find better prices. Participants noted that they did not plan and prepare food according to the food they have at home. In relationship to attending workshops at Primary Care Centres, participants reported that they do not participate, but stated that their choices may be influenced if they attended.

Conclusions: The factors that influence food-purchasing decisions for the home of families with preschool and school age children were: cost of food and taste. It is necessary to strengthen strategies of food education that involve the nuclear family.

Keywords: Purchasing decision, focus group, food availability.

BELIEFS ABOUT THE BENEFITS AND DANGERS OF COW'S MILK CONSUMPTION BY WOMEN AND CHILDREN IN SOME PERI-URBAN COMMUNITIES IN GHANA

[1]Otoo, Gloria; [2]Colecraft, Esi; [3]Amissah, Niilante; [4]Blay-Adjei, Maame; [5]Hanson-Kunadu, Angela; [6]Afrifa-Anane, Ernest.

[1]PhD. Nutritionist. Department of Nutrition and Food Science. University of Ghana. Ghana; [2]PhD. Nutritionist. Department of Nutrition and Food Science. University of Ghana. Ghana.; [3]PhD. Food Scientist. Department of Family and Consumer Sciences. University of Ghana. Ghana.; [4]PhD. Food Scientist. Department of Nutrition and Food Science. University of Ghana. Ghana.; [5]PhD. Food Scientist. Department of Nutrition and Food Science. University of Ghana. Ghana.; [6]PhD. Research Associate. Regional Institute for Population Studies. University of Ghana. Ghana.

Background and objectives: Dairy products are a source of quality protein and bioavailable micronutrients important for women of reproductive age (WRA) and children. However, negative beliefs about milk may limit their consumption. Understanding beliefs about milk relative to WRA and young children may inform interventions to enhance milk consumption and contribute to addressing the high burden of malnutrition among WRA and preschool age children. We assessed perceptions about the benefits and harms of milk consumption by WRA and young children among adults in some peri-urban communities in Ghana.

Methods: Exploratory qualitative study comprising 26 focus group discussions (FGD) conducted among the following groups: Adult men and different categories of WRA; mothers with children <5y, lactating mothers, pregnant women, non-pregnant and non-lactating women. Trained moderators facilitated the FGD either in English or the local language of choice. A socio-demographic questionnaire was administered and a semi-structured interview guide was used to solicit information on their beliefs and attitudes towards milk consumption. The discussions were record-

ed, translated and transcribed into English. The transcripts were then coded and analyzed using the thematic analysis approach.

Results: A total of 190 people participated in the FGD, 81.6% were women, 17.9% were 40y and above, 7.9% had no formal education, 14.9% were unemployed and 75.1% were married. While dairy were generally perceived as nutritious and healthy for children and WRA, the FGD also identified positive and negative beliefs about milk consumption. The most salient positive beliefs about milk consumption emphasized their perceived benefits for pregnant and lactating women. For pregnant women, milk was said to 'give blood', prevent dizziness and heartburn. For breast-feeding women, it was believed to enhance breast milk output. For young children, dairy consumption was believed to promote growth, intelligence and advance puberty. However, it was cautioned that consumption levels for milk needed to be moderated as high consumption frequency could cause diarrhea and stomach sores particularly among children.

Conclusions: The largely positive beliefs about milk suggest a favorable attitude towards drinking milk in the communities studied. However many of these positive and negative beliefs were misconceptions that will need to be addressed through nutrition education.

Keywords: Dairy, milk consumption, beliefs, benefits, Ghana

INVOLVEMENT OF SOCIAL AND GENDER ASPECTS IN THE CHOICE OF NUTRITION

[1]Castro Alija, Mª José; [2]Jiménez Pérez, José María; [3]Garcia del Rio, Ana; [4]Lopez Vallecillo, Maria; [4]Frutos Martin, Manuel; [2]Cao Torija, Mª José.

[1]MD, PhD. Faculty of Nursing. University of Valladolid. Endocrinology and Clinical Nutrition Research Center (ECNRC), University of Valladolid. Spain.; [2]RN. PhD. Nursing Faculty, University of Valladolid. Spain. Endocrinology and Clinical Nutrition Research Center (ECNRC), University of Valladolid. Spain.; [3]MSNc. Nursing Faculty, University of Valladolid. Spain.; [4]RN. PhD. Nursing Faculty, University of Valladolid. Spain.

Background and objectives: There are few studies about sociocultural aspects which origin are in some food behaviour, in this particular case of women. Future studies will be required to introduce the routine demanded by dietary advice in every day life.

Determine the causes that lead to women to decide their diet.

Methods: Transversal descriptive study consisted of 38,455 women, of which we selected by random sampling a proportional and representative sample of 500 women, aged between 40 and 60 years. These women are subjected to an own design questionnaire, with socioeconomic, demographic variables, and some of them related with attitutes and lifestyles. We took aspects of the image body shape questionnaire of Cooper et al., (1987) and eat-

ing attitudes test of Garner et al., (1982), which we added others of interests for us.

Results: Firstly we consider of the women:

- Economy 45.53%
- Children and/or couple preferences 14.35%
- Fashion style 9%
- Ease of study preparation 9%
- Health 4.46%
- Other reasons (esthetic among them) 26.66%

98.19 % of women are responsible for family diet.

80.4 % of women recognizes that they eat things that are not in their interest, even though they know that it is so, conditioned by the above issues.

93.69% of women of the sample consider of interest to receive in diet topics.

Conclusions: Family economy is the first reason that determines the choice. Nowadays, related with the economic crisis.

About the other reasons, the main is pleasing children and couple. Fullfilling the women role to assume nutrition responsibility, that exclusively falls on them. Meaning satisfaction of all, although that may condition that the feeding of the women themselves distract from what is convenient, with consequences of their health.

Keywords: Gender Identity, diet, Social Determinants of Health.

EVALUATION OF FOOD WASTE AND THE PROMOTION OF THE FULL USE OF FOODS IN AN INSTITUTION OF LONG PERMANENCE FOR ELEDERLY (ILPE)

[1]Alonso Balthazar, Emilia; [2]De Souza Araújo, Sarah; [3]Moura de Moraes, Carlos Leonardo; [2]De Souza Araújo, Priscila.

[1]PhD. Nutritionist. Federal University of Grande Dourados - Faculty of health science - Course Nutrition; [2]Nutritionist; [3]graduate student; nutrition; Federal University of Grande Dourados; Faculty of science healh.

Background and objectives: Most of the Long Permanence Institutions for the Elderly (ILPE) in Brazil are philanthropic, and the food comes from individuals and legal entities donations, which could lead to nutritional deficits due to a lack of adequate nutrition planning. However, nutrient deficiencies can be minimized by full utilization of food. This work aims to evaluate and promote the integral utilization of food by a ILPI in Dourados, MS (Brazil).

Methods: This is an action- intervention study that belongs to na extension Project held in the year 2015. In a period of thirty days, there was the weighing of the unconventional parts of the food discarded by the institution. In the second stage, the illustrative booklet with recipes was elaborated according to the non-use of the vegetable/ fruits observed. The kitchen employees also completed a self-administered questionnaire with seven mixed questions adapted from Da Rosa (2009). The questions were to evaluate the knowledge about the integral use of food and were applied before and after the course. Two practical mini-course (4 hours each) approaching the benifts of integral use of food and the preparation of 4 recipes contained in the booklet and randomly selected were made: salted pie made with peel and stalks of vegetables and sweet made with the shell / crust of watermelon with coconut; and banana peel jelly and carrot dip.

Results: It can be observed that the vegetables/fruits were not fully utilized by the institution. In addition, 6,672 kg of lettuce (leaf, stem), 1.278 kg of tomato, 492 g of cabbage, 678 g of arugula, 400 g of chard, 396 g broccoli were discarded for lack of storage and excessive withdrawal during pre-preparation. The results of the questionnaire showed that the employees already had some knowledge about the integral use of the food, but they didn't use the technique, due to the lack of knowledge of the variety of recipes.

Conclusions: It could be noted that there is food waste in this institution due to the lack of instruction regarding the integral use of food, that can be used to reduce waste and enrich the elderly's diet.

OBESITY: ANALYSIS OF THE USE OF A COMPREHENSIVE SYSTEM OF CARE, THEIR ADJUSTMENTS AND THERAPEUTIC COURSE OF THEIR PATIENTS THROUGH A RETROSPECTIVE STUDY

[1]Zullich, Karina; [2]Ravenna, Maximo; [2]Olkies, Abel.

[1]MD General practitioner. Maximo Ravenna therapeutic Centre;
[2]MD. Maximo Ravenna Therapeutic Centre. Buenos Aires. Argentina.

Background and objectives: Background: We understand obesity is closely related to lifestyle; where the context and meanings about commensality and the automatism of habits, represent the backbone that sustains the disease, and in turn these patterns of behavior sustained over time leave a neuroendocrine footprint that demand more therapeutic resources to be modified. Our therapeutic setting is an integral and dynamic interdisciplinary approach through individual consultations and group meetings high frequency, with a multicentric experience of 23 years.

Objective: To observe the use of a comprehensive health system by obese patients

Methods: Retrospective analysis of 13 years database, Markie, stata sand Microsoft Excel programs were used, in front of therapeutic adaptations implemented in the institution.

Results: Total population 31815 patients (75% female, mean age in years (SD): 44.20 (11.6))

Significant differences between an early period 2003 to 2011 were observed and one late in the 2011-2015 which had already settled many therapeutic adaptations strategic (diversification for monitoring and patient care, multidimensional motivational enhancement, decisive changes in dietary patterns adaptations performance modules, etc. Noting the following differences:

Patients reached the maintenance first time: P1 (P=period of time) = 13%; P2= 53%. Patientes that returned to the system: P1= 1r (r=re-entry): 25%; At least 2r 8.6%; At least 3r : 3%; At list 4r: 1%. P2= 1r: 36%; 2r: 12%; 3r: 2%; 4r: 0.35%. Weight threshold recovered: P1= 90% returned at least 1 time with weight regain but less weight than income; 78% returned at least one more time but with less weight than they had in the first return; 77% less weight than the second return. P2= 92% returned at least 1 time but with less weight than the start; 81% patients returned at least one more time but less than the last weight; 92% returned at least one more time but with less weight previous.

Number of active groups in maintenance: P1= 1; P2= 6. Rate asset maintenance patients: P1= 0.2%; P2= 12%.

Conclusions: The adjustments to the professionals to the needs of patients, and maturation of resources has a positive impact on the thresholds and therapeutic goals

Keywords: Comprehensive health system obese patients

Conflict of Interest Disclosure: It is important to mention for the analysis of implications that the researcher belongs to the institution in which it is investigated, this being the same one that funds the investigation. Private institution that performs activities of private order (individual attention in medical and nutritional clinics and therapeutic groups) and also public order activities (such as collaboration with public canteens, schools, physical activity open to the community in parks)

BENEFITS OF DIETARY FIBRE FOR HUMAN HEALTH AND EATING HABITS IN DIFFERENT COUNTRIES

[1]*Leal, Marcela;* [2]*Guiné, Raquel;* [3]*Tarcea, Monica;* [3]*Fazakas, Zita;* [4]*Vittadini, Elena;* [5]*Klava, Dace;* [6]*EL-Kenawy, Ayman.*

[1]MSc. Faculty of Health Sciences. Maimonides University. Argentina.; [2]PhD. CI&DETS Research Centre. Polytechnic Institute of Viseu. Portugal.; [3]PhD. University of Medicine and Pharmacy from Tirgu-Mures. Romania.; [4]PhD. Department of Food Science. University of Parma. Italy.; [5]PhD. Latvia University of Agriculture. Jelgava. Latvia.; [6]PhD. Genetic Engineering Institute. University of Sadat City. Egypt.

Background and objectives: Because DF has unequivocally demonstrated many benefits for the human health, its consumption should be encouraged. In this way, this research aimed at identifying the eating habits regarding fibre rich foods and assessing the knowledge about the effects of DF as enhancers of human wellbeing. The study was undertaken simultaneously in five countries situated in different parts of the globe, namely South America (Argentina), Africa (Egypt), South Europe (Italy), Central Europe (Romania) and North Europe (Latvia).

Methods: A descriptive cross-sectional study was carried out on a non-probabilistic sample of 2290 participants from 5 countries. The data collection was made by a questionnaires translated into the native languages in all participating countries.

Results: The consumption of vegetables and salads was higher for Argentina and lower for Egypt while fruits are more consumed in Italy and less in Latvia. Whole grains are more consumed in Latvia and Romania and less in Argentina and Italy. The knowledge about the benefits of DF for cardiovascular diseases and cholesterol is higher in Argentina, for bowel cancer and diabetes in Romania and for obesity and constipation in Latvia. Still, an important number of participants do not have opinions about the different health benefits of DF.

Conclusions: In general, the participants showed a moderate consumption of vegetables and fruits but low in whole cereals. The level of knowledge about the effects of DF on human health is still far from desirable levels, and differs considerably from country to country.

Keywords: Dietary fibre, eating habits, fibre rich foods, questionnaire survey

FOSTERING SCIENTIFIC RESEARCH ON FOOD AND NUTRITION IN SCHOOLS. EXPERIENCE AT THE "TORRENT DE CAN CARABASSA" SCHOOL IN BARCELONA

[1]*Rivero Urgell, Montserrat;* [3]*Chifré Petit, Ricard.*

[1]Catalan Foundation for Research and Innovation (FCRi). Barcelona. Spain. Royal Academy of Pharmacy of Catalonia (RAFC). Spain. Catalan Academy of Food Sciences. Spain.; [3]Catalan Academy of Food Sciences. Spain.

Background and objectives: The Catalan Foundation for Research and Innovation (FCRi) participates in the project "Amgen Exper(i)encia" within a European program, to provide a more complete and up-to-date scientific and technical education to our young people through the participation of retired scientists in the school centres.

Methods: The school "Torrent de Can Carabassa" in Barcelona is one of those participating in this program. 39 students with a mean age of 10 years participated in this program with retired pharmaceutical researchers in the field of food and nutrition. A survey was conducted to evaluate healthy habits of these children, regarding physical activity and diet, to focus on the scientific aspects in this field.

The intervention consisted in several talks, debates and workshops with a duration of 8 hours distributed in two months, with participation of students and professors.

Results: The discovery of the importance of research and the knowledge about relevant scientists gave as a result that 79% of

children expressed interest in being scientists as a future profession. Among the high quantity of results obtained from the survey, it should be noted that 55% of the children ate sweets or buns daily. 45% did not achieve the recommended intake of fruits and vegetables. 48% dedicated 2 to 3 hours per day to watch TV, play at the computer or console, and 21% did not perform any physical activity outside school.

Conclusions: Learning about science and the introduction to the scientific method in the classroom encourages scientific vocations. The collaboration of scientists with teachers has been much appreciated and is a great tool to introduce science in classrooms. It is possible to improve the knowledge of the children in the mistaken habits detected.

THE RELATIONSHIP BETWEEN GENDER, BODY IMAGE, BODY SIZE AND REMOTENESS WITH DISCRETIONARY INTAKE AMONG A NATIONALLY REPRESENTATIVE SAMPLE OF INDIGENOUS AUSTRALIANS

[1]Fayet-Moore, Flavia; [2]McConnell, Andrew; [3]Kim, Jean; [4]Petocz, Peter.

[1]MNutrDiet, PhD. Nutritionist. Nutrition Research Australia; [2]HBSc. Mathematician. Nutrition Research Australia. Australia; [3]PhD. Scientist. Nestlé Australia. Australia; [4]PhD. Associate Professor. Department of Statistics. Macquarie University. Australia.

Background and objectives: Over a quarter of the Burden of Disease among the Australian Indigenous population can be reduced by eliminating poor diet, alcohol and high body mass. Adolescents have the greatest intake of nutrient-poor foods and beverages and are more likely to have body image issues. We aimed to determine the relationship between discretionary food intake among adolescents and demographic, geographic, anthropometric and body image variables.

Methods: Day 1 data from 12-18 year olds in the 2012-13 National Aboriginal and Torres Strait Islander Nutrition and Physical Activity Survey were used (n=588). Discretionary foods and beverages (DF) are high in saturated fats, added sugars, and/or salt. Waist circumference to height ratio classified participants' risk of metabolic complications. Remoteness, body image, dieting and DF contribution to total energy were analysed.

Results: Prevalence of being at increased risk of metabolic complications was significantly higher among boys (42.6%) than girls (28.2%) (P<0.05), and all boys (100%) who perceived themselves overweight were at risk of metabolic complications compared to 58.8% of girls. 9.6% of girls were dieting compared to 4.1% of boys, and dieting was higher among those at risk of

metabolic complications (19.4% of girls, 10.3% of boys). 55.0% of girls and 17.6% of boys who perceived themselves overweight were on a diet. DF contributed 39.9% of total energy, almost half came from lunch (25.1%) and dinner (24.2%), was similar between boys (40.9%) and girls (38.9%), and was significantly lower among those from remote (33.5%) compared to non-remote (41.5%) areas (P<0.05). The energy contribution from DF was higher among boys who perceived themselves overweight (56.3%) than girls (26.9%), and higher among girls who perceived their weight as acceptable (43.6%) than boys (39.7%).

Conclusions: Boys were more likely to be at risk of metabolic complications, and those at risk had a greater discretionary contribution than those not at risk. By contrast, girls at risk of metabolic complications had a lower contribution from DF than those not at risk. These results support a need to reduce DF intake among Indigenous adolescents, and to implement gender specific strategies related to dieting and body image, taking remoteness of location into account.

Keywords: Indigenous, adolescent, body weight, body image, discretionary foods

ASSESSING THE EFFECT OF THE PLATE COLOUR ON ENERGY INTAKE DURING AN OPEN BUFFET MEAL

[1]Akyol, Asli; [2]Samur, Gulhan; [3]Eroglu, Elif; [3]Cetin, Cansu; [2]Ayaz, Aylin.

[1]PhD. Lecturer. Hacettepe University, Department of Nutrition and Dietetics, Ankara. Turkey; [2]PhD. Lecturer. Department of Nutrition and Dietetics. Hacettepe University. Turkey.; [3]Research Assitant. Department of Nutrition and Dietetics. Hacettepe University. Turkey.

Background and objectives: Recent research suggests that the plate colour may affect the amount of the food consumed. More specifically, colour red was shown to reduce the intake of food due to its act as a consumption-stopping sign. In light of this, the main objective of this study was to determine whether the food consumption during an open buffet meal was different when using same sized white, red or black plates.

Methods: This was a cross-over study conducted on 54 female participants aged 18-27 years with normal BMI levels. Participants were recruited from Hacettepe University and the surrounding community. On experimental days, participants ate a standard breakfast and were then randomly assigned to eat lunch (pasta with tomato sauce and soft drinks) using white, red or black plates. Energy and macronutrient intakes during lunch were recorded..

Results: Results indicated that plate colour exerted a significant effect on food intake during the test days (p=0.021). The average total energy intake on red (1102.16±47.12 kcal, p=0.05) and black plates (1113.19±47.12 kcal, p=0.034) were significantly in-

creased when compared to white plate (945.72±47.12 kcal). There was no difference between red and black plates (p=0.985).

Conclusions: In this study, colours red and black did not induce a suppressing effect on food intake. These results supported the notion that the food colour is also a crucial determinant of energy intake. The contrast between the plate colour and the food colour should be considered as an important factor when making recommendations about this topic.

Keywords: Plate colour, energy intake, satiety response

CHARACTERISTICS OF MEALS IN HOUSEHOLDS WITH MIDDLE SCHOOL STUDENTS WHO RARELY EAT BREAKFAST WITH THEIR FAMILIES THOUGH HAVE A POSITIVE QUALITY OF LIFE

[1]Sakamoto, Tatsuaki; [2]Hosoda, Kouhei.

[1]PhD. Department of food and health Sciences. Faculty of environmental and symbiotic sciences. Prefectural University of Kumamoto. Japan.; [2]MLS. Department of health and nutrition. Faculty of human life studies. University of Niigata Prefecture. Japan.

Background and objectives: Family meals frequency link healthy dietary behaviors and quality of life (QOL). This study was made to clarify the characteristics of meals in households with middle school students who rarely eat breakfast with their families and have good QOL.

Methods: A survey was conducted in September 2015 of 797 second year middle school students in seven schools in Fukui Prefecture, Japan and the results of valid responses from 762 students were analyzed. The questions covered general attributes, the way students ate meals with their families, their enjoyment of meals, and their QOL. Regarding the way students ate meals with their families, the survey asked about how often breakfast and dinner were eaten together with their families, the duration of dinner on weekdays and weekends, whether families listened to them during meals, and how often families scolded them during meals. For QOL measurement, a QOL assessment designed for middle school students (Kiddo-KINDLR) was used. The students who responded that they "almost never" ate breakfast with their families were divided into a low QOL group and a high QOL group based on median total QOL scores of all participants. The study compared the way students in each of these groups ate with their families.

Results: Of the 300 students who almost never eat breakfast with their families, 63 male and 56 female students were in the high QOL score group. The high QOL score group ate dinner with their families more often than the low QOL score group, were more often listened to by their family members during meals, were less often scolded during meals, and more students in this group reported enjoying eating with their families.

Conclusions: These results suggest that among middle school students who rarely eat breakfast with their families, eating dinner together frequently, being listened to by family members often

during meals, and enjoying meals with family are characteristics associated with a positive QOL.

Keywords: Middle school students, quality of Life (QOL), family meal

RESCUING FOOD CULTURE WITH EDUCATIONAL STRATEGIES IN THE SCHOOL ENVIRONMENT: INTERSECTORAL ACTION BETWEEN HEALTH AND EDUCATION

[1]Andrade, Samantha Caesar de; [2]Santos, Camila Vieira dos; [3]Machado, Maria Elizabeth; [1]Vieira, Viviane Laudelino.

[1]PhD in Science. Food and Nutrition Reference Center (CRNutri). Teaching Health Center Geraldo de Paula Souza. School of Public Health - University of São Paulo. Brazil.; [2]Undergraduate in Nutrition. Department of Nutrition. School of Public Health. University of São Paulo. Brazil.; [3]PhD in Science. Nutritionist and teacher. Department of Nutrition. School of Public Health - University of São Paulo. Brazil.

Background and objectives: The relationship between school and basic health unit strengthens food and nutrition education activities (FNE) from the perspective of an integral development, interfering in the culture and in the social production of health. This article takes educational strategies in order to rescue food culture in the school environment, linking health and education.

Methods: CRNutri belongs to the Teaching Health Center Geraldo de Paula Souza of the University of São Paulo, Brazil - and it aims to promote health together with the prevention and treatment of diseases related to food and nutrition. During 2016, nutritionists and nutrition undergraduates, acted collectively in order to rescue food culture at a Children's Educational Center (CEC), in the Teaching Health Center area. The activity has reached all CEC team, joining board, pedagogical coordination, educators, and administrative officials, in addition to 56 children participants.

Results: Five strategies were used to build a multidisciplinary and shared knowledge and to rescue food culture in the school environment: 1) Motivational Meeting with the team of the CEC, using dynamics to create links, identify knowledge, myths and activities already carried out on food and nutrition and raise expectations; 2) Motivational meeting with the child's guardians, dynamics development to enhance the shared construction and the importance of different social roles; 3) Application of a questionnaire to the child's guardians to identify family eating habits/culture, directing the two proposed practical workshops with staff and students in order to expand food recipe options through regional food and with children, encourage the consumption of

different foods; 4) Anthropometric assessment, diagnosing children's nutritional status using the results to sensitize stakeholders and direct the planning of activities and 5) Observational activity: witness students' lunch hour to experience the environment, the individual and the interpersonal relationship between the child and the act of eating, identifying and developing attitudes that may influence on food choices.

Conclusions: Through strategies, it was possible to insert different actors in the methodological process towards working with FNE, which unable a collective construction and generated an identity for the intervention moments, making everyone involved responsible and encouraging the rescue of food culture.

PERCEPTIONS ON FOOD AND NUTRITION EDUCATION OF THE ACADEMIC COMMUNITY OF THE SCHOOLS OF NUTRITION AND DIETETICS OF THE UNIVERSITY OF ANTIOQUIA (UDEA)-COLOMBIA, AND THE NATIONAL UNIVERSITY OF CORDOBA

[1]Alzate, Teresita; [2]Cárdenas, Valentina; [3]Del Campo, María Lis; [4]Tamayo, Alba Luz; [3]Martinich, Erica; [3]Bergero, María; [5]Giraldo, Paula; [2]Jiménez, Karina.

[1]PhD. Nutritionist. Nutrition and Dietetic School. University of Antioquia. Colombia; [2]Research student. Nutrition and Dietetic School. University of Antioquia. Colombia; [3]MSc. Nutritionist. Nutrition School. National University of Cordoba. Argentina; [4]MSc. Nutritionist. Nutrition and Dietetic School. University of Antioquia. Colombia; [5]Nutritionist. Nutrition and Dietetic School. University of Antioquia. Colombia.

Background and objectives: In 2011, FAO conducted a study on best practices in nutritional education in South America and found that 43.6% of the participating programs in the region rated good practices; The study in Colombia reported 30% and in the case of Argentina, 33% of the programs described as good practices.

Objective: To determine and to understand the perceptions that professors and students have of the careers of Nutrition and Dietetics about Food and Nutrition Education and to relate them to the criteria of Good Practices in this field, referring to the change of alimentary habits.

Methods: Qualitative research, through semi-structured surveys and focus groups. The sample was composed of 86 students and 31 professors of the UdeA, and 174 y 37 of the National University of Córdoba (UNC) during the year 2015, and content analysis was carried out following the Minayo method.

Results: For UdeA students there is a full connection between pedagogical references and eating habits; they propose the nutritional education in function of the change of habits improper, defined by the nutritionist reason why the valid knowledge is the

one that it owns; For their part, those of the UNC perceive contradictions between the subjects that develop content on Nutrition Education, since the model in which the subject is theoretically positioned becomes in tension with the type of practice performed by the teacher. According to UdeA teachers, the nutritional education is recognized as a transmission, promoted by the hidden curriculum exercised by teachers of the basic scope and discipline of knowledge; In the UNC the Nutritionist educator can be conceived with predominant traits as facilitator and transmitter that seeks the modification of the alimentary practices from a process, considered of long term, since it implies profound changes in the social and cultural life of the subjects.

Conclusions: In both universities, they conceive of nutritional education as a process, which is expressed in the transmission of knowledge, from a manifest intention of transcending the educational level of information, towards a change in dietary practices, to constructions involved in social development, which are sometimes incompatible with each other

INFLUENCE OF AN EDUCATIONAL INTERVENTION IN THE DEVELOPMENT OF OBESITY IN SCHOOLCHILDREN OF 6-8 YEARS

[1]Menor Rodríguez, Maria Jose; [2]Aguilar, Maria Jose; [3]Perez, Maria Teresa.

[1]Director of nursing; [2]Catedrática Enfermeria. Universidad de Granada; [3]Bioestadistica. Colegio de Enfermería de Ourense.

Background and objectives: The school stage is a stable period of growth and development, physical and intellectual, where a healthy diet is based on a correct nutritional education, as it is where they begin to settle the eating habits, that will be resistant to changes in adulthood. It is a key moment to form and consolidate "eating habits" that will keep adult.

Objective: To evaluate the influence of an educational intervention in school children 6-8 years of public schools and its influence on levels of Overweight/obesity.

Methods: A design was used quasi-experimental with a single group, with measurements (just prior to the implementation of the proposal) pretest, posttest to establish comparisons. The sample was 205 school (89 boys and 116 girls) aged between 6-8 years. The proportion of overweight (obesity overweight) has been estimated by calculating the index of body mass (IMC) by the formula weight (kg) / size in m2 and using as a reference the standards of who

Results: Girls have values significantly higher BMI than children in the pre-intervention educational analysis, thus noted that the 28.4% of girls were obese face a 6.7 per cent of children. After the realization of educational interventions such as RPG (Cook), Video class, interactive lectures to children and parents, BMI fell

by 2.6% in girls (25.4% obese female) and a 2.3% in children (4.4% children obese).

Conclusions: The implementation of educational intervention is an effective tool to improve eating habits at school as an initiative of individual empowerment. The previous identification of healthy lifestyle habits in schoolchildren; It allowed to design, implement, and evaluate educational intervention, which through an integrated to the Act of teaching and learning process helped promote healthy habits in schoolchildren and consustancialmente raised the level of knowledge

Keywords: Childhood obesity, school children, dietary habits

Conflict of Interest Disclosure: It was felt that the design of the study was the most suitable due to the characteristics of the programme for the promotion of healthy living, and also the duration of the same. The reason for not choosing a group on which the educational intervention is carried out and compare it to another without training talks, was due to the low number of students within the centres at each educational level

EFFECTIVENESS OF AN EDUCATIONAL INTERVENTION ON LIFE HABITS ASSOCIATED WITH SCHEDULE TV CONSUMPTION DAILY IN SCHOOL CHILDREN FROM 6 TO 12 YEARS

[1]*Menor Rodríguez, Maria Jose;* [2]*Aguilar, Maria Jose;* [3]*Perez, Maria Teresa.*

[1]Director of nursing; [2]Catedrática Enfermeria. Universidad de Granada; [3]Bioestadistica. Colegio de Enfermería de Ourense.

Background and objectives: During childhood and adolescence conform the main features of learning, thus acting in these ages is key to obtain a greater impact on the development to future of certain diseases.

Objective: To determine if an educational intervention carried out by a health professional improves the habits of life associated with the consumption of hours of tv daily in school children 6-12 years and check their relationship with the presence or not of television in the child's room.

Methods: A written pre-test consisting of questions about healthy lifestyle habits associated with the use of tv, internet and the existence or not of tv and computer in the fourth and socio-demographic characteristics was given to 322 students from 6-12 years of Orense. Subsequently, was an educational intervention supported by videos and informative talks about the risks associated with an elevated daily tv consumption. Two months later was reassessed through a pos test habits.

Results: After the educational intervention, the intervention group students have improved their consumption habits of daily tv by 44% with respect to the pre test.

Conclusions: Education about healthy lifestyle habits activities implemented by health care professionals provide an increase

in knowledge about our school, it would be so interesting to complement the training with such activities

Keywords: Habits of healthy lives, school, Television

Conflict of Interest Disclosure: The results obtained in this study reflect that age may have influenced positively in the acquisition of healthy lifestyle habits in schoolchildren after the educational intervention. It is important to also highlight an adequate environment organization, including spaces, material resources and time distribution, was fundamental to the achievement of the proposed objectives

DEVELOPMENT OF A SMARTPHONE APPLICATION FOR HEALTHY NUTRITION HABITS AND PHYSICAL ACTIVITY FOR PREVENTION OF WEIGHT GAIN IN CHILDREN

[1]*Reininger, Mara Edith;* [2]*Minuzzi, Pedro Gustavo;* [3]*Katz, Mónica;* [4]*Pentimalli, Hernan.*

[1]MS Software Engineering. Universidad Nacional de la Matanza. Bs. As. Argentina. Seis Grados Salud. Argentina; [2]PhD Universidad Nacional de Córdoba. Córdoba. Argentina. Seis Grados Salud. Argentina; [3]PhD Nutricionista Universidad de Bs. As. Buenos Aires Argentina; [4]Técnico Informático UBA Buenos Aires Argentina. Seis Grados Salud. Argentina.

Background and objectives: Background
Current generations of children and teenagers are considered mobile first, they use smartphones as primary source of entertainment, social media and information consumption. There is an ongoing child obesity epidemic that's being addressed using traditional treatment or prevention strategies based on classic media channels leaving these new digital tools underexplored and used.
Objectives
The purpose of this study was to evaluate and generate a functional product description to develop a smartphone application scientific based for children that maximizes the adoption, usage and retention rate while strictly following the medical objective of spreading healthy nutrition habits in children aged 10-12.

Methods: Gamification strategies were explored as the chosen age range has a natural ludic tendency. A cartoon character-based strategy was selected as it had the best feedback during early reviews with children. The set of medical requirements was worked through a multidimensional matrix including positive and negative emotions, physical self awareness, nutritional information, exercise levels producing a dynamic schedule of games, contents, contacts using push notifications and other activities. A list of the top 100 both commercial and government-backed smartphone applications were evaluated. The list was built using the highest ranked applications from the Apple's App Store and Google Play store.

Results: Application's full specifications were developed, including wireframes, high definition screen and screen transitions,

functional descriptions, process rationales and medical argumentations for critical decisions.

Conclusions: The system developed during this study might provide a unique opportunity to prevent weight gain in children in a highly cost-effective basis. A positive feedback loop of test-feedback-development, as it is usual in this type of processes, will be necessary.

Keywords: Child obesity, smartphone, physical activity, health education.

KNOWLEDGE AND REALIZATION OF BREAST-FEEDING BY WOMEN OF A FAMILY HEALTH UNIT IN THE CITY OF DOURADOS-MS

(1)Lima, Cláudia; (1)Basile, Lívia; (2)Rodrigues, Sandra.

(1)PhD. Nutritionist. Nutrition Course. Federal University of Grande Dourados. Brazil.; (2)Nurse. Family Health Unit Novo Horizonte. Department of Health. Brazil.

Background and objectives: Currently, according to the World Health Organization, many scientific studies demonstrate the relevance of breastfeeding for maternal and child health and for spacing gestations as a factor of decreased fertility. The objective of this study was to evaluate the knowledge and the realization of breastfeeding by women of a Family Health Unit in the city of Dourados-MS.

Methods: The study was carried out with 23 women, who participated in an extension project entitled "Promotion of Breastfeeding - PROAMA II", registered in SIGProj under number 218095.1107.199203.18112015. Before the initiation of educational actions, a diagnostic evaluation was applied through a questionnaire to characterize the population and verify the knowledge and realization of breastfeeding by these women.

Results: Of the women evaluated, the mean age was 25.4 ± 6.4 years, 47.8% had primary education, 39.1% had only one child, 56.5% had previously breastfed and 87.0% had been breastfed. It was observed that 95.7% reported knowing the signs of correct baby's handhold on the breast, however, only 21.7% knew how to respond adequately when questioned about these signs. Of the women evaluated, 47.8% reported that the baby is always breastfeeding and 30.4% give the breast when the baby is hungry. Regarding breastfeeding, 96.7% were breastfeeding at the time of the evaluation, 100.0% started breastfeeding at the hospital, 78.3% breastfed during the first hour of the baby's life, 50% were mixed breastfed, 65.2% had help in the first feeding, and for 86.7% this help was provided by the nurse. It was also observed that 91.3% of the women reported that the first time they breastfed was more pleasant than they had imagined.

Conclusions: Most women reported knowing the signs of correct baby's handhold on the breast, although they did not have ad-

equate knowledge, were breastfeeding their babies, started breastfeeding at the hospital and breastfed for the first hour of the baby's life. The evaluation made it possible to verify the importance of carrying out educational actions with this population on the realization of adequate breastfeeding.

ANTHROPOMETRIC PROFILE AND NUTRITIONAL EDUCATION FOR INDIGENOUS SCHOOLCHILDREN IN THE CITY OF DOURADOS-MS

(1)Lima, Cláudia; (1)Basile, Lívia; (2)Souza, Gabriela; (2)Marques, Giselle.

(1)PhD. Nutritionist. Nutrition Course. Federal University of Grande Dourados. Brazil.; (2)Student. Nutrition Course. Federal University of Grande Dourados. Brazil.

Background and objectives: The city of Dourados has the second largest indigenous urban reserve in Brazil, with approximately 11 thousand indians. Many are the factors by which the lifestyle of these peoples had great modifications, culminating both in the commitment of their food security and in the consumption of industrialized foods, especially sugar. The objective of the present study was to do anthropometric evaluation of indigenous schoolchildren and promote healthy eating habits for these students.

Methods: It is an extension project, registered in SIGProj about number: 180319.878.185668.19052014, done with forty seven students of the fourth year of an indian school in the city of Dourados-MS. In 2016 four nutrition education workshops were started with the presentation and explanation of the theme, followed by games to fix the content. An anthropometric evaluation of weight and height was also performed at the first and last meeting. The topics covered were Personal Hygiene, New Food Guide for the Brazilian Population, Food Builders and Food Labeling. Some methods used were: handshake dynamics, handwashing with gouache paint, food tray, food semaphore, posters, games and shopping list.

Results: The processed foods were the ones that generated the most doubts among the students. Milk and dairy products and beans were not recognized as protein sources by most students. It was observed that 78.3% of the students had between 70 and 100% of hits in the shopping list. In the initial anthropometric evaluation, 100% of the students had adequate weight for age and height for age, and according to BMI for age, 64.8% were eutrophic, 31.9% overweight and 4.2% obese. In the final evaluation, 100% had adequate weight for age, 97.5% adequate height for age, and according to BMI for age, 65.8% were eutrophic, 29.2% overweight and 5.0% obese.

Conclusions: The results obtained with this work demonstrate the importance of continuing the development of nutritional ed-

ucation activities with indigenous schoolchildren, in order to enable them to make good food choices and to stimulate hygiene habits, preventing chronic and infectious parasitic diseases and controlling the development of overweight and obesity in this population.

CULTURAL DOMAIN ANALYSIS: FINDINGS FROM FORMATIVE IMPLEMENTATION RESEARCH IN NORTHERN SENEGAL

(1)Parker, Megan E Parker; (2)Zobrist, Stephanie; (3)Pelto, Gretel; (4)Diallo, Abdoulaye Moussa; (5)Kalra, Nikhila; (6)Ndoye, Tidiane; (7)Wone, Issa; (8)Amundson, Kimberly; (9)Milani, Peiman; (10)Kreis, Katharine.

(1)PATH; (2)BA, MPH. Nutrition Innovation. PATH. USA.; (3)BA, MA, PhD. Division of Nutritional Sciences. Cornell University. USA.; (4)BA, MA. Cheikh Anta Diop University. Senegal.; (5)BA, MSc, PhD. Nutrition Innovation. PATH. USA.; (6)BA, MA, PhD. Cheikh Anta Diop University. Senegal.; (7)MD, MSc, MPH. University Assane Seck. Senegal.; (8)BS, MSPH, RDN. Maternal, Newborn, Child Health and Nutrition. PATH. USA.; (9)BSc, MSc, MBA. Sight and Life Foundation. USA.; (10)BS, MPH. Nutrition Innovation. PATH. USA.

Background and objectives: Infant and young child feeding (IYCF) practices are a product of culture and context. Effective IYCF interventions should be grounded in formative implementation research that provides an understanding of caregivers' knowledge systems and values that inform their complementary feeding practices. The objective of this study was to examine cognitive frameworks of Senegalese caregivers with respect to IYCF using cultural domain analysis techniques.

Methods: Selected modules of the Focused Ethnographic Study for Infant and Young Child Feeding Manual were administered to a sample of 46 caregivers from rural (N=22) and peri-urban (N=24) communities in Saint-Louis, Senegal. Respondents first rated 38 food items on a scale of 1 (low) to 5 (high) according to five dimensions that were hypothesized to influence IYCF: appeal, child acceptance, convenience, healthiness, and modernity. Then, respondents were asked to group the 38 foods into piles based on their own sorting criteria. Data analysis was conducted using R-Cmap, a concept-mapping technique included in the R analytic package. Multidimensional scaling (MDS) analyses produced graphical outputs of aggregate food clusters, separately for each location. Cluster rating maps were produced by combining the mean food rating values with the clusters generated by MDS, and comparison of statistical significance between clusters was conducted using the Tukey method. Rural and peri-urban samples were analyzed separately.

Results: The analysis showed that peri-urban respondents identified five clusters ("foods that are good for the body," "snack foods," "light foods," "heavy foods," and "packaged foods"), and rural respondents identified four clusters ("heavy foods," "snack foods," "light foods," and "foraged foods"). In the rural community, "snack foods" received the highest mean rating across all value dimensions, whereas "foraged foods" received the lowest mean rating on all dimensions except convenience. In contrast, the peri-urban community rated "packaged foods" highest across all dimensions except appeal.

Conclusions: This study reveals both similarities and differences between the knowledge frameworks of caregivers in the rural and peri-urban study sites, as well as broader differences in both from biomedical concepts of nutrition. These findings provide instructive information to inform the design of complementary feeding interventions in northern Senegal.

Keywords: Cultural domain analysis, Senegal, implementation research, pile sort, rating

COGNITIVE MAPPING TECHNIQUES REVEAL CULTURAL INFORMATION ON INFANT AND YOUNG CHILD FEEDING DECISIONS TO INFORM DESIGN OF NUTRITION INTERVENTIONS IN NORTHERN SENEGAL

(1)Zobrist, Stephanie; (2)Pelto, Gretel; (3)Parker, Megan; (4)Diallo, Abdoulaye Moussa; (5)Kalra, Nikhila; (6)Wittenbrink, Brittney; (7)Ndoye, Tidiane; (8)Wone, Issa; (9)Milani, Peiman; (10)Kreis, Katharine.

(1)BA, MPH. Nutrition Innovation. PATH. USA.; (2)BA, MA, PhD. Division of Nutritional Sciences, Cornell University. USA.; (3)BSc, MSc, PhD. Maternal, Newborn, Child Health and Nutrition. PATH. USA.; (4)BA, MA. Cheikh Anta Diop University. Senegal.; (5)BA, MSc, PhD. Nutrition Innovation. PATH. USA.; (6)BSc, MSc. Nutrition Innovation. PATH. USA.; (7)BA, MA, PhD. Cheikh Anta Diop University. Senegal.; (8)MD, MSc, MPH. University Assane Seck. Senegal.; (9)BSc, MSc, MBA. Sight and Life Foundation. USA.; (10)BS, MPH. Nutrition Innovation. PATH. USA.

Background and objectives: Caregivers of infants and young children make decisions about feeding their children based on complex interactions of knowledge, beliefs, and values, as well as situational determinants, such as economic and social constraints and opportunities. Because of the relationships and influences of these factors on adopting new infant and young child feeding behaviors, the design and development of nutrition interventions must be grounded in knowledge about the target population. This study used cognitive mapping techniques to gain insight into caregivers' knowledge and perceptions of local foods for infants and young children and examined their potential significance for feeding decisions in northern Senegal.

Methods: Guided by mixed methods protocols from the Focused Ethnographic Study for Infant and Young Child Feeding Manual, in-depth interviews that included qualitative discussions

and cognitive mapping techniques were conducted with 46 caregivers in rural and peri-urban communities of Saint-Louis, Senegal. We explored caregivers' perceptions about five dimensions that were hypothesized to affect food decision-making (healthiness, convenience, child acceptance, appeal, and modernity), examining perceptions of 38 food items in relationship to these dimensions. Data analysis entailed a combination of qualitative thematic analysis and descriptive statistics.

Results: In both communities, "healthiness" was the most valued dimension for food decision-making by a large margin (total mean rating[SD] of 4.7[0.8]), followed by child acceptance (3.6[1.1]), appeal (2.7[1.2]), modernity (2.6[1.0]), and convenience (2.5[1.5]). We explore how different interpretations of these dimensions, and their relationships to local foods, may influence the design and planning of nutrition interventions. For example, respondents almost unanimously associated healthiness, the most highly valued dimension, with cleanliness. With respect to specific foods, eggs, watermelon, Cerelac, and the generic category of vegetables were all rated highly (mean rating >4.5) as healthy foods by both rural and peri-ruban communities.

Conclusions: Caregivers weigh many competing factors when making decisions about foods for infants and young children, particularly in low- and middle-income settings where choices are limited and resources are scarce. This study describes caregiver perceptions in two Senegalese communities using a mixed methods, ethnographic approach that illustrates simple and efficient techniques to illuminate the emic perspectives of caregivers, which can be used in designing nutrition interventions.

Keywords: Senegal, food decision-making, focused ethnographic study, implementation research, cognitive mapping

FOLIC ACID FORTIFICATION OF CORN MASA PRODUCTS: ASSESSING THE CONSUMPTION, IMPORTANCE OF FORTIFICATION AND NEED OF NUTRITION EDUCATION AMONG HISPANIC POPULATION LIVING IN NEW MEXICO, USA

[1]Diaz Campos (Phillips), Sylvia G.; [2]Lee, Deanne.

[1]PhD Student. Msc. Registered and Licensed Dietitian. Family and Consumer Sciences Department. New Mexico State University. United States of America.; [2]MSc Student. Dietetic Intern. Family and Consumer Sciences Department. New Mexico State University. United States of America.

Background and objectives: Folic acid (FA) intake is a key micro nutrient for human cell metabolism. One of the most striking consequences of FA insufficiency is a birth defect called: Spina bifida. Arth et al (2016) reported, spina bifida and anencephaly are preventable with sufficient FA intake and "mandatory folic acid fortification of 200 µg/day" has reduced the incidence of birth defects to a minimum of 0.5 per 1000 births. A remarkable reduction, however Latin American descent population might not get enough folic acid through corn masa products which is a staple

for the population. The US Food and Drug Administration (FDA) in 2016 approved for manufacturers voluntarily to fortified corn masa flour products, such as corn tortillas.

Objectives:

1.- Understand the major sources of folic acid and folate and identify the most commonly consumed corn masa product among Hispanics of Southern New Mexico (NM), USA.

2.- Assess FA fortification need and education among residents and corn masa products (CMP) manufacturers.

Methods: The descriptive research surveyed Hispanic residents of Southern NM about their diets with a 24-hour food recall. Calculation of FA intake was assessed, 36 different food items like natural sources of folate, FA fortified wheat products, and non-fortified corn masa products. Food data bank from USDA was used. Data was collected from population, ages 18-85.

Results: 42 surveys were gathered from the region. Participants consumed an average of:

5.7 servings of non-fortified corn product per day (70%), compared to 2.4 servings of fortified wheat products (30%).

407 mcg of folate of natural sources, 404 mcg of FA fortified wheat products & 135 mcg of FA non-fortified corn masa products (CMP).

The most common non-fortified CMP was corn tortilla.

Conclusions: The Hispanic population continues with corn products as a staple in this part of the USA.

Consumption of non-fortified corn products is greater (70%) than fortified wheat products (30%). This is a concern, especially in child-bearing age women, Hispanics have a higher risk of FA deficiency birth defects. It's important to educate young hispanic population on how to read food labels and identify FA fortified CMP. Education of CMP manufacturers will be key as well.

Keywords: Corn masa products, Hispanics, Folic Acid fortification, Birth defects prevention

A THREE PRONGED APPROACH TO E-LEARNING: THE NEED FOR NUTRITION EDUCATION/INNOVATION PROGRAMME

[1]Bradfield, James; [2]Ray, Sumantra; [3]Kohlmeier, Martin; [4]Bhat, Shivani.

[1]Nutrition Science Intern. NNEdPro Global Centre for Nutrition and Health. Cambridge. United Kingdom; [2]Chair. NNEdPro. Cambridge. United Kingdom.; [3]Professor. UNC Chapel Hill. United States of America; [4]NNEdPro Global Centre for Nutrition and Health. Cambridge. United Kingdom.

Background and objectives: Technology is an essential part of almost all aspects of daily life nowadays however the way we teach students has largely remained the same for generations. Blackboards became PowerPoint presentations and chalk became

---

laser pointers yet students are still trained that learning reams of material from textbooks verbatim is still an effective way to learn coursework and prepare them for the wordforce. The Need for Nutrition Education/Innovation Programme (NNEdPro) is attempting to modernise the way nutrition is taught to students using a three-point plan.

NNEdPro is aiming to use the technology many of us have grown up using daily to teach nutrition education.

Methods: A 360 degree assessment of teaching and learning via participant interaction and review, focus group work on various aspects of nutrition education and KAP surveys throughout NNEdPro activities.

Results: NNEdPro has established three main platforms to achieve its goal:

(1) Using the Nutrition in Medicine platform at University of North Carolina at Chapel Hill to create the NNEdPro-NIM Global platform. This material will be specially designed for medical professionals only.

(2) Utilising the Virtual Learning Environment (VLE) team at the University of Cambridge to tailor specific video podcasts for medical students through the Nutrition Education Review Group (NERG).

(3) Designing its own platform to present lectures from the annual Summer School in Applied Human Nutrition in an interactive manner. This is the outward facing platform as all members of the public are eligible to apply to attend the Summer School where they would be granted access to this material.

Each of these platforms will present interactive modules rather than simply relying on a video of a lecture.

Conclusions: Though NNEdPro has achieved some success so far in the area of e-Learning, it is clear that there is much to do in this area. Through the continued support of its partner organisations, NNEdPro can continue to pursue the aim of improving nutrition education among medical professionals, student and the general population.

IMPROVING HOUSEHOLD FOOD SECURITY, DIET AND NUTRITION STATUS THROUGH WOMEN'S GROUPS IN EASTERN DEMOCRATIC REPUBLIC OF CONGO

Funna Evelyn, Sonya.

Adventist Development and Relief Agency (ADRA) International, Maryland, USA.

Background and objectives: Adventist Development and Relief Agency (ADRA) implemented a USAID funded project (Jenga Jamaa II) from 2012 to 2016 aimed at improving food security in Eastern Democratic Republic of Congo (DRC). Johns Hopkins Bloomberg School of Public Health was the operations research partner for the evaluation program activities. As part of this project, women empowerment groups (WEGs) were established to enhance the business skills and bargaining power of women, their knowledge on proper family nutrition, leadership and life skills. This study focuses on evaluating the effectiveness of the WEGs in improving household food security and nutritional status.

Methods: The household food security and nutrition indicators measured included the household dietary diversity score (HDDS) and the prevalence of wasting, underweight and stunting. In each of the 13 WEG villages, one WEG group and one control group of households not participating in WEGs was selected, encompassing a total of 325 households. Baseline and endline data, collected through a structured questionnaire were used for data collection.

Results: At the end of the project, 62% of the WEG participants achieved the target HDDS. The mean HDDS significantly increased from 3.40 in the baseline to 5.51 at the endline. The WEGs showed a statistically significant difference in household food insecurity improvement as compared to the control group. Although the mean height for age and weight for age scores among the WEG beneficiaries significantly improved from baseline to endline, there were no significant differences between the prevalence of wasting and stunting in the WEG and control groups at the endline.

Conclusions: The study shows that including nutrition activities in women empowerment interventions is a feasible way to improve household food security. However, a detailed analysis of the determinants of malnutrition is necessary to identify other factors contributing to change in nutrition outcomes.

Keywords: Women Empowerment Group (WEG), Democratic Republic of Congo (DRC), stunting, dietary diversity, food security.

SUGAR CONTENT IN FOOD PRODUCTS ASSUMED BY THE INDUSTRY AS "HEALTHY"

Martinik, Carolina Alejandra.

Affiliation: HZGA Dr. Arturo Oñativia. Rafael Calzada. Buenos Aires. Argentina.

Background and objectives: There are numerous terms to define sugars, with an indiscriminate use by the industry in products that claim to be "healthy." On the other hand, the epidemic of chronic non- transmissible diseases are increasing despite of the availability of these products. Several studies suggest that the consumption of high fructose corn syrup (HFCS) and other added sugars could be compromised in their development.

To record the presence, percentage content, types of sugar and / or their counterparts in products alleged to be "healthy" by the industry.

Methods: A descriptive, cross-sectional study was conducted. Data were obtained from the acquisition of products that in their containers contain concepts of "claims" such as:

- Light
- Recommended by scientific societies
- Fiber Source
- Only" x "Kcal
- Food for a better life
- Start or eat well
- Healthy

Available in the most known supermarket chains of the city of Lomas de Zamora during the period of November 2016-February 2017

Results: We analyzed 19 types of cookies and cereals, 7 low calorie drinks and 8 snacks, alleged as "healthy" by the industry.

The 94.7% (n18) of the cookies, 85.7% (n6) of the drinks and 100% of the snacks registered the presence of sugar. The 44.4% (n8) of the cookies and 37.5% (n3) of the snacks contain more than 11 grams of sugar in 100 grams of product. The 42.9% of beverages contains less than 10%. The 66.7% of the cookies, 50% (n3) of the drinks and 25% of the snacks (n2) contain 2 to 5 different types of added sugars. (Sugar, HFCS, malt extract, maltodextrin, molasses and glucose syrup).

Conclusions: The 93.4% of the analyzed products alleged to be healthy by the industry contain sugar and / or their counterparts. The 47.2% contain more than 2 types of added sugars. The 40.95% of the cookies and snacks have more than 11 grams of sugar in 100g of product.

Keywords: Sugar, healthy food, industry

AGRICULTURAL DEVELOPMENT INTERVENTIONS AND DIETARY DIVERSITY OF RURAL SMALLHOLDER FARMING HOUSEHOLDS IN EAST AND SOUTHERN AFRICA (ESA)

[1]Amaka, Marian Odenigbo; [2]Idemudia, Patience.

[1]PhD. Special Adviser on Nutrition. East and Southern Africa Division. International Fund for Agricultural Development. Italy.; [2]PhD. Professor. Department of Sociology. University of Saskatchewan. Canada.

Background and objectives: International Fund for Agricultural Development (IFAD) is proactively promoting nutrition-sensitive agriculture agenda in its operations. To provide guidance for an effective nutrition mainstreaming in IFAD's work, this study was conducted to map various nutrition sensitive interventions in IFAD portfolio; identify pathways for nutrition outcomes; identify challenges; and areas of opportunities for scaling.

Methods: This is a cross-sectional survey conducted in July and August 2016 which involved three countries and five study projects in the ESA region. The investment theme for the various study projects were agribusiness (Zambia); dairy (Kenya); productivity promotion (Zambia); rural marketing (Mozambique); and natural resource management (Kenya). Quantitative data was collected from 402 beneficiary households while qualitative data came from 161 focus group discussants and 34 community key informants (IFAD Country teams, project management staff and implementers). Dietary diversity was evaluated at both household (Household dietary diversity score: HDDS) and individual levels (Minimum Dietary Diversity for women: MDD-W & Minimum Dietary Diversity for children: MDD-C). Multiple Classification Analysis (MCA) model was adopted to relate key project interventions as variables to the dietary diversity.

Results: The quantitative and qualitative data indicated that integrated nutrition activities i.e. nutrition education; food demonstration; recipe development; kitchen garden as well as key project investment i.e. diversification of food production; women empowerment; commercialization and access to market; production-focused training had positive effects on dietary profile. The proportion for good dietary diversity was higher for HDDS (63.7-97.3%) as compared to MDD-W (22.5-63.5%) and MDD-C (1.2-47.6%). The MCA analysis showed that HDDS varied significantly according to diversification of services, market linkages, women empowerment, capacity building and literacy status. For the women group, household size, women empowerment and diversification were found as strong determinant factors. Whereas capacity building indicated the most influence on dietary diversity for children.

Conclusions: This study conceptualized a simplified framework of integrated impact pathways with distinctive focus on nutrition knowledge, climate and women empowerment as influencers in maximizing impact of agricultural development interventions for improved dietary intake.

DEVELOPMENT, CHARACTERIZATION AND SENSORY ANALYSIS OF SUGAR-FREE PRICKLY PEAR JAM (OPUNTIA FICUS INDICA)

[1]Gozzi, Marta Sofía; [2]Barroso, Bárbara Malén; [2]Parés, Carolina; [3]Faggi, Gabriela Marta.

[1]MSc. Food Technologist. Instituto de Tecnología. Universidad Argentina de la Empresa. Argentina; [2]BSc. Food Technologist. Departamento de Biotecnología y Tecnología Alimentaria. Facultad de Ingeniería y Ciencias Agrarias. Universidad Argentina de la Empresa. Argentina.; [3]BSc. Agronomist Engineer. Instituto Nacional de Tecnología Agropecuaria. Estación Experimental Agropecuaria Las Breñas. Argentina.

Background and objectives: Diabetes is one of the most common metabolic disorders in the world and its prevalence has been increasing in the last decades. Besides, more and more people are concerned about their health choosing sugar-free products. The aim of this work was to develop a jam with a non-traditional fruit like prickly pear, containing no added simple sugars, and to evaluate their physicochemical, microbiological and sensory characteristics.

Methods: The sugar-free jam was made with the whole fruit pulp of orange variety. Stevia was added as a non-nutritive sweetener, and agar-agar and locust bean gum as gelling agents. Sorbitol, maltodextrin, potassium sorbate, ascorbic and citric acid were also added. It was determined the proximate composition, pH, °Brix, and color. Carbohydrate content was estimated by difference. Microbiological analyses were performed. Sensory analysis was taken with 26 non-trained people who evaluated color, brightness, flavor, texture, taste and global acceptance, using a 5-point hedonic scale.

Results: The final sugar-free jam contained (g% wb): moisture 62.8, carbohydrate 33.3, protein 1.10, fat 0.9, ashes 1.0, fiber 0.9, pH of 4.3 and 21°Brix. Total energy was 138 Kcal/100g, 54% less than traditional prickly pear jam. Chromatic parameters L*, a*, b* and DE (fresh fruit as reference) were 30.98, 7.00, 20.20 and 7.58, respectively. In the sensorial test the flavor showed the lowest score (3.35) perhaps because people is not accustomed to this fruit. Color and brightness had the best scores (3.88 and 3.85, respectively) and to the global acceptance was 3.77. The jam met the microbiological standards of current legislation.

Conclusions: This sugar-free prickly pear jam could be a novel option for diabetics and people who wants to avoid sugar-sweetened products.

Keywords: Key words: jam, tuna fruit, diabetes, sugar-free

INVESTIGATION OF THE REACTIONS OF THERMAL PROCESS CONTAMINANTS IN BISCUITS DURING DIGESTION

[1]Hamzalıoğlu, Aytül; [2]Gökmen, Vural.

[1]PhD candidate. Food Scientist. Department of Food Engineering. Hacettepe University. TURKEY; [2]PhD. Prof. Food Scientist. Department of Food Engineering. Hacettepe University. Turkey.

Background and objectives: Processing of foods cause to the formation of toxic compounds in foods which possess detrimental effects on human health. Acrylamide, 5-hydroxymethylfurfural, α-dicarbonyl compounds are such process contaminants formed as a result of high temperature processing of carbohydrate rich and low-protein crops such as potato, wheat. Besides these contaminants, foods also bear reactive components thus their interactions during digestion is of importance. This study aimed to investigate the reactions of thermal process contaminants including acrylamide, 5-hydroxymethylfurfural (HMF), methylglyoxal (MGO) and 3-deoxyglucosone (3-DG) in biscuits during digestion.

Methods: An in vitro enzymatic digestion system simulating gastric, duodenal and colon phases was used and the change in the amount of these compounds was monitored during digestion of different biscuits.

Results: Acrylamide levels as well as MGO and 3-DG levels of biscuits gradually decreased through gastric, duodenal and colon phases of digestion. At the end of digestion, acrylamide reduction ranged between 49.2% and 73.4%. Similarly, 3-DG and MGO reduction was found to be varying between 23% and 58.91%, 50.08 %and 77%, respectively. On the other hand, dramatic increase was observed in HMF contents of biscuits at the end of gastric phase. However, with the progress of digestion, HMF concentration significantly decreased, as well. Since these contaminants contain reactive carbonyl groups, reactions with amino and sulfhydryl groups of amino acids might take place. To understand this, model systems composed of contaminants and amino acids including lysine and cysteine were subjected to digestion. The results revealed that disappearance was due to interactions of reactive carbonyl groups with the accumulating amino and sulfhydryl groups

during digestive process. By high-resolution mass spectrometry analysis in model systems and biscuits, the formation of adducts of contaminants with amino or sulfhydryl groups of amino acids were confirmed.

Conclusions: In conclusion, simulated digestion conditions favored the addition of amino acids to process contaminants. Owing to its two nucleophilic groups (–SH, –NH2), cysteine becomes highly reactive among the amino acids. Gastrointestinal conditions and the ingested food composition affect the levels of bioavailable process contaminants, and should be taken into consideration.

Keywords: acrylamide, HMF, α-dicarbonyl compounds, in vitro digestion, biscuits

POTENTIAL OF ALTERNATIVE FOOD NETWORKS IN MEDELLÍN

[1]Cadavid Castro, Martha Alicia; [2]Alvarez Castaño, Luz Stella; [3]Quintero-Vergara, Shirley Daniela; [3]Martínez-Bedoya, Ximena; [3]Martínez-López, Angie Paola.

[1]Nutritionist. MSc Food and Human Nutrition. Nutrition and Diet School. Unversity of Antioquia. Colombia.; [2]Nutritionist. HD Master in Public Health. Nutrition and Diet School. University of Antioquia. Colombia.; [3]Student. Nutrition and Diet School. Unversity of Antioquia. Colombia.

Background and objectives: New kind of networks to produce, distribute, and consume foods is being developed in several countries around the world. The alternativeness consists of growing organically produced foods without using a chemical toxic product. The transportation is done with very few intermediaries and short trips, producers have stable and fair price systems and relations between producers and consumers are close and direct. They are called Alternative Food Networks (AFN), which seek to become an alternative to the conventional food system, driven by multinational food producers and big chain retailers, located especially in urban areas. This study aimed to characterize the AFN of Medellin. AFN specifically practices, acts, motivates the camaraderie relations among producers, distributors, and consumers, promoting an ethical and professional behavior.

Methods: A qualitative study collective cases; semi-structured interviews were conducted with producers and distributors taking part of 12 AFN in Medellin. Assessments of the participants were also carried out at food sales sites to observe interrelations and practices.

Results: This study found that in Medellin are incipient AFN experiences. They encompass producers, distributors, and consumers. They sell different products mainly fruits and vegetables. In fewer amounts, they sell: rice, quinoa. Finally, they handmade processed meals like chocolate, cocoa, butter, and cheese. These networks promote local development and use short trade channels because foods are grown in rural Medellin areas or nearby regions. Its consumers are people of high social socio-economic strata and with high educational level. Consumers of high strata buy this type of food especially to preserve their health, take care of the environment, and support the small producers.

Conclusions: There are AFNs existing in Medellin which are of recent creation; they share the alternativeness of other networks around the world and in the future may become an alternative food system that transforms the current hegemonic model.

Keywords: Alternative Food Networks, Food supply, Sustainable agriculture, Organic foods, Food production

EFFECTS OF SEASONALITY ON HOUSEHOLD FOOD SECURITY AND FOOD CONSUMPTION PATTERNS OF PASTORALIST'S CHILDREN IN KAJIADO COUNTY, KENYA

[1]Chege, Peter; [2]Muthamia, Olive.

[1]Department of Food, Nutrition and Dieteics, Kenyatta University, Kenya; [2]Department of Nutrition and Dietetics, Mount Kenya University, Kenya.

Background and objectives: The livelihood of communities in arid and semi-arid lands of Kenya is mainly pastoralism. Climatic seasonality is one of the determinants of food security. Food consumption patterns have been shown to fluctuate depending on the food security situation in a household. Households in ASALs are more likely to be affected by the fluctuations of the seasons which in turn affect food availability. This study aimed to investigate the effect of seasonality on food security and food consumption patterns among children (6 - 59 months) from pastoralists' households.

Methods: The study adopted a longitudinal, observational study design, following on households for one year. The study was carried out on 150 randomly selected households in Kajiado County. Data were collected on a monthly basis for one year. Data on the climatic profile was obtained from the meteorological department. Analysis of variance was used to assess for any differences in food security and food consumption patterns across the seasons. ANOVA was used to analyze for significant differences across different seasons.

Results: The dietary diversity score was significantly higher ($p < 0.05$) during the long rains season (5.13 ± 0.06) as compared to short rains (4.13 ± 0.04) and the dry season (3.45 ± 0.03). During the dry period, the households lacked the capacity to access adequate food due to low production, high food prices and low income from livestock and livestock products. Food scarcity was noted in the markets especially during the dry period due to low supplies. During dry seasons, there was a low frequency of food consumption, less number of meals consumed and reduced nutrient intake among children.

Conclusions: Seasonality had a significant effect on food security with the situation becoming worse during the dry season. The change in dietary diversity, the number of meals consumed per day, the frequency of food consumption across seasons was an in-

dicator of how different seasons affected household food security and food consumption patterns. This study recommends promotion of food preservation during the plenty seasons, production of drought-resistant crops, initiation of irrigation projects and use of social safety nets during extreme conditions.

RECONCILING SAFETY ALLOWANCES FOR BETA AGONIST RESIDUES IN MEAT FROM FOOD ANIMALS

Centner, Terence.

Professor. Agricultural and Applied Economics. University of Georgia. USA.

Background and objectives: Cattle and hog producers are adding beta agonists to feedstuffs in the United States and Canada that leave residues in meat products consumed by humans. Both the U.S. Food and Drug Administration and a Joint FAO/WHO Expert Committee on Food Additives have decided that low amounts of beta agonist residues do not pose a health problem for humans. Conversely, evaluating nearly identical data, the European Food Safety Authority decided that beta agonists had not been shown to be safe for human ingestion. This research explains how the U.S. and EU have reached different conclusions on the safety of beta agonist residues.

Methods: Affect and availability heuristics of animal production practices in the United States and the European Union are analyzed to explain why regulators relying on the same data have adopted divergent provisions for beta agonists. Through the identification of different approaches to animal production, the divergent conclusions reached on the risks of beta agonist residues in food products can be explained.

Results: Animal production technologies previously regulated in the U.S. and EU were identified that may account for the discrepancies in the regulatory regimes on beta agonists. Six technologies authorized in the U.S. and limited in the EU offer an explanation for difference conclusions by regulators on risks posed by beta agonist residues in meat products.

Conclusions: Regulators in the U.S. had authorized concentrations of animals, tail docking of pigs, castration of male pigs without anesthesia, and the use of hormones, recombinant bovine somatotropin, and non-therapeutic antibiotics. EU regulators had placed limits on these six technologies or banned them. Given these foundations of regulatory controls over food animal production, regulators in the US and EU developed divergent regulatory approaches for beta agonist usage. They weighed risks differently, and cultural beliefs on animal welfare and human health led to different interpretations of data regarding beta agonist residues in food products.

Keywords: beta agonists, Codex, U.S. Food and Drug Administration, World Trade Organization

TRANSFORMATIONS IN AGRICULTURE AND MEETING THE FOOD NEEDS OF POPULATION AS A RESULT OF CLIMATIC CHANGES

Banski, Jerzy.

Professor, Institute of Geography and Spatial Organization, Polish Academy of Sciences.

Background and objectives: The paper is an attempt at evaluation of the oncoming transformations in the food economy induced by climatic changes. The paper focuses on the regional diversity and arising from the consequences of food security. The basic hypothesis is, climate change, deepening of negative spatial polarization in food production.

Methods: The study is based on the analysis of statistical data (FAO, EUROSTAT, ESPON), IPCC reports and cartographic methods.

Results: It is assumed that climate warming in the next decades is a phenomenon the most probable to occur. Consequently, it may bring about spatial polarization in the food production - a growth in rich countries (located in the temperate zone) and decrease in poor nations (mainly in the tropical and equatorial areas). In temperate zones the expected changes may result in a growth in potential production of food in view of the increasingly extended vegetative period and widening the geographical ranges of crops. Meanwhile, today is observed in the EU countries the problem of overproduction of food, which seeks to mitigate the CAP. One of the activities is extensification of food production and reduction of agricultural land. In turn, warm areas, including primarily exposed to prolonged droughts increase in average temperatures will bring more negative effects. The most vulnerable continent to climate change seems to be Africa. Limitation of precipitation will strengthen the process of desertification, especially at the edge of the Sahara and south of the continent. This problem is aggravated by the fact that the greater part of its population depends on farming. Present and future interactions between the climate and food security can also be considered in the context of demographic processes. The greatest increases in population will be witnessed in countries that are currently affected by problems in access to food. The result of these processes will be great migrations of population and social conflicts.

Conclusions: Climate change probably will not stop. Therefore, it is important to introduce in poor regions a modern methods of food production and to ensure proper distribution of food. We must also be prepare for the major societal challenges.

Keywords: food, production polarization, climate change, agriculture

COGNITIVE BIAS IN FOOD HANDLERS: MORE KNOWLEDGE MEANS FOOD SAFETY?

[1]Gomes de Freitas, Rayane Stephanie; [2]Thimoteo da Cunha, Diogo; [3]Stedefeldt, Elke.

[1]MS student. Nutritionist. Universidade Federal de São Paulo. Brazil.; [2]PhD. Nutritionist. Faculdade de Ciências Aplicadas. Universidade Estadual de Campinas. Brazil.; [3]PhD. Nutritionist. Centro de Desenvolvimento do Ensino Superior em Saúde. Universidade Federal de São Paulo. Brazil.

Background and objectives: As food handlers are liable to contaminate food by inappropriate behaviors. In this sense, training is the strategy indicated to instruct them in order to prevent foodborne diseases (FBD) outbreaks. Cognitive biases are hard to prevent and may puzzle correct decisions. The objective of this study is to discuss the relation between knowledge about sanitary norms and cognitive biases.

Methods: Ethnography and participant observation were the main strategies used. Participant observation was carried out in six commercial restaurants of two Brazilian cities during 42 days. Information related to foodservice infrastructure, service characteristics, location, details about the agents, their speeches, non-verbal communications, interpersonal relationship, work routine and relation with food safety were written in field diaries. Content analysis of the thematic type was used to elucidate data. It was observed 68 food handlers. Six of them, one of each local, voluntarily answered to questionnaires which provided data about optimistic bias and locus of control.

Results: These workers presented an optimistic bias tendency in those questions related to consumer, family and friend's risk of having a FBD when eating a meal which was prepared by them. Despite the disconnection between observed practices and adequate knowledge, those workers showed internal locus of control when they assumed their responsibility for food safety. Optimistic bias and illusion of control seem to manifest only in the presence of knowledge about sanitary norms, since workers felt overconfident. When workers perceive the sanitary risk they may act in a way to prevent it if they know the adequate practices and the negative implications to client's health, as well as if the infrastructural conditions and time are favorable to them. External locus of control corroborates with the belief the occurrence of FBD is not possible and that workers are protected by religious adornments and their beliefs. These situations may increase the risk of FBD.

Conclusions: Workers' risk perception becomes permeated by cognitive biases that arise with the help of knowledge about sanitary norms. It is suggested that the training approach does not reach the depth needed to transform the food handlers' thinking and their work environment towards food safety.

Keywords: risk perception, cognitive biases, food safety, food handlers, ethnography.

Universidad de Ciencias Empresariales y Sociales (UCES). Enfermeira. Universidade Aberta da Terceira Idade (UNATI/UEA/AM). Brasil.; [5]Assistente Social. Especialista em Política Pública de Atenção a Família. Universidade Aberta da Terceira Idade (UNATI/UEA/AM). Brasil.; [6]Fisioterapeuta. Universidade Aberta da Terceira Idade (UNATI/UEA/AM). Brasil.; [7]Diretora da 1ª Vara da Família do Tribunal de Justiça do Amazonas (TJAM). Bacharel em Direito. Especialista em Processo civil. Assistente Social. Brasil.; [8]Advogada. Assessora Jurídica. Tribunal de Justiça do Estado do Amazonas. Brasil.; [9]Acadêmica de Enfermagem. Universidade Paulista (UNIP/AM). Universidade Aberta da Terceira Idade (UNATI/UEA/AM). Brasil.; [10]Educadora Física. Secretaria de Educação do Estado de São Paulo.

Background and objectives: One of the branches of law is in charge of legislating on food-related issues in Brazil. In a country with great territorial extension and still marked by much informality in several sectors of the production chain, it is necessary to act rigorously through a law on the production of foodstuffs to guarantee the protection of consumer health. Objective: To emphasize the elementary importance of the legal mechanisms acting in consonance with inspection agencies in the food production chain in the national territory.

Methods: This study is an integrative literature review. The search was carried out on the SciELO platform (Scientific Electronic Library Online), with the descriptors Legislation, Food and Brazil. The platform returned 65 results, the search was filtered searching for texts strictly related to the subject and incomplete texts were duplicated, before the year 2012 or published in a language other than Portuguese, English or Spanish. There remained only nine texts. The research was complemented with textbooks.

Results: Brazil has a broad legislative mechanism for the production, packaging, transport, conservation and commercialization of food products. One of the main obstacles to the fulfillment of all determinations is the difficulty of inspection in such a large territory. Added to this is the lack of knowledge of many operational procedures by the producers. It is noted that some themes also acquire bioethical connotations, as in the case of transgenics.

Conclusions: This legislative branch will ensure an increase in the quality of national food production, given that the country is

quite heterogeneous. Patent registration benefits greatly from such legislation, and any crimes of this scope end up being inhibited.

Keywords: food law; inspection; national food production

SOCIAL WORK IN FOOD SECURITY FOR THE ELDERLY POPULATION

[1]Costa, Michelle Silva; [2]Ribeiro, Euler Esteves; [3]Ribeiro, Ednéa Aguiar Maia; [4]de Souza Praia, Raquel ; [5]Neta, Inez Siqueira Santiago; [6]Oneti, Ciro Félix; [7]Mortágua, Andréa Rebouças; [8]Araújo, Arthenize Riame Praia G. Background and objectives: The determinants of the health of the population, focused on food and nutritional security may be a reflection of the socioeconomic conditions of the population. Data from the 2002/2003 Family Budget Survey (POF) report that there is a prevalence of overweight in low income families in Brazil. Other studies bring an increase in cardiovascular diseases, type 2 diabetes and fixed types of cancer, accentuating morbimortality related to nutritional status. Objective: To identify a role of the social worker inserted in the multiprofessional team of health care, for an insertion of the low income elderly into social food programs of the Brazilian government.

Methods: This is a review of the literature in the SciELO database and Virtual Health Library (VHL), 6 studies were selected from the inclusion criteria. Other materials such as books and sites of governmental social programs focused on a theme were also used.

Results: The research evidenced that there is a shortage of studies on the performance of the professional social worker of the identifier by the health team of low income elderly people without access to basic foodstuffs and in sufficient quantity, who seek the health service or are assisted in their Home Programs such as fed-

eral government hunger zero, aims to combat hunger and ensure food and nutritional security in low-income populations. However, for the acquisition and consumption of food, development must be done through actions. In this way, as well the Federal Council of Social Service (CFESS), the product in care provided by the social worker, should give through A direct relationship with its users, in relation to the elderly, this with the caregiver / family.

Conclusions: The treatment of a multiprofessional and intersectoral work relationship, without social service qualities of the most varied dimensions in which the elderly person finds himself needs a dialogue, appropriate social programs aimed at food security when necessary, in view of the vulnerability For the promotion of health.

MICROBIOLOGICAL ANALYSIS OF FOOD MANIPULATION SURFACES IN CANTEENS OF A PUBLIC UNIVERSITY

[1]Mont'alverne Jucá Seabra, Larissa; [2]Pereira Nogueira, Josimara; [2]Santana Luz, Anna Beatriz; [1]Florentino da Silva Chaves Damasceno, Karla Suzzane.

[1]PhD. Nutritionist. Department of Nutrition. Federal University of Rio Grande do Norte; [2]Nutritionist. Department of Nutrition. Federal University of Rio Grande do Norte.

Background and objectives: Foodborne Diseases (FD) are all clinical occurrences caused by the ingestion of food that may be contaminated with pathogenic microorganisms, chemicals, harmful objects or that contain toxic structures in amounts that affect the health of the consumer, individually or collectively. Food-producing establishments are conducive to microbial contamination. The objective of the study was to evaluate the sanitary quality of the surfaces used for food manipulation in scholar canteens of Brazil

Methods: The survey was conducted at 11 canteens located at Federal University of Rio Grande do Norte (UFRN) between February and March of 2016. The study was submitted and approved by the Research Ethics Committee of the University Hospital of UFRN under the number 737.109.

The samples were collected in the canteens using the swab technique and were transported to the Laboratory of Food Microbiology in thermal box with ice bags immediately after their collection to determine the Most Probable Number (MPN) of Coliforms at 45 ° C and Mesophilic Aerobic Bacteria.

Results: Coliforms at 45°C were detected in cutting boards used in 63% of the evaluated establishments. The counts were higher than the microbiological sanitary standard in 7 of the 11 canteens investigated. The sites in which they obtained an unsatisfactory classification showed results between 3.0 and 1100 MPN / 50 cm2.

For aerobic mesophilic bacteria, the cutting boards showed a high count in 73% of the canteens classified as unsatisfactory.

For sites that presented unsatisfactory environmental conditions, a minimum and maximum contamination value of 216 and 4600 CFU respectively was observed.

Conclusions: The results showed unsatisfactory microbiological quality of the cutting boards utilized in canteens. Considering that food handling surfaces are utensils directly related to the high number of foodborne diseases, this study demonstrates the need to take urgent and effective measures to reduce or eliminate the microbiological contamination found in cutting boards of these food-services.

LEVERAGING PRIVATE SECTOR FOR GENDER AND NUTRITION RESPONSIVE AGRICULTURE

Ladd, Nofirstname.

Ladd, BS, MS, RDN. Senior Technical Director, Nutrition. ACDI/VOCA.

Background and objectives: Zambia PROFIT+ is a USAID Feed the Future project which operates a market led approach where private sector partnerships drive mutually beneficial development for them and the target communities. A major emphasis in the project is the promotion of job creation through entrepreneurship with the private commissioning Community Agro dealers (CA) to provide services in rural Zambia reaching the most rural areas or "last mile". In addition to input supplies, farm services such as mechanization, and spraying services, the CA provide a variety of training including nutrition, use of improved and nutrient-rich commodities, in addition to creating savings and credit groups. The project trained 334 CA's (28% women), reached over 182,000 smallholder farmers (55% women).

An assessment of the CA model was conducted to determine if the program design and outcomes were reached which included: increased household income, improved production, gender empowerment, and nutrition transformation, as well as improvement in climate smart agriculture practices in the communities.

Methods: The assessment included focus group discussions designed to assess the CA model's impact on women's empowerment, nutrition, introduction of nutrient-rich commodities, increased household incomes, and improved production patterns. The interviews involved 286 CAs in 33 groups across the program area.

Results: The CA are recognized as role models and change agents in their community. They report an 40% increase in household assets (proxy for income). Farmers working with CA's report a 24% increase in yield as well as increase in production of nutrient rich crops. The Ministry of Health, Ministry of Agriculture, NGOs and private sector leverage the CA's to deliver nutrition and health messages due to their reach into the rural communities or "last mile". In addition, 35% of the women report they are respected as leaders within their communities.

Conclusions: Leveraging the private sector to support a market based approach to improve nutrition, increase incomes and improve gender empowerment is sustainable and scalable model thus reducing the need for continued donor funding. By linking CA's with the private sector, this sustainable model reaches rural communities, improves their livelihoods and nutritional status, and increase women's empowerment.

Keywords: nutrition-sensitive agriculture, gender, private sector

MILKING FOR ALL IT'S WORTH: WOMEN, NUTRITION, AND LIVESTOCK

Ladd, Nofirstname.

Ladd, BS, MS, RDN. Senior Technical Director, Nutrition. ACDI/VOCA.

Background and objectives: Livestock raising in developing world offers the potential to significantly increase incomes and improve household nutrition. RWANU a USAID/Food for Peace Development Food Aid Program in southern Karamoja challenged the cultural norms of male dominated, lucrative, nutrient-rich livestock value chains by engaging women to own and sale livestock, and to also use the income and livestock products for household nutrition.

An assessment of the Women's Livestock Groups was conducted to determine if the program design and outcomes were reached which included: improved women's empowerment, improved nutrition, and improved women's participation in livestock activities.

Methods: The assessment used both primary and secondary data sources through a desk review of key programmatic and research documents and through in-depth interviews and focus groups with program beneficiaries, community leaders, key household members, and women not chosen for the program.

Results: The assessment showed the program was successful in changing gendered norms around goat ownership, making it socially acceptable for women to own goats and increasing women's sole and joint decision-making power in households. The increase in women's status and value in the household improved along with family relationships. A majority of women reported increased milk consumption especially among small children. On the negative side the men still controlled the selling of the goats, thus control over the money.

Conclusions: All three major pathways from livestock (agriculture) to nutrition were affected by this activity: production (home consumption of milk), increased incomes and women's empowerment. Working through women's groups for livestock production allowed the program to explore the social norms and complexities surrounding women's engagement in livestock value chains to improve income and nutrition. However, the assessment found that despite the improvements on improving consumption of milk and changing gender norms around goat ownership, men still maintain primary responsibility for goat care and management, as well as their sale and purchase. Therefore, it is impor-

tant when designing gender-sensitive livestock projects to include women's economic empowerment activities that will address the social norms that prevent women from engaging and benefiting from their labor.

Keywords: livestock, nutrition-sensitive agriculture, women

ALUMINIUM-CONTAINING FOOD ADDITIVES EXPOSURE ASSESSMENT

Degrossi, María Claudia; Fattori, Susana.

Department of Chemical Engineering. Buenos Aires Institute of Technology. Argentina.

Background and objectives: Available studies show adverse effects of aluminium on the nervous and reproductive systems in animals. The major source of exposure to aluminium for the general population is through the diet. Aluminium in foods originates from its natural occurrence, from the use of aluminium-containing food additives and from the presence of aluminium in food contact materials. The main purpose of this study was to evaluate the presence of food additives containing aluminium in foods, to analyze aluminium content in them and to estimate possible exposure for the general population. JECFA (Joint FAO/WHO Expert Committee on Food Additives) recommended a Provisional Tolerable Weekly Intake (PTWI) of 2mg/kg bw.

Methods: A survey was carried out in supermarkets of Ciudad Autónoma de Buenos Aires to determine through the reading of food labels the presence of aluminium-containing food additives authorized for use in food by national legislation. Samples were microwave digested and analyzed by direct graphite furnace atomic absorption spectrometry in order to determinate the total aluminium content. Finally, a possible scenario of exposure was established and a weekly potential exposure was estimated.

Results: The results of the survey in the supermarkets indicated that flour-based food products as cakes, croissants, rolled cakes, cake powder mixes, among othersare the products that mainly contribute to the ingestion of aluminium. All analyzed products complied with the Food Code limits for food additives containing aluminium (content ranged from less or equal to 0,01 to 0,1g/100g).

On the basis of analytical results, it is possible to infer that the ingestion of one biscuit portion (40g), containing 0,028 g% of aluminium (maximum level detected), 3 times per week, for a 15 kg bw kid represents a potentially weekly intake of 2,2 mg/kg bw, higher than PTWI.

Conclusions: Considering that other sources of exposure are possible, and that food industry is using levels of these additives below the maximum allowed amount by national legislation, a deeper risk assessment is required.

Keywords: aluminium exposure, risk assessment, food additives, tolerable weekly intake, flour-based food products

POPULAR RESTAURANT PROGRAM: GUARANTEE OF SAFE MEALS?

(1)Mont'alverne Jucá Seabra, Larissa; (2)Valdejane Silva Souza, Camila; (3)Batista Lima, Luciana.

(1)PhD. Nutritionist. Nutrition Pos graduate program. Federal University of Rio Grande do Norte. Brazil.; (2)PhD. Nutritionist. Nutrition Pos graduate Program. Federal University of Rio Grande do Norte. Brazil; (3)Nutritionist. Federal University of Rio Grande do Norte. Brazil.

Background and objectives: The main objective of 'Popular Restaurant Program' is to provide adequate nutritional meals at low cost, to people in risk of food insecurity in Brazil. This work aimed evaluate hygienic-sanitary conditions in Popular Restaurants of Rio Grande do Norte (RN) state.

Methods: RN has 24 Popular Restaurants units, and 10 different cities were selected by random sample system. For data collection, a checklist was applied based on Brazilian federal law (RDC 216/2004), containing 183 verification items grouped in 12 evaluation blocks, which allowed the evaluation of the hygienic-sanitary conditions of the establishments. A single visit to the restaurants was carried out to fill out the checklist. To obtain the final diagnosis of each unit, the average of the items in the list was calculated. The restaurants were classified in: "Very bad": 0 to 19% of adequacy of the requirements; "Bad": 20 to 49%; "Regular": 50 to 69%; "Good": 70 to 90% and "Very good": 91 to 100%.

Results: The overall adequacy of the 10 Popular Restaurants was 69%, classifying the units as "Regular". The block "building, facilities, equipment, furniture and utensils" was the one that presented the highest percentage of inadequacies. The managers of the visited units reported that the buildings were adapted, and because they were planned for another purposes and not for food production, they did not allow an ordered flow of the food, as well as favored the shelter of vectors and urban pests.

Conclusions: The study showed that the establishments presented inadequate conditions for food production and there is no guarantee of safe food to consumers.

INTERNATIONALLY COMPARABLE PRICES OF HEALTHY AND UNHEALTHY FOODS IN 176 COUNTRIES: IMPLICATIONS FOR FOOD AND NUTRITION POLICIES

Headey, Derek.

PhD Economist. Poverty Health & Nutrition Division. International Food Policy Research Institute. USA.

Background and objectives: While diets typically diversify as incomes rise, decisions on which foods to consume may heavily

depend on relative food prices. Prices will not vary substantially across countries if a food is highly tradable. But while many unhealthy foods are non-perishable and therefore highly tradable (e.g. Coca Cola, oils, salt, sugar), many health foods are highly perishable imperfectly tradable (e.g. eggs, fresh milk). Despite this intuition, no previous research has systematically examined the affordability of different foods across countries.

Methods: We use data on the prices of homogeneously defined foods for 176 countries from the 2011 round of the International Comparison Program (ICP). We construct a novel measure of relative prices, the price of 1 kg of a given food ("large brown eggs") relative to the price of 1 kg of the cheapest cereal in each country. This measure captures how expensive it is for households to diversify out of cereals into a specific food group. We compare means and variance of relative food prices across regions, and use least squares regressions to assess cross-country relationships between relative food prices and the consumption patterns of children aged 6-23 months, after controlling for GDP per capita.

Results: As expected, relatively unhealthy foods vary little across countries and are often cheap sources of calories. Prices of healthy fruits and vegetables are relatively cheap in developed countries but somewhat more expensive in poorer regions. Animal sourced foods (ASFs) vary substantially across countries and are often very expensive sources of calories, generally 5-15 times more expensive in poor countries compared to OECD countries. Among major food groups it is only the consumption of ASFs that is strongly associated with their own relative prices and with GDP per capita.

Conclusions: The expensiveness of healthy foods, particularly ASFs, is a major obstacle to improving diets in poor countries. This suggests that conventional remedies for monotonous diets - income transfers and behavioral change interventions - may be less effective for poor populations facing extremely high ASF prices. This justifies an important role for food policies to drive down the relative prices of nutritious foods.

Keywords: Food prices; ASFs; dietary diversity

EFFECT OF ROSEMARY ON COLORIMETRIC STABILITY OF FLYING FISH HAMBURGER

[1]Suzanne Florentino Silva Chaves Damasceno, Karla; [2]Vanessa Silva Moreira, Camila; [3]Antonio Ponce de Leon F Carvalho, Rodrigo; [4]Oliveira Lima, Patrícia; [5]Francisca Marcelino de Paula, Hellen; [6]Mont'alverne Jucá Seabra, Larissa.

[1]PhD. Nutritionist. Nutrition Pos graduate program. Federal University of Rio Grande do Norte. Brazil.; [2]MSc. Nutritionist. Nutrition Postgraduate Program. Federal University of Rio Grande do Norte. Brazil.; [3]PhD. Engineer. Jundiaí Agricultural School. Federal University of Rio Grande do Norte. Brazil.; [4]PhD. Zootechnist. Semi-arid Federal Rural University. Brazil.; [5]Nutritionist. Federal University of Rio Grande do Norte. Brazil.; [6]PhD. Nutritionist. Nutrition Postgraduate Program. Federal University of Rio Grande do Norte. Brazil.

Background and objectives: Obtaining Mechanically Separated Meat (MSM) is an alternative to recovery edible parts of low commercial value fishes. Flying fish (Hirundichthys affinis) constitutes an important fishing resource in the northeast region of Brazil and can be used like raw material in food products. The use of natural compounds as antioxidant has been used to retard undesirable reactions that occur in fish products during storage. Thus, the objective of this work was to evaluate the effect of rosemary (Rosmarinus officinalis) on color stability of 3 different formulations of flying fish hamburger, during freezing storage.

Methods: Color determinations were performed on 0, 30, 60 and 90 days of freezing storage with Minolta CM-5 spectrophotometer (CIE L^* a^* b^*). The formulations of hamburger differed in the quantity of rosemary: F1 (0), F2 (0.5%) and F3 (1.0%).

Results: The values of lightness (L^*) increased throughout the time for all samples at the end of the storage period ($p<0.05$). Values of b^* did not changed throughout the time in F1. However, the samples with rosemary (F2 and F3) had the values of b^* increased in the day 90. The values of a^* were higher in the samples with rosemary for the analysis carried out in the days 0, 30 and 60, which ensures the increase of the red color intensity in the hamburger, directly proportional to the amount of rosemary in these days of analysis.

Conclusions: Formulations with rosemary obtained better color indices during storage, indicating maintenance of the quality when compared to the formulation without rosemary.

Keywords: rosemary; fish hamburger; color stability

FOOD ALLERGEN LABELING AND DETECTION OF TRACES OF MILK, SOY AND EGG IN FOOD PRODUCTS USUALLY CONSUMED BY CHILDREN

[1]Ronayne de Ferrer, Patricia Ana; [2]Binaghi, María Julieta; [3]Giacomino, María Silvia; [2]López, Laura Beatriz.

[1]PhD. Biochemist.Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Bromatología. Argentina; [2]PhD. Biochemist. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Bromatología. Argentina; [3]BsC. Biochemist. Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Cátedra de Bromatología. Argentina.

Background and objectives: Food allergens labeling will soon be incorporated in the Argentine Food Code (article 235 seventh). The objectives of the present study were: to analyze allergen declaration and the presence of precautionary statements in the labels of food usually consumed by children, to quantify traces of milk, soy and egg using commercial ELISA kits in the same products and to evaluate the possible declaration of these allergens according to either Japanese legislation or VITAL 2.0, which establish thresholds in different foods.

Methods: Two different batches of 11 commercial products were analyzed, which were randomly acquired in supermarkets in Buenos Aires, Argentina. Correct statements of allergens ac-

cording to article 235 seventh were assessed. Milk, soy and egg allergens were determined using commercial ELISA kits from the brands R-Biopharm, Neogen and/or Romer (two for each allergen).

Results: In the case of milk and egg, the kits showed the same behavior in all the analyzed foods and in most of the samples coincided with what was stated on the labels. However, in one of the samples traces of milk were detected even though there was no statement about possible presence of milk in its labeling. The values were 3.9 and 4.2 ppm of milk protein with the R-Biopharm kit and 2.4 and 3.5 ppm of skim milk powder with the Neogen kit. In the analysis of the soy allergen, different results were obtained with the two kits used in some of the samples analyzed. In addition, positive results were obtained for soy in almost all the analyzed samples (9/11 samples), even in 4 samples that did not declare soy at all. In these samples, the values were between 3.6 and 8.7 ppm of soy proteins with R- Biopharm kit. Regarding the Japanese legislation or the VITAL 2.0 system, it is very difficult to conclude what declaration must be made since they are based on different criteria.

Conclusions: The final approval of article 235 seventh will be surely a tool of great value for the food industry and allergic patients since the label of any food should provide safe and reliable information for allergic patients and their families.

PHYSICOCHEMICAL QUALITY ASSESSMENT OF COMMERCIALISED FISH (LUTJANUS JOCU) IN A BRAZILIAN PUBLIC MARKET

[1]*Suzanne Florentino Silva Chaves Damasceno, Karla;* [2]*Maria Lima Silva, Denise;* [2]*Patrícia Cabral Ribeiro, Penha;* [2]*Ucella Dantas Medeiros, Igor;* [2]*Vanessa Silva Moreira, Camila;* [3]*Silva Souza, Camila Valdejane;* [2]*Albert Baracho Rüegg, Rodrigo;* [3]*Silva Araújo, Samária;* [4]*Germana Leite, Ana;* [5]*Mont'alverne Jucá Seabra, Larissa.*

[1]PhD. Nutritionist. Nutrition Postgraduate Program. Federal University of Rio Grande do Norte.; [2]MSc. Nutritionist. Nutrition Postgraduate Program. Federal University of Rio Grande do Norte. Brazil.; [3]Nutritionist. Nutrition Postgraduate Program. Federal University of Rio Grande do Norte. Brazil.; [4]Nutritionist. Federal University of Rio Grande do Norte. Brazil.; [5]PhD. Nutritionist. Nutrition Postgraduate Program. Federal University of Rio Grande do Norte. Brazil.

Background and objectives: There are several studies that identify health benefits associated with regular consumption of fish and it is important to emphasize that this consumption may be associated with reduced risk of various diseases. However, fishery products are very perishable compared to others of animal origin due fish's own susceptibility for microbial growth and chemical changes. This study aims to assess the physicochemical quality of Lutjanus jocu samples exposed in a Brazilian public market.

Methods: The study included 4 lots of fish species Lutjanus jocu, each batch consisting of 5 fish samples. These samples were obtained gutted, headless and without scales on a fish market in the city of Natal/Rio Grande do Norte/Brazil, and subjected to determination of Total Volatile Bases (TVB) and pH analyses.

Results: Among the samples analyzed, 75% had TVB values above the limit allowed by current legislation (30 mg N/100g). TVB values ranged from 25.69 to 50.12 mg N/100g and all samples from batch 2 and 4 showed TVB values above the maximum allowed value. Regarding the pH values, 55% of the samples weren't according to the Brazilian legislation. The pH values found were between 5.52 and 7.55.

Conclusions: Most fish batches were inadequate in terms of physicochemical quality parameters. Therefore, a risk to the health of the consumer was evidenced, and the forms of manipulation and commercialization should be reviewed in order to control this risk.

UMAMI TASTE PREFERENCE (MONOSODIC GLUTAMATE) IN MEXICAN SCHOLAR CHILDREN

[1]*Tinoco-Mar, Briscia Anaid;* [2]*Valdés Miramontes, Elia Herminia;* [3]*Virgen-Carrillo, Carmen Alejandrina;* [4]*Sánchez-Murguía, Tania Paola.*

[1]PhD Student Innovation and Biotechnology, Center for Research and Assistance in Technology and Design of the State of Jalisco, AC (CIATEJ),; [2]Ph D. Chemist pharmacobiologist. Centro de Investigaciones en Comportamiento Alimentario y Nutrición. CUSur. University of Guadalajara. Mexico.; [3]BSc. Physician. Centro de Investigaciones en Comportamiento Alimentario y Nutrición. CUSur. University of Guadalajara. Mexico.; [4]MSc. Nutritionist. Centro de Investigaciones en Comportamiento Alimentario y Nutrición. CUSur. University of Guadalajara. Mexico.

Background and objectives: Taste is a predictor of food choice. Umami taste is found naturally in food, but monosodium glutamate (MSG) is the main stimulant of umami taste in food. The addition of MSG to food has been popularized being one of the most used and commercialized food additives increases palatability, sensorial qualities and product preference. MSG has specific brain receptors, which block satiety signaling of the consumer, which may contribute to an increase in obesity. In addition, the use of MSG has been associated with adverse side effects such as depression, cardiac arrhythmias and allergies. Research has shown that the taste of MSG is preferred by the entire population, regardless of age, worldwide. The aim of this work was to determine the preference for the umami taste (MSG) in Mexican children.

Methods: 120 children (8-11 years) participated, both sexes. The preference for the umami flavor was determined by two sensory evaluation tests: forced double-choice test (2AFC) and analogue visual scale (VAS) range of (0-10), for two types of cracking

one with 0.1% MSG added and another without adding. Statistical analysis was performed by an ANOVA and Chi2 test to determine the preference for a cracking with MSG added or not added.

Results: It was determined by VAS that the umami flavor cracker is not rated as preferred by children with a recovery range of 0-3.5 points on the scale; the mean was 2.75 ± .50. 88% of children prefer cracking without added MSG, statistically significant difference. There were no differences by gender or age. The results obtained by 2AFC and VAS are similar to each other.

Conclusions: The children who participated in this study prefer a cracking without the addition of MSG and it was determined that the preference for a food with added MSG is low. it should be avoided adding MSG in food because of the adverse effects that its consumption contracts. In Mexico, although some of the industrialized products are highly consumed and contain MSG, children have not generated a taste for the use of this ingredient, so habituation to MSG has not achieved a good percentage of acceptance.

POTASSIUM CONTENT IN TEA INFUSIONS

[1]Raimondo, Emilia; [2]Gálvez, Laura; [3]Mezzatesta, Pablo; [2]Flores, Daniel Gustavo; [2]LLaver, Maria Cecilia.

[1]Universidad Juan Agustín Maza. Universidad Nacional de Cuyo; [2]Universidad Juan Agustin Maza; [3]Universidad Juan Agustín Maza.

Background and objectives: The concentration of intracellular potassium is 150 mEq/L and the extracellular concentration of 4-5 mEq/L. There is severe health complications when this balance is broken. In renal patients with glomerular filtration <10% or when potassium intake is multiplied by 20, the potassium balance is altered and it is necessary to control the contribution of the mineral. The aim of the study was to determine the potassium content per cup, for different contact times, types and forms of presentation.

Methods: It was worked with 20 types of tea of different brands, in their different presentations: black, green, strands and bags. The infusions were prepared with 2 g of each type of tea and two volumes of hot water: 100 ml and 150 ml, with different contact times: 1, 3, 5 and 7 minutes. It was obtained 280 infusions and it was determined potassium by flame photometry. It was a quantitative and experimental study, in which the variable potassium concentration (dependent) was related to contact time, water volume, type of tea and form of presentation (independent), applying descriptive statistics to the results.

Results: It was demostrated that a cup of 150 ml of tea provided the following amounts of potassium: black (strands) from 63±3 mg to 87±4 mg; black (bags): 75±2 mg to 109±4 mg; green (strands): 80±2 mg to 118±4 mg; green (bags): 68± mg to 93±3 mg; the ranges correspond to different contact times.

Conclusions: The results obtained from the potassium content in tea are useful to consider in acute kidney injury, both in the oliguric phase, where it should not exceed 30-50 mEq/day of the mineral, as in the polyuric phase, where is essential to restore the losses of water and electrolytes. It should be noted that in hemodialysis or dialysis with acidosis and without diuresis, potassium should be restricted to 1 mEq/kg/day to avoid complications. The data obtained provide information that must be taken into account for the calculation of potassium intake.

EVALUATION OF THE MECHANISMS OF MAYONNAISE PHOSPHOLIPID PEROXIDATION

[1]Nakagawa, Kiyotaka; [2]Kato, Shunji; [2]Otoki, Yurika; [2]Ito, Junya; [3]Miyazawa, Teruo.

[1]PhD. Agriculture. Graduate School of Agricultural Science. Tohoku University. Japan.; [2]PhD. Agriculture. Graduate School of Agricultural Science. Tohoku University. Japan; [3]PhD. Agriculture. New Industry Creation Hatchery Center (NICHe). Tohoku University. Japan.

Background and objectives: Mayonnaise, which is widely used in foods, is rich in lipids and therefore susceptible to oxidation during the manufacturing process, which can result in loss of quality. Hence, an improved understanding of the cause of mayonnaise lipid peroxidation could lead to a means of ensuring maintenance of the quality of the product.

Several classes of lipid hydroperoxides may be present in mayonnaise, such as triacylglycerol hydroperoxide, cholesterol hydroperoxide and phospholipid hydroperoxide. Of these lipid hydroperoxides, we have recently developed a sensitive and selective liquid chromatography-tandem mass spectrometry (LC-MS/MS) method for detecting phosphatidylcholine hydroperoxide (PCOOH), a primary oxidation product of phosphatidylcholine (PC). Determination of the hydroperoxide group position in PCOOH isomers may be helpful for elucidating the cause of mayonnaise lipid peroxidation, as demonstrated in our previous study (Anal. Biochem., 471, 51-60, 2015) in which we analyzed PCOOH isomers in human plasma and found that radical (and/or enzymatic) oxidation, rather than singlet oxygen-oxidation, is likely the cause of plasma PC peroxidation.

Methods: Based on above findings, we analyzed PCOOH isomers in 3 commercial mayonnaise using LC-MS/MS in the present study.

Results: PCOOH analysis was carried out with 3 commercial mayonnaise products immediately after unsealing. From the analysis, it was estimated that about 0.01-0.03% of PC had already been oxidized to hydroperoxide prior to opening. To the best of our knowledge, this is the first report demonstrating that oxidized phospholipid was detected in mayonnaise, despite of the freshness. The PCOOH isomer composition suggests that mayonnaise phos-

pholipid peroxidation is predominantly initiated by radical-oxidation (i.e. upon autoxidation), rather than singlet oxygen-oxidation (e.g. upon light exposure), during manufacturing, packaging and/or storage. Hence, antioxidants such as tocopherol (radical trapping reagent), rather than carotenoids (singlet oxygen trapping reagent), can be more useful to prevent mayonnaise phospholipid oxidation.

Conclusions: The present LC-MS/MS method will be useful for elucidating the cause of lipid peroxidation in mayonnaise and related foods. Such information will be valuable to ensure maintenance of product quality.

CHANGES IN ARSENIC CONTENT IN THE DIFFERENT ORGANS OF SEAWEED; AKAMOKU, SARGASSUM HORNERI, AFTER PARBOILING

[1]*Murakami, Kaori;* [2]*Sugawa-Katayama, Yohko;* [2]*Katayama, Masayuki.*

[1]Associate Professor. Department of Food Sciences and Biotechnology. Faculty of Life Sciences. Hiroshima Institute of Technology. Japan.; [2]Professor. Department of Health and Nutrition, Osaka Aoyama University.

Background and objectives: Akamoku, Sargassum horneri Turner C. Agardh, is an annual seaweed that grows along ocean coasts, and is considered a good foodstuff consisting as it contains high amounts of dietary fiber and minerals (Murakami et al., 2016, Natural Resources). This seaweed is native to Asia with a wide distribution range from the Japanese coast to the East and the South China Seas. However, this seaweed was observed in California, USA and Baja California, Mexico in recent years. Similar to the other members of Phaeophyta, Akamoku contains a rather high level of arsenic (Katayama et al., 2008, Trace Nutrient Research). Akamoku has been used as food only in a few areas of Niigata and Akita Prefectures, Japan, but recently, Toyama, Iwate, and Fukuoka Prefectures have begun using it as a food material. We measured the arsenic accumulation in Akamoku in order to gain a better perspective on the species' safety and usability as a seafood product. Further, we attempted to understand the arsenic accumulation behavior in different part of the seaweed for its better utilization as a foodstuff.

Methods: Akamoku plants were harvested in March 2017 at Suo-oshima, Inland Sea, Seto, Japan. Mature male and female plants were harvested separately, washed thoroughly, and separated into inedible and edible portions; receptacles, branch (with leaves and air-vesicle), and stalks. Half of edible portion was parboiled with 2.2%NaCl for 1 min. The boiled sample was then refrigerated with ultrapure water for 1 min. The total arsenic and inorganic arsenic contents were determined by atomic absorption spectrophotometry and high performance liquid chromatography with inductively coupled plasma mass spectrometry.

Results: Our results showed that parboiling decreased the arsenic contents in the edible portion of Akamoku by about 85% by processing for food (Murakami et al., 2013, ISUN 20th International Congress of Nutrition. PO3182). Further, we report changes in arsenic contents in the diferent organs of Akamoku after parboiling.

Conclusions: The biochemical mechanism of the arsenic accumulation in high level in the intact plants are yet obscure, a proper treatment to the plants will lead to a good foodstuff to supply dietary fiber and minerals.

Keywords: Sargassum horneri, Akamoku, arsenic, seaweed, brown alga

EDIBLE PROTEIN ENERGY RETURN OF INVESTMENT (EP-EROI) AS A TOOL TO ECO-NUTRIENT COMPARISON OF CANNED SEAFOOD PRODUCTS

[1]*Aldaco García, Rubén;* [2]*Laso, Jara;* [3]*Margallo, María;* [4]*Vazquez-Rowe, Ian.*

[1]Associate Professor. Department of Chemical and Biomolecular Engineering. Cantabria University. Spain.; [2]PhD student. Department of Chemical and Biomolecular Engineering. Cantabria University. Spain.; [3]Assistant Professor. Department of Chemical and Biomolecular Engineering. Cantabria University. Spain.; [4]Associate Professor.Pontificia Universidad Católica del Perú. Departamento de Ingeniería. Red Peruana Ciclo de Vida. Peru.

Background and objectives: Each year approximately 1.3 billion tons of edible food are wasted throughout global food supply chain generating emissions of 3.3 Gt CO2 eq. This value will be increased due to the global population is expected to increase from the current 7 billion to nearly 10 billion by 2050. These facts make that current patters of food production and consumption are increasingly considered to be unsustainable, i.e. the amount of energy used to produce, process, package, store, and transport food is seven and half times the amount of energy the food actually provides in return. In addition to cause environmental impact, wasting food involves the loss of nutrients along the food supply. The cooking way and eating habits can vary the nutrient content of food, because up to 42% of food waste is produced by households. In this context, the European Commission is conducting several improvement measures to reduce food loss and waste by 50% by 2020. The Bioeconomy Strategy aims to pave the way to a more innovative, resource efficient and competitive society that reconciles food security with the sustainable use of renewable resources while ensuring environmental protection. On the other hand, Food 2030 initiative have four priorities: (i) nutrition for sustainable and healthy diets, (ii) climate smart and environmentally sustainable food systems, (iii) circularity and resource effi-

ciency of food systems, and (iv) innovation and empowerment of communities.

Methods: In this framework, this work develops a methodological approach, which assess and compares both the environmental impact of a food product and its energy content returned to consumer. The environmental impact is evaluated with the standardized methodology, life cycle assessment (LCA). On the other hand, the nutrient properties of the product are analyzed by means of the protein content along the life cycle chain.

Results: Both metrics can be expressed in terms of energy consumption (Cumulative Energy Demand) and energy content (protein content) by means of the Edible Protein Energy Return of Investment (Ep-EROI).

Conclusions: This methodology can be applied to all food chain products; however, this paper is focused on canned anchovy products.

Keywords: European anchovy; protein content; environmental impact; food supply chain.

ACCUMULATION PROCESSES OF NUTRITIONALLY BENEFICIAL MINERALS IN A BROWN ALGAE, HIJIKI (SARGASSUM FUSIFORME), DURING GROWTHFUSIFORME), DURING GROWTH

[1]Katayama, Masayuki; [2]Sugawa-Katayama, Yohko; [3]Murakami, Kaori.

[1]PhD. Professor. Department of Health and Nutrition. Osaka Aoyama University. Japan.; [2]PhD. Professor. Department of Health and Nutrition. Osaka Aoyama University. Japan; [3]PhD. Associate Professor. Department of Food Sciences and Biotechnology. Hiroshima Institute of Technology. Japan.

Background and objectives: The brown algae Hijiki, Sargassum fusiforme, is an important foodstuff for Japanese, and serves as a rich supply of minerals and dietary fiber. Warming of the earth elevates the ocean-water temperature year by year, and exerts ecological influences. Hijiki also seems to change their regular growing processes, becoming chlorotic earlier than before. To know the physiological changes during their growth, we studied the accumulating processes of several nutritionally beneficial minerals in Hijki plants during their growth from the primary leaf stage to their chlorotic state. Although the accumulation of arsenic (As) occurred in plants during their growth, arsenic (As) could be mostly removed during the pre-cooking process of the commercial dried Hijiki products.

Methods: Hijiki plants were harvested at the seashore of Kushimoto, Wakayama Prefecture, Japan. The fresh samples of Hijiki plants were lyophilized and decomposed with conc perchloric acid - conc nitric acid, or with conc sulfuric acid - conc nitric acid. The ashed samples were dissolved in 1N hydrochloric acid, and the concentrations of arsenic (As), calcium (Ca), iron (Fe), magnesium (Mg), manganese (Mn), potassium (K), and zinc (Zn) in

the plant tissues were determined by atomic absorption spectrophotometry .

Results: The concentration of calcium (Ca) per tissue weight increased gradually coming to a rather constant value before the appearance of genital organs on the plants, although the concentration of arsenic (As) continued to increase. Until that time, the concentrations of zinc (Zn) and manganese (Mn) continued to increase further. The concentration of iron (Fe) and magnesium (Mg) increased gradually, expressing a strong correlation between them, but the concentration of magnesium (Mg) was not uniform in the chlorotic plants.

Conclusions: From the viewpoint of nutritional value, matured plants of Hijiki had better be harvested, but to keep good quality of the products, fine days under the sunshine should be selected, even before complete maturation.

Keywords: Hijiki, Sargassum fusiforme, mineral accumulation, growing process.

FOOD LOSSES AND FOOD SECURITY AND NUTRITION: ESTIMATING THE POTENTIAL OF A RESPONSIBLE FOOD PRODUCTION AND CONSUMPTION

[1]Aldaco García, Rubén; [2]Garcia-Herrero, Isabel; [3]Fullana, Pere; [4]Bala, Alba; [5]Laso, Jara; [6]Vazquez-Rowe, Ian; [7]Durá, María José; [8]Abajo, Rebeca; [8]Sarabia, Carmen; [9]Gazulla, Cristina.

[1]Associate Professor. Department of Chemical and Biomolecular Engineering. Cantabria University. Spain.; [2]Researcher. Department of Chemical and Biomolecular Engineering. Cantabria University. Spain; [3]Professor. UNESCO Chair in Life Cycle and Climate Change. Escola Superior de Comerç International (ESCI), Universitat Pompeu Fabra (UPF). Spain; [4]Researcher. UNESCO Chair in Life Cycle and Climate Change. Escola Superior de Comerç International (ESCI), Universitat Pompeu Fabra (UPF). Spain; [5]PhD student. Department of Chemical and Biomolecular Engineering. Cantabria University. Spain; [6]Researcher. Pontificia Universidad Católica del Perú. Departamento de Ingeniería. Red Peruana Ciclo de Vida. Perú; [7]Associate Professor. Nursing Department. Cantabria University. Spain; [8]Assistant Professor. Nursing Department. Cantabria University. Spain; [9]Researcher. Lavola Cosostenibility. Barcelona. Spain.

Background and objectives: Food and nutrition security is a complex concern, related to health through malnutrition, but also to sustainable economic development, environment, and trade. Europe and Central Asia as a region has achieved the Millennium Development Goal hunger target of reducing by half the proportion of people affected by hunger. At the same time, large amounts of food are being wasted, food that still may contain important nutrients and micronutrients. An estimation of macronutrient and micronutrient loss resulting from food waste may be helpful for people trying to prevent food waste by engaging the public and

companies and increasing awareness on this subject. Estimation of the impact of food waste on health and nutritional issues can be performed by calculation of nutrient losses resulting from food waste.

Methods: A comparison of loss of nutrients by losing and wasting food, with the recommended daily intake (RDI) of that specific nutrient or micronutrient has been calculated in this work. Two parameters are needed to perform such a calculation: i. amounts of wasted products, and ii. nutritional data describing the macronutrient and micronutrient composition.

Results: Taking as a case study the food losses in Spain, preliminary results shows that the estimated amount of vitamin C that is lost in Spain in a year as a result of food waste may contain the equivalent of 1.9 billion "recommended daily intake portions" which is equivalent to the amount of vitamin C that is needed by 5.3 million people a day.

Conclusions: Reducing food waste has enormous potential for reducing the resources we use to produce the food we eat. Being more efficient will save money and lower the environmental impact of food production and consumption, contributing to a global nutrition security.

Keywords: Food loses; food security; environmental friendly nutrition

NON-DESTRUCTIVE RIPENING INDEXES OF PRICKLY PEAR (OPUNTIA FICUS-INDICA) FOR AN OPTIMAL FREEZE-DRYING

[1]Ramírez Anaya, Jessica del Pilar; [2]Castañeda-Saucedo, María Claudia; [3]Martín del Campo Barba, Sandra Teresita; [4]Gómez Hernández, Hector Eduardo; [5]Mendez Morán, Lucila.

[1]PhD. Food Tecnhologyst. Universidad de Guadalaja, Centro Universitario del Sur, Departamento de Desarrollo Regional; [2]PhD. Agricultural studyes. Depto. Sociedad y Economía. Universidad de Guadalajara. Centro Universitario del Sur. Ciudad Guzmán. México.; [3]PhD. Food Technolysts. Departamento de Industrias Alimentarias. Instituto Tecnológico y de Estudios Superiores de Monterrey. Querétaro. México.; [4]PhD. Food Technologyst. Depto. de Ingeniería. Química. Universidad de Guadalajara. Centro Universitario de Ciencias Exactas e Ingenierías.; [5]PhD. Genetics. Departamento de Ecología. Universidad de Guadalajara. Centro Universitario de Ciencias Biológicas.

Background and objectives: Prickly pears (Opuntia ficus-indica va. Burrona) are climacteric fruits and usually are marketed in fresh. Freeze-dry can be used to obtain innovative foods with higher added value that can help to improve the Mexican economy

of semiarid zones. It is known that some variations in raw material characteristics determined the quality in the final product. Our aim was to non-destructively select raw material with the optimal ripening conditions to freeze-dry prickly pear slices in order to obtain the best-rehydrated products. By accumulated growths curves, the ripening index was determined during pre-harvest of 300 fruits that were obtained from the central Mexican zones.

Methods: Each week, the change of color, texture, acidity, pH, chlorophyll content, reducing and total sugars content were evaluated. The fruits were selected by their peel color using a* parameter, for freeze-drying experiments under laboratory conditions. ANOVA (a=0.05) was used to determine the effect of two slice thickness (1 and 1.5 cm) and two plate temperatures (15 and 30oC), in relation with; pulp drying time, rehydration coefficients of freeze-dried products, color and texture of rehydrated products.

Results: The fruit ripening process began on day 90 after full bloom, where the soluble solids/tritiable acidity ratio (r=0.75) as well as fruit texture (r=0.78) correlated in a positive way with a*, making it possible to differentiate fruits in the different ripening stages. The fruits with a* value of -7.6± 0.43 (111 days after flowering) were selected as an optimal raw material for freeze-drying. Drying time was significantly reduced in a 1 cm slice thickness and 30oC of plate temperature. These results compared with fresh slices, showed that dried slices had higher L* and a* intensity. However, the rehydration coefficient was low with a loss on texture, as well as reduction on L* and a* after rehydration.

Conclusions: Fruit peel color makes it possible to non-destructively differentiate fruits during ripening. Freeze-dried slices of prickly pears are a healthy snack and are a marketing option, due to do not show signs of retraction and their flavor is preserved.

Keywords: Freeze-dry, prickly pear, ripening index, rehydration, color

DETERMINATION OF MAGNESIUM IN SPINACH UNDER DIFFERENT COOKING METHODS

[1]Raimondo, Emilia; [2]Farah, Silvia; [3]Dip, Gladys; [3]Gascón, Alejandro.

[1]Universidad Juan Agustín Maza- Universidad Nacional de Cuyo; [2]Universidad Juan Agustín Maza; [3]Universidad Nacional de Cuyo.

Background and objectives: Magnesium is necessary for about 300 biochemical reactions of the body, with a requirement of 260 mg/d for a healthy adult. Therefore the aim of the study was to determine how the content of magnesium in spinach varies under different cooking processes.

Methods: To carry out this experience it was used 10 kg of spinach, acquired and processed on the same day. For the sampling, each plant was divided into 5 equal parts, obtaining 5 lots submitted to different cooking techniques: Lot 1: raw spinach, which was reserved for analysis; Lot 2: spinach cooked by boiling; Lot 3: sauteed spinach; Lot 4: steamed spinach; Lot 5: spinach

cooked using microwave. It was determined the centesimal composition of raw and cooked product applying official laboratory techniques. The magnesium content was determined by atomic absorption spectrometry on ash dilution. In order to establish if there is statistically significant differences. It was applied analysis of variance (ANOVA) for a level of significance alpha ≤ 0.05.

Results: The loss of humidity was statistically significant for sauteed spinach (73 g%) and cooked with microwave (60 g%). The fat content is increased from 0.3 g to 12.58 g in sauteed spinach, which represented a 5.4 times more caloric intake. The magnesium content was 64 ± 3 mg% in raw spinach; by boiling 52 ± 2 mg%; sauteed 86 ± 3 mg%; steamed 63 ± 3 mg% and microwave 99 ± 4 mg%.

Conclusions: Spinach processed with microwaves presented the greatest loss of weight and volume (-70%), but concentrated in a 50% the magnesium content, in relation with the loss of humidity. The one cooked by boiling had the greatest loss of magnesium (leaching of minerals). Steamed spinach maintained the content of magnesium. The sauteed one had a loss of weight and volume of 18%, and also it concentrated 35% magnesium respect to raw spinach, but increased its caloric value.

Keywords: Magnesium, cooking techniques, nutritional composition, caloric intake.

ENRICHMENT EFFECT TO FINAL COMPOSITION OF COMPLEMENTARY FEEDING PREPARATIONS

[1]Kabbache, Diana Miriam; [1]Batista, Mariana; [2]Ketelhohn, Belen; [3]Olagnero, Gabriela.

[1]Nutritionist (BSc). Técnica Dietoterápica. Universidad de Buenos Aires. Universidad del Salvador. Buenos Aires. Argentina.; [2]Nutritionist (BSc). Scientific Coordination. Research and Development. Danone Nutricia. Buenos Aires. Argentina.; [3]Nutritionist (BSc). Scientific Coordination. Research and Development. Danone Nutricia. Buenos Aires. Argentina.Buenos Aires.

Background and objectives: Nutrition during childhood is key for diseases prevention in adult life. Complementary feeding carries the risk of micronutrients inadequate intake.

Homemade meals elaboration implies vitamins losses in different cooking procedures. Using enriched weaning food would cover nutrient recommendations. The study aims to evaluate Retinol and Ascorbic Acid's concentrations variation secondary to cooking procedures, on meals intended for children, using micronutrients enriched infant cereal as an ingredient.

Methods: Exploratory experimental study analysed Ascorbic Acid and Retinol in two recipes with different cooking procedures. These vitamins were selected as indicators of lability between hydrosoluble and liposoluble vitamins. The recipes were elaborated as homemade meals under replicable conditions.

Retinol was analysed through HPLC and Ascorbic Acid by capillary electrophoresis.

Results: Retinol and Ascorbic Acid were detected in cooked and enriched samples, and consequently pre and post-cooking samples were analysed.

Retinol increased its concentration in post-cooking samples due to water loss secondary to evaporation (11% between non-enriched, 14% among enriched). Between cooked samples, enriched sample presented an 18% increase versus non-enriched one, whereas among raw samples it was 15%.

Ascorbic acid content increased due to enriched cereal addition. Cooking generated a partial loss (less than 15%). In all samples, variations were related to initial concentrations and cooking methods that included different heat transfer and O2 partial pressure.

Vitamin loss is partial and predictable, obeying to a natural chemical behaviour rather than the procedure itself: solutes with higher concentrations are the most affected by changes in environment conditions.

Conclusions: Complementary feeding is one of the critical moments for micronutrients intake. Partial and predictable vitamin losses in homemade preparations turn micronutrients enriched cereal into a useful tool to fortify children's meals, ensuring an adequate micronutrients supply.

Keywords: Retinol, Ascorbic Acid, complementary feeding, homemade meals

Conflict of Interest Disclosure: The study was funded by Danone Nutricia ELN.

HARNESSING AGRICULTURE FOR NUTRITION OUTCOMES: EXPERIENCE FROM TANZANIA

[1]Roschnik, Natalie; [2]Kivuyo, Nengilang'et G.; [3]Muruve, Joanita Aigi; [4]Ngombalu, Assumpta Ndumi Ngombalu Ngombalu; [5]Copestake, James; [6]Remnant, Fiona.

[1]MSc. Senior Research and Impact Advisor. Save the Children. UK; [2]MSc. Regional Programme Manager. Save the Children. Tanzania; [3]MPH. Deputy Director Program Quality and Development. Save the Children. Tanzania; [4]MPH. Nutrition Adviser. Save the Children. Kenya; [5]PhD. Professor of International Development. Centre for Development Studies. University of Bath. UK; [6]MSc. Director. Bath Social and Development Research Ltd. UK.

Background and objectives: The causal pathway between food production, consumption, knowledge and improved nutrition outcomes is neither direct nor simple and depends on a complex interaction of a range of factors. The Harnessing Agriculture for Nutrition Outcomes (HANO) project was designed to explore the linkages between household agricultural production with dietary patterns and nutrition. The project was implemented from

December 2012-present in Lindi and Ruangwa districts in Lindi region Tanzania, with an aim to prevent chronic malnutrition among children under two years by combining nutrition interventions with a range of agricultural activities.

Methods: To assess the project's impact, an end line evaluation will be undertaken at the end of the project in May 2017 using the Qualitative Impact Protocol (QuIP). Data will be collected from a sample of the intervention villages using semi-structured interviews with 30 households and 4 focus groups – using blindfolded, independent researchers. The questionnaire makes no reference to the project, but is designed to capture information on wellbeing domains expected to have been impacted according to the project's theory of change. The narrative data collected is then analysed against the project's theory of change to identify unexpected as well as anticipated drivers of change, and the interaction of the intervention with these drivers.

Results: QuIP sets out to generate differentiated evidence of impact based on narrative causal statements elicited directly from project beneficiaries. Evidence of attribution is sought through respondents' own accounts of causal mechanisms rather than by relying on statistical inference based on variable exposure. Data is presented according to whether it a) explicitly attributes impact to project activities, (b) makes statements that are implicitly consistent with the project's theory of change, (c) refers to drivers of change that are incidental to project activities. This data can then be triangulated with routine monitoring data in 'unblindfolding' workshops, assessing what the findings mean for future project design.

Conclusions: We hope that conducting a 'deep-dive' using the QuIP methodology will help to provide much richer information on the causal impacts of different activities and drivers of change in Lindi and Ruangwa districts. The results of the evaluation will be presented.

Keywords: agriculture, nutrition, QuIP, evaluation

THE SENSORY ACCEPTABILITY OF TWO BIO-FORTIFIED IRON/ZINC BEAN VARIETIES BY PRE-TEENS FROM RURAL- AND SEMI-RURAL AREAS IN THE ANDEAN REGION OF COLOMBIA

[1]Beintema, Joni Jade Serena; [2]Gallego- Castillo, Sonia; [3]Restrepo-Manjarres, José; [4]Talsma, Elise Francina.

[1]MSc. Nutritionist. Harvestplus, International Centre for Tropical Agriculture (CIAT). Colombia; [2]BSc. Chemical engineer. Harvestplus. International Centre for Tropical Agriculture (CIAT). Colombia; [3]MSc. Agronomist. Foundation for Agricultural Research and Development (FIDAR). Colombia; [4]PhD. Nutritionist. Harvestplus. International Centre for Tropical Agriculture (CIAT). Colombia.

Background and objectives: Iron and zinc deficiency are mayor public health problems, mostly affecting vulnerable popu-lations such as young children and women of reproductive age in low- and middle- income countries. Biofortified beans with substantial concentrations of iron and zinc were introduced in Colombia in 2016. These beans have the potential to reach vulnerable populations and to improve their nutritional statuses, considering beans are staple crops and frequently consumed in Colombia. Successful implementation however, depends on the acceptability of these newly bred varieties. Therefore we studied the sensory acceptability of two biofortified bean varieties high in iron and zinc and a commonly eaten local bean variety.

Methods: Two biofortified bush-beans varieties known as BIO-101 and BIO-107 were included, with iron and zinc concentrations between 8.2 -8.3 mg/100g and 4.3-4.4 mg/100g, respectively. Schoolchildren (n=174), aged between 10-15 years old, from (semi-) rural areas in the departments of Cauca and Valle del Cauca were asked to evaluate these varieties and a local bean variety. The three bean varieties were presented as blind-labeled samples of 20 grams and assessed on color, size, smell, taste and texture using a five-point facial likert scale.

Results: The overall mean scores were 3.88 ± 0.64, 3.79 ± 0.74 and 3.81 ± 0.76, for BIO-101, BIO-107 and the control sample respectively and these scores did not significantly differ from each other ($p>0.05$). The children in Cauca (n=61) slightly preferred BIO-107 over the control sample ($p <0.05$), but not over BIO-101, based on color, smell and taste. The children in Valle del Cauca (n=113) slightly favored the control sample over BIO-107 ($p<0.05$), but not over BIO-101, regarding size, smell and taste.

Conclusions: Overall, all varieties are well and equally accepted, which seem to have promising implications for the implementation and impact of biofortified iron/zinc beans.

LABELING AND REPORTING OF SALT/SODIUM IN PACKAGED FOODS

[1]Singh, Meenu; [2]Chandorkar, Suneeta.

[1]Post Doctoral Fellow. Division of Nutrition. St. John's Research Institute. St. John's National Academy of Health Sciences. Bangalore 560034. Karnataka. India.; [2]Assistant Professor. Department of Foods and Nutrition. Faculty of Family and Community Sciences. The Maharaja Sayajirao University of Baroda. Vadodara 390002. Gujarat. India.

Background and objectives: Packaged foods report salt in the ingredients list and sodium content in nutrition facts panel. Information on salt and/or sodium content can be used to select low sodium foods to reduce the risk of hypertension and resultant coronary heart diseases. Therefore, the aim of the present investigation was to evaluate the accuracy and reliability in reporting of salt/sodium content on labels of packaged foods.

Methods: A total of 1,020 packaged foods (29=food categories, 10=food groups) were surveyed from supermarkets (n=4)

and grocery-stores (n=4) in Vadodara, Gujarat, India and the labels were studied for compliance with the legislations laid down by Food Safety and Standards Authority of India (FSSAI). One hundred and fifty four packaged foods were analyzed for sodium content by AOAC 969.23 method using Flame Photometer (Model: Elico CL 361).

Results: Results revealed that 11% of the products had multiple and alternative sources of salt/sodium (common salt, rock salt, sodium-carbonate/caseinate/molybdate, monosodium glutamate) in ingredients list, making them high in sodium content. Ready-to-cook/eat products had the highest percentage (4.4%) of products listing multiple sources of salt followed by snacks (2.9%), wheat and oats based products (1%), bakery products (0.9%), confectionery (0.5%), food adjuncts (0.3%), milk based products (0.1%). When MSG (a source of sodium) and salt were considered together, ready to cook/eat products were found to have highest percentage (4.5%) of Salt+MSG. Four percent of the products had multiple sources of MSG (namely, hydrolyzed-vegetable protein/corn solids, yeast extract, etc). Multiple MSG sources were highest in ready-to-cook/eat products (2.1%) followed by wheat and oats based products (1%), snacks (0.6%) and food adjuncts (0.2%). Ingredient claims like "no added salt" and "No MSG" were not substantiated by any of the product's ingredients list. Products with higher analyzed values for sodium than those reported on the label were found to have multiple/alternate sources of sodium in the ingredients list.

Conclusions: There is lack of accuracy and reliability in reporting of salt/sodium and MSG information on packaged food labels. There is a need to improve compliance with legislation for labeling of packaged foods laid down by FSSAI for improved Public Health and Nutrition outcomes.

Keywords: Salt, Sodium, Mono-sodium glutamate (MSG), Food Labeling, Packaged Foods.

TRANS FATTY ACIDS: AFTER 14 YEARS OF BRAZILIAN LEGISLATION ARE THE LABELING ADEQUATED?

[1]*Mafioletti, Marina;* [2]*Yoshime, Luciana;* [3]*Sattler, José Augusto;* [4]*Corsi, Giovanna;* [2]*Melo, Illana Louise;* [5]*Mancini-Filho, Jorge.*

[1]SI. Graduate student of Nutrition. Faculty of Pharmaceutical Sciences. University of Sao Paulo. Brazil; [2]PhD. Nutritionist. Faculty of Pharmaceutical Sciences. University of Sao Paulo. Brazil.; [3]PhD Candidate. Nutritionist. Faculty of Pharmaceutical Sciences. University of Sao Paulo. Brazil.; [4]SI. Graduate Student of Nutrition. Faculty of Pharmaceutical Sciences. University of Sao Paulo. Brazil.; [5]PhD. Senior Professor. Faculty of Pharmaceutical Sciences. University of Sao Paulo. Brazil.

Background and objectives: The excessive intake of trans fatty acids (TFA) has been related to the development of cardiovascular diseases. Recent researches show the Brazilian popula-

tion diet exceeds the recommendation for TFA, by high consume of processed food. According to Resolution RDC 360/2003 of the National Health Surveillance Agency/Ministry of Health, it is required the grade of TFA on labeling of packaged foods, this is a strategy for chronic diseases prevention. The World Health Organization warned of the need of less TFA consume, which culminated in the recommendation for its elimination in 2004. The result of this control will be the improvement of the health of the population. Considering the legal requirements and the consumer's right to obtain reliable information, the objective is to address aspects about TFA, emphasizing food labeling and Brazilian legislation.

Methods: SciELO and Lilacs databases were used, with the terms "trans fatty acids" and "hydrogenated fatty" alone or in conjugated with "labeling", "regulation" or "legislation". The search was from 2003 to 2017, were included original articles and excluded researchers outside Brazil or reviews, were selected 10 originals articles.

Results: Several categories of industrialized products were evaluated for the TFA content and their labeling. Among them are snacks, fast foods, pasta, cereals, dairy products, infant formulations, vegetable oils, among others. All the articles analyzed have concluded that industrialized product labels require greater scrutiny and the need to revise national legislation on the amount of TFA to be declared. The TFA content is higher in 56% of the analyzed articles compared to the declared on the label and exceeds the limit allowed by the legislation.

Conclusions: After 14 years of implementation of the legislation in Brazil, the indication of TFA on labels and their use by the industry are still inadequate. Need for revision of the legislation in the indication of the content of TFA in the label and change of the nutritional information for a percentage of the food instead of the portion in grams. Increased vigor in the regulation and monitoring of nutrition labeling will be beneficial to consumer health, thus reducing the risk of developing chronic diseases and public health expenditures.

DEVELOPMENT OF NUTRITIONAL AND HEALTHY BAKERY PRODUCTS BY INCORPORATION OF QUINOA

[1]*Haros, Claudia Monika;* [2]*Fernández-Espinar, María Teresa;* [3]*Gil, José Vicente.*

[1]PhD. Chemist. Cereal Group. Institute of Agrochemistry and Food Technology (IATA CSIC). Valencia. Spain.; [2]PhD. Biologist. Biological Activity of Food Compounds. Institute of Agrochemistry and Food Technology (IATA CSIC). Valencia. Spain.; [3]3PhD. Biologist. Departamento de Medicina Preventiva y Salud Pública, Ciencia de Alimentos - Toxicología y Medicina Forense. University of Valencia. Spain.

Background and objectives: Today, nutrition is located as part of the prevention or reduction of certain diseases. The ob-

taining and characterizing new ingredients with high technological potential, high nutritional value and bioactive compounds, opens up a promising field of competitiveness to the food industry with which to be able to establish itself in the food market. Consumption of whole grain or wholemeal can play an important physiological role in maintaining general well-being and health, not only because of its fibre content but also because it contains numerous bioactive components. Quinoa grains (Chenopodium quinoa) are characterized by a high concentration of proteins with excellent amino acid profile in addition to a high content of minerals, vitamins, unsaturated fatty acids and antioxidants. The objective of this research has been to develop new bakery products by replacing flour with whole quinoa flour from Bolivia (white, red and black varieties), to evaluate its functionality as a bakery ingredient.

Methods: The nutritional, technological and sensorial quality of the developed products was determined in terms of moisture, starch, proteins, dietary fibre, ash, polyphenols, colour parameters and sensorial analysis.

Results: The incorporation of quinoa increased significantly the content of dietary fibre (soluble and insoluble), proteins, lipids and minerals. The colour of the crust and crumb was significantly modified with quinoa variety in comparison to control sample. Polyphenolic profile by HPLC showed the presence of more polyphenol classes in quinoa flours than in wheat flour. Their inclusion produced breads with increased polyphenol content and DPPH radical scavenging activity always in levels significantly higher compared to the control. The sensory analysis indicated that the substitution of 25% of flour for quinoa did not significantly affect the overall acceptability of bread, with slightly better scored products with quinoa than control sample.

Conclusions: Whole quinoa flour could be a good replacement for wheat flour in bread formulations, increasing the product's nutritional value and bioactive compounds with only a small depreciation in bread quality at 25g/100 g of flour substitution. The inclusion of quinoa flours had a positive effect on the technological and sensory value of the bread products, and therefore its inclusion is recommended.

Keywords: quinoa, bakery products, dietary fibre, polyphenols, minerals

REDUCTION OF SODIUM CONTENT, INCREASE OF DIETARY FIBER AND YEAST, AND NUTRITIONAL INFORMATION: DO THEY AFFECT THE ACCEPTABILITY OF OPTIMIZED BREAD REGARDING CONSUMERS IN BUENOS AIRES, ARGENTINA?

[1]Watson, Dana Zoe; [1]Hernández, María; [2]Lema, Silvia; [2]Vázquez, Marisa Beatriz.

[1]BSc. Nutritionist. Escuela de Nutrición. Universidad de Buenos Aires. Argentina.; [2]PhD. Nutritionist. Escuela de Nutrición. Universidad de Buenos Aires. Argentina.

Background and objectives: A reduction in salt (NaCl) intake and an increase in fiber promote the prevention of cardiovascular diseases. In Argentina, the daily salt intake is higher and dietary fiber is lower than the recommendations. Bread is one of the main sources of sodium in the diet and can carry dietary fiber. Variations in the addition of salt and fiber in the formulation of bread may require changes in amount of yeast. The nutritional information or label may influence its acceptability.

The objectives of this study have been: develop healthful optimized bread and evaluate its sensory acceptability blind and with label.

Methods: The optimized bread was successfully made: 35% less of NaCl added, 50% more of yeast and 75% more of fiber than white bread (in a previous study 15 prototypes had been evaluated using response surface methodology).

112 students and educational and non-educational staff of Facultad de Medicina, Odontología, Farmacia y Bioquímica, and Veterinaria of Universidad Buenos Aires tested it in two stages: blind and with label. Consumers evaluated appearance, smell, texture (crumb's elasticity), taste; and overall acceptance according to a 10-point scale (I=dislike extremely and 10=like extremely). An interval of 7 days was allowed between stages. Participants also answered: willingness to consume and day time in which they would consume it.

Results: The optimized bread was successfully developed. Participants were mainly students (92.8%), 82% female and median age 22 years (RI: 6).

The acceptability average values for attributes and overall acceptance were very good (all above 7). No differences were observed among the age groups. The average scores of willingness to consume were also very good (7 for blind stage, 7.3 with label), no differences between stages. Breakfast (29.7%), lunch (23.3%) and in-between meals (19%) were the most preferable moment to consume it. Cheese was most chosen for being consumed with the bread in-between meals.

Conclusions: It was possible to develop an optimized bakery that obtained good values of acceptability in the evaluation stages. This bread would appear to be an adequate strategy to increase the amount of dietary choices to prevent cardiovascular diseases.

Keywords: acceptability test – sodium reduction – dietary fiber – bread – optimization

CONTRIBUTION OF TRANS FATTY ACIDS BY FOODS MOST PREFERABLY CONSUMED BY A GROUP OF STUDENTS

[1]Mereles Ceuppens, Laura Graciela; [2]Coronel Mendez, Eva Eugenia; [2]Wiszovaty, Lourdes; [2]Caballero, Silvia; [2]Piris, Patricia; [2]Michajluk, Javier Boris; [3]Araujo Pino, Silvia Stella; [3]Gonzalez Cespedes, Laura Elizabeth; [3]Aguilar Rabito, Ana Carolina; [3]Morínigo Martínez, Macarena.

[1]PhD. Biochemistry. Departamento de Bioquímica de Alimentos. Dirección de investigaciones. Facultad de Ciencias Químicas. Universidad Nacional de Asunción. Paraguay; [2]Departamento de Bioquímica de Alimentos. Dirección de investigaciones. Facultad de Ciencias Químicas. Universidad Nacional de Asunción. Paraguay; [3]Departamento de Nutrición. Dirección de investigaciones. Facultad de Ciencias Químicas. Universidad Nacional de Asunción. Paraguay.

Background and objectives: The selection of food for college students is determined by socio-cultural characteristics, economic availability and feasibility of access to them, which in general have high fat contents, and all would indicate that also trans fatty acids (TFA) from the partial hydrogenation of oils. The WHO recommends that consumption not exceed 1% of VT of trans fatty acids (TFA) as a strategy for prevention, reduction and control of cardiovascular diseases. Therefore, the aim of the present work was to identify the foods most preferably consumed by university students of the Biochemistry career of the Faculty of Chemical Sciences of the National University of Asunción and determine in them the content of total AGT.

Methods: In 51 university students, we carried out a cross-sectional study and applied a Food Consumption preference (FCP) survey based on the LATINFOODS categories. For the quantification of total TFAs, food samples were taken from canteens and we used the Infrared Spectrometry (IR) method according to the specifications of the official methods of AOAC (994.14. and 965.34).

Results: The average age of university students was 22.7 ± 2.8 years, 84% were female. Of the 60 foods in the FCP, we observed that the sandwich (with ingredients such as bread, butter, ham and cheese) was the food most frequently consumed in the week, followed by whole-grain crackers, baked goods and fried pies. The total TFA contents of industrial origin were: 2.64±0.24gTFA/100g in whole-grain crackers (brand A), 2.49±0.50gTFA/100g in whole crackers (brand B), 3.80±0.26 gAGT/100 g in the semi-defatted doughs, 3.20±0.14gAGT/100g in the frying pastry disks and 2.81±0.22gAGT/100g in sandwiches.

Conclusions: The AGT content varies by food group and serving size. All foods analyzed contain significant amounts of TFA (≥0,2g/portion) and it was observed that TFAs of industrial origin account for 15 to 39% of the fat in the foods analyzed. The results obtained alert the need to reinforce the strategies to reduce the content consumption of TFA in order to prevent cardiovascular diseases.

Keywords: Trans fatty acids, contents, foods, preferential consumption, students.

EFFECT OF GLYPHOSATE ON ACID LACTIC BACTERIA

[1]Lourenço da Costa, Elizabete; [2]Silva, Caroline; [3]Antunes, Adriane; [4]Addad, João.

[1]Universidade Católica de Santos; [2]BSc. Nutritionist. Catholic University of Santos; [3]PhD. Nutritionist. School of Applied Sciences, University of Campinas; [4]PhD. Geologyst. Technical Department. Tertium Brazil.

Background and objectives: Glyphosate is a broad spectrum systemic herbicide that is among the most widely used pesticides in the world. Due to its antimicrobial effect, its association with intestinal dysbiosis has been proposed, related to the etiology of intestinal inflammation, obesity, among other pathologies. The objective of this work was to evaluate the effect of glyphosate on five species of bacteria.

Methods: The microorganisms used were Bifidobacterium animalis, Lactobacillus acidophilus, L. rhamnosus, L. Casei and L. paracasei. Each single bacteria was reactivated in MRS broth, scattered on the surface of Petri dishes containing MRS agar, then sterile filter paper disks containing 15 μL of the herbicide (0.24%) were arranged on each plate. After incubation (36ºC / 72 hours), the sensitivity was verified by the absence of growth around the disc. To obtain the growth curve, MRS broth tubes with increasing concentrations of the herbicide (0 to 0.03%) were incubated in a the same conditions previously described, with agitation, and the measurement of optical density (OD) in spectrophotometer (600nm) was carried out on each one hour, by 8 hours and after 24 hours.

Results: All the microorganisms tested showed sensitivity to the herbicide, both in the broth culture and in the agar diffusion assay. When bacteria were cultured without inhibition they showed a shift from the latency phase to the exponential phase after 4 hours of incubation, whereas in the presence of the herbicide containing glyphosate (0.03%, 0.0015% and 0.0075%), even after 24 hours of incubation there was no change in OD of broth cultures.

Conclusions: The present work confirms the susceptibility of the five strains of probiotics to the glyphosate herbicide even when the contact with low concentrations were used.

Keywords: acid lactic bacteria, glyphosate, herbicide, dysbiosis.

THE IMPACT OF SOLAR MARKET GARDENS ON CHILD GROWTH, IRON AND VITAMIN A STATUS IN THE KALALÉ DISTRICT OF NORTHER BENIN

[1]Taren, Douglas; [2]Alaofe, Halimatou; [3]Burney, Jennifer; [4]Naylor, Rosemond.

[1]PhD. Professor. Health Promotion Science. University of Arizona. USA; [2]PhD. Professor. Health Promotion Science. University of Arizona. USA.; [3]PhD. Professor. School of Global Policy & Strategy. University of California - San Diego. USA.; [4]PhD. Professor. Earth Energy and Environmental Sciences. Stanford University. USA.

Background and objectives: Developing a sustainable agricultural system to improve the nutritional status of children is a challenge in Sub-Saharan Africa where irrigation is labor intensive and crops are rainfed. The objective of this study was to evaluate how Solar Market Gardens (SMGs), a labor-saving solar power drip irrigation system at the village level, impacts the nutritional status of chidren.

Methods: The study was conducted in 8 intervention villages and 8 control villages using traditional hand-irrigation. Baseline and 1-year follow-up data were obtained for the same child (12-59 months of age) per household from 134 randomly-sampled control village households (C-H), 126 control village women group households (C-WG), 229 randomly sampled intervention village households using traditional irrigation (I-H) and 185 intervention village women's group households with SGMs (I-WG). Anthropometric measures and blood samples were collected to determine the impact of the SMGs on child growth, iron and vitamin A status by determining the impact estimate (IE) using difference-in-difference analysis.

Results: At baseline, children were 22.2 +/- 12.4 months of age, 23% were underweight, 36% were classified as stunted and 12.1% with wasting. Low hemoglobin concentrations (< 11g/L) were present in 80%, and 27.2% had a serum retinol < 0.70 mol/L. For all children, the I-WG households had a significant increase (p<0.05) in hemoglobin (IE 0.32) and weight-for-age z-scores (WAZ, IE 0.31) compared with all households, and a slight increase (p<0.10) for serum retinol (using RBP) compared with I-H. For children < 36 months of age at baseline, children from I-WG had a significant increase (p<0.01) for their WAZ (IE 0.44) and their height-for-age z-score (HAZ, IE 0.47) compared with all groups, and a slight increase (p<0.10) in their weight-for-height z-scores (WHZ, IE 0.41) compared with all groups and for serum retinol compared with I-H (IE 0.10).

Conclusions: SMGs appeared to have significantly supported the nutritional status of children in year 1 of the intervention. However, more time may be needed to obtain the full impact of SMGs. Measures of increased crop production, food security, income, and women's empowerment are potential mechanisms for the improved nutritional status.

TOXICITY OF LEACHATE FROM PLASTIC PACKAGING IN TWO BIOLOGICAL MODELS

[1]dos Santos Gonçalves, Thaís; [2]Lourenço da Costa, Elizabete; [3]Eduardo Addad, João.

[1]BSc. Nutritionist. Institute of Scientific and Technological Analysis. Catholic University of Santos. Brazil.; [2]PhD. Nutritionist. Institute of Scientific and Technological Analysis. Catholic University of Santos. Brazil.; [3]PhD. Geologist. Technical Department. Tertium. Brazil.

Background and objectives: Plastic occupies first place in the market of packaging for the food sector, guaranteeing better presentation to foodstuffs. However, to improve their aesthetic or technological features, metallization or addition of pigments to plastic packaging is employed, many of which may contain heavy metals as contaminants. The objective of this work was to evaluate the toxicity of plastic packaging leachates using the germination of lettuce seeds (Lactuca sativa) and Caenorhabditis elegans, a nematode widely used to evaluate the anthropogenic action.

Methods: Low density polyethylene packages, laminated or not pigmented, were chopped and kept in contact with solutions for leaching at different pH and time conditions. After filtration, an aliquot of the solutions obtained in each condition was used for analysis of metals (Cd, Cu, Pb and Cr) by atomic absorption spectrophotometry. Another aliquot was reserved for the biological assays, which included the germination of lettuce seed, which were placed in Petri dishes, on filter paper moistened with the solutions. After the incubation, the effect on the germination index was evaluated by measurement with a pachymeter. The conditions those caused, the greater interference on the seeds germination, were applied to observe the fecundity of the nematode C. elegans, put in contact from the embryonic stage.

Results: It was observed that the seeds placed in contact with the leachate obtained from laminated plastic packing presented alterations in their length, and reduction in egg production in C. elegans. The migration of cadmium to the aqueous medium was higher in the neutral leachate. But the interference in the metabolism of the studied organisms showed the greatest impact after the contact with the experimental condition obtained an acidified leachate from laminated plastic packaging.

Conclusions: The lack of correlation observed on better condition to metals migration and the one that showed the higher impact on organisms, points that probably others compounds from plastic polymer matrix has interfered on biological models, strengthening the perception about the limitation of chemical measurements. This finding is a worrying indicator, since a large number of foods in this type of packaging present a pH about 4.5, remaining stored for several months.

Keywords: Caenorhabditis elegans, Lactuca sativa, plastic packaging, heavy metal.

ACCUMULATION PROCESSES OF NUTRITIONALLY BENEFICIAL MINERALS IN A BROWN ALGAE, HIJIKI (SARGASSUM FUSIFORME), DURING GROWTH

[1]Katayama, Masayuki; [2]Sugawa-Katayama, Yohko; [3]Murakami, Kaori.

[1]PhD. Professor. Department of Health and Nutrition. Osaka Aoyama University. Japan.; [2]PhD. Professor. Department of Health and Nutrition. Osaka Aoyama University. Japan; [3]PhD. Associate Professor. Department of Food Sciences and Biotechnology. Hiroshima Institute of Technology. Japan.

Background and objectives: The brown algae Hijiki, Sargassum fusiforme, is an important foodstuff for Japanese, and serves as a rich supply of minerals and dietary fiber. Warming of the earth elevates the ocean-water temperature year by year, and exerts ecological influences. Hijiki also seems to change their regular growing processes, becoming chlorotic earlier than before. To know the physiological changes during their growth, we studied the accumulating processes of several nutritionally beneficial minerals in Hijiki plants during their growth from the primary leaf stage to their chlorotic state. Although the accumulation of arsenic (As) occurred in plants during their growth, arsenic (As) could be mostly removed during the pre-cooking process of the commercial dried Hijiki products.

Methods: Hijiki plants were harvested at the seashore of Kushimoto, Wakayama Prefecture, Japan. The fresh samples of Hijiki plants were lyophilized and decomposed with conc perchloric acid - conc nitric acid, or with conc sulfuric acid - conc nitric acid. The ashed samples were dissolved in 1N hydrochloric acid, and the concentrations of arsenic (As), calcium (Ca), iron (Fe), magnesium (Mg), manganese (Mn), potassium (K), and zinc (Zn) in the plant tissues were determined by atomic absorption spectrophotometry.

Results: The concentration of calcium (Ca) per tissue weight increased gradually coming to a rather constant value before the appearance of genital organs on the plants, although the concentration of arsenic (As) continued to increase. Until that time, the concentrations of zinc (Zn) and manganese (Mn) continued to increase further. The concentrations of iron (Fe) and magnesium (Mg) increased gradually, expressing a strong correlation between them, but the concentration of magnesium (Mg) was not uniform in the chlorotic plants.

Conclusions: From the viewpoint of nutritional value, matured plants of Hijiki had better be harvested, but to keep good quality of the products, fine days under the sunshine should be selected, even before complete maturation.

Keywords: Hijiki. Sargassum fusiforme. mineral accumulation. growing process.

NUTRITION SENSITIVE AGRICULTURE FOR IMPROVING FOOD SECURITY: A CASE FROM ANF4W

[1]Uddin, MD AMIN; [2]Asif, Chowdhury Abdullah Al; [3]Waid, Jillian; [4]Stormer, Ame; [5]Mundy, Gary; [6]Sultana, Nigar; [7]Talukder, Aminuzzaman.

[1]Md Amin Uddin. (B.Sc. Ag. (Hons.), MBA). Director (Food Security & Livelihood). Chowdhury Abdullah Al Asif. MDS. Research and Evaluation Manager. Jillian L. Waid. Director Research Learning and Evaluation. Ame Stormer. PhD. Regional Director for Progra; [2]MDS. Research and Evaluation Manager. Helen Keller International. Dhaka. Bangladesh.; [3]MSW. Director Research Learning and Evaluation. Helen Keller International. Dhaka. Bangladesh.; [4]PhD. Regional Director for Programs. Regional Office. Helen Keller International. Phnom Penh. Cambodia.; [5]MA. Regional Monitoring and Evaluation Advisor. Regional Office. Phnom Penh. Cambodia; [6]MSc. Nutrition Specialist. Helen Kellen International. Dhaka. Bangladesh.; [7]MPH. Country Director. Helen Keller International. Dhaka. Bangladesh.

Background and objectives: Since 2014, the ANF4W project in Bangladesh has been training small-scale farming households in agronomic bio-fortification of rice with zinc, and providing female farmers with training in homestead food production, nutrition education, gender empowerment and nutrition sensitive agriculture. This study was conducted to evaluate the factors influencing food security among participants.

Methods: A panel survey was conducted among 332 female farmers, consisting of 156 households that had been participating in the ANF4W program for 2 years, and 176 households that had been participating for one year. We used the Household Food Insecurity Assessment Scale (HFIAS) to assess food security, dichotomizing values into 'food secure' and 'food insecure'. We ran a logistic regression model to test associations between food security and household size, women's decision-making ability in the household, self-reported years of experience in home gardening, length of involvement in the project, size of cultivated land, and dietary adequacy of female farmers.

Results: We found that years of experience in home gardening (OR -0.006, p<.05) and women reporting that they have decision making power about major household purchases (OR -1.068, p<.05) were positively and significantly associated with households being food secure. No other variables were found to be significantly associated with food security.

Conclusions: More experienced home gardeners have greater resilience against food insecurity, but this experience was not a result of project participation. It is possible that the length of time for both groups was not sufficient to show a difference or an impact; further, longer term investigation is needed. Households where women have a greater role in major household purchases are more likely to be food secure, suggesting that there are benefits to agriculture and nutrition programs focusing on empowering women beyond the sphere of agricultural production.

QUALITY CHARACTERISTICS, CONSUMPTION PATTERNS AND NUTRIENT PROFILE OF YELLOW FLESH CASSAVA VARIETIES AND THEIR PRODUCTS

[1]*Akwaa Harrison, Obed;* [2]*Duah, Elizabeth;* [3]*Baah, Rose;* [4]*Parks, Elizabeth);* [5]*Saalia, Firibu;* [6]*Steiner-Asiedu, Matilda.*

[1]Mphil Nutrition (Final year). Department of Nutrition and Food Science. University of Ghana . Accra-Legon; [2]MPhil Nutrition. Department of Nutrition and Food Science. University of Ghana, Legon.; [3]Bsc. Nutrition. Department of Nutrition and Food Science. University of Ghana, Legon.; [4]PhD. Harvestplus cassava Breeder. International Institute of Tropical Agriculture. PMB 5320. Ibadan 200001. Oyo State. Nigeria.; [5](PhD). Associate Professor in Food Science. Head of Department of Food Engineering and Processing Sciences. Senior Lecturer. Department of Nutrition and Food Science. University of Ghana. Accra. Ghana.; [6]Associate Professor in Nutrition. President of Ghana Nutrition Association. Dean of School of Biological Sciences. Senior Lecturer. Department of Nutrition and Food Science. University of Ghana. Accra. Ghana.

Background and objectives: Cassava is a popular root crop in the world which contributes to the staple of most populations in the subtropics and contributes significantly to food and nutrition security in deprived populations since both roots and leaves are eaten. Additionally, cassava leaves are excellent source of proteins, vitamins (B1, B2, C) and essential minerals (iron and zinc). Yellow-fleshed varieties with high carotenoids content have been developed with the aim of combating hidden hunger. The study aimed at determining the carotenoid content of fresh cassava roots, processed products (gari and kokonte) from the roots, including the iron and zinc contents of the cassava leaves.

Methods: Fifteen(15) varieties of fresh yellow flesh cassava (YFC) roots and leaves were obtained from the Crop Research Institute. 5 of samples 301, 303, 305, 307, and 315 were chosen by the processors' analysis. Total carotenoids was determined using the ICHECKTM carotene device. The TCC of gari and kokonte were determined as described by BioAnalyt (2014). Iron and zinc contents were determined using AOAC(2005) methods. A consumer acceptability was done using 5 a point hedonic scale for gari samples in terms of their overall acceptability, appearance, aroma, flavour, and mouthfeel

Results: The processor's TCC of the fresh YFC samples ranged between 10.12 mg/kg to 4.68 mg/kg. Gari from sample 301 had the highest TCC of 7.67 mg/kg whereas sample 305 had the least value of 4.82 mg/kg however that in kokonte was too small to be detected. Boiled cassava had highest TCC of 2.16 mg/kg and least of 1.24 mg/kg for samples 315 and 305 respectively. The iron content of fresh cassava leaves was between 3.89 ± 0.01 µg/g and 1.51 ± 0.01 µg/g for samples 310 and 308 respectively. The zinc content of cassava leaves ranged from 0.42 ± 0.04 µg/g for sample 310 to 0.05 ± 0.01 µg/g for sample 308. More than half of the respondents (51.2 %) were willing to accept the yellow flesh cassava as well as use it.

Conclusions: Thus YFC has potential in enhancing Food and Nutrition security in Ghana and beyond by curbing hidden hunger as judged by the preliminary studies.

Keywords: Cassava, bio-fortification, food and nutrition security, carotenoids

NUTRITIONAL VALUE OF SNACKS COMMERCIALIZED IN PRIVATE UNIVERSITY IN SÃO PAULO CITY

[1]*Poltronieri, Fabiana;* [2]*Pádua, Amanda Batista Vilas Boas;* [2]*Carnelossi, Ana Cecília;* [2]*Olhera, Camila Carolina Bernardes;* [2]*Massignani, Giuliana Cravero;* [2]*Barroso, Helainne Kristina Benedito.*

[1]PhD. Nutritionist. Faculdade das Américas. FAM.; [2]Nutritionist. São Paulo. SP. Brazil.

Background and objectives: The brazilian population's eating habits indicates that the consumption of processed foods and ready meals increased, and traditional foods such as rice and beans reduced their participation in the daily calories of brazilians' intake. High consumption of fast foods, including snack foods, has worried public health officials about the prevalence increase of noncommunicable chronic diseases. The objective of this work was to determine the chemical composition of samples of snack foods marketed in private university (São Paulo-SP).

Methods: Approximately 500g of 4 different kinds of snacks were collected: 2 fried (rissoles, "coxinha"), and 2 baked snacks (esfiha, croissant). The snacks weighted 150g each. The percentages of moisture, proteins, lipids, ashes and carbohydrates of the samples were determined by chemical analysis. The total dietary fiber was estimated based on the brazilian table of food composition.

Results: The moisture of the analyzed samples ranged from 45.98 ± 0.09 to 73.46 ± 0.12. The rissoles had the highest ashes concentration (1.95 ± 0.03) and the croissant the lowest (0.66 ± 0.00). The sample "coxinha" had the highest lipid concentration (6.38 ± 0.11), and croissant the lowest (3.13 ± 0.03). However, the croissant showed the lowest protein concentration (3.70 ± 0.04), and "coxinha" , the highest (8.58 ± 0.03). The total dietary fiber content did not reach 1% in all samples analysed. The concentration of carbohydrates, obtained by difference, was approximately 18% in all samples, except for the esfiha that was almost 38%.

Conclusions: The results revealed that the snacks had high lipid, and low dietary fiber concentration. Therefore, the daily consumption of these foods is a nutritionally inadequate option.

Keywords: food composition, snack foods

BIOACCESSIBILITY AND TOTAL CONTENT OF TRACE ELEMENTS IN DIFFERENT VARIETIES OF COOKED RICE

[1]Ortiz, Maria Laura; [2]Cámara Martos, Fernando; [3]Brem, Juan José; [3]Trulls, Horacio.

[1]MSc. Biochemist. Department of Basic Sciencies. Universidad Nacional del Nordeste. Argentina; [2]PhD.Department of Bromatology and Food Technology. Universidad de Córdoba. Spain.; [3]PhD.Veterinarian .Department of Basic Sciences. Facultad de Ciencias Veterinarias. Universidad Nacional del Nordeste. Corrientes. Argentina.

Background and objectives: Rice (Oryza sativa) is a crop of great, economic and social importance worldwide. At present, the study of trace elements in foods, both beneficial to health and potentially toxic, has been prioritized, and rice grain is being one of the cereals characterized by a selective accumulation of these elements. The total concentration of the different trace elements in food to be consumed, allows estimate the dose of exposure, while the soluble fraction present in the intestinal lumen after the digestive process, shows its bioaccessibility, so this is a more precise nutritional evaluation of the food. The objective of the present work was to determine the total and bioaccessible concentration of iron (Fe), copper (Cu), manganese (Mn) and zinc (Zn) in samples of different varieties of cooked, lyophilized and ground rice.

Methods: The bioaccessible fraction was determined by an in vitro solubility method, the total and solubilized minerals, after ashing, were determined by Flame Atomic Absorption Spectrophotometry.

Results: The results were ranges of total values (μg / g) of Cu: 1.45-5.59; Mn: 2.45- 13.61; Zn: 8.82-12.93 and Fe: 6.50-15.28, while the percentages of solubilized and bioavailable minerals were Cu: 24.01-79.30%; Mn: 5.30 - 27.31%; Zn: 6.70-22.53% and Fe: 24.80-92.60%.

Conclusions: It is concluded that, both, the total content of minerals as the soluble fraction to be used by the organism, are influenced by the different physical and chemical characteristics of the studied varieties, so the brown rice, with high fiber content, has showed the lowest bioaccessibility percentage values of these studied trace elements.

Keywords: Bioaccessibility, rice, varieties, minerals, soluble fraction.

THE IMPACT OF SOLAR MARKET GARDENS ON DIETARY DIVERSITY, WOMEN'S NUTRITIONAL STATUS AND COMPONENTS OF WOMEN'S EMPOWERMENT IN THE KALALÉ DISTRICT OF NORTHER BENIN

[1]Alaofe, Halimatou; [2]Douglas, Taren; [3]Burney, Jennifer; [4]Naylor, Rosemond.

[1]PhD. Nutrinnist. Health Promotion Sciences. University of Arizona. US; [2]PhD. Nutritionist. Health Promotion Science. University of Arizona. US; [3]PhD. Environmental Scientist. School of Global Policy & Strategy, University of California - San Diego. US; [4]PhD. Economist. Earth Energy and Environmental Sciences. Stanford University. US.

Background and objectives: Rainfed agriculture poses growing production risks with increased climate variability and change in Sub-Saharan Africa (SSA), largely due to low use of irrigation and fertilizer. However, to date, few studies have analyzed the impact of irrigation interventions on nutrition, health, and women's empowerment, despite the large potential of irrigation to increase agricultural production. The objective of this study was to evaluate the impact of Solar Market Gardens (SMGs) on dietary diversity, women's nutritional status and components of women's empowerment in the Kalalé district of Northern Benin.

Methods: The study was conducted in 8 intervention villages and 8 control villages using traditional methods. Baseline and 1-year follow-up data were obtained for childbearing age women (15-45 years old) from 185 SMGs women's group (WG) households and randomly selected 229 non women's group (NWG) households, 126 control women's group (CWG) and 234 control non women's group (CNWG) households. Collected nutrition-related indicators included household (HDDS) and women (WDDS) dietary diversity score, body mass index (BMI), prevalence of thinness (BMI<18.5 kg/m2), anemia, iron (ID) and vitamin A (VAD) deficiencies, while women's empowerment measures included decision making, physical mobility, male household involvement, self-confidence, economic independence and group membership components. The Impact estimate (IE) of the SMGs was determined using difference-in-difference between WG and control households (NWG, CWG, and CNWG).

Results: The SMGs women's group households were associated with a significant increase in HDDS (IE 0.36), WDDS (IE 0.47), and a significant reduction in anemia prevalence (IE -0.77), whereas there was no significant impact on BMI, thinness, ID and VAD (p>0.05). SMGs women had also greater self-confidence (IE 0.58), decision making (IE 0.74), and group membership (IE 0.66), but no impact was observed with physical mobility, male household involvement, and economic independence components of women's empowerment.

Conclusions: Solar Market Gardens have the potential to improve women's nutritional status and components of women's empowerment in the Kalalé district of Northern Benin. However, the lack of impact on BMI, iron and vitamin A deficiencies, and economic independence components of women's empowerment

points out the urgent need for behavior changes communication interventions to improve women nutrition status.

Keywords: irrigation; dietary diversity; women's nutrition status; women's empowerment; Benin

Gerald J. and Dorothy R. Friedman School of Nutrition Science and Policy. Tufts University. USA.

Background and objectives: Aflatoxin exposure (AFB1) has been linked to poor growth patterns in infants and young children; however, little is known of the relationship of aflatoxin exposure in pregnancy and low birth weight (LBW). This study estimated the prevalence of LBW (< 2.5 kilograms) and assessed the association of aflatoxin exposure in pregnancy and LBW prevalence.

Methods: Data from newborn infants enrolled in an ongoing USAID-supported birth cohort study in Banke, Nepal, was used for this analysis. Only infants measured within 72 hours of birth were included in this analysis (n=1484, 96% of total recruited). Data on AFB1, socio-demographics, anthropometry and health were collected during the pre-natal visit. Binary logistic regression was used to identify potential risk factors associated with LBW. Statistical analyses were conducted with Stata® SE version 14.

Results: Approximately 20% of the infants were born with a LBW. The average AFB1-lysine adduct levels in maternal serum were 3.4 (±8.4) pg/mg for women with LBW infants and 3.1 (±8.1) pg/mg for women with normal birth weight infants. Significant bivariate associations were found between: LBW and maternal aflatoxin levels, maternal schooling, dietary diversity score, wealth quintile, short stature (<145 centimeters), hemoglobin, mid-upper arm circumference (MUAC) and female child. After adjusting for socio-demographic variables and potential confounding factors, findings showed the odds of a LBW infant increased with increases of AFB1 albumin adducts (OR=1.14; 95% CI: 1.01-1.28 p=0.031). Moreover, the odds of having a LBW infant decreased with each additional year of education (OR=0.95; 95% CI: 0.91-0.98, p=0.001), each unit increase in dietary diversity score (OR=0.84; 95% CI: 0.76-0.93, p=0.001) and each centimeter increase in MUAC (OR=0.89; 95% CI: 0.83-0.94, p=0.000). Short maternal stature (OR=2.05; 95% CI: 1.45-2.89, p=0.000) and female gender (OR=1.42; 95% CI: 1.08-1.85, p=0.011) increased the odds of LBW.

Conclusions: The results indicate a high prevalence of LBW among the study population and confirm that aflatoxins may increase the risk of adverse birth outcomes such as LBW. Findings suggest that in addition to increased education and improved maternal anthropometry, interventions to reduce LBW should encourage improvements to safe and balanced diets before and during pregnancy.

Keywords: aflatoxin, low birth weight, Nepal

COMMUNITY LEVEL EFFECTS OF A TARGETED, HOMESTEAD FOOD PRODUCTION INTERVENTION

[1]Kader, Abdul; [2]Abdullah Al Asif, Chowdhury; [3]Hasan, Md. Mehedi; [4]Ali, Masum; [5]Rahman, Arafat; [6]Waid, Jillian.

[1]MPH, Deputy Director - Research, Learning, and Evaluation, Helen Keller International, Bangladesh Country Office; [2]MPH, Monitoring and Evaluation Manager, Helen Keller International, Bangladesh; [3]MPH, Sr. Program and Research Analyst, Helen Keller International, Bangladesh; [4]MA, Program and Research Analyst, Helen Keller International, Bangladesh; [5]MA, Sr. Program and Research Analyst, Helen Keller International, Bangladesh; [6]MSW, Director - Research, Learning, and Evaluation, Helen Keller International, Bangladesh.

Background and objectives: Helen Keller International Bangladesh implemented the Making Markets Work for Women (M²W²) project in two sub-districts of the Chittagong Hill Tracts (CHT). The goal of the project was to eliminate extreme poverty through introducing sustainable agricultural and improved animal husbandry and building marketing skills. We seek to measure the impact of this project on income, food security, and diets, as well as elements of behavior change along the pathway among the population in these areas as a whole.

Methods: We used propensity score matching methods to identify 24 control villages that were the most similar to 24 of the 72 villages M2W2 worked in, based on distance from the road, ethnic makeup, population size, literacy rates, quality of housing, and quality of sanitation facilities. From each of these 48 villages we surveyed 30 households three times in order to estimate the

impact of the project. The first survey was after two years of the intervention (October 2015), followed by two rounds of data collection in the year following the scale down of the intervention. This analysis only utilizes the first survey round.

Results: In treatment villages, an average of 36% of surveyed households were directly involved in the program (range 6 to 94%). In treatment communities, a greater proportion of households were involved in agriculture (90% vrs. 76%, p<0.02), had livestock (82% vrs. 71.9, p<0.05), had savings (58% vrs. 38%, p<0.01), had daily percapita expenditure above the poverty line (52% vrs. 42%, p<0.01), and had more months of adequate food provisioning (11.4 vrs. 11.0, p<0.02). There was no significant impact on women's dietary diversity (4.2 vrs. 4.1, p<0.25) and on mean percapita expenditure (79 vrs. 74 taka, p<0.40).

Conclusions: There is evidence of some project impact both along the causal pathway and in increasing food security, limited impacts in improving income, and no significant impact in improving diet. Future work will use difference-in-difference analysis to examine differences in the trajectory of change between treatment and control communities, and participant and non-participant households in treatment communities over a longer time period.

Keywords: food security, dietary diversity, evaluation, impact pathways

BUTYROPHILIN ECTO-DOMAIN OF MILK FAT GLOBULE MEMBRANE PROMOTES MUCIN PRODUCTION FROM THE INTESTINAL EPITHELIAL CELLS

[1]Ogawa, Takenobu; [2]Namgung, Hyejin; [3]Kuwana, Yuki; [3]Furue, Ayami; [1]Masuda, Tetsuya; [4]Shirai, Nobuaki; [1]Tani, Fumito.

[1]PhD. Graduate School of Agriculture. Kyoto University. Japan.; [2]BSc. Graduate School of Agriculture. Kyoto University. Japan.; [3]MSc. Graduate School of Agriculture. Kyoto University. Japan.; [4]PhD. Graduate School of Agriculture. Kyoto University. Japan; Industrial Research Center of Shiga Prefecture. Japan.

Background and objectives: Butyrophilin (Btn) was first discovered as a transmembrane protein in milk fat globule membrane. This archetypal Btn (Btn1a1) is also known to modulate the production and the secretion of milk fat globules in the epithelial cells of mammary glands. Recently the primary sequence of the ecto-domain of Btn1a1 was found to have a homology to that of the co-stimulatory B7 molecule, so that many homologs of Btn1a1 have been identified so far. Btn and Btn-like proteins are expressed on the surface of intestinal epithelial cells as well as T cells. The aim of this study is to examine how Btn1a1 functions on the epithelial cells in the gastrointestinal tract.

Methods: The ecto-domains of human, murine, and bovine Btn1a1 were expressed as fusion proteins with immunoglobulin Fc fragment, respectively. The gene coding the ecto-domain of Btn1a1 was subcloned into the expression vector pFUSE-hIg-G1e3-Fc and Expi293 mammalian cells were transfected with the expression vectors. The Btn1a1 fusion proteins secreted into the culture supernatant were purified by a protein G column. HT29-MTX-E12 cells were cultured for 21 days to differentiate into mucin-producing cells. RNA was extracted from HT29-MTX-E12 cells to quantitate the gene expression level of mucins by real-time PCR after Btn fusion proteins were added. Lectin assay was used to quantitate mucins secreted in the culture supernatant.

Results: Expression level of the genes muc5ac and muc17 significantly increased 0.5 to 2 hours immediately after the addition of a fusion protein regardless of species-specificity of Btn1a1. The level of secreted mucins was markedly promoted by the addition of any kind of fusion protein in the dose and time-dependent manner.

Conclusions: Considering that mucins can exert as a barrier against bacteria and viruses infected, we suggest that mucosal homeostasis of the infants may be physiologically controlled by Btn1a1 molecules in milk fat globules.

Keywords: butyrophilin; milk fat globule membrane; mucin; intestinal epithelial cell

MAINSTREAMING NUTRITION INTO REGIONAL AGRICULTURE INVESTMENT POLICY AND STRATEGY OF THE ECONOMIC COMMUNITY OF WEST AFRICAN STATES (ECOWAS) 2016-2025

[1]Giyose, Boitshepo; [2]Seki, Richemont; [2]Sablah, Mawuli; [3]Ag Bendech, Mohamed; [4]Dufour, Charlotte.

[1]Senior Nutrition Officer. Policy and Porgammes. UNFAO. Italy; [2]Nutrition Officer. UNFAO. Ghana; [3]Senior Nutrition Officer. UNFAO. Ghana; [4]Nutrition Officer. UNFAO. Italy.

Background and objectives: With persistent high levels of undernourishment and malnutrition in West Africa, it is necessary to invest in every sector that could contribute to reverse the situation. Agriculture remains a very important sector, which can significantly influence the nutrition status of West African population. It is important to ensure that any agricultural strategy or interventions are tailored to have nutrition objectives and impacts. West Africa's agriculture has shown some improvements in its performance, resulting in a drastic reduction of undernourishment-from 24% in 1990-1992 to 10% in 2014-2016. ECOWAS and its member states have embarked on a multi-sectoral planning exercise that will lead to the formulation and implementation of a new and second phase of ECOWAP (2016-2025) that will better integrate nutrition aspects.

Methods: Strong advocacy at political and technical levels, as well as sharing of guidance materials and best practices were undertaken by relevant institutions, including, the Food and Ag-

riculture Organization of the United Nations (FAO) and the New Partnership for Africa's Development (NEPAD). In addition, FAO provided technical assistance to better mainstream nutrition into the ECOWAP 2016-2025 process. This was supported by strengthened partnerships and coordination at regional and national level

Results: This collaborative work between ECOWAS and regional and national stakeholders have led to the elaboration of the ECOWAP Strategic Orientation Framework 2016-2025 and the Regional Agricultural and Food and Nutrition Security Investment Program (RAFNSIP) 2016-2020, with a stronger integration of nutrition (from objectives to interventions, indicators and budget). Concerning national support, activities are being carried out to ensure a better integration of nutrition into their National Agricultural and Food and Nutrition Security Investment Plans. through effective engagement of multi-sectoral training workshops.

Conclusions: The progress made so far highlights the necessity to develop strong commitment and ownership by Regional Economic Communities, and to strengthen partnerships both at regional and national levels. The need to also build capacities of all stakeholders to develop more agricultural policies/programs and investments with a "nutrition lens" is fundamental to ensure that agricultural transformation plays a stronger role in combating food insecurity and malnutrition.

INCREASING CONSUMPTION POTENTIAL BY REDUCING LOSS AND WASTE OF FRUITS AND VEGETABLES THROUGH GENETIC IMPROVEMENT

[1]Lemke, Shawna; [2]Purcell, John; [3]Kishore, VK.

[1]PhD; [2]PhD. Vice President Global Research and Development Lead. Monsanto Vegetable Seed Division. United States; [3]EMEA Solanaceous Breeding Lead. Monsanto Vegetable Division. United States.

Background and objectives: Fruits and vegetables are important sources of nutrients and are associated with the reduction of risk from non-communicable diseases. Despite these benefits, there is a gap in consumption. The World Health Organization equated 5.2 million deaths globally in 2013 to inadequate fruit and vegetable consumption.

There are many contributing factors to the lack of consumption including spoilage, lack of availability, taste and other consumer preferences. Through genetic improvement methods, such as breeding, and improved management practices, these issues are beginning to be addressed, and continue to improve as the science advances.

Methods: In this study we assessed the market needs and opportunities for addressing food loss and waste for fruit and vegetable products. Results of our findings on key areas of impact and gaps will be presented. In addition, detailed examples with be provided to illustrate the findings. For example, tomato transportation losses in India are estimated at 40% after harvest due to the lack of cold storage and inadequate infrastructure, which is devastating in a country where nearly half of the children are malnourished and underfed. By using breeding techniques, researchers addressed two contributing factors to the spoilage to tomatoes – shelf life and the firmness needed to make the journey to market – while still maintaining flavor and color quality consumers demand. Over a two-year period more than 500 tomato genotypes were evaluated for transportability traits. Analysis was done on the firmness, color, brix and acidity.

Results: This led to two tomato hybrids being commercialized. These tomatoes feature a 12-14-day shelf life, much improved over the 5-7-day range before the tomatoes would typically spoil. This has allowed tomatoes to be accessible to almost all of India, rather than just the central regions, close to the farms.

Conclusions: By developing strong genetic traits that disable challenges from farm to table, consumers can access the produce that is important for their nutritional needs.

DIFFERENTIAL PREDICTORS OF HOUSEHOLD DIETARY DIVERSITY IN RURAL SMALL HOLDER FARMING COMMUNITIES IN MALI, SIERRA LEONE AND DEMOCRATIC REPUBLIC OF CONGO

[1]Gichohi, Wanjiku; [2]Dontsop, Paul; [3]Yomeni, Marie; [4]Akem, Chrysanthus.

[1]PhD. Nutritionist.International institute of Tropical Agriculture. Dar es Salaam.Tanzania; [2]PhD.Economist.International institute of Tropical Agriculture.Kalambo.DRC; [3]PhD.Agronomist. International Institute of Tropical Agriculture.Free Town.Sierra leone; [4]PhD.Plant pathologist.International Institute of Tropical Agriculture.Ibadan, Nigeria.

Background and objectives: Studies have shown that dietary diversity is associated with socio-economic status and household food security. Conducting household dietary diversity surveys within agricultural projects is important for targeting as well as to assess the impact of these projects on food and nutrition security. Household dietary diversity survey was conducted in household that were part of the Support to Agricultural Research for Development of Strategic Crops in Africa (SARD-SC), is a multi- national CGIAR-led project, whose overall objective was to enhance food and nutrition security and contributing to reducing poverty in selected Regional Membership Countries (RMCs) in Africa.The main objective of conducting the household dietary diversity score in this case was to assess the impact of the project on household food access but also to determine the predictors of dietary diversity. We present herein the results of the predictors of dietary diversity.

Methods: The household dietary diversity questionnaire was administered to the person who was responsible for meal preparation for the household the previous day. The respondent was asked about all foods eaten inside the home during the previous day and night, by any member of the household. Foods were then classified and scored into 12 food groups and an overall score obtained.

Results: Mean HDDS were 4.5, 4.4 and 4.9 in Mali, Sierra Leone and DRC respectively. In investigating the predictors of HDDS in Mali, proportion of household (HH) members working on farm, proportion of HH members working off farm, proportion of time women spend farming, number of parcels operated, parcel size and whether a farmers household received fertilizer subsidies or not and household income were predictors of HDDS (P<0.05). In addition to this, predictors of HDDS in Sierra Leone were the proportion of household members aged 15-65 years (P<0.05). Proportion of family members working on farm was not a significant predictor of HDDS. The only significant predictor of HDDS in Zanzibar was proportion of HH members working on farm.

Conclusions: Different factors influence HDDS in different settings. A thorough understanding f these factors is important for program design and optimal targeting.

MODERATE AND SEVERE FOOD INSECURITY WAS ASSOCIATED WITH STUNTING AMONG PANAMANIAN CHILDREN UNDER FIVE YEARS OLD IN RURAL COMMUNITIES

[1]Barría, Maika; [2]Barría, Maika; [3]Rios, Israel; [4]Barba, Armando; [5]Mojica, Eyra; [6]Vergara, Omaris.

[1]Nutritionist. Research and Innovation Division in Genetic and Biodiversity Resources. The Panama Agricultural Research Institute (IDIAP).; [2]Nutritionist. Research and Innovation Division in Genetic and Biodiversity Resources. The Panama Agricultural Research Institute (IDIAP). Panama.; [3]MSc. Nutritionist. Regional Nutrition Officer. Food and Agriculture Organization of the United Nations. Sub Regional Office for Mesoamerica. Panama.; [4]MSc. Nutritionist. Panama Ministry of Health. Panama; [5]Nutritionist. Consultant HarvestPlus for Latin America and the Caribbean. Panama.; [6]MSc. Food Engineer. School of Science and Food Technology. Regional Centre of the University of Panama. Penonome City. Panama.

Background and objectives: The Panama Agricultural Research Institute (IDIAP) has implementing a national project using high nutritional quality crops. The prevalence of Stunting among children under five years old in indigenous communities is a current public health problem in Panama. There is no evidence in Panama about the association between food insecurity at household level and stunting prevalence. Objective: to explore the association between food insecurity at household level with stunting in children under five years old in Panamanian rural communities.

Methods: A cross-sectional study with 135 children under five years old in five geographically-dispersed rural areas (indigenous: Nole Düima and Müná; and non-indigenous: Soná, Olá, and Los Pozos). Data was collected from June-September 2015. Food insecurity was defined using the Latin America and the Caribbean Food Security Scale (ELCSA), adequate food provision monthly-based (AFPMB); anthropometric measurements (weight and height were using to calculate haz and baz according with WHO2008 growth standards); and sociodemographic data were also collected. Univariate statistical analyses, principal components analysis for categorical data, and multivariate logistic regression area, age and sex controlled with robust standard errors were used to assess the association between stunting prevalence with moderate and severe food insecurity and AFPMB.

Results: Age mean and standard deviation (SD) was 33.7±18.2 months, (50% female and 55% from indigenous area). Mean and SD for HAZ was 1.16±1.34, a significantly difference were found in indigenous (-1.73±1.14) than in non-indigenous (-1.73±1.14) (ttest, p<0.05); for BAZ was 0.67±0.99, a significantly difference were found in indigenous (0.98±0.91) than in non-indigenous (0.29±0.96) (ttest, p<0.05). Also, the prevalence of food insecurity (moderate and severe) was significantly higher in indigenous (84.9%) than non-indigenous (31.2%) (proportional test, p<0.05). Principal component analyses show relation among area (indigenous vs non-indigenous), food insecurity and AFPMB. After controlling by area, sex and age, stunting prevalence was significantly associated with food insecurity OR=4.4 (CI95%=1.1-17.9), AFPMB OR=4.5 (CI95%=1.2-17.4), and indigenous area OR=5.2 (CI95%=1.7-15.7).

Conclusions: moderate and severe food insecurity was strongly associated with stunting among children under five years old living in indigenous area. Comprehensive nutritional interventions should incorporate strategies to promote dietary food diversification using biofortified crops in vulnerable groups.

INCREASING PRODUCTIVITY OF SMALLHOLDER FARMERS THROUGH IMPROVED TOOLS AND EDUCATION

[1]Lemke, Shawna; [2]Purcell, John; [3]Edge, Mark; [4]Young, Mark.

[1]PhD. Food Strategy and Stakeholder Lead. Monsanto Company. United States; [2]PhD. Vice President Global Research and Development Lead. Monsanto Vegetable Seed Division. United States; [3]Director of Collaborations for Developing Countries. Monsanto Company. United States; [4]Chief Techology Officer. Climate Corp. United States.

Background and objectives: The Food and Agricultural Organization of the United Nations has identified advancements

in productivity of smallholder farmers as critical to improve food security and nutrition, reduce poverty and increase employment. To achieve enhanced productivity, programs have been developed with the aim of empowering farmers with tools and agronomic knowledge. Two programs in Africa and India will be shared.

Methods: In Africa, the Water Efficient Maize for Africa (WEMA) is a partnership with Bill and Melinda Gates Foundation that is bringing royalty-free improved seed to drought susceptible areas. Over the next 10 years, farmers are expected to see an 20-35% increase in grain production due to improved drought hybrids and biotechnology that deliver insect protection and water utilization traits.

Rural isolation and limited agronomic resources makes it challenging for smallholder farmers to evaluate and address agronomic challenges. Building on the rapid adoption of smartphones in India, the FarmRise program is launching this year to a limited area. This is an android based solution designed to bring smallholder farmers weather information, agronomic advice and market pricing designed to make them more productive and profitable. Climate Corp, who is leading this project, is currently seeking partners to create additional resources including equipment leasing and government services, such as insurance and credit options. FarmRise intends to create a platform for startups to participate and expand the target geography to reach Asia, Africa and grow across India.

Results: Progress from the seven years of WEMA to date will be shared along with the early findings from the FarmRise program.

Conclusions: The primary focus of these programs is grower empowerment through access to agricultural tools and knowledge. Over time the increased productivity is expected to translate to income and other social benefits.

Keywords: Smallholder Farmers Increased Productivity Empowerment

BIOACTIVE COMPOUNDS IN URUGUAYAN WHEAT GENOTYPES

[1]Russo, Monica Russo; [2]Cadenazzi, Monica.

[1]Nutritionist. Escuela de Nutrición. Universidad de la Republica. Montevideo. Uruguay; [2]Agronomist Engineer. Agronomy University of the Republic. Uruguay.

Background and objectives: Wheat is a major crop, and its products are an important component of the human diet. Epidemiological studies show that the consumption of whole grain decreases the risk of developing chronic diseases of high prevalence. The beneficial properties are attributed to a combination of natural and synergistic action of bioactive compounds present in whole grains, that reduce oxidative stress. The objective of this research is to generate information in the content of phenolic compounds (Cf), tocopherols (Tc), phytosterols (Fo) and carotenoids (Ct) in differents genotypes and locations.

Methods: Twenty two "wheat bread" genotypes (Triticum aestivum) of INIA (National Institute of Agriculture Research), of short (CC) and long cycle (CL) were evaluated, cultivated in Uruguay, in 2013, in 2 locations. The average content and the coefficient of variation (CV) were studied in each component. Stadistical differences between the averages, by cycle and location were measured with the test of Student.

Results: The average values in the wheats of CC and CL content were: 921 and 979 μg / g of Cf; 48.2 and 59.3 moles / ng of Tc; 16.1 and 12.2 (area) of Fo and 11.2 and 94.8 (area) of Ct, respectively. CV values ranged from 8.8 to 105%, corresponding the highest values to Fo and Ct. Significant differences ($p<0,05$) were observed among genotypes (CC and CL) grown in the same location, in the average content of Ct, and the content of Tc, only in varieties of CL. Significant differences were found also, between the averages of the genotypes corresponding to each locality, in the content of Ct y Tc (CC and CL).

Conclusions: The results of this study have demonstrated a wide variation between the bioactive compounds in the studied genotypes. Although more research is required to analyze the effect of the environmental conditions, the differences between genotypes suggest that it may be possible to develope varieties of wheat with high concentration of beneficial compounds for the health of consumers.

Keywords: wheat, whole grain, health, nutrtion.

INSIGHTS FROM THE SEQUENCING AND ANNOTATION OF THE STEVIA REBAUDIANA GENOME AND THEIR APPLICATION IN AGRONOMY AND HEALTH

[1]Schauer, Stephen; [2]Huang, Tengfang; [3]Samuel, Priscilla; [4]Khazi, Fayaz; [5]Markosyan, Avetik.

[1]PhD. Applied Systems Biology. Keygene Inc. Rockville. MD. USA; [2]PhD. Applied Systems Biology. Keygene Inc. Rockville. MD. USA.; [3]PhD. Global Stevia Institute. Oak Brook. IL. USA; [4]PhD. Applied Systems Biology, Keygene Inc., Rockville, MD 20850, USA;; [5]PhD. Research & Development. PureCircle Ltd. Kuala Lumpur. Malaysia.

Background and objectives: Obesity is a global health issue affecting millions and reducing sugar intake with non-caloric sweeteners is one potential path to reducing energy consumption that can have a positive health impact. The leaves of the Stevia rebaudiana (Bertoni) plant produce steviol glycosides (SGs) which include stevioside, rebaudiosides (Reb) A, B, C, D, E, F, M, dulcoside A, rubusoside and steviolbioside. SGs are 200-350 times sweeter than sugar but contribute no calories, therefore making stevia a leaf crop of significant economic value. The food industry has a very positive outlook on the opportunities for stevia-derived ingredients in zero or calorie-reduced products. Consequently, the

stevia ingredient market is expected to cross \$700M. High yields, desired quality traits, resistance to pests and diseases, and dependable economic returns are key characteristics of any domesticated commercial crop. Such basic characteristics are generally selected over many generations through intensive plant breeding efforts to create improved varieties. Although systematic cultivation of stevia started in the 1970s in China, South America and Japan, only recently crop improvement efforts have been focused on making stevia more scalable and an economically sustainable crop.

Methods: Despite limited understanding of genetics, biology and physiology of stevia, recent demand for SGs requires rapid improvement of stevia cultivars currently used in commercial cultivation. To rapidly facilitate this, we have sequenced, generated a chromosomal level genome assembly, and fully annotated the genomes of three commercial stevia varieties with improved levels of minor rebaudiosides.

Results: This data has been further integrated into a comprehensive bioinformatics database for visualization and analytics of all available genomic, transcriptomic and metabolomic stevia datasets. This interface will enable specialists from multiple disciplines, such as chemists, biochemists and geneticists, to mine this database to understand and improve existing SG biosynthesis pathways through traditional breeding or discover new pathways or compounds for similar non-GMO improvement.

Conclusions: This information can be used to enable improved traditional stevia breeding for improved agronomic and sustainability benefits and to improve the production of SGs to enable reduced sugar intake, which can contribute to improved health.

Keywords: stevia, genome, breeding, agronomy, steviol-glycosides

Conflict of Interest Disclosure: Dr(s) Stephen Schauer, Tengfang Huang and Fayaz Khazi work at Keygene.

Dr Priscilla Samuel works at the Global Stevia Institute which is funded by PureCircle Ltd.

Dr Avetik Markosyan works at PureCircle Ltd that funded the genome research.

THE MODAL SALIENT BEHAVIORAL, NORMATIVE AND CONTROL BELIEFS ABOUT NUTRITIONAL CLAIMS ON PREPACKAGE FOOD PRODUCTS

[1]Opolski Medeiros, Caroline; [2]Macedo Fraiz, Gabriela; [1]Labronici Bertin, Renata; [1]Stangarlin Fiori, Lize.

[1]PhD. Nutritionist. Department of Nutrition, Federal University of Paraná, Brazil.; [2]BsC. Nutritionist. Department of Nutrition, Federal University of Paraná, Brazil.

Background and objectives: Consumers make purchasing decisions very quickly, so, brief messages, related to nutritional content, printed on food product labels can stimulate their decisions. These messages are known as nutritional claims. There are few studies that evaluate the use of nutritional claims in the moment of food purchase and the consumer beliefs. This study iden-

tified the modal salient beliefs about the use of nutritional claims on prepackage food products among nutrition students.

Methods: The exploratory qualitative research were conducted with 13 nutrition students in November 2015, considering the Theory of Planned Behavior. A focus group was used to identify consumers' salient beliefs. The discussion was recorded with two recorders and data transcription was then conducted to allow content analysis of the focus group, by two independent evaluators. Modal salient beliefs were considered those mentioned at least, 75% of the total number of citations.

Results: All students were single and female with an average age of 20.2 ± 1.2 years. Two modal salient behavioral beliefs were identified and considered as a disadvantage of using food label: "products are more expensive to have these nutritional claims" and "nutrition content are not specific as it should be". Considering the modal salient control beliefs, most nutrition students did not mention factors that facilitate or impede them at the purchasing moment. However, one student mentioned the "facility in accessing the nutritional claim" as a factor that facilitates the use of nutritional claims in the moment of food purchase. In regard of modal salient normative beliefs, only one belief was identified: "food product producers". Prepackage food producers were mentioned as the people who would approve the use of nutritional claims since it could help consumers to buy their products.

Conclusions: Six modal salient beliefs were identified. They are important to explain the participant's behavior of using nutritional claims on prepackage food products. Considering the consumer's beliefs is relevant to develop actions and measures that aim the health education to increase their knowledge about nutritional claims.

Keywords: Food label. Consumer behavior. Behavioral research.

FAMILY ORCHARD-GARDENS AND BACKYARD POULTRY AS AL ALTERNATIVE FOR IMPROVING FOOD SECURITY: UNDERGRADUATE STUDENT'S EXPERIENCE IN A MAZAHUAS COMMUNITY IN MEXICO

[1]Maafs Rodríguez, Ana Gabriela; [2]Gutierrez Gomez, Yareni Yunuen; [3]Carrillo Domínguez, Silvia; [4]Amezcua Jagger, Teresita.

[1]Nutritionist, M. Ed. Department of Animal Nutrition. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. Life Sciences Department. Instituto Tecnológico y de Estudios Superiores de Monterrey. Mexico.; [2]Nutritionist, MSc, PhD. Life Sciences Department. Instituto Tecnológico y de Estudios Superiores de Monterrey. Mexico.; [3]Veterinarian, MSc, PhD. Department of Animal Nutrition. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. Mexico.; [4]Veterinarian, MSc. Department of Animal Nutrition. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. Mexico.

Background and objectives: Challenge based learning allows students to submerge in real life problems while developing knowledge and skills. The Mazahuas are an ethnic minority in

Mexico, with high prevalence of food insecurity, marginalization and poverty. Most families possess ground for growing vegetables and fruits, and keeping poultry. However, their current practices are not enough to ascertain an adequate nutrition. This context represented a great opportunity to set the goal for nutrition and sustainability engineering undergraduate students to analyze food security, family orchard-gardens and backyard poultry practices in eight Mazahua families, to identify strategies in order to improve food security in a different environment.

Methods: During an intensive week in September 2016, 40 nutrition and sustainability-engineer undergraduate students visited a Mazahua community to assess food security, agricultural and poultry activities of eight families. The evaluation was conducted using context-adapted questionnaires from FAO: Food Security Scale for Latin America and the Caribbean (ELCSA) and Revisions of Poultry Development. Data was analyzed to stablish food insecurity level, agricultural and poultry activities. Students put forward strategies to improve food security in the evaluated families.

Results: All families presented food insecurity, have a family orchard-garden and sufficient cultivation ground. Only five families grow enough food for selling and self-consumption. Products losses occur mainly due to weather changes and lack of water. All households have livestock, but only 4 families are able to obtain animal products sufficient for selling and self-consumption, and there is little or no control on the animal's diet. Students proposed strategies to improve current practices, including vegetables exchange among farmers, "nopal" wall for preventing crops freezing, use of waste for improving animal's diet and incrementing egg production for hens.

Conclusions: Real-life experiences are an excellent opportunity for students to understand concepts related to their filed work and to promote adequate practices in family orchard-gardens, livestock and backyard poultry in order to improve food security by increasing food variety, enhancing animal production and improving orchard care. At the same time, the experience allowed students to understand the importance of multidisciplinary work.

Keywords: Family orchard-gardens, backyard poultry, food insecurity, marginalized communities.

Program (PNAE – Programa Nacional de Alimentação Escolar in Portuguese). The aim of this study was to discuss how the interface between family farming and school feeding has being built in Santa Catarina state, southern Brazil, in terms of the factors that represent obstacles to its consolidation and also on those that are mechanisms for addressing and overcoming those limitations, from the perspective of different social actors involved in the process.

Methods: In order to collect data, a semi-structured interview technique was used, applying specific guides for each category of social actor. For data analysis, one adopted the technique of thematic content analysis, from two previous categories: barriers and coping mechanisms in the construction of the family farming interface with school feeding. The Ethics Committee for Research Involving Human Subjects approved this study (Opinion No. 1,207,443).

Results: The group of the research subjects consisted of 35 social actors involved in the studied interface: managers (8 technical managers, nutritionists responsible for PNAE); farmers (9 family farmers); consumers (10 members of the School Feeding Council/CAE, teachers, principals and school cooks); members of the Technical Assistance and Rural Extension/ATER (8 technicians and rural extensionists). The barriers identified were the cost of goods, bureaucracy, insufficient technical assistance, resistance to changes, weaknesses in the organization of farmers and public managers. The coping mechanisms observed in facing those obstacles were dialogue, intersectionality, investment, training activities and organization. These mechanisms have encouraged the establishment and strengthening of trustful relationships that promoted awareness of all parties about the importance of PNAE and contributed to making the necessary adjustments to meet the program requirements, guided by its goals and guidelines.

Conclusions: We conclude that public policies as PNAE can provide favorable changes for farmers and the students and their communities, contributing to local development and for achieving higher levels of food security and nutrition both in rural as in urban spaces. Acknowledgements: CNPq/Brasil (445595/2014-0).

FAMILY FARMING AND SCHOOL FEEDING: PERCEPTIONS OF SOCIAL ACTORS ON THE LEGISLATION AND ITS IMPLEMENTATION

[1]Teo, Carla Rosane Paz Arruda; [2]Mossmann, Márcia Pozzagnol.

[1]PhD. Nutritionist. Health Sciences Area. Universidade Comunitária da Região de Chapecó/Unochapecó. Brasil.; [2]MSc. Nutritionist. Health Sciences Area. Universidade Comunitária da Região de Chapecó/Unochapecó. Chapecó. Brasil.

Background and objectives: In Brazil, Law 11.947/2009 determines that 30% of funds transferred to municipalities by the Federal Government to support the National School Feeding Program (PNAE) must be applied in purchasing from family farming

food that promote healthy eating. The study aimed to identify perceptions of different social actors on the Law 11.947 / 2009 and its implementation.

Methods: This is a qualitative research with 35 social actors involved in school feeding in Santa Catarina state, southern Brazil: 8 nutritionists; 9 family farmers; 10 members of the School Feeding Council; 8 rural extensionists. The Ethics Committee for Research Involving Human Subjects approved this study.

Results: The Law emerged as an element of strengthening family farming, by providing social valuation and income generation for the segment, resulting in a greater possibility of family permanence in the field. Local development was perceived as a positive repercussion of the Law, as it increases the economic situation of the municipality and the farming families. Therefore, the Law was perceived as a vector for healthy eating, family farming strengthening and local development. Regarding the implementation of the Law, different factors were pointed out as being involved in this process: initiative, mobilization and participation. The initiative was, mainly, from the nutritionists. The mobilization of the other actors took place by dissemination mechanisms, mapping the local production and encouragement to the family farmers become suppliers. In the scope of participation, there was a certain passivity of some actors, such as the members of the School Feeding Council, who were generally not very active. We also observed some distancing from the rural extensionists, which revealed a lack of articulation with other sectors involved. Thus, it was verified the centrality of the process is placed in the nutritionist. In addition, it is worth noting that farmers do not perceive themselves as actors in the process, which certainly limits the production of more expressive advances in the implementation of the Law.

Conclusions: We conclude that encouraging the participation and leadership of all the actors involved is strongly recommended. Acknowledgements: CNPq/Brasil (445595/2014-0).

GRAIN LEGUME CULTIVATION AND CHILDREN'S DIETARY DIVERSITY IN SMALLHOLDER FARMING HOUSEHOLDS IN RURAL GHANA AND KENYA

[1]de Jager, Ilse; [2]Abizari, Abdul-Razak; [3]Douma, Jacob C.; [4]Giller, Ken; [5]Brouwer, Ingeborg.

[1]Msc. Nutritionist. Division fo Human Nutrition. Wageningen University. The Netherlands; [2]PhD. Nutritionist. Department of Community Nutrition. School of Allied Health Sciences. University for Development Studies. Tamale. Ghana; [3]PhD. Researcher. Centre for Crop Systems Analysis group. Wageningen University. The Netherlands; [4]Professor. Plant Production Systems group. Wageningen University. The Netherlands; [5]PhD. Nutritionist. Division of Human Nutrition. Wageningen University. The Netherlands.

Background and objectives: Boosting smallholder food production can potentially improve children's nutrition in rural

Sub-Saharan Africa through a production- own consumption and/or an income-food purchase pathway. Rigorously designed studies are needed to provide evidence for nutrition impact, but are often difficult to implement in agricultural projects. Mixed method design is used more frequently in project evaluations as the triangulation of complementary methods may add to the rigor in evaluations. Structural equation modelling (SEM) may be a relevant new and additional method in this field.

Methods: In the framework of a large agricultural development project supporting legume production (N2Africa), we studied the potential to improve children's dietary diversity by comparing N2Africa and non-N2Africa households in a cross-sectional quasi- experimental design followed by structural equation modelling (SEM) and focus group discussions in rural Ghana and Kenya.

Results: We found no evidence that participating in N2Africa is associated with improved children's dietary diversity, mainly due to methodological limitations. For soybean, SEM indicated a relatively good fit to the posteriori model in Kenya but not in Ghana, and in Kenya only the production-own consumption pathway was fully supported with no effect through the income-food purchase pathway. Results: **Conclusions:** These findings confirm the importance of the food environment for translation of enhanced production into improved nutrition. This study shows that in a situation where rigorous study designs cannot be implemented, SEM is a useful option to analyse whether agriculture projects have the potential to translate in improved nutrition.

Keywords: dietary diversity, legume production, SEM analysis, children, Ghana

PRODUCTION OF ORANGE-FLESHED SWEET POTATO (IPOMOEA BATATAS) INTERCROPPED WITH MORINGA OLEIFERA IN KAFFRINE, AGRO-ECOLOGICAL ZONE OF GROUNDNUT BASSIN IN SENEGAL

[1]Sylla, Papa Mamadou dit Doudou; [2]Tall, Ndéye Codé Laure; [3]Mbaye, Mame Samba; [3]Ndoye, Fatou; [2]Diallo, Bassirou; [4]Diouf, Adama; [4]Dossou, Nicole; [5]Donnen, Philippe; [4]Wade, Salimata; [3]Noba, Kandioura.

[1]MSc. Nutritionist. Botany and Biodiversity Laboratory. Cheikh Anta Diop University.; [2]PhD. National Laboratory for Plant Production Research. Senegalese Institute of Agricultural Research.; [3]PhD. Botany and Biodiversity Laboratory. Cheikh Anta Diop University.; [4]PhD. Nutritionist. Nutrition Laboratory. Cheikh Anta Diop University.; [5]Université Libre de Bruxelles. Ecole de Santé Publique Médecine.

Background and objectives: Biofortification is key to improve household nutrition. In Senegal, the prevalence of vitamin A deficiency (VAD) remains high, and affects 24% of children in rural areas. To prevent VAD, an intercropping trial of orange-fleshed sweet potato, an excellent source of provitamin A, with Moringa

oleifera was undertaken for the first time in the agro-ecological zone of groundnut basin of Senegal. The objective of this study is to identify varieties that adapt better to the agro-ecological conditions of the Kaffrine region and which gives better results in association with Moringa oleifera.

Methods: Our study is conducted in a randomized complete block design with three replications for a varietal test of 4 cultivars of sweet potato and a growing test associated with the Moringa oleifere. The Four different cultivars of sweet potato were tested in pure stand and in association with Moringa oleifera variety PKM1. These cultivars differing in the color of the tuber flesh, Kander (orange), Yajendee (light orange), Caromex (yellow), Gandiol1 (white). Growth and physiological parameters were recorded in four steps during the plant life cycle. After 135 days, tubers were harvesting and the nutritional quality analysed to determine carotenoid composition of tested cultivars.

Results: Results showed that, the four cultivars behave well under the agro-ecological conditions of groundnut bassin. A low incidence of diseases and pests for the different cultivars both in pure and intercropping situations is observed. significant increases of tuber weight and size in intercropped plots for Kander and Yajendee cultivars compared to pure culture. Moreover, the Kander cultivar had the highest concentration in carotenoids (84.6 ± 24 mg/kg).

Conclusions: Sweet potato cultivars performed well under agroclimatic conditions of Kaffrine. There is no difference in behavior under pure culture conditions, whereas intercropping with Moringa oleifera has a positive effect on tuber development of the Kander and Yajendee varieties. Thus, this cropping system would be a promising route for the sustainable production of sweet potatoes with orange flesh in this area.

Keywords: Orange-fleshed sweet potato, moringa oleifera, Provitamin A, Senegal

HEALTH RISK INDEX OF HEAVY METALS IN COMMONLY CONSUMED CONTAMINATED VEGETABLES IN OGUN STATE. NIGERIA

[1]Wahab, Nimot; [2]Adedokun, Balikis.

[1]Tai Solarin University of Education. Ijebu-Ode. Ogun state. Nigeria.; [2]Student. Department of Home Economics and Hotel management. Tai Solarin University of Education. Ijebu-Ode. Ogun State. Nigeria.

Background and objectives: As long as vegetables are consumed almost raw, heavy metals accumulated in higher quantities in them get transferred into human body which can pose a life threaten risk to human health. This study thus assessed the health risk index of heavy metals (As, Cd, Hg and Pb) in contaminated vegetables present in the root, stem and leafy shoot of six leafy vegetables (Corchorus oliotorus, Celosia argentia, Telfairia occidenta-lis, Talinum triangulare, scotty bons and egg plants). Commonly grown and consumed by the populace of Ijebu Ife, Ijebu East Local Government area Ogun State.

Methods: A total of eighteen samples (three samples of leaf, stem and root) of each vegetables were randomly collected from three different gardens at the study area. Concentration of the metals were determined using Atomic Absorption Spectrophotometer. Daily intake of vegetables were determined from the consumption pattern of the vegetables using direct weighing, and the daily intake of metals (DIM) were calculated through the contaminated vegetables using the relationship given by Cui, Zhu, Zhai, Huang, Qui &Liang, 2004: DIM =Cmetal X Dintake of vegetable/ Average body weight of respodents. Health Risk Index (HRI) were thus calculated Using the formular : HIR= DIM/ ORD(Oral Reference Dose by WHO/FAO). If HIR is lesser than 1, the exposed population is considered to be save (Hassan et al, 2012).

Results: The range of various metals concentration of Pb, As, Cd and Hg were 0.103-0.141, 0.095-0.163, 0.085-0.118, 0.0000-0.014 in leaf, 0.113-0.165, 0.103-0.181, 0.103-0.141, 0.0003-0.018 in stem and 0.121-0.172, 0.114-0.194, 0.111-0.149, 0.0005-0.024 in root respectively. The results of the findings showed that the ORD of mercury for all vegetables is above the WHO/FAO permissible limit of 0.0001 and as such the HRI is greater than 1. The high permissible intake were also noticed by some of the metals in some vegetable.

Conclusions: consumption of average amount of these contaminated vegetables might pose a health risk for the consumers due to high concentration of metals especially mercury as the value obtained were above the provisional tolerable intake (PTDIs) by joint WHO/FAO .

Keywords: Heavy Metals Concentration. Vegetable, Health Risk Index.

ACCEPTANCE OF SOAKED AND GERMINATED CHICKPEA-BASED DISHES

[1]Haileslassie, Hiwot; [2]Henry, Carol; [3]Tyler, Robert.

[1]BSc. MSc. College of Pharmacy and Nutrition. University of Saskatchewan. Canada.; [2]MEd. PhD. College of Pharmacy and Nutrition. University of Saskatchewan. Canada.; [3]B.S.A. PhD. College of Agriculture and Bioresources. University of Saskatchewan. Canada.

Background and objectives: Chickpeas are important sources of protein, folate and minerals. However, they contain anti-nutrients which form complexes with minerals such as zinc, iron and calcium, rendering them less available or unavailable for absorption. The level of these anti-nutrients may be reduced by applying food processing techniques such as soaking and germination applicable at household level. Sensory evaluation of the processed dishes is key in determining whether the dishes prepared by applying these strategies will be accepted and utilized by consumers. Thus, we evaluated the effect of soaking and germination on sensory attributes of chickpea-based dishes.

Methods: We applied different times of soaking (6, 12, 18 hour) and germination (24, 48, 72 hour) to three chickpea varieties grown in Ethiopia, namely Habru, Mastewal and local. Sensory attributes including appearance, odour, texture, taste and overall acceptability were assessed using 9- and 5-point hedonic scales in phase 1 and 2, respectively. Phase 1 was carried out at Hawassa University School of Nutrition, Food Science and Technology with fifteen panellists recruited from the school. The evaluation was carried out in triplicate. Consumer acceptance tests were conducted in phase 2 in chickpea-growing communities with 30 participants.

Results: The overall acceptability of chickpea-based dishes ranged from 5.6 ± 1.6 to 7.1 ± 1.5, that is from "neither like nor dislike" to "like moderately". The highest value for sensory attributes was observed for a Habru-based dish prepared from seed soaked for 18 hours. The lowest score for appearance was seen for a Mastewal-based dish prepared from seed soaked for 6 hours. From germinated chickpeas, Habru germinated for 24 hour received the highest score for appearance, texture, odour and overall appearance.

Conclusions: Compared to ordinarily cooked dishes, there was no significant difference in sensory attributes for most chickpea-based dishes.

Keywords: Sensory evaluation, soaking, germination, chickpea

BRAZILIAN FOOD LAW: AN INTEGRATIVE LITERATURE REVIEW

(1)Oneti, Ciro Félix; (1)Oneti, Ciro Félix; (2)Nascimento, Lucy Christiane de Souza Hossaine do; (3)Nascimento, Lucy Christiane de Souza Hossaine do.

(1)Enfermeiro. Universidade Aberta da Terceira Idade (UNATI/UEA/AM). Brasil.; (2)Advogada. Assessora jurídica. Tribunal de Justiça do Estado do Amazonas. Brasil.; (3)Assistente Social. Especialista em Assistência e Família. Universidade Aberta da Terceira Idade (UNATI/UEA/AM). Brasil.

Background and objectives: One of the branches of law is in charge of legislating on food-related issues in Brazil. In a country with great territorial extension and still marked by much informality in several sectors of the production chain, it is necessary to act rigorously through a law on the production of foodstuffs to guarantee the protection of consumer health. Objective: To emphasize the elementary importance of the legal mechanisms acting in consonance with inspection agencies in the food production chain in the national territory.

Methods: This study is an integrative literature review. The search was carried out on the SciELO platform (Scientific Electronic Library Online), with the descriptors Legislation, Food and Brazil. The platform returned 65 results, the search was filtered searching for texts strictly related to the subject and incomplete texts were duplicated, before the year 2012 or published in a language other than Portuguese, English or Spanish. There remained only nine texts. The research was complemented with textbooks.

Results: Brazil has a broad legislative mechanism for the production, packaging, transport, conservation and commercialization of food products. One of the main obstacles to the fulfillment of all determinations is the difficulty of inspection in such a large territory. Added to this is the lack of knowledge of many operational procedures by the producers. It is noted that some themes also acquire bioethical connotations, as in the case of transgenics.

Conclusions: This legislative branch will ensure an increase in the quality of national food production, given that the country is quite heterogeneous. Patent registration benefits greatly from such legislation, and any crimes of this scope end up being inhibited.

Keywords: food law; inspection; national food production

PEDIATRIC NUTRITIONAL CARE BASED ON FOOD SAFETY: BASIC CONTROLS

(1)Mestre, Graciela Maria; (2)Brea, Mercedes Maria; (2)Guma, Florencia; (2)Soto Montesano, Betiana; (2)Blasi, Sandra Nora.

(1)Nutricionist. Food and Nutrition Area. Pediatric Hospital Prof. Dr. J. P. Garrahan. Buenos Aires . Argentina; (2)Nutricionist. Food and Nutrition Area. Pediatric Hospital Prof. Dr. J. P. Garrahan. Buenos Aires. Argentina.

Background and objectives: Preventing foodborne infections in inpatients is a mission of the Food and Nutrition Area, supporting their nutritional care. The prevention of food infections is performed using a self-control system of risk assessment of the assisted population and hazards analysis in production and service, keeping the processes controlled and verified according to the protocol. The system requires that three basic controls work effectively: health, hygiene and hygienic habits of staff (based on training), institutional kitchen and equipment hygiene and water safety.

Aim: To evaluate the effectiveness of basic controls over the period 2014-2016

Methods: A descriptive, retrospective, cross-sectional study of microbiological records of hand swabs, food contact surfaces and monthly public water sampling was conducted.

The swabs that verify handwashing of handlers are performed while they were doing their routine activities, surface swabs after sanitizing, and tap water samples are taken. Samples are microbiologically analyzed by accredited laboratories, their results collated with the criteria of the protocol. The following levels are considered acceptable: for hands: <10 CFU/ hand for coliform, absence / hand for S. aureus, E. coli and Salmonella ssp / Shigella ssp. Criteria for surfaces are <1 CFU / cm2 for enterobacteriaceae, <10 CFU / cm2 for mesophilic aerobic bacteria, absence for Listeria monocytogenes . Criteria for water are <0.5 NTU for turbidity (WHO criteria for immunosuppressed people), <3 CFU / ml for mesophilic aerobic bacteria, absence in 100 ml for E. coli and Pseudomona aeruginosa.

Results: All the data of hand swabs from handlers (n: 88) were adequated to criteria. Of the 94 surface swabs, 97% were adequated and 3% acceptable. Thirty samples of water yielded 100% satisfaction for coliforms and Pseudomona aeruginosa, 90% for mesophilic aerobic bacteria and 78% for turbidity.

Conclusions: Tap water, regarding turbidity, did not meet the consumption criteria for immunosuppressed patients, but is safe for healthy people according to the Argentine Food Code. In our institution tap water is used for hygiene processes. For drinking and food preparation it is subjected to heating to 100°C. Basic controls are efficient allowing for proper nutritional, dietary and infectious care of pediatric patients.

Keywords: nutrition, food-safety, infection prevention

CONDITIONS OF VULNERABILITY OF THE LIVELIHOODS IN NATIVE COMMUNITIES OF PARAGUAYAN CHACO THREATENED BY DROUGHT

[1]Gavilán Jiménez, Mónica; [2]Ferreira Perez, Elisa; [2]Villalba de Gómez, Norma.

[1]PhD Candidate. Agricultural Engineer. Facultad de Ciencias Agrarias. Universidad Nacional de Asunción. Paraguay; [2]MSc. Agricultural Engineer. Facultad de Ciencias Agrarias. Universidad Nacional de Asunción. Paraguay.

Background and objectives: This research was executed in the Paraguayan Chaco, an extended territory, characterized to have a population relatively small and disperse (3% of country population) which have the human development index (HDI) most lower of the country. The population of this region is compound of original native people, Mennonite settlers, and Latin population. The objective was performing one line of base to characterize the conditions of vulnerability of the livelihoods in native communities of Paraguayan Chaco threatened by drought.

Methods: The type of investigation was descriptive with analytical components and quali-quantitative focus. The study zone covered two departments (President Hayes and Boquerón), where were selected 68 hamlets of 15 native communities, through stratified probability sampling, determined in base geographical criteria. The universe of study corresponded 2.312 homes (11.352 peoples).

Results: The most relevant results are:

Livelihoods: The qualification of the human resources in terms of the alphabetism rate is found in 60.8%. The schooling rate stood at in 51.4%. Houses are precarious and overcrowded, assented in ancestral lands. Employment is shortage and poorly paid.

Food security and nutritional status: Food comes from forage, the agricultural production, purchase and donations. Access, consume and stability of the food, present variations throughout the year, in wintertime. In terms of evaluation nutritional status (EEN) children less than 5 years old, were found low size for the 26% and the risk of low size 13%. Age group of 6-18 years old, BMI values is adequate for the 59%. The malnutrition by excess

is predominant in adults (51%). For its part, level of food security in homes, measured through the Latin American and Caribbean Food Security Scale (ELCSA), categorized 98% families with children under 18 years old with food insecurity.

Access and availability of water: The water supply is diverse; most used are cutwater, community cistern. Lack of water in 92% of homes, especially in winter.

Resilience: most of pressing events they face are mainly food scarcity, employs, medical care and medicines.

Conclusions: With all displayed can be concluded that indigenous families of sample had high levels of vulnerability of their livelihoods, compromising for consequence food security, health and development of themselves.

Keywords: vulnerability of the Livelihoods, Food security, Resilience.

NUTRITION-LED AGRICULTURE: SYNERGIES BETWEEN AGRICULTURAL AND NUTRITION INTERVENTIONS IN SENEGAL

[1]Steinberg, Douglas; [2]Rosenberg, Karl; [3]Crosby, Todd.

[1]MSc. Director of Programs Africa. National Cooperative Business Association. USA; [2]MA. Chief of Party. Yaajeende. National Cooperative Business Association. Senegal; [3]MA. Senior Technical Director. National Cooperative Business Association. USA.

Background and objectives: The Yaajeende Agriculture and Nutrition Development Project is a USAID funded initiative implemented since 2011 by NCBA CLUSA and partners. Taking a food systems approach, the project's goal is to improve the economic and nutritional status of the very poor in four rural regions of Senegal. Yaajeende employs a "Nutrition-Led Agriculture" approach, which promotes improved production, trade and local consumption of nutritious foods. Yaajeende also emphasizes institutional capacity building and private sector strengthening to effectively integrate agriculture and nutrition and to contribute to sustainability. These institutions include citizen working groups, mother-to-mother groups, livestock rearing groups, and networks of "community based service providers" who are linked to private sector suppliers. The project is based on a theory of change that posits that mutually supporting interventions of nutrition and agriculture will be more efficacious in improving nutritional status than either component on its own; this theory has largely been confirmed after seven years of field level implementation.

Methods: An external mid-term evaluation1 during the fifth year of implementation utilized a mixed-method approach involving a non-experimental quantitative strategy and qualitative techniques. On the quantitative side, a population-based survey

was administered to 2,720 households in treatment and control villages across 19 rural communes. A multi-stage cluster sampling approach was used to select households that participated in the project baseline survey (2011) along with households from 27 new intervention villages.

Results: The mid-term evaluation supported the original hypothesis that households benefiting from both project components have improved or suffered less in the context of food insecurity compared to those who benefit from neither or from only one. At least two high order outcomes have shown improvement:

- 7 percentage points decrease (p=0.008) in stunting among beneficiaries.
- Treatment effect of about 2.9 percentage points in poverty reduction in high-intensity areas (but no evidence of synergy in the high-intensity group (p=0.01)).

Conclusions: While the outcomes of the study revealed variability across households and regions, Yaajeende's combined effects were generally synergistic across many key indicators, supporting the hypothesis that impacts on poverty and malnutrition are stronger when the agriculture and nutrition interventions are conducted simultaneously with a target population.

Keywords: Agriculture, nutrition, poverty, synergy, evaluation.

FORTY YEARS OF INNOVATED INDUSTRIAL BASED AGRI-TECH IN SUSTAINABILITY FOR ZERO FOOD WASTE

Liaqat, Ali.

Liaqat Corp Pvt. Ltd.

Background and objectives: Being seed/food industry, funder to small scale farmers since 1975, we were distributor of EU/USA seed companies for Pakistan. Our funding to farmers is at buy-back, suffered losses in agriculture initially, INNOVATED KITCHEN based nutri- research in drying for production lines at sourcing sites of farming/ fruit/vegi/grain markets, factories, infrastructure, seasonal stations etc.

Methods: Prior to 1975, we used to manage nutrition losses by manual sun-drying , have developed multiple value added manual to mechanized processing sheets to eradicate spoilage as per sourcing. This type of NUTRITECH gave positive results. In processing of agri-nutrition, a wide range of techniques were developed. In-kitchen processing trials achieved positivity in converting manual processing lines to mechanized , partial drying was experimented to eliminate perishability by mobile drying units, all challenges were resolved scientifically.

Results: To reduce nutritional losses, food/ agriculture system was reshaped by introduction of value added multiple intermediate drying technologies. All spoilage was salvaged by technical drying solutions leading sustainability , developed food/agriculture partnerships for nutritional security. All elaborated processes were applied by sustainable drying technology. Environmental issues were faced technically. Industrial based affordable accessibility is being applied at sourcing sites, to gain nutritional positivity. Our future-based research balanced nutritional values. Female drying encouraged our nutri-productivity. Due to instant check on spoilage by female labour, Nutritional losses are being instantly stopped by our teams.

Conclusions: Our qualitative/quantitative INNOVATED drying impacted funding, improved lost NUTRI conditions ,delivered field farming productivity, pre/postharvest LOSSES were improved , by value added technologies, focused at loss sourcing . innovated game changing NUTRI technologies facilitated food/ Agri partnerships, clusters has been enhanced in surrounding largely with industrial/future based technologies. Practical researched network has been shared by Agri/NUTRI stakeholders . our 40 years of innovated ind based nutri/ tech is ready to start saving nutritional values by 2017-18, instead of 2050 with partnership of ICN.

Keywords: innovated reshaped processing lines, innovated production sheets as per sourcing sites, cost-effective processing lines, sustainability by eradication of losses at sourcing sites, reduction of perishability instantly

Conflict of Interest Disclosure: Low income women are integral part of nutritional security as , domestically trained in processing .SDGs has been converted to our in-house INNOVATED tech,reshapd EU/USA processing/production lines at less cost of 15 times,with equal outputs,consumer/oriented tech followed by smallholders.

IMPACT OF SANITIZING AGENTS ON THE MICROBIOLOGICAL AND PHYSICAL-CHEMICAL QUALITY OF CUCUMBERS

[1]*Freitas Brilhante de São José, Jackline;* [2]*Morandi Lepaus, Bárbara;* [2]*Henrique Cesconetto Coswosck, Kaio;* [2]*Augustinho Giorgette, Mylena;* [2]*Souza Rocha, Jéssica;* [3]*Almeida Costa, Luciana.*

[1]PhD. Nutritionist. Departament of Education Integrated Health. Federal University of Espírito Santo. Brazil.; [2]Nutritionist. Departament of Education Integrated Health. Federal University of Espírito Santo., Brazil; [3]MSc. Nutritionist. Departament of Education Integrated Health. Federal University of Espírito Santo. Brazil.

Background and objectives: The washing step associated with the use of sanitizing solutions is the only one processing step that reduc-

---

es the number of microorganisms, and it is important that the stage not cause losses for the sensorial and nutritional characteristics. Sanitizing is an essential step in assigning greater safety and shelf life to minimally processed products and fresh produce and, as future restrictions on the use of chlorine are desirable, there is a need to evaluate alternative methods. The aim of this study was to evaluate the effectiveness of alternative sanitizers to chlorinated compounds in removing natural contaminants, removal of Salmonella enterica Enteritidis and evaluate the effects on the chemical characteristics of cucumbers.

Methods: Treatments with 1 and 2 % acetic acid and 1 and 2 % lactic acid, 3 % hydrogen peroxide, 200 mg/L sodium hypochlorite and 200 mg/L sodium dichloroisocyanurate were evaluated. The control was samples without sanitization. After each treatment, a microbiological analysis was conducted for the samples. The analysis examined the impact of the treatments in reducing aerobic mesophilic bacteria and molds and yeasts as well as Salmonella enterica Enteritidis inoculated on the surface. The values of pH, total titratable acidity, total soluble solids, phenolic compounds, antioxidant capacity were also determined.

Results: The reduction of aerobic mesophilic bacteria was between 1.10 – 2.08 log CFU/g in cucumbers. The molds and yeasts contamination was between 0.88 – 1.58 log CFU cucumber samples, respectively. After the sanitization treatments with hydrogen peroxide and 2 % lactic acid reductions of 2.71 log CFU/g and 2.34 log CFU/g, , respectively, were achieved. Cucumbers presented no significant difference (p> 0.05) for pH values, total titratable acidity and total soluble solids/total titratable acidity ratio. In the evaluation of the impact of the sanitizers on the total phenolic compounds of cucumber it was observed that there was no significant difference between the non-sanitized and treated samples. This indicates the preservation of the nutritional characteristics of the vegetables after the sanitization treatments.

Conclusions: The results of this study show the potential of the proposed strategies to replace chlorinated compounds in the sanitization step of fresh produce.

Keywords: Sanitizers, fresh vegetables, Salmonella, quality, safety

---

NUTRITION, SAFETY, AND TRUST: THE CASE OF INFANT FORMULA CONSUMPTION IN URBAN CHINA

[1]Gan, Caixia; [2]Conroy, Denise; [3]Lee, Michael.

[1]PhD Candidate. Department of Marketing. The University of Auckland. New Zealand.; [2]Senior Lecture. Department of Marketing. The University of Auckland. New Zealand.; [3]Senior Lecture. Department of Marketing, The University of Auckland, New Zealand.

Background and objectives: Nutrition and safety are essential to consumers regarding their food for daily need. Yet for av-

erage consumers, nutritional value is mostly regarded as credence attribute as they can hardly verify this attribute even after purchase (Grunert, 2005). This indicates consumers' need for trust in food before consumption, especially in the context of high involvement. This research explores the role of consumer trust in the case of uncertainty concerning food safety and nutrition in the context of infant formula consumption in urban China.

Methods: This is a longitudinal qualitative research based on an initial face-to-face semi-structured in-depth interview with 28 pregnant women living in urban China, and a follow-up interview with the same group of mothers at the time when the babies are about 8-9 months old.

Results: For Chinese mothers, infant formula is a high-involvement food category in both functional and emotional aspects. In the wake of infant formula incidents in China in the past decade, safety has become the primary concern of infant formula for Chinese mothers. As public trust in domestic food regulation system has been damaged by past incidents and not yet rebuilt, Chinese mothers turned to food regulation systems of other countries and utilised interpersonal relationships to get connected with those more trustworthy-perceived food systems, namely, friends or relatives living overseas. In terms of the nutritional content, mothers seemed to have neither professional knowledge nor expertise to verify health claims of infant formula products. They tended to rely on word-of-mouth information from trusted acquaintances and brand reputation as cues to decide which brands can be under consideration for further purchase. Asking overseas friends and relatives to purchase infant formula from foreign markets, some Chinese mothers believe that international brands are safe and advanced in providing better nutrition for babies, while some others argue that overseas infant formula may not be perfectly suitable for Chinese babies, yet still, are willing to compromise nutrition needs in order to secure the safety of baby food.

Conclusions: In the case of uncertainty concerning food safety and nutrition, trust in food is necessary for consumers to proceed food consumption practice.

Keywords: Consumer trust, food safety, infant formula consumption, urban China

DIETARY DIVERSITY AND SCALING UP THE PRODUCTION IRON AND ZINC- RICH YELLOW POTATOES YELLOW POTATOES IN COLOMBIA

[1]del Castillo, Sara Eloisa; [2]López, Claudia; [3]Mosquera, Teresa.

[1]PhD. Professor. Department of Nutrition. National University of Colombia. Colombia.; [2]Master Student. Nutritionist. Department of Nutrition. National University of Colombia. Colombia.; [3]PhD. Professor. Faculty of Agricultural Sciences. National University of Colombia. Colombia.

Background and objectives: Food insecurity among rural Colombian households is high, reaching 90% in some regions. Almost all farmers from the Colombian-Andean region rely on po-

tatoes as their staple food and as their main income source. In this presentation, we discuss an ongoing project in Nariño, a region dependent on potato farming, that has high rates of food insecurity, malnutrition, and nutritional deficiencies, particularly iron and zinc. Our aim is to increase the availability of more nutritious potatoes for Colombian consumers through a strategy that integrates agriculture and nutrition.

Methods: We will introduce three varieties of yellow potatoes with better agronomic properties (i.e. higher yields, better resistance to blight) and higher zinc and iron content compared to potatoes currently being grown. These potatoes can provide up to 0,5 mg iron and 0,3 mg zinc per 100g potatoes. These potatoes have potential to impact nutritional status, as the Institute of Medicine recommended dietary allowances for women of reproductive age are 18 mg and 8 mg for iron and zinc, respectively.

Results: Potatoes are a staple food for Colombians, therefore the introduction of novel high-mineral potatoes maybe part of a sustainable option to combat micronutrient deficiencies when it is part of a diverse diet, alongside increased consumption of locally produced fruits and vegetables from home gardens. Although the iron and zinc in the novel potato varieties is not as bioavailable as animal-source foods, Colombian consumers do not always have the economic resources to purchase these foods. This strategy therefore, becomes a successful experience of a local agriculture sensitive to the nutritional needs of vulnerable communities of a region or a territory.

Conclusions: To date, we conducted a baseline survey and one follow-up survey measuring: the production and consumption of the varieties of yellow potatoes among the families of the project; dietary diversity of project households (dietary diversity score through 24-hour Recall); and monitoring the nutritional situation of children under 5 years of age in project households; This last will be measured through anthropometric measurements such as: weight and height and biochemical measurement such as: iron status (hemoglobin, ferritin, transferrin) , zinc and vitamin A.

DEVELOPMENT OF THE NATIONAL FOOD SAFETY STANDARD: MULTI-NUTRIENTS SUPPLEMENTARY FOOD FOR PREGNANT AND LACTATING WOMEN

[1]Huang, Jian; [2]Huo, Junsheng; [1]Sun, Jing; [3]Han, Junhua; [3]Liang, Dong; [2]Wang, Lijuan; [4]Chen, Chunming; [4]Wang, Yuying; [2]Yang, Zhenyu; [2]Tang, Yanbin.

[1]BD. Nutritionist. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China.; [2]PhD. Nutritionist. National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China.; [3]PhD. Nutritionist. China National Center for Food Safety Risk Assessent. China.; [4]PhD. Nutritionist. ILSI Focal Point in China. China.

Background and objectives: Since the national food safety standard for complementary supplements was issued in 2008, yingyangbao as a complementary supplement has been widely used in the poverty rural areas, yearly covering 1.27 million children aged 6-24 months. Because the nutrition conditions during the first 1000 days of life is critical for future potential health, it is necessary to develop the products to improve the nutrition status for pregnant and lactating mother, and the associated national food safety standard should be regulated.To develop the food safety national standard for applying complement supplements to pregnant and lactating mothers.

Methods: The related international materials were investigated including standards, technology, reporting results for the effectiveness of micronutrient interventions, as well as the nutrition and dietary status of pregnant and lactating mother in China. The CAC standard, WHO guidelines and related standards in China have been compared. The micronutrient exposure was evaluated. In addition, the experts in this research areas attended meetings for discussions, and social opinions were also considered.

Results: This standard stipulates the supplement food for pregnant and lactating mothers as special dietary to provide high quality proteins, vitamins and minerals. The maximum of daily portion is 50 g, among which the protein accounts for 18% to 35%. Iron, vitamin A, vitamin D, folic acid, vitamin B12, totally five micronutrient is compulsorily to be added in, the other 14 micronutrients is optional. The daily portion could provide 50% of RNIs of micronutrient. This standard also limits the amount of pollutants, mycotoxin, microorganism, urease and so on.

Conclusions: The standard of "the National food safety standard: Multi-nutrient Supplementary Food for Pregnant and Lactating Women" (GB 31601-2015) was issued in November, 2015, by Health and Family Planning Commission in China, and officially implemented in November, 2016.

Keywords: Pregnant women, lactating mothers, first 1000 days of life, nutritional supplements, standard

ECONOMIC EVALUATION OF A NOVEL HOME-STEAD FOOD PRODUCTION PROGRAM IN RURAL CAMBODIA

[1]*Lynd, Larry;* [2]*Lakzadeh, Pardis;* [3]*Talukder, Aminuzzaman;*
[4]*Stormer, Ame;* [5]*Kroeun, Hou;* [6]*McLean, Judy;* [7]*Green, Tim.*

[1]PhD. Professor. Faculty of Pharmaceutical Sciences. University of British Columbia. Canada.; [2]MSc. Research Analyst. Broadstreet Health Economics & Outcomes Research. Canada.; [3]MPH. Country Director. Asia-Pacific Regional Office. Helen Keller International. Cambodia.; [4]PhD. Regional Director. Asia-Pacific Regional Office. Helen Keller International. Cambodia.; [5]MPH. Program Manager. Asia-Pacific Regional Office. Helen Keller International. Cambodia.; [6]PhD. Nutritionist. Senior Instructor International Nutrition. Department of Food, Nutrition and Health. University of British Columbia. Canada.; [7]PhD. Affiliate Professor. Discipline of Pediatrics. University of Adelaide. Principal Nutritionist. Healthy Mothers, Babies & Children Theme. South Australian Health and Medical Research Institute. South Australia. Australia.

Background and objectives: Background: For over 20 years Helen Keller International has implemented homestead food production (HFP) programs in developing countries to improve the nutritional status of women and children, household food security and income. The HFP model encourages year-round food production through home gardens and animal husbandry. Although, HFP has been successful in increasing household food production, economic assessment of this program has been limited. In order for program implementers to allocate limited resources efficiently, there is a need for a rigorous economic assessment of HFP programs.

Objective: To (1) identify factors associated with household income in rural, Cambodia, (2) to systematically measure and monetize food production from gardens and fishponds, and explore the cost-effectiveness of HFP in Cambodia in a cost-benefit analysis (CBA), using data from a randomized control trial (RCT), (3) explore the sensitivity of the CBA results and alternative scenarios for program implementation.

Methods: Factors associated with household income, were examined using a generalized linear mixed model at a univariate and multivariate level. Food production was estimated from multiple longitudinal data sources. The program benefits (food production) were monetized using local village market values, while costs were determined through a micro-costing analysis. A CBA was carried out from the project iii perspective and the net monetary benefit in each study arm was estimated and compared to control households. Lastly, the sensitivity of the CBA results was tested in a one-way sensitivity and scenario analysis.

Results: Assessment of baseline household income revealed that in rural Cambodia fishponds and pigs were associated with income. Households in the HFP program produced more food, relative to the control. The results from CBA show that home gardens are a cost-effective HFP intervention. The results from the scenario analysis suggest that the addition of fishponds to gardens may also be cost-effective if implemented outside a RCT.

POTENTIAL CONTRIBUTION OF YELLOW FLESHED CASSAVA PRODUCTS TO VITAMIN A INTAKE IN WOMEN AND CHILDREN

[1]*Eyinla, Toluwalope;* [2]*Maziya-Dixon, Busie;* [3]*Sanusi, Rasaki.*

[1]Dept. of Human Nutrition, UI, Ibadan and International Institute of Tropical Agriculture, Ibadan; [2](PhD)Food & Nutrition Sciences Laboratory,International Institute of Tropical Agriculture, Ibadan, Nigeria; [3]PhD)(Department of Human Nutrition, University of Ibadan, Ibadan, Nigeria.

Background and objectives: Background: Introduction of yellow fleshed cassava has resulted in the production of analogous foods of the white fleshed varieties. With Pro-vitamin A content (especially β-carotene) degrading quickly when subjected to usual traditional processing methods. It is important to understand the possible contribution of these new foods to dietary intake.

Objectives: Evaluation of the β-carotene concentrations in local staples namely eba (Dough cooked from fried cassava granules) and fufu (dough cooked from cassava mash), lafun (Dough cooked from milled chips). Comparing these concentrations with usual dietary intake in women and children and calculate the possible contribution to vitamin A intake

Methods: Matured roots of four Cassava varieties (TMS01/1371, TMS07/593, TMS07/539 and NR07/0220) were processed into eba, fufu and lafun. The fresh roots and products were analyzed for their β-carotene contents using HPLC. Mean portion sizes (in grams) of products from white fleshed variety were compared with concentrations in the similar products from yellow cassava varieties to calculate possible contribution to RDA of Vitamin A intake.

Results: The β-carotene concentration in eba was highest in TMS01/1371 at 3.79μg/g. In fufu it was the highest in NR07/220 at 5.38μg/g. In lafun it was the highest in NR07/220 at 3.19μg/g. The lowest values were found in TMS07/593 at 0.08 μg/g, 0.85 μg/g and 1.52 μg/g in lafun, fufu and eba respectively. The portion sizes ranged from 236g in eba to 267g in lafun in children while the portion sizes ranged from 225g in fufu to 633g in lafun in women. Contributions to RDA of Vitamin A show that for children fufu can give 18% contribution through NR07/0220 followed by eba giving 11% in TMS01/1371 followed by 8% in fufu from TMS07/0539. In women, eba from TMS01/1371 was highest at 16% followed by NR07/0220 providing 10% from lafun.

Conclusions: The varying potential of the varieties is evident. The information can be valuable when questions regarding bio-availability and bioefficacy of these local food products are raised.

Keywords: Beta-Carotene, Cassava, Eba, Fufu, Vitamin A

B -CAROTENE RETENTION IN YELLOW CASSAVA IS NOT ONLY DEPENDENT ON GENOTYPE BUT ALSO ON PROCESSING METHOD

[1]Eyinla, Toluwalope; [2]Maziya-Dixon, Busie; [3]Sanusi, Rasaki; [4]Alamu, Oladeji.

[1]MSc.Nutritionist. Dept. of Human Nutrition, UI, Ibadan and International Institute of Tropical Agriculture,Ibadan; [2]PhD. Senior Scientist.Food & Nutrition Sciences Laboratory,International Insitute of Tropical Agriculture, Ibadan, Nigeria; [3]PhD.Nutritionist.Department of Human Nutrition, University of Ibadan, Ibadan, Nigeria; [4]PhD.Scientist.Food & Nutrition Sciences Laboratory,International Insitute of Tropical Agriculture, Ibadan, Nigeria.

Background and objectives: Carotenoid losses in yellow cassava during food processing is of particular interest since pro-vitamin A content (especially β-carotene) degrades quickly when exposed to sunlight or to different forms of processing. It is well known that retention ability is genotype dependent. The study therefore sought to evaluate the retention capacity of β -carotene in recently released cassava varieties when processed into local staples namely Eba (Dough from Cassava granules) and Fufu (dough cooked from cassava mash).

Methods: Matured roots of four Cassava varieties (TMS 01/1371, TMS 07/593, TMS 07/539 and NR 07/0220) were harvested and processed into Eba and Fufu. The fresh roots and products were analyzed for their β-carotene contents. Percentage true retention was used to evaluate retention. Precautions were taken to avoid unnecessary carotenoid loss during processing.

Results: Beta-carotene content of the fresh roots ranged from 5.32μg – 7.8μg, the processed product, Eba had retention ranging from (0.05% - 16.6%). TMS 01/1371 had the highest retention while TMS 07/539 had the lowest retention. The processed fufu had retention ranging from (6.9% - 24.7%). NR 07/0220 had the highest retention while TMS 07/593 had the lowest retention.

Conclusions: The varying retention ability of the varieties is evident. While this is expected, it is observed that some varieties may offer more significant contribution to nutrient intake than others. This can maximize the potential contribution to pro-vitamin A intake and ultimately vitamin A intake for women and children.

Keywords: Beta-Carotene, Cassava, Eba, Fufu, Retention

CONCEPT OF FOOD AND NUTRITIONAL SECURITY FROM THE COMPLEXITY

Rodriguez Leyton, Mylene.

Magister, Nutritionist, Research Professor. Nutrition and Dietetics Programan. Metropolitan Univerisity of Barranquilla. Colombia.

Background and objectives: Food and nutritional security are inherent to life; since the beginning of humanity, there is an interest in guaranteeing self-sufficiency of food that has remained a priority issue for organizations and governments. The concept today relates food and nutritional security with availability, access, consumption, use and quality and safety of food.

The objective of this investigation was construct a concept of food and nutritional security from a perspective of complexity.

Methods: This research is qualitative of an exploratory, descriptive nature; is a genealogical investigation from bibliographic searches of publications in databases, review of public policy guidelines and action plans proposed in declarations of world food summits from 1974.

Description, interpretation and construction-ofconstruction were carried out; a systemic and complex hermeneutics of the relations that make up the food-nutritional security network was applied and emerging thoughts were identified.

Results: A genealogy of the famines was a source of systemic elements that contribute to the understanding and interpretation of hunger in its historical moments and contexts. Hunger occurs in situations of conflict when the dominated countries lose their autonomy for food supply and this forces them to generate mechanisms to provide a solidarity response by food aid.

A detailed review and identification of the interrelationships in global declarations for the eradication of hunger and Malnutrition, originating from food summits since 1974; their contributions to the conceptual transition of food and nutritional security. Despite the efforts the purpose of reducing the hungry people, is far.

Food-nutritional security of "new time" is the environmental adventure of nurturing life, it is the biological and social relations, the warp of food-nutritional, man-ecosystem in a network of complex relationships in feedback loops between peoples and land, peoples and their ecosystemic and cultural contexts.

It constitutes a framework of knowledge that connects both the natural sciences and the social sciences such as, anthropology and ecology.

Conclusions: A critical look that gives way to a perspective from the reorganization of knowledge towards a complex, systemic vision, as a network of networks; Which invites us to interpret the language of discourses in new ways, expanding possibilities of observing and interpreting the transition towards food-nutritional security.

N-GLYCOLYLNEURAMINIC ACID LEVELS IN RED MEAT OF 7 ANIMAL SPECIES: GUIDELINE FOR HUMAN CONSUMPTION

[1]*Wang, Bing;* [2]*Jahan, Marefa;* [3]*Wynn, Peter.*

[1]Graham Centre for Agricultural Innovation. Charles Sturt University. Australia; [2]PhD student. Graham Centre for Agricultural Innovation. Charles Sturt University. Australia; [3]Dr. Graham Centre for Agricultural Innovation. Charles Sturt University. Australia.

Background and objectives: Many studies have shown that red meat-derived sialic acid (Sia) N-glycolylneuraminic acid (Neu5Gc) promotes inflammation and cancer progression (1). However red meat are a good natural source of protein and iron. Our aim was to quantify the Neu5Gc, N-acetylneuraminic acid (Neu5Ac) & 2-keto-3-deoxy-D-glycero-D-galactonononic acid (KDN) level in conventional rad meat of thigh muscle in cattle, goat, sheep, pig, deer, horse, kangaroo and estimate the level of dietary consumption of the non-human Neu5Gc from different species rad meat and its potential for inflammatory diseases.

(1). Samraj AN. A red meat-derived glycan promotes inflammation and cancer progression. Proc Natl Acad Sci U S A. 2015 Jan 13;112(2):542-7

Methods: Neu5Ac, Neu5Gc, KDN were determined in the muscle meat of 7 different animal species (n=3) by UHPLC using DMB derivatization.

Results: Sia concentration in the red meat of 6 tested animal species varied from Neu5Ac 168~661μg/g protein, Neu5Gc 0~166 μg/g protein; KDN 0~4 μg/g protein and total 207~814 μg/g protein respectively. There was significant difference in concentration of Neu5Gc ($P= 0.022$), but not for Neu5Ac, KDN and total Sia in the muscle meat of 7 animal species. The predominate form of each family Sia was conjugated including Neu5Ac (70~95%), Neu5Gc (85~99%) and total Sia (55~90%), which is the bioavailable form and can be digested and incorporated into human tissue. Although, KDN concentration was negligible to absent in all animal species muscle meat, free KDN was the predominant form. Neu5Gc concentration in the muscle meat from high to low was in goat, cattle, pig, sheep, horse and deer. Interestingly Kangaroo muscle meats were devoid of any Neu5Gc.

Conclusions: The conventional red meat contained the relatively high concentration of bioactive form Neu5Gc, except kangaroo meat that did not contain any Neu5Gc. Therefore kangaroo meat is a much safer source of red meat in terms of Neu5Gc intake. Our new findings may aid in reducing the risk of cancer, cardiovascular and inflammatory diseases among the red meat consumption population by recommending that they choose low Neu5Gc containing meat.

NUTS AND DRIED FRUIT CONSUMPTION AND HEALTH: NEW INSIGHTS

DRIED FRUIT CONSUMPTION AND OSTEOPOROSIS (BONE HEALTH)

Arjmandi, Bahram.

PhD. RDN. Florida State University. Center for Advancing Exercise and Nutrition Research on Aging. USA.

Osteoporosis is characterized by a loss of bone mass and quality leading to an increased risk of fractures. Postmenopausal women are at the greatest risk of developing osteoporosis.. A search for promising non-pharmacological alternative therapies for osteoporosis is important as medications used for osteoporosis can be associated with side effects and low compliance. Nutrition can reduce the risk of developing osteoporosis and therefore play an important role in bone health. In terms of nutrition, dried plum has been shown to be one of the most efficacious interventions for preventing and reversing bone loss in a rat model of osteoporosis and in postmenopausal women. The purpose of this presentation is to provide an overview of the efficacy of dried plum for preventing and reversing bone loss associated with ovarian hormone deficiency and to highlight possible mechanisms of action. Our follow-up study demonstrated that postmenopausal women taking dried plums during our one year clinical trial conducted five years earlier retained bone mineral density compared to the control. Overall, these findings suggest that dried plum is a promising functional food therapy for postmenopausal bone loss with the potential for a long-lasting bone-protective effect.

5TH YINI SUMMIT–FERMENTED FOODS AND HEALTH: THE INTERSECTION OF GUT MICROBIOTA AND FERMENTATION MICROBES

THE GUT MICROBIOTA: THE INTERSECTION BETWEEN DIET AND HEALTH?

Donovan, Sharon.

B.S. and Ph.D. Dept Food Science and Human Nutrition, University of Illinois, Urbana, USA.

Over the past decade, our understanding of the composition of the gut microbiota has been advanced through the use of next generation sequencing approaches. More than 50 bacterial phyla have been detected in the human gut but, the gut microbiota are dominated by ~ 1000 microbial species belonging to the Bacteroidetes and the Firmicutes phyla. These microbes encode a substantially larger number of genes than the human host and interact with the host through specific receptors on gut epithelial, neural and immune cells as well as through the production of hormones and metabolites that signal to the host to influence health and disease. Studies in germ-free animals have shown that the gut microbiota are essential for normal gastrointestinal, immune, metabolic and cognitive development and function. Clinical and epidemiological studies have linked an imbalance of the normal gut microbiota, or dysbiosis, to gastrointestinal conditions such as inflammatory bowel disease and irritable bowel syndrome, as well as extra-intestinal diseases such as obesity, type 2 diabetes, and atopy. There is broad interest in better understanding how microbial dysbiosis is associated with non-communicable diseases as well as to develop strategies to manipulate the gut microbiota to improve health outcomes through diet. Two common approaches are the provision fermentable substrates (fibers and prebiotics) or live microbes (probiotics). Probiotics can be administered as supplements of single or multiple microbial species or by consumption of fermented foods containing live microbial species, such as yogurt. This presentation will focus on how dietary intake impacts the gut microbiome and the potential benefits of probiotics on the gut microbiome and disease.

Keywords: Gut microbiota, non-communicable diseases, diet, probiotics

Conflict of Interest disclosure: Dr. Donovan serves as co-Chair of the Yogurt in Nutrition Initiative (YINI) and received travel support and an honorarium to present at the IUNS meeting.

YOGURT INTAKE AND PREVENTION OF CARDIOMETABOLIC DISEASES: THE ROLE OF FERMENTATION PRODUCTS

Marette, Andre.

Ph.D. Biochemist. Cardiology axis of Laval Hospital, Department of Medicine. Laval University. Quebec. Canada.

A healthy dietary pattern has been identified as a pillar for the prevention of weight gain and cardiometabolic diseases (CMD). A growing body of evidence suggests that yogurt consumption is linked to healthy dietary patterns, lifestyles and reduced risk of CMD, particularly type 2 diabetes (T2D). However, to date, there have been few to no randomized clinical trials (RCT) investigating yogurt intake in relation to cardiometabolic clinical outcomes. Furthermore, there has been little attempt to clarify the mechanisms that underlie the potential beneficial effects of yogurt consumption on CMD. Yogurt is a nutrient dense dairy food and has been suggested to lower weight gain and prevent CMD by contributing to intakes of protein, calcium, bioactive lipids and several other micronutrients. In this presentation we will focus on recent evidence that dietary proteins are key regulators of immunometabolic factors and the gut microbiota. In addition, fermentation with bacterial strains generates bioactive peptides from dairy proteins resulting in a potentially greater beneficial effect of yogurt on metabolic health compared with non-fermented dairy products such as milk. I will outline potential mechanisms that can underlie the inverse associations between yogurt intake and incidence of CMD and that are related to its bacterial constituents and bioactive peptides released during fermentation and compared with other fermented or non-fermented dairy products. A review of current gaps and challenges in identifying such mechanisms, and a perspective on future research needs that are necessary to validate the proposed role of yogurt in protecting against CMD will also be provided.

IMPROVING YOUR DIET WITH FERMENTED FOODS: HARMONIZING DIETARY GUIDELINES INCLUDING FERMENTED MILKS

Salminen, Seppo.

Professor, Director, Faculty of Medicine, Functional Foods Forum, University of Turku, 20014 Turku, Finland.

Microbes are an essential part of our environment and food. Beneficial microbes derive mainly from fermented foods which have a long history of safe use The species Lactobacillus has been defined as the 5th most important factor for human evolution due to the importance of lactobacilli in food fermentation and health promotion by strengthening intestinal mucosal barrier. Yogurt is defined as milk fermented with Streptococcus thermophilus and Lactobacillus delbrueckii subsp. bulgaricus (Codex Standard Number 243/2003) with the organisms viable through the shelf-life.

Yogurt and fermented milks are a significant sources of viable bacteria and fermentation products which enhance nutritional quality and palatability of milk and provide metabolites, enzymes (eg. lactase) and flavor components. In Europe, only one health claim has been approved for beneficial microbes: yogurt improves the handling of lactose. Five EU member states have national nutrition guidelines or recommendations that include either probiotics or yogurt with live bacteria. A recent report demonstrates that yogurt is recommended as a good source of nutrients in many countries (14 EU member states recommend yogurt as a recommended part of local diet and nutrition). Five of them explicitly mention probiotic beneficial effects and four give examples of probiotic bacteria. Several physiological effects of probiotics are well established. Yogurt and yogurt with probiotics, have benefits to humans: yogurt is easily digestible with live microbes. The inclusion of yogurt in food based dietary guidelines has been suggested and knowledge on health benefits suggest opportunities for evidence-based dietary guidelines with yogurt and yogurt with probiotic bacteria.

Keywords: Dietary guidelines, fermented foods, fermented milks

Conflict of Interest disclosure: Prof Salminen serves as member of the Yogurt in Nutrition Initiative (YINI) and received travel support and an honorarium to present at the IUNS meeting

HEALTH BENEFITS OF FERMENTED DAIRY FOODS: MICROBIOTA AND BEYOND

Hutkins, Robert.

Ph.D. Microbiologist. Department of Food Science and Technology. University of Nebraska. USA.

Increased consumption of yogurt, kefir, and other fermented dairy products has been driven, in part, by the health benefits these products are thought to confer. For example, epidemiological studies have shown that yogurt consumption is generally associated with reduced risks of type 2 diabetes (T2D), metabolic syndrome, and heart disease, and improved weight management. Although these products are good sources of protein, calcium, and other nutrients, the live microorganisms present in these products are now considered responsible for many of these health benefits. Included are the yogurt starter culture organisms, Streptococcus thermophilus and Lactobacillus delbrueckii subsp. bulgaricus, as well as strains of Bifidobacterium and Lactobacillus added specifically for their probiotic properties. The physiological mechanisms by which these microbes interact with the gut microbiota and contribute health benefits are now the subject of considerable interest. One major topic of research for establishing a role for these

organisms is the well-known phenomenon of colonization resistance. Specifically, the healthy human gastrointestinal tract contains a diverse, complex, and stable microbiota that is resistant to colonization by exogenous microorganisms. These could include pathogenic organisms as well as bifidobacteria and lactobacilli that are added to fermented milk products as probiotics. Nonetheless, clinical studies have reported several health benefits from yogurt consumption for several conditions. Among the most well established effect is the role of yogurt bacteria on improving lactose digestion in individuals with lactose maldigestion, mediated via in vivo expression of the lactose-hydrolyzing enzyme β-galactosidase. However, clinical evidence has also emerged showing that consumption of yogurt containing probiotics also improves both intestinal and extra-intestinal health. Examples include infectious diarrhea, respiratory infections, and improved immune and anti-inflammatory response. More recently, the effect of probiotics and probiotic yogurts on behavior and the microbiota-gut-brain axis has become an active area of research.

SSS_144/1012

CHRONONUTRITION: CHRONOBIOLOGY INFLUENCE ON FOOD INTAKE AND METABOLIC HEALTH

AN INTRODUCTION TO CHRONONUTRITION: IS WHEN YOU EAT AS IMPORTANT AS WHAT YOU EAT?

Escobar, Carolina.

PhD. Research Professor. Department of Anatomy. Faculty of Medicine. Universidad Nacional Autónoma de México. México.

In the last 20 years the role of the time of food ingestion has shown to be a main factor for metabolic balance and weight gain. Why the time? How does this influence energy balance?

Research in chronobiology using experimental animals as well as clinical studies have evidenced that the efficiency and the response of organs involved in digestion and nutrient metabolism varies along the 24 hours. This confers a dynamic and economic system that increases the metabolic activity during hours when individuals are expected to be awake and lowers this activity in order to save energy during rest and seep hours. The circadian system transmits time signals and coordinates all involved organs so that they can give high or low orchestrated responses. The main entraining signal from the environment to the circadian system is the light-dark cycle, however the cycles of feeding –fasting have proven to be powerful time signals for several organs and brain systems that coordinate metabolism.

Recent research indicates that ingesting food at the time when the circadian system indicates a sleep stage elicits conflicting energy training signals and disrupts the expression of circadian rhythms. Also ingesting food at the wrong time has a bad metabolic outcome favoring the development of overweight, and metabolic syndrome. This condition is promoted by night-work, jet-lag and "social" jet-lag, affecting a wide proportion of individuals.

In my conference I will present experimental studies where the mechanisms linking the circadian system with the metabolic outcome is discussed. The relevance of feeding patterns, will be discussed in the context of different experimental models for night-work, jet-lag and social jet-lag, and their consequence on body weight and indicators for metabolic syndrome. The impact of a disrupted feeding pattern on the circadian system will also be discussed. The main message is that the time of food ingestion can disrupt the circadian system and that a homeostatic condition can only be achieved when the time of feeding is orchestrated with the temporal signals for sleep and wakefulness given by the circadian clock.

Data presented have been supported by CONACyT 239403 and DGAPA-PAPIIT IG200417.

THE HUMAN CIRCADIAN TIMING SYSTEM AND ITS INFLUENCE ON METABOLIC PROCESSES

Scheer, Frank.

Brigham and Women's Hospital and Harvard Medical School. USA.

Obesity and diabetes have obtained epidemic proportions and contribute significantly to cardiovascular disease and mortality. Most research and clinical attention has focused on the importance of what we eat and how much we exercise in these developments. However, in recent years it has become clear that also other modern life style changes such as the timing of food intake, of physical activity and of sleep importantly impact metabolism and cardiovascular risk factors. This presentation will focus on the role of the endogenous circadian system, and its interaction with a disturbed timing of the behavioral/environmental sleep/wake, rest/active, fasting/feeding, and dark/light cycles on cardiometabolic function. For example, the circadian system and circadian misalignment (i.e., the misalignment between the circadian system and the

behavioral/environmental cycle) influence glucose metabolism, energy expenditure, food intake, weight regulation, inflammation, and cardiovascular function in humans. These new observations provide possible mechanistic evidence for the adverse cardiometabolic effects observed with shift work, late night snacking, and circadian-related gene variants. Given the high prevalence of sleep restriction, sleep disorders, and shift work, as well as the increasing rate of diabetes and obesity, there is an urgent need to increase our understanding of the impact of sleep, circadian rhythm, and their disturbances on cardiometabolic function and disease. The objectives of my talk will be to (a) discuss the effects of the human circadian system and circadian misalignment on glucose control, metabolism, inflammation, and cardiovascular function; (b) present data on the effect of melatonin and its interaction with type 2 diabetes risk variant MTNR1B on glucose control; and (c) discuss the evidence for the importance of not just what you eat, but also of when you eat for health and disease.

Keywords: Circadian misalignment, circadian rhythms, metabolism, glucose, weight regulation

CHRONIC FORCED CIRCADIAN DESYNCHRONIZATION AFFECTS LOCOMOTOR ACTIVITY, BODY WEIGHT AND METABOLISM IN MICE

[1]Golombek, Diego; [2]Casiraghi, Leandro; [3]Alzamendi, Ana; [3]Giovambattista, Andres; [1]Chiesa, Juan Jose.

[1]National University of Quilmes. National Research Council (CONICET). Argentina.; [2]National University of Quilmes. Argentina.; [3]Unidad de Neuroendocrinologia, IMBICE (CONICET-CICPBA). Argentina.

Circadian rhythms control our daily activities; indeed, circadian disruption in animal models and humans has a profound effect on our behavior and physiology. Chronic desynchronization results in changes in mood, immune and endocrine variables (among many others) and even susceptibility to disease. In addition, metabolic functions are synchronized by the circadian clock setting daily patterns of food intake, nutrient delivery, and behavioral activity.

We have developed a murine model of chronic circadian desynchronization and found that it induces significant changes in locomotor behavior, resulting in two independent bouts of daily activity (i.e., internal desynchronization). Moreover, we studied the impact of chronic jet-lag (CJL) on metabolism, and tested manipulations aimed to overcome potential alterations.

We recorded weight gain in C57Bl/6 mice under chronic 6 h advances or delays of the light–dark cycle every 2 days (ChrA and ChrD, respectively). Indeed, ChrA, but not ChrD, induced forced desynchronization of locomotor activity rhythms in mice. Body weight was rapidly increased under ChrA, with animals tripling the mean weight gain observed in controls by day 10, and doubling it by day 30 (6% vs. 2%, and 15% vs. 7%, respectively). Sig-

nificant increases in retroperitoneal and epididimal adipose tissue masses (172% and 61%, respectively), adipocytes size (28%), and circulating triglycerides (39%) were also detected. Daily patterns of food and water intake were abolished under ChrA. In contrast, ChrD had no effect on body weight. Wheel-running, housing of animals in groups, and restriction of food availability to hours of darkness prevented abnormal increase in body weight under ChrA. Our findings suggest that the observed alterations under ChrA may arise either from a direct effect of circadian disruption on metabolism, from desynchronization between feeding and metabolic rhythms, or both. Direction of shifts, timing of feeding episodes, and other reinforcing signals deeply affect the outcome of metabolic function under CJL. Such features should be taken into account in further studies of shift working or other disrupting schedules in humans.

MICRONUTRIENTS FOR OPTIMUM HEALTH

VITAMINS AND MINERALS DEFICIENCIES: THEIR ROLE IN CHRONIC NON COMMUNICABLE DISEASES

Katz, Mónica.

Dr. Favaloro University. Buenos Aires. Argentina.

Micronutrients are essential to sustain life and for optimal physiological functions. Hidden hunger is a global health issue. Micronutrients deficits coexist. It presents with no clinical symptoms but can interfere with an optimal health and lead to several chronic diseases. Micronutrients intervene in immunity, inflammation, oxidative damage, are cofactors and coenzymes in several metabolic pathways, modulate genomic stability processes, act as glycation inhibitors, anti oxidants and have a protective effect on bone health, diabetes mellitus and cardiovascular disease. Suboptimal levels of micronutrients are associated with metabolic anomalies that can be prevented: molecular damage associated to aging, repair failure caused by chemical and physical changes like cross linking, advanced glycation end products (AGEs), free radicals (oxidative damage) and changes in the cellular / matrix structure / function. There are many risk groups for developing vitamin and mineral deficiencies: women, pregnant women, people who carry out diets for medical or cosmetic reasons, athletes, dancers, older adults, vegans, bariatric patients, and even lonely people. In fact each adult can suffer during the course of his life from any deficiency because modern diet patterns in general show a low correlation with the current dietary guidelines recommendations. Food consumption is a biomarker of diet quality and a strong determinant of health disease processes. There is an association between consumption of specific food or nutrients with increased risk or a protective effect for developing chronic diseases like obesity, type 2 diabetes, and osteoporosis. Aging process is inevitable. But the damage can be maintained at a sub patogenic level to prevent chronic diseases. The treatment of vitamin and mineral deficiencies is one of the most extraordinary development-related scientific advances of recent years. Probably no other public health strategy available today offers an opportunity to improve lives and accelerate development at such a low cost and in such a short time. Eliminating hidden hunger will not be easy. Challenges lie ahead. Much still needs to be done to ensure that people around the world gain access to nutrient-rich foods and diversified diets. Meanwhile two other strategies are at reach: fortifying foods and multivitamin-mineral supplementation.

STATUS AND NUTRITIONAL GAPS IN ARGENTINA: UPDATED EVIDENCE

Britos, Sergio.

University of Buenos Aires. Buenos Aires. Argentina.

The first National Nutrition Survey in Argentina was conducted eleven years ago; the study represented a complete diagnosis of the prevalence of different forms of malnutrition, children and women dietary patterns and insufficient intake or excess of different nutrients. After the survey, only studies with a more limited representation have been carried out. The three editions of the National Risk Factors Survey (ENFR), included indicators about food patterns and anthropometric measures in the adult population, and reported a high prevalence of overweight and obesity (57,6%) and low intakes of nutrient rich foods.

A dietary pattern with low intakes of high nutrient-dense foods combined with high consumption of high caloric density ones is associated with the development of obesity, especially if accompanied with low caloric expenditure patterns.

The analysis of these aspects of diet quality has been the focus of our studies in the last seven years, through two lines of research: we analyzed the food gaps of general population, measuring each food group consumption against the recommendation of dietary guidelines and expert organizations (WHO). We also described the nutritional gaps, both in the local market available foods and in the consumption pattern of the population. The nutritional gap is the difference between the nutrient profile of nutrients to limit or to promote and its standard values developed from nutrient density recommendations.

In general population (2012) the most significant gaps for low consumption were in vegetables, fruits and grains and whole grains (average -66%); Also in dairy products (-39%) and on the other hand excesses gaps were described in sugars, flour, bakery and very refined cereals and meats (in all cases above 50%). When nutrient profile was aplied to foods, the main nutritional gaps were found in sweetened beverages, sweets, processed meats and cheese.

The results on food gaps for deficits were also analyzed in another study, in this case a representative national survey in a sample of 1000 adults over 18 years old (2015). Only 17% of the population reported they reached the recommended consumption of three or more groups of food guides simultaneously.

Both lines of research allow us to conclude that the high prevalence of overweight in children and adults in Argentina is accompanied by malnutrition caused by inadequate intakes of essential nutrients due to low consumption of their food sources.

Based on this background, we will present model scenarios oriented to calculate the improvement in diet quality (NRFI and NutriScore methods) in children and adults through different mix of increase in the consumption of essential nutrients food source and decrease in nutrients to limit ones.

VITAMIN D AND IMMUNE FUNCTION

Gombart, Adrian.

PhD. Linus Pauling Institute. Department of Biochemistry and Biophysics. Oregon State University. United States of America.

Inadequate levels of vitamin D due to deficiency and insufficiency are a global health issue for over one billion individuals. This includes regions of North and South America, Africa, Europe, Australia and Asia where one would assume that sun exposure is sufficient for efficient cutaneous vitamin D synthesis. The modern lifestyle of many populations limits synthesis via UVB exposure due to extended time spent indoors and the use of topical sunscreens. Older individuals are particularly prone to low vitamin D serum levels as cutaneous synthesis is less efficient due to age related changes of the skin and their reduced levels of outdoor activity. Insufficient vitamin D levels are associated with poor bone health, impaired muscle function, cardiovascular disease, cancer, autoimmune disorders and infectious diseases. Since the early 19th century, both environmental (i.e. sunlight) and dietary sources (cod liver) of vitamin D were identified as treatments for tuberculosis. The discovery that vitamin D induces antimicrobial peptide gene expression and the expression of other genes involved in immune function has greatly renewed interest in the ability of vitamin D-containing supplements to improve immune function by raising overall serum levels. The importance of vitamin D throughout the course of infection from the initial exposure to the pathogen through the resolution of tissue damage and inflammation indicates that individuals need to maintain adequate levels of vitamin D for an optimal immune response against both bacterial and viral infections. The prevalence of vitamin D deficiency both globally and in the Latin American region is strongly associated with increased risk for respiratory tract infections in adults and children. Several studies indicate that vitamin D deficiency may contribute to increased severity and duration of infection. Research findings support a role for vitamin D in immunity and protection against respiratory tract infections. A very recent systematic review and meta-analysis of individual participant data from randomized controlled trials showed that vitamin D supplementation protected against acute respiratory tract infection overall. Those patients that were severely deficient and started taking supplemental vitamin D daily or weekly benefited the most over those who received bolus doses. While many observational studies link low vitamin D levels and respiratory tract infections and numerous trials show that supplementing with vitamin D can lower one's risk of getting a respiratory infection, the results are mixed. Carefully designed studies to address supplementation dosing intervals and levels, and protective serum vitamin D levels will help determine if taking vitamin D supplements can protect against respiratory tract infections.

ROLE OF MICRONUTRIENTS FOR PUBLIC HEALTH

THE ROLE OF MICRONUTRIENTS FOR PUBLIC HEALTH

Eggersdorfer, Manfred.

DSM, Nutrition Science & Advocacy. Switzerland.

According to the World Health Organization (WHO), "in almost every country, the proportion of people aged over 60 years is growing faster than any other age group. This population ageing can be considered as a success story for public health policies and for socioeconomic development, but it also challenges society to adapt, to maximize the health of people." Life-long health promotion, with an emphasis on the fundamental role of nutrition and essential micronutrients to reduce risk of chronic disease, can prevent or delay the onset of non-communicable diseases, such as heart disease, diabetes, osteoporosis, Alzheimer disease, and others. Nutrition is recognized as being an important factor in optimal health throughout the life course and the United Nations declared the Decade of Action on Nutrition.

Nutrition is a complex topic in itself, and so are its fields of application. Nevertheless, a significant scientific and medical consensus exists as to the importance of an appropriate level of micronutrient intake throughout the life course to foster health, and prevent the onset of diseases. A balanced diet rich in fruits and vegetables can provide the essential micronutrients according recommendations; however, a major part of the population does not follow or achieve the recommendations. Food fortification and the use of supplements are proven, cost efficient and safe ways for an adequate intake of essential micronutrients. To increase the recognition of the importance of micronutrient interventions, policy makers, health insurers and other stakeholders should give a healthy diet, including the use of supplements, a higher priority. The health benefits of fortification or supplementation with micronutrients are evident; examples on health and reduction of health care costs will be presented.

Subsequent to these lectures the DSM Nutritional Sciences Award will be presented, whereas the award 2017 is dedicated to Human Nutrition, with special emphasis on vitamins, carotenoids, polyunsaturated fatty acids, enzymes, pre- and probiotics and naturally occurring bioactive compounds. Scientists from all parts of the world, who have made major contributions to fundamental or applied research in this field, were nominated for the award. An international judging committee has reviewed the nominations and select the winner. We are pleased to welcome the winner for a keynote lecture, followed by an award ceremonial and reception.

EATING PATTERNS AND DIETARY INTAKE OF INFANTS, TODDLERS AND CHILDREN: INSIGHTS FROM CROSS-COUNTRY ANALYSIS

INTRODUCTION TO FITS AND KNHS: METHODOLOGICAL CHALLENGES IN DIETARY INTAKE COLLECTION AMONG INFANTS, TODDLERS AND CHILDREN IN AUSTRALIA, CHINA, MEXICO, RUSSIA AND THE US

[1]Eldridge, Alison; [2]Afeiche Zehil, Myriam; [3]Denney, Liya; [4]Jacquier, Emma; [2]Kassis, Amira; [2]Mathias, Kevin; [2]Semenova, Iaroslava; [5]van der Horst, Klazine; [3]Wang, Dantong.

[1]PhD, RD. Expert Scientist. Institute of Nutritional Science. Nestle Research Center. Lausanne. Switzerland.; [2]PhD. Scientist. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.; [3]PhD. Senior Scientist. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.; [4]PhD. Country Lead Scientist USA. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.; [5]PhD. Group Leader Dietary Intake. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.

Background and objectives: The Feeding Infants and Toddlers Study (FITS) and the Kids Nutrition and Health Study (KNHS) are large-scale cross-sectional surveys designed to explore nutrient intakes, food sources of nutrients, eating patterns and key behaviors related to energy intake and expenditure in infants and children in different countries around the world.

Methods: In each country, dietary intake is assessed using trained interviewers and multiple-pass 24-hr recalls on one or more days. The FITS and KNHS use data from national nutrition and health surveys when available, but when data do not exist for our age groups of interest, we collect data using similar methods. To date, a common analysis approach has been applied across data from the following countries: Australia, China, Mexico, Russia and the United States (US).

Results: Although many countries that conduct national nutrition surveys employ 24-hr recalls for individual-level intake estimations, other aspects of the survey methodology differ considerably. Some do not collect intake information on infants or young children. Food composition tables vary, limiting accurate intake estimates to only a few nutrients in some places. Different countries use different age classifications and different food grouping schemes, making comparisons across countries more difficult. Not all surveys record details about the meals or times when foods are consumed. As much as possible, the FITS and KNHS have standardized reporting of age categories and food groupings so comparisons can be made. In addition, we have imputed missing values to complete data sets for nutrients of interest. When national survey data did not include the age categories needed, we have supported primary data collection to fill gaps in knowledge.

Conclusions: This presentation provides an overview of the individual studies and country data that comprise the current FITS and KNHS. The following presentations in this symposium will cover important nutritional issues in diets of infants, toddlers and children, including complementary feeding practices, intakes of total and added sugars, and the role of snacking in the diets of children.

Keywords: Dietary intake, child nutrition, survey

COMPLEMENTARY FEEDING AND THE TRANSITION TO FOODS OF THE FAMILY TABLE IN CHINA, MEXICO, RUSSIA AND US

[1]Denney, Liya; [2]Afeiche Zehil, Myriam; [2]Semenova, Iaroslava.

[1]PhD. Senior Scientist. Institute of Nutritional Science. Nestlé Research Center, Lausanne. Switzerland.; [2]PhD. Scientist. Institute of Nutritional Science. Nestlé Research Center, Lausanne. Switzerland.

Background and objectives: Timely introduction of appropriate complementary foods is essential for optimal growth and development of infants and young children. The aim of this study is to describe and compare complementary feeding practices in four culturally diverse regions represented by China, Mexico, Russia and the United States (US).

Methods: Dietary intake data on infants and toddlers aged 6-23 months in China, Mexico and US were from the Maternal Infant Nutrition Growth (MING) study 2012 (n=906), the Mexico National Health and Nutrition Survey 2012 (ENSANUT) (n=767) and the Feeding Infants and Toddlers Study 2008 (FITS) (n=1430) respectively. Dietary intake data on infants and toddlers aged 7-23 months in Russia were from the Russian National Nutrition Survey 2013 (n=3294). In each study, trained interviewers collected 24-hour dietary recalls from parents or caregivers on behalf of their children. The percentage of infants and toddlers consuming foods from specific food groups and the average amount consumed (per capita) was estimated and presented for 3 age groups.

Results: The percentage of infants consuming breast milk was generally low, ranging between 33-58% at 6-8 months and 33-43% at 9-11 months. Several large differences in complementary food consumption were observed. In China, cow's milk consumption was very low whereas infant formula/growing-up milk was highly consumed (270-317g/d). Rice was a main grain consumed at all ages. In Mexico, infant cereal consumption was low, while a substantial amount of cow's milk was consumed before 12 months of

age. Sugar sweetened beverages were highly consumed in all age groups and the amount increased significantly with age (64-219g/d). In Russia, infant cereal consumption was low whereas white potatoes were highly consumed as a vegetable. Consumption of sugar sweetened beverages in Russia appeared to be the highest (114-242g/d) across the 4 countries. In the US, consumption of vegetable and fruit baby foods resulted in higher overall vegetable and fruit intakes among infants compared with other countries. However, vegetable consumption was significantly reduced after 12 months of age. 100% fruit juice was a main beverage and highly consumed at all ages.

Conclusions: In this study, early feeding of relatively high amounts of empty calorie foods, such as sugar sweetened beverages and sweets and high consumption of low-nutrient dense food such as rice or white potatoes was observed. This compromises intakes of more nutritious foods such as vegetables and fortified infant cereals. In addition, early introduction of cow's milk was found in Mexico. These findings provide culture-specific and food based information for healthcare professionals to understand the improvement needs in their country and offer more targeted guidance on complementary feeding practices.

Keywords: Complementary feeding; China; Mexico; Russia; US

INTAKE OF TOTAL AND ADDED SUGARS AMONG CHILDREN IN AUSTRALIA, CHINA, MEXICO, RUSSIA AND US

[1]Eldridge, Alison; [2]Afeiche Zehil, Myriam; [3]Shaheen Koyratty, Bibi Nadia; [4]Wang, Dantong; [2]Semenova, Iaroslava; [2]Mathias, Kevin; [5]Jacquier, Emma; [4]Lê, Kim-Anne.

[1]PhD, RD. Expert Scientist. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.; [2]PhD. Scientist. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.; [3]MS. Student. Epidemiology and Environmental Health. The State University of New York at Buffalo. USA.; [4]PhD. Senior Scientist. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Swizterland.; [5]PhD. Country Lead Scientist USA. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Swizterland.

Background and objectives: Sugar consumption is high across the world. However, it is unclear to which proportion added sugars contribute to total sugars, and how intakes differ across geographies. Targets to limit consumption have been set by various national and international organizations. The aim of this study was to assess differences in intakes of total- and added sugars in 4-13y old children in China, Mexico, the US, Australia, and Russia. The secondary aim was to identify main sources of total- and added sugars in the diets of these children.

Methods: Secondary data analysis was conducted using the 2011 China Health and Nutrition Survey, 2012 Mexican National Health and Nutrition Survey, 2009-2012 US National Health and Nutrition Examination Survey, 2011-12 Australian National Nutrition and Physical Activity Survey, and the 2013 Russian National Nutrition Survey. Total- and added sugar intakes were calculated using the US Food Patterns Equivalents Database for China, Mexico, and the US; and using the respective national food composition databases for Australia and Russia.

Results: US children had the highest mean intakes of added sugar (76g/d), followed by Russian (68g/d), Australian (59g/d), Mexican (55g/d), and Chinese (9g/d) children. Intakes of total sugars followed a somewhat similar order, with Russian children having a mean intake of 127g/d, followed by US children with 124g/d, Australian children with 121g/d, Mexican children with 92g/d, and Chinese children with 26g/d. The top food sources of total sugar in China were fruits and vegetables, contributing to 42% of intake among Chinese children. Beverages (such as sugar-sweetened beverages, fruit drinks, and milk-based beverages) were the top sources of total sugar in other countries, contributing to 50% (Mexico), 44% (US), 33% (Australia), and 33% (Russia) of the total sugar in diets of children in these countries.

Conclusions: Despite very distinct geographies and cultures, it appears that in all countries studied except China, beverages are the major source of total sugar intakes. This strengthens the need to have global public health and industry efforts towards this specific product category, as it is a high contributor to sugar intakes in children in many countries.

Keywords: Total sugars, added sugars, children, food sources

THE ROLE OF SNACKING IN THE DIETS OF CHILDREN IN AUSTRALIA, CHINA, MEXICO AND US

[1]Jacquier, Emma; [2]Afeiche Zehil, Myriam; [2]Mathias, Kevin; [3]Wang, Dantong.

[1]PhD. Country Lead Scientist. USA. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.; [2]PhD. Scientist. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.; [3]PhD. Senior Scientist. Institute of Nutritional Science. Nestlé Research Center. Lausanne. Switzerland.

Background and objectives: Eating between main meals or "snacking" is becoming more prevalent world-wide. Eating patterns and snacking behaviors are strongly influenced by culture. Our objective is to evaluate the similarities and differences in snacking habits among children from Australia, China, Mexico and the US.

Methods: National survey data were used for the comparisons across countries, including the National Nutrition Survey 2011-12 (Australia), the China Health and Nutrition Survey 2011 (China), the Mexican National Health and Nutrition Survey 2012 (ENSANUT; Mexico), the Feeding Infants and Toddlers Study 2016 (US)

and National Health and Nutrition Examination Survey 2009-2012 (NHANES; US). Trained interviewers collected 24-hr dietary recalls from parents or caregivers (for younger children) or from the children themselves. Snacking occasions were either defined by the participants (China, Mexico, US) or by time of day of consumption between meals (Australia).

Results: Snacking frequency varied widely across countries, with only 11.4% of 4-8y and 7.5% of 9-13y consuming snacks in China, in contrast to 98.9% of Australian children 2-16y consuming snacks. Snacking prevalence was intermediate in Mexico with 69.3% of 4-8y and 66.7% of 9-13y consuming snacks on any given day. The frequency of snacking in the US approached Australia (96.6% and 94.8% for 4-8y and 9-13y, respectively). FITS 2016 data demonstrated that snacking patterns appear in the toddler/preschool years, stabilizing to provide approximately 25% of energy from snacks from 3y. US children continued to get 25% of energy from snacks from 4-13y. Snacks contributed 11.4% of daily energy for Chinese 4-8y olds and only 7.5% for 9-13y. In Mexico, snacks contributed 15.2% of energy for 4-8y and 14.9% in 9-13y. In contrast, 33.6% of daily energy came from snacks among children in Australia. Foods consumed during snacks also varied widely: Chinese children most frequently consumed fruits and dairy; Mexican children preferred salty snacks, candy, and fruit; children in the US consumed milk and sweet bakery (mostly cookies); and children in Australia consumed fruit/vegetable juices or drinks and bread or rolls.

Conclusions: Despite differences in survey methodology, a common analysis approach provided valuable insights into snacking behaviors around the world. Snacking habits and foods consumed as snacks are important contributors to energy in the diets of children, but amounts and foods consumed vary considerably among the countries studied. In addition, we found that many of the foods typically consumed as snacks are needed to help children meet dietary recommendations, but there is still room for improvement in many snacking choices for children.

Keywords: Snacking, children, dietary intake.

THE ROLE OF FAMILY/PARENTS IN NURTURING HEALTHY EATING HABITS IN CHILDREN

THE ROLE OF FAMILIES IN NURTURING HEALTHY EATING HABITS IN CHILDREN

Goulet, Olivier.

MD. PhD. Necker Enfants Malades Hospital. University Paris Descartes. President of the Danone Institute International. France.

With the increasing development of a 'global' world, many social, economic and cultural issues arise as the family structure evolves from a more traditional model. Busy parents struggle to balance work and family life, resulting in less time to prepare and share mealtimes together as a family, and less time to enjoy quality moments together.

Across the world, the incidence and prevalence of overweight and obesity are reaching alarming levels . A growing body of evidence indicates that the family environment plays an integral role in children's and adolescents' weight status and unhealthy weight-related behaviours.

Childhood is a formative period for the development of children's healthy eating habits; consequently, it is a crucial time to build the most optimal foundations for positive and sustainable health behaviours.

The home environment is a critical source of positive influence, with the family having a great impact upon the shaping of children's first choice foods, therefore a family-centred approach is of crucial importance.

Danone Institute International (DII) gathered experts (dieticians, nutritionists, pediatricians, psychologists, sociologists, and public health professionals) to work together in collecting data, to develop a unique perspective on the topic.

It clearly emerged that to positively impact children's healthy eating, it is essential to shift the emphasis from "what we eat" to "how we eat".

Three key levers, supported by a strong body of evidence, all related to the family, have been identified, which all have a special emphasis on the pleasure of eating: Positive parenting, Eating together and a Healthy home food environment.

With three distinguished experts in the field, this symposium aims to share a consensus on key recommendations, by identifying relevant and innovative strategies to support families in making positive decisions for nurturing healthy eating in children.

Keywords: Healthy eating habits, children, eating together, healthy home food environment, food parenting

PARENTAL SOCIALIZATION OF HEALTHY EATING HABITS AMONG CHILDREN

Hughes, Sheryl.

PhD. Developmental Psychologist. USDA ARS Children's Nutrition Research Center. Baylor College of Medicine. Houston. Texas. USA.

Developmental theory posits that parents socialize their children by encouraging them to internalize the goals and values that parents deem important. The goal of most parents is that, by early adulthood, their children will be making appropriate choices in their daily lives. When it comes to healthy eating, the parenting environment remains the first and most fundamental context in which children's eating behaviors are socialized. Child eating socialization is characterized by at least three broad areas of food parenting: 1) coercive control, 2) structure, and 3) autonomy

support. Food parenting used by parents of young children may not be appropriate for older children and adolescents. During a child's early years, more guidance is needed as parents teach children basic eating skills, promote appropriate food preferences, and support child eating self-regulation. During the elementary school years, when children experience a wider range of food environments, parents change their behaviors to more developmentally appropriate practices to promote healthy eating in children. During adolescence, parents continue to guide eating behaviors by supporting autonomy in their children with the hope that the youth will internalize the norms and values accepted within the extended family.

A recent literature review highlighted the food parenting practices that either foster or hinder the development of healthy eating habits in children. In younger children (preschool through kindergarten), the use of coercive control is common. Collectively, coercive control strategies with young children have been shown to be related to higher consumption of unhealthy foods. In contrast, the use of structure (i.e., monitoring) and autonomy support (i.e., encouragement and praise) were shown to be related to healthier child eating habits. In elementary school aged children, the use of coercive control continued to be seen; however, the use of these food parenting practices with child food intake appeared to show little impact on intake. Structured activities (availability, accessibility, and modeling) were associated with healthier eating in this age group. It was expected that autonomy promotion (i.e., modeling, encouragement and praise) would be used extensively with older children and adolescents. However, our literature review did not show the use of these practices—at least in the empirical studies we located. We will critically review the evidence supporting associations between coercive control, structure, autonomy support, and child food intake in these age groups. In addition, we will point to gaps in the literature and discuss where future research should be targeted.

IMPROVING CHILDREN'S EATING HABITS THROUGH EATING TOGETHER

Haines, Jess.

Department of Family Relations and Applied Nutrition. University of Guelph. Guelph. Canada.

Eating together is generally regarded as a child having a planned meal with at least one parent. While the frequency of eating together varies by geographic region, research suggests that the number of meals that children report eating with their families has been declining over the past four decades. Numerous observational studies have found that eating together has a positive sustained impact on children's dietary intake. This may because foods eaten together as a family are healthier than those consumed alone or outside of the home or the time spent together as a family allows parents an opportunity to model healthful dietary intake and eating patterns. Observational research has also found that regularly eating meals together is associated with lower risk of obesity among children and adolescents. As a result of these findings, the American Academy of Pediatrics and the European Society for Pediatric Gastroenterology, Hepatology and Nutrition recommends that families should regularly eat meals together as part of childhood obesity prevention strategies. One key limitation of these findings from observational studies is that families who eat meals together may differ from those who do not eat together on characteristics, such as family functioning or level of chaos in the home, which may influence child diet and weight outcomes. Failing to appropriately account for these potential confounders may result in biased estimates of the impact of eating together. To address this limitation of observational research, researchers have begun to design and test interventions to increase the frequency of families eating together. The focus of this presentation is to critically review the observational and intervention research on eating together. We will present key research findings on the associations between eating together and children's behavioural and health outcomes. We will also discuss results from existing intervention studies and their implications for future intervention efforts.

Keywords: Eating together, family meals, healthy eating, obesity prevention, children

HOW TO CREATE A HEALTHY HOME FOOD ENVIRONMENT

Lytle, Leslie.

PhD. Professor. Departments of Health Behavior and Nutrition. Gillings School of Global Public Health. University of North Carolina at Chapel Hill. North Carolina. USA.

The home food environment is the most proximal influence over youth eating behaviors and has a strong influence on the habituation of food practices that continue into adulthood. The home environment includes both physical and social factors that youth are exposed to. The physical environment includes the availability of and accessibility to foods in the home. The provision of healthy foods available at home and parental role modeling of healthful eating habits increases the likelihood that youth in the family will be willing to eat and enjoy a greater variety of healthy foods. Research suggests that not only is it important for families to provide healthy foods to their children but it is also important to help teach children how to be more intentional about what, when, where and how they eat. The social environment includes myriad factors that youth are exposed to by observing and interacting with the adults and other children living in the home. This social environment includes role modeling by parents and other household members, family rules around eating and meal time, and cues and reinforce-

ments for eating behavior. Creating a healthy home food environment requires a consideration of how to positively impact both the physical and social environments of homes. Using this framework, this session will discuss the interventions that have been tested to positively influence the home food environment and the best practices that have emerged from the empirical literature to date. We will also discuss the potential for future intervention efforts.

Keywords: Home food environment, family-based interventions, obesity prevention healthy eating habits

Conflict of Interest disclosure: I received speaker fees from Danone Institute International for this presentation.

SSS_144/1010

MINDFUL EATING APPLIED TO SNACKING: A BEHAVIORAL APPROACH SUPPORTED BY RECENT SCIENTIFIC FINDINGS (DRAFT)

SNACKING IN DIFFERENT PARTS OF THE WORLD: A MARKER OF DIETARY ANARCHY OR A USEFUL CONTRIBUTOR TO DIET QUALITY AND WEIGHT CONTROL?

Bellisle, France.

Nutritional Epidemiology. University Paris 13. France.

The present "epidemic" of obesity has been attributed to a growing trend for snacking (Murakami, 2015). Dietary surveys in various parts of the world reveal that "snacks" (eating occasions at other moments than main meals) do bring a significant amount of energy and nutrients to the daily diet. Even in countries where the traditional pattern of three "main meals" is maintained, most individuals snack at least once daily. One daily snack is frequent in France (mostly at the occasion of the traditional afternoon "goûter") but up to 8 or 12 habitual daily snacks have been reported in Scandinavian countries (Bellisle, 2014; Lund, 2014). In the USA, snacks have increased in frequency over the last decades and three or more snacks a day now bring over 23% of the daily energy in men and women (Kant, 2015). Snacks can represent between 4% (China) and more than 50% (Finland) of daily energy intake (Lund, 2014; Duffey, 2014). Clearly, the important contribution from snacks to the daily intake can affect body weight control and quality of the diet. A review of the abundant literature about snacking reveals at least two contrasting pictures (Bellisle, 2014; Hess, 2016). In many studies, snacking is presented in a favorable way, highlighting its contribution to the daily intake of valuable micronutrients and the flexibility it confers to adjust the daily energy intake to fluctuating energy needs. By contrast, other reports view snacking as a source of excessive energy intake, facilitating weight gain, with little contribution to the quality of the diet (1). The potential value of snacking is obviously modulated by the selection of good nutritional quality foods, but also by other types of factors, for example: eating in the absence of hunger in response to external non-physiological cues, irregular as opposed to regular

snacking, snacking while watching television or screen. Evidence exists that paying attention to the act of eating facilitates both satiation and satiety, perhaps by optimizing the sensory experience of ingestion and facilitating the memory processes that contribute to inhibiting further eating. The regularity of snacks can make them small "meals" that occur predictably in the daily schedule. The French "goûter" ingested by all children and many adults in the middle of the afternoon not only allows them to cope with the very long time interval between lunch and dinner, but generates the physiological responses usually triggered by regular meals. Physiological cues typically present at the outset of a "main" meal (among which a small decline in glycemia) are also present at the beginning of a regular "goûter", preparing the organism to respond to the nutrient load. Such physiological responses are not present when snacking is triggered by external cues in the absence of hunger. The potential beneficial effects of snacking (intake of valuable micronutrients, facilitated adjustment of intake to needs) take place when snacking is a regular, mindful eating event as opposed to an irregular, externally triggered, impulsive behavior.

EATING MINDFULLY AS A SUSTAINABLE HEALTHY BEHAVIOR: THEORY AND EVIDENCE

Kristeller, Jean.

Indiana State University. USA.

Mindful eating is a unique way of relating to the many food choices we face every day. Our minds and our bodies can provide us much wisdom, not only to eat in a more healthy and flexible way, without dieting, but also to enjoy our food more – not less. Although snacking is often identified as an undesirable aspect of food intake, evidence suggests that regular meals can be supplemented by snacks within healthy parameters, particularly in regard to quantity, but also related to quality of foods chosen. One of the challenges of highly restrictive diet programs, which generally curtail virtually all commercially available snack foods is that little awareness is developed regarding how to eat such foods in a more balanced, limited but sustainable way.

This presentation will provide an introduction to the basic elements of the Mindfulness-Based Eating Awareness Training (MB-EAT) program, including a brief introduction to the theory of mindfulness meditation and the mindful eating experiences used in the program (Kristeller, 2016; Kristeller & Wolever, in press). Core goals within the MB-EAT program, a structured 12 session manualized intervention, include heightening interocep-

tive awareness of physical hunger, taste, and fullness; heightening awareness of non-nutritive cues for eating, including thoughts and feelings, and external triggers such as the presence of food, and social pressure; and mindful use of nutritional information. Heightening awareness of taste satisfaction and taste satiety (sensory-specific satiety) is a core element throughout. Multiple eating awareness exercises occur across the program, including use of snack foods such as high energy dense foods, and participants' personally preferred snack foods. Rather than restricting these foods, which often results in rebound overeating, the message is to consider how to obtain maximal pleasure from smaller, rather than larger, quantities, and to make more mindful choices to reflect caloric and health needs. At the same time, healthier foods are also presented as important alternatives, but again, in a balanced rather than exclusive way.

The presentation will review research evidence from several NIH-funded clinical trials, application to a range of clinical populations, including those with binge eating disorder (Kristeller, Sheets, & Wolever, 2013; Kristeller & Wolever, 2011), type II diabetes (Miller, Kristeller, et al., 2012; 2014), and obesity-related eating patterns (Daubenmier, Moran, Kristeller et al., 2016). Our research to date suggests that individuals can bring compulsive overeating under control, improve emotional regulation related to eating, and decrease weight, and that improvement across a range of variables is associated directly with amount of mindfulness practice. The implications of this approach for helping individuals create a more balanced, sustainable, yet flexible relationship to eating and food, will be discussed.

Keywords: Mindful eating; MB-EAT; sensory-specific satiety; binge eating disorder; weight loss.

HOW MINDFULNESS CAN BENEFIT TO SNACKING?

Cornil, Yann.

Sauder School of Business. University of British Columbia. Canada.

The growing trend for snacking among children and adults over the past forty years has been potentially identified as one of the factors contributing to the obesity epidemic. Because of the type of food being consumed (high in calorie, sugar and fat), but also the timing of consumption (between meals) and the mode of consumptions (for instance, while watching TV), a habit of snacking represents a challenge for energy balance and body weight control. By contrast, evidence exists that "mindfulness" can benefit to snacking. Mindfulness typically increases consumers' awareness of and responsiveness to internal signals of satiety, but it also increases food enjoyment and savoring. It can thus decrease the occurrence of impulse-based or mindless snacking episodes, but also promote more qualitative snacking with the aim to appreciate the sensory quality of snacks rather than satisfying an appetitive impulse.

We know that satiety is only marginally influenced by the actual quantity of energy being ingested, and is largely driven by a vast array of cognitive factors, including consumption norms, visual perception of food quantity, and monitoring of eating (Cornil 2017). Hence, behavioral research has shown how purposeful changes in food marketing and environments can promote positive eating behaviors like mindful snacking, and more generally decrease food intake without reducing satiety or satisfaction (Chandon and Wansink 2012; Wansink and Chandon 2014). Small changes in package shape and dinnerware size can have a large impact on consumers' perception of food volumes, and therefore increase the perceived (but not the actual) amount of food being eaten (Krishna 2006; Van Ittersum and Wansink 2012). Size labels (for instance, labeling the same portion size "large" rather than "normal") and assortment sizes (for instance, adding an "extra large" or an "extra small" option in the choice set) influence consumption norms, and can thereby impact the satiating power of a snack for the same actual quantity (Aydinoglu and Krishna 2011; Sharpe, Staelin, and Huber 2008). Also, subtle cues can encourage better monitoring of eating and limit mindless eating sequences, leading to faster satiation—for instance, inserting potato chips of different colors at regular intervals in a tube of chips as a way to "segment" consumption (Geier, Wansink, and Rozin 2012).

Growing research inspired by mindfulness techniques has also shown that encouraging consumers to focus on the sensory characteristics of foods can increase eating enjoyment while reducing calorie intake (Tapper 2017). This is because a higher sensory focus increases awareness of and responsiveness to satiation cues, and in particular to "sensory-specific satiety", which predicts that the first few bites of a food are the most pleasurable, then pleasure declines with each subsequent bite. Hence, positioning a snack food as a way to emphasize its multisensory qualities (taste, aromas, texture) can increase the appeal of smaller portion sizes (Cornil and Chandon 2016). This shows that mindfulness techniques applied to foods can be a viable alternative to health warnings in order to encourage consumers to snack more healthily , while preserving—and even enhancing—the pleasure of eating.

Keywords: Mindfulness, snacking, portion size, satiety

FOOD FORTIFICATION: A NEW VISION FOR AN OLD PROBLEM

STUDY OF THE CONTRIBUTIONS IN BREAD RELATED TO THE CONTRIBUTION OF FORTIFICATION LEVEL OF IRON IN WHEAT FLOUR

[1]López, Ximena; [2]Geria, Rodrigo; [3]Salazar, Karen; [3]Arqueros, Valeria; [3]Gonzalez, Miluzka; [3]Benavides, Clara; [3]Trejo, Maricela.

[1]Master en Ciencia y tecnología de los Alimentos. Universidad de Valencia. España.; [2]Ingeniero Químico; [3]Ingeniero en Alimentos.

Flour Fortification is a very old Public Health Program in Latin America, even beginning in Chile in 1958, after the countries of North America. Although some countries have joined just a few years ago, there are already 33 countries in the Region that are fortifying wheat, corn and rice flour. Mostly wheat and corn flour are subscribed as Public Fortification programs and are monitored by the Ministries of Health of each country.

The objective of this work is to have a vision of the levels of iron found in the bread from Flour Fortification. This work will be carried out in five countries: Mexico, Ecuador, Peru, Argentina and Chile, where 180 samples will be obtained from typical high-consumption bread that is sold in bulk in the most populated and representative urban sectors of the capital area.

Once the bread samples were obtained, the iron tracer was selected as an indicator that the flour used was fortified. The analytical determination of Iron used is by Atomic Absorption Spectroscopy. A methodology based on the Official Method A.O.A.C. 999.10. In this way, we wish to show in a very simple way, what is the actual benefit of iron and establish what its contribution means on the health of people.

EPIDEMIOLOGY OF MICRONUTRIENT DEFICIENCY IN LATIN AMERICA, PUBLIC HEALTH SIGNIFICANCE

Morán, Javier.

Catholic University of Murcia (UCAM). Spain.

We reviewed at this conference the epidemiology of micronutrient deficiency in Latin America with special reference to the iron deficiency and how these deficiencies have a great impact in terms of public health.

We also review the interest of the fortification of new food matrices that allow the fortification to be carried out to all the population and particularly to children and adolescents.

Keywords: Food fortification; iron deficiency; public health

NUTRIENT PROFILING STRATEGIES IN LATIN AMERICA AND ITS INFLUENCE ON THE CONTROL OF MICRONUTRIENT DEFICIENCY

[1]Gil, Ángel; [2]Soto-Méndez, María José.

[1]PhD. Prof. Department of Biochemistry and Molecular Biology. Institute of Nutrition and Food Technology. Centre of Biomedical Research. University of Granada. CIBERobn. Spain.; [2]Ph.D. Scientific Coordinator. Fundacion Iberoamericana de Nutrición. Granada. Spain.

The increasing of overweight and the obesity epidemic, in addition to the increase of diet-related non-communicable diseases, are among the main consequences of dietary changes, in conjunction with the physical inactivity of the populations.

Within the context of interest of the Latin American countries, already affected by obesity and non-communicable chronic diseases, but still experiencing the problems of undernutrition and micronutrient deficiencies, governments and regional organizations have promoted actions of generating comprehensible, suitable, accurate and standardized information on the content of food products in order to allow the consumer to make healthier choices, promoting the consumption of more complete foods; all these actions can be reached by implementing Nutrient Profiling models.

The definition of Nutrient Profiling was proposed by the WHO in 2015 as "the science of classifying or ranking foods according to their nutritional composition for reasons related to preventing disease and promoting health".

There are nutrients classified as of public health relevance, some of them because of their harmful effects and high consumption (e.g. total fat, saturated fatty acids, trans fatty acids, sugars and sodium), and others for their positive effects on health but not reaching the daily recommendations (e.g. dietary fiber, unsaturated fatty acids, vitamins and minerals [vitamin D, iron, calcium, zinc, potassium]).

One of the first approaches of Nutrient Profiling was the regulation of claims; now the use has extended to other actions, for example, nutritional education conducted by health professionals, and be a guideline for consumers and assist them to make "healthier" decisions against a wide variety of products offered in the market, nutrient profiling strategies have also increased privately and publicly to establish industrial food labeling using graphs or representative symbols (logos) on the products to communicate nutritional information to the consumer or to label products as "healthy" food.

Several countries in Latin America, such is the case of Mexico, Costa Rica, The Caribbean, Ecuador, Peru, Bolivia, Brazil, Argentina and Chile, have developed initiatives that involve the use of Nutrient Profiling, as recent as 2016 a regional model of Nutrient Profiling was generated by the Pan-American Health Organization to be taken as basis for local policies in different countries.

Whether the nutrient profiling would be positively adapted by the countries taking into account the relevance of food groups, their role in the diet and the contribution of the nutrients to the overall diet of a population or a particular group within a population is an arising question.

The creation of nutrient profiling should respond to a systematic, transparent and logic methodological process, ideally agreed between the different sectors of each country or region involved (governmental organizations, public bodies, food industry and consumers' organizations). The proper use of Nutrient Profiling could lead to the Latin American consumers to select products that let them reach their micronutrient requirements and promote a more balanced diet.

Keywords: Nutrient Profiling, Public health. Nutrient information. Nutritional claims.

UNITED FOR HEALTHIER KIDS: A PROGRAM TO HELP PARENTS ESTABLISH HEALTHIER EATING AND LIFESTYLE HABITS

UNITED FOR HEALTHIER KIDS PROGRAM EXPERIENCE–IS IT ON TRACK TO ACHIEVE ITS GOALS: COUNTRY EXPERIENCES FROM PAKISTAN AND MEXICO

Das, Jai.

MD. Senior Instructor. Division of Women and Child Health. Aga Kahn University. Karachi. Pakistan.

The multi-level United for Healthier Kids program (U4HK), initiated and catalyzed by Nestlé, is intended to provide families with children under 12 years with new tools to inspire and enable dietary and behavioral change and focused on six behaviors. It was launched in countries around the world with each country choosing the behaviors and activities that apt to the local context. We will discuss two country examples of Mexico and Pakistan to gauge the success of U4HK so far. Both the countries vary in the burden of malnutrition as Mexico has one of the highest prevalence of childhood overweight and obesity, while Pakistan has one of the highest prevalence of childhood undernutrition and stunting.

Mexico was the first country to launch U4HK and chose four behaviors including 'Manage Portions', 'Choose Nutritious Foods and Varied Options', 'Choose to Drink Water' and 'Feed your Baby Like a Baby' and 'Move More, Sit Less. Multiple partnerships were developed with the Ministry of Health, Ministry of Education, Kimberly Clark and Televisa and multiple communication channels were used to create awareness and reach large segments of the population, including digital media, mass media by broadcasting a reality show. Pakistan focused on three behaviors including

'Choose to drink water', 'Move more sit less' and 'Choose nutritious & varied options'. It utilized various channels to communicate the selected messages including digital media, mass media and school platforms and engaged celebrities to endorse the messages.

It was intended to measure the success of the program at three levels - Reach, Engage, and Impact. Initial evaluation from these two countries suggest that U4HK has been successful in reaching and engaging with its target population as in Mexico, digital media generated more than 13.5 million exposures with sufficient engagement rates and Pakistan showed greater awareness amongst mothers regarding the behaviors. A study on purchase and consumption of food patterns in Mexican families with children under 12 years suggested increase purchase and use in the healthy basket and a decrease of the unhealthy basket, with greater increase in consumption of fruits and vegetables.

U4HK is a comprehensive program designed to help parents establish healthier eating and lifestyle habits for their kids. Its strength of forming partnerships and using multiple communication channels has been effective to broaden its exposure and reach a large target audience. U4HK will also aid global understanding to design, implement and evaluate multipronged approaches to changing behaviors.

BEHAVIOUR CHANGE PROGRAMS DRIVING HEALTHIER DIETS AND LIFESTYLES: WHAT DO WE KNOW?

French, Jeff.

PhD. Visiting Professor. Brighton University. Brighton. United Kingdom.

In this presentation a summary of what we currently know about how to design programmes aimed at influencing healthy diets and related lifestyle issues such as exercise will be presented. The presentation will cover what we know about the design characteristics of successful programmes including how they should be established, developed managed and evaluated. The presentation will be illustrated using examples of both success and failure from around the world. The presentation will also explore the role of different intervention 'Types' and 'Forms' and how these different approaches can be integrated into an effective and efficient programme mix.

Keywords: Social Marketing, diet, lifestyle, behavior change

Prentice, Andrew M.

PhD. FMedSci. MRC Unit The Gambia and London School of Hygiene & Tropical Medicine.

Malnutrition in all its forms threatens the health and development of hundreds of millions of children worldwide. The prevalence of stunting and underweight is gradually declining as many countries pass through the economic transition. But the decline in undernutrition is being more than offset by a global rise in childhood overweight and obesity that heralds a future explosion in nutrition-related non-communicable diseases.

There are numerous societal and environmental drivers of the growing obesity pandemic that will require cross-sectoral approaches if they are to be reversed. Many parents lack awareness of the importance of their children maintaining a healthy body weight through appropriate diets and exercise and, even if concerned by their child's weight status may lack the life skills to implement effective change within the family.

United for Healthy Kids (U4HK) is an international programme that sets out to empower families to live a healthier lifestyle. The programme offers advice, training and participatory strategies to help parents effect healthy change in six core skills: Manage Portions; Choose Nutritious and Varied Options; Choose to Drink Water; Enjoy Meals Together; Feed Your Baby Like a Baby; and Move More, Sit Less.

U4HK represents a new model of private-public engagement that seeks to mobilise multiple governmental, non-governmental and private agencies to maximise its reach and impact. Country-specific implementation of the programme utilises the core suite of evidence-based skills but tailored to local needs. Innovative use of social media platforms provides a powerful tool for dissemination and reinforcement of key messages, interactive engagement with families and evaluation of impact.

U4HK has so far been implemented in 13 countries and has reached over 150m participants.

FROM PPP TO PPE: A NEW OPPORTUNITY FOR ENGAGEMENT

Drewnowski, Adam.

Center for Public Health Nutrition, University of Washington, USA.

Multi-sectoral initiatives involving private industry are increasingly viewed as a necessary step to improve both diet quality and population health. Public private partnerships (PPPs) have addressed a number of global nutrition challenges, ranging from biofortification and fortification to the promotion of more nutrient-rich diets and healthier lifestyles . The Food and Agriculture Organization (FAO) and the World Food Program (WFP) look to industry partners to improve the quality of the global food supply.

The traditional role of the private sector has been to provide technical assistance, knowledge transfer, and financial support for activities ranging from preventing hunger to promoting optimum health. Companies have used PPPs to alleviate hunger, promote food security, or help develop microenterprises or small businesses. Often, those activities were led by policymakers, local health jurisdictions, or international agencies, with industry assuming a secondary role.

The multi-sectoral U4HK program was created in direct response to calls by international agencies for more engagement by private companies to address the double burden of malnutrition in low and middle income countries (LMIC). Its development was consistent with the published principles on creating PPPs to address complex public health nutrition issues. The challenges, risks and benefits of PPPs have been set out in influential past work, notably by Kraak et al. (2011). While preserving those principles, the U4HK program represents a novel type of private-public engagement (PPE), distinct from the traditional PPP structure. A central feature of PPE is that the private sector takes the leading role in bringing together multiple actors, including families, schools, communities, policymakers, the media, and NGOs. Here, the rapid growth of social media has made it possible to reach families directly with messages about optimum diets and child health.

The U4HK protocols followed standard principles, such as having a clearly defined and achievable goals, clear statements of work, rules, and responsibilities, as well as an evaluation component. Details of U4HK design and implementation will be presented in this symposium.

THE SIX HEALTHIER HABITS TARGETED IN UNITED FOR HEALTHIER KIDS

Rolls, Barbara.

PhD. Professor in Nutritional Sciences. Department of Nutritional Sciences. The Pennsylvania State University. Pennsylvania. USA.

United for Healthier Kids (U4HK) aims to create a social movement through social media platforms that target parents and carers of children up to 12 years of age. A panel of global, independent experts with different expertise in public health, behavioural psychology and nutrition, and with different geographical backgrounds advised U4HK on a framework of six healthier hab-

its to target. These are 'Manage Portions', 'Choose Nutritious and Varied Options', 'Choose to Drink Water', 'Enjoy Meals Together', 'Feed Your Baby Like a Baby', and 'Move More, Sit Less'. The habits were chosen based on in-depth evaluation of scientific evidence and were framed to affect a change in behaviours that could help minimize the risk of childhood obesity and under-nutrition. Each country in which U4HK is introduced choses which of the six behaviours will receive the most attention. The choices depend on and are tailored to the local context and the specific nutritional needs, health priorities, and available resources at each country location. Thus far, countries have chosen to activate up to 3 to 5 of the healthier habits. All countries have included 'Choose Nutritious and Varied Options' and 'Choose to Drink Water'. In this presentation, the science behind several habits and the varied ways they have been adapted and implemented by different countries will be discussed.

Keywords: Habits, dietary behaviors, under-nutrition, obesity

NUTRIENTS AND BEYOND NUTRIENTS: SOCIAL, CULTURAL, AND ENVIRONMENTAL DRIVERS OF FOOD CHOICES GLOBALLY

WHEN IS CHOICE AN OPTION?

Fischler, Claude.

PhD. Interdisciplinary Institute for Contemporary Anthropology (IIAC). EHESS/CNRS,.

Choice has become an omnipresent notion in nutrition and public health literature as well as in lay parlance. Consumers are told, or read in the media, that their choices of foods are detrimental to their health. They are repeatedly reminded that they have to make the right choices , i.e. the healthy choices.

Choice goes hand in hand with decision. An influential 2008 paper stated that 2.4 million deaths in 2000 can be attributed to personal decisions and could have been avoided if readily available alternative choices were made. In the paper, diet was one of the prominent sets of personal decisions involved.

The Oxford Dictionary defines decision as a conclusion or resolution reached after consideration. Using choice and decision to denote behavior implies assuming some degree of deliberation and/or intention. Assumed intentionality and free will make individual subjects the essential link in the causal chain. This in turn easily leads to holding them as solely responsible for their predicament.

Meanwhile, in recent decades, various disciplines, particularly in the social sciences (e.g. history, anthropology, sociology, social psychology), have shown that one of the most striking features of human eating is that it is an essentially social activity. In most societies, not just those labeled traditional, eating is performed collectively. It is regulated by a body of rules (etiquette) adjusting individual behavior to fundamental principles of solidarity, hierarchy, morality, propriety. Children are socialized into these rules on the occasion of meals. In more traditional societies, lone eating is stigmatized and the very notion of likes, dislikes and aversions, particularly about staple foods, is irrelevant or non-existent: to that extent, choice is simply not an option.

For several decades, in contemporary, affluent societies, individual autonomy has enjoyed ever increasing recognition in most areas of life, including eating. But even in those individualistic cultures most daily eating unfolds according to an implicit, cultural script, and social interactions can, according to context, both inhibit or stimulate food intake. Moreover, degree of individualization as well as appreciation of choice are shown to vary considerably, including across Western cultures.

The unfounded assumption that food is just another form of consumption and that what people eat essentially depends on free will, choices and decisions is not just a cause for repeated failure in nutrition education and public health campaigns. There is some indication that it helps make the problem worse by promoting anxiety, confusion and aberrant dieting.

It is urgent to integrate into nutrition the wide, cross-disciplinary spectrum of knowledge relevant to the understanding of the human omnivore's eating behavior and complex relationship to food.

Keywords: Food selection, food habits, social and cultural determinants, individualization

Conflict of Interest disclosure: CF has received funding from public agencies and private or semi-private sector to investigate structure and evolution of food and eating patterns.

TASTE RULES FOR KIDS

Orlet Fisher, Jennifer.

PhD. Professor of Social and Behavioral Sciences. Associate Director. Center for Obesity Research and Education. Temple University. USA.

Early childhood is considered to be a critical period for establishing healthful eating habits. At the same time, many of the poor dietary patterns seen among adults begin to emerge early in life. It has long been appreciated that taste plays a central role in shaping children's food preference and is rooted in biology. Preferences for sweet and savory tastes as well as rejection of bitter and sour tastes are seen well before children experience the first tastes of solid or complementary foods. From this perspective, children's love of sweets and dislike of vegetables seem a foregone conclusion. To what extent does taste actually rule when it comes to food choices among young children? While taste (and more recently temperament) predisposes children to readily prefer certain types of foods over others, the trajectory of food acceptance is fundamentally driven by experience that starts in early development. Children show the capacity to learn to accept a wide variety of foods in their diets, including vegetables which are neither particularly sweet nor energy-dense. Thus, the rules of taste are less deterministic

and more pliable than often perceived by parents and other adults who routinely feed young children. What are the essential rules for promoting acceptance of healthful food choices? Context is everything. Familiarity is one of the most fundamental dimensions of food preferences: children eat what they like and like what they know. A large body of evidence demonstrates that repeated exposure promotes liking via the accumulation of positive experiences around eating—both social and biological. Practices of caregivers, along with the broader socioeconomic environment, set the stage for these experiences. Caregivers determine which foods will become familiar to children, exhibit like and dislike of foods that children learn to model, and use practices that shape children's food preferences and choice. Children's preferences for sweets, for instance, are not only rooted in taste biology but are also socially reinforced by the use of such foods as treats, rewards, and celebration. Social context not only shapes children's understanding what and how much to eat, but also the time of day when eating should occur (e.g. snacks), the way foods are prepared and paired at a given eating occasion (e.g. a meat and a vegetable at meals), and salient qualities of those foods (e.g. healthy, treats). Practices around feeding children, in turn, reflect conditions of the local environment (e.g. availability and cost) as well as norms, values, and behaviors of family, community, and culture. For instance, snacking and eating sweets between meals is normative among US children, but uncommon in other countries. Collectively, these observations suggest that taste rules are universal but are not destiny for food choice among children. Rather, children's choices are rooted in the accumulation of day-to-day experiences—at the family table, in the school cafeteria, eating with their grandparents—and the multi-faceted social contexts in which those experiences occur. Repeated exposure to healthful foods in positive social contexts is the key rule for promoting healthful dietary patterns in early childhood.

COST AND CONVENIENCE IN FOOD CHOICE

Drewnowski, Adam.

Center for Public Health Nutrition. University of Washington. USA.

There is more to eating than nutrient consumption. There is more to non-communicable diseases than nutrient excess. Studies in nutritional epidemiology have tried to convince us that a single food, nutrient, or dietary ingredient could be linked to a specific health outcome, after adjusting for multiple covariates. Typically, socioeconomic variables were adjusted for, and thus removed from consideration, in order to show us the "true" relation between dietary components and health. As nutrition has come to embrace the social sciences, it has become clear that it is impossible to separate the food from the person and the person from society. The current trend is to analyze total food patterns, rather than nutrients, and their likely impact on health and well-being.

Indeed, recent dietary advice in the US has focused on total diets, with a focus on the USDA-style, Mediterranean style, DASH, and vegetarian food patterns. More attention is being paid to social inequities and to the socioeconomic determinants of both diets and health. The "new nutrition" science draws on insights from allied disciplined to illustrate the dynamics of food decision making across the world. Any attempts to improve dietary behaviors in target populations must be respectful of both cultural and social boundaries and economic constraints.

People with one type of dietary pattern may differ in several unobserved ways from people with another dietary pattern. In marketing studies, taste, cost, convenience, health, and variety are recognized as the key drivers of food choice, along with the food environment and socioeconomic status. Yet the monetary cost of diets and the geography of food retail and food consumption patterns have not yet entered mainstream nutritional epidemiology. First, linking dietary intakes from 24h recalls, food records, or food frequency questionnaires with retail prices (per 100g, edible portion) allows for the estimation of diet costs at the individual level. The monetary costs of foods is effectively treated as another nutrient vector; cost calculations follow the same principles as calculations of diets' energy or vitamin content. This procedure has permitted new studies on the relation between diet quality, diet cost and health outcome. Not surprisingly, higher diet cost was associated with better long term health outcomes.

Second, geo-location of dietary intakes data opens the door to new studies in spatial nutritional epidemiology. We have developed microsimulation modeling tools to map food related attitudes, diet quality and even obesity rates at the unprecedented census block level. Geo-positioning trackers have been used to map shopping patterns. Again, socioeconomic variables predicted the relative consumption of sugary drinks versus salad in Seattle King County. Dietary choices appeared to be driven by economics.

Within cities and countries, and across the world, there are dramatic social disparities in diet quality. This talk will consider how geography and economics influence food choice, and ultimately health. There are also opportunities to extend these procedures across regions and globally.

Keywords: Spatial epidemiology, food prices, diet costs, economics, geo-location

STEVIA: AN ALLY TO SUPPORT NUTRITION AND HEALTH

HEALTH AND WELLNESS OF STEVIA

Ayoob, Keith.

EdD, RD. Nutritionist. Associate Professor of Pediatrics. Albert Einstein College of Medicine. New York City. United States of America.

According to the latest WHO report, an estimated 422 million adults were living with diabetes in 2014, compared to 108 million in 1980. Now, one in twelve adults around the world has diabetes. In addition, the prevalence of overweight and obesity is one of the most serious health challenges of the century. Worldwide obesity has doubled since 1980 with almost two billion adults 18 years and older being overweight, of that, more than 600 million being obese.

Global policy guidelines have called for healthier lifestyles in general, for adults and children, and more specifically for reductions in calories and sugar consumption. Global and national health organizations recommend reducing added sugar to less than 10% of calories, with the WHO recommending aiming for less than 5% of total calories from added sugar. Achieving this is nearly unrealistic without the use of low- and zero-calorie sweeteners.

Stevia, being calorie-free, is part of the solution towards sugar reduction and weight management while providing sweet taste and it is a relevant option for a healthy lifestyle and for the diabetic population. Stevia leaf extracts have key health and wellness benefits due to their zero contribution to caloric intake. Emerging evidence suggests stevia may have a unique role in helping diabetics manage blood glucose levels. Additionally, stevia is plant-derived, providing an option for diabetics and others who prefer a naturally sourced zero-calorie sweetener.

Conflict of Interest disclosure: This symposium was sponsored by International Stevia Council (ISC) & Calorie Control Council (CCC) (Belgium)

GLOBAL DEMAND FOR STEVIA AND STEVIA LABELLING WORLDWIDE

Scardigli, Maria Teresa.

Executive Director. International Stevia Council.

Increased consumer interest in calorie-reduced products combined with a stronger than ever call for natural products has boosted the demand for high purity stevia extracts. In the last 3 years stevia has become a mass volume natural sweetening ingredient and has been heavily endorsed by core brands at the worldwide level: this trend is expected to continue in the future. Such development positively impacts all the players in the stevia value chain, including stevia leaf growers and will benefit many regional economies, such as in the Latin American region. Depending on the region, product labeling requirements vary slightly but the ability to use the word "natural" or "naturally occurring" in advertising materials varies more widely. The presentation aims at giving an overview of the global demand for stevia as well as an overview of the differences in labeling across several regions of the world.

Keywords: Stevia. Sweetening ingredient. Calorie-reduced products. Latin American region. Labeling.

OVERVIEW OF STEVIA APPROVALS BY THE GLOBAL SAFETY AUTHORITIES

Roberts, Ashley.

Intertek Scientific and regulatory Consultancy.

The presentation will review and evaluate the extensive research conducted to demonstrate the safety of high purity stevia extracts and how in particular the metabolic profile for the various glycosides including those conjugated with glucose, rhamnose and xylose permit the bridging of toxicological studies conducted with stevioside and rebaudioside A to all glycosides present within the leaf. The presentation will focus on the derivation of the ADI particularly by JECFA, which has been adopted on an International basis and the current global regulatory status taking in to account various estimated exposure paradigms, within different demographic populations. In addition to the evaluation of the steviol glycosides present within the leaf, new technologies are continuously being developed including those associated with a) enzyme modified glycosides, b) bioconversion and, c) steviol glycosides from genetically modified yeast. The presentation will therefore look briefly at the differences in production processes and provide a summary of the current international regulatory status of these materials.

Keywords: Stevia, Glycosides, regulatory

APPLICATION AND INNOVATION IN STEVIA AND TASTE DEVELOPMENT

Fry, John.

Director. Connect Consulting. UK.

This presentation focusses on technological advances in understanding sensory properties of leaf-derived steviol glycosides. The objectives were to investigate the taste relationships of simple combinations of pure glycosides and to develop a predictive methodology to assist the formulation of leaf-based ingredients of improved performance. Such advances aim to satisfy expectations of global consumers for sugar reduction through zero-calorie sweeteners with sugar-like taste.

Intensive sensory investigations of purified individual glycosides allowed the creation of concentration-response curves for sweetness, bitterness and the licorice side-taste. Glycosides were then examined in pairs, looking for synergy in sweetness or suppression of undesirable tastes. Where beneficial responses were found, these pairs were supplemented further with single glycosides to create ternary and quaternary mixtures.

The data from these interactions allowed mathematical modelling of their taste relationships. The models, in turn, indicated unsuspected combinations of glycosides with potentially superior taste performance. The model combinations were then created on a laboratory scale and checked by taste panel for quality.

This approach resulted in a number of novel glycoside mixtures, including minor glycosides, that maximised sweetness while minimizing unwanted side-tastes. Key to this success were critical concentrations of rebaudiosides A, B, D and, surprisingly, stevioside.

With this knowledge, natural leaf extracts of different composition could be selected and blended to produce ingredient-grade materials of outstanding taste. The performance of these leaf extracts, verified in consumer products, allows greater degrees of sugar reduction (70%+) than earlier types, such as those based on about 80% rebaudioside A content. The latter were limited to about 30-50% sugar reduction in a 10% sucrose equivalent sweetness intensity beverage.

PHYTOCHEMICALS & NON-COMMUNICABLE DISEASES

NON-NUTRIENT PHYTOCHEMICALS & NON-COMMUNICABLE DISEASES

Li, Duo.

Qingdao University. China.

Malnutrition is sharply decreased, and over or imbalanced nutrition and lifestyle related disorders are dramatically increased during past two decades globally. Food and medicine arise from the similar origins. In the early era, people experienced sickness, diarrhea, unconsciousness, even death due to ingestion of poisonous plants, while some ailments were alleviated or relieved after eating certain plants. Over time, we have learnt to identify and classify plants based on their characteristic features, as well as developed knowledge about herbal medicines. During the past century, scientists have isolated and identified thousands of compounds from natural sources, and exploited their usage and the relationships between these compounds and their molecular mechanisms. Numerous preparations of natural products are commercially available on the market worldwide. Substantial functional foods and nutraceuticals have been developed such as omega-3 fatty acid, flavonoids and isoflavones, isothiocyanates, carotenoids, dietary fiber, probiotics, prebiotics, phytosterols, polyphenols, alkaloids, terpenoids, saponinoids, polysaccharides, peptides, curcumin, parthenolide, cucurbitacins, 1,8-cineole, pseudopterosins, catechins, capsaicin, conjugated linoleic acid, fucoxanthin, soy isoflavone, glabridin, astaxanthin and cyaniding-3-glucoside, lyprinol, bromelain, marine sponge natural products and Boswellia serrata gum resin etc. They are widely used to adjunctive prevent and treat lifestyle-related continually increasing non-communicable diseases such as diabetes, cardiovascular diseases, cancers, mental disorders, senile dementias, body weight control etc.. However, some functions are need to be confirmed by randomised controlled clinical trial, and detailed mechanism need to be explored.

XANTHINE OXIDASE INHIBITORY CONSTITUENTS OF CELERY SEEDS

[1]*Chen, Jijun;* [2]*Yang, Tong-Hua;* [3]*Lu, Chen-Jie;* [3]*Lu, Cheng-Qian.*

[1]Prof. State Key Laboratory of Phytochemistry and Plant Resources in West China. Kunming Institute of Botany. Chinese Academy of Sciences. China.; [2]State Key Laboratory of Phytochemistry and Plant Resources in West China. Kunming Institute of Botany. Chinese Academy of Sciences. China.; [3]Beijing Sunwins Commodity Sales Co. Ltd.. China.

Apium graveolens is a well known herb of family apiaceae. The seeds, i.e. celery seeds are used as flavoring agents and as an an-

ti-rheumatic formulation and showed significant effects on arthritic pain relief, for treating rheumatic conditions and gout. According to our bioassay, the 50% ethanol extract of celery seeds showed moderate inhibitory activity on XOD. To clarify its active constituents, the extract was further separated to provide two flavone glycosides named graveobioside A (1) and luteolin-7-O-β-D-glucoside (2) elucidated by MS/MS and NMR techniques. Graveobioside A and luteolin-7-O-β-D-glucoside possessed potent activities against XOD with IC50 values of 287.17±2.3 and 77.36 ± 4.70 μg/mL, respectively. To further investigate inhibitory activity of graveobioside A on XOD, three types of animal models were established to evaluate its effects in mice. The effect of graveobioside A on potassium oxonate-induced hyperuricemia in mice was determined. The results indicated that the serum uric acid level in each dose group of graveobioside A(20 mg/kg10 mg/kg and 5 mg/kg) significantly was reduced than that of hyperuricemic group (P<0.01);In addition, the middle and high dose groups of graveobioside A could obviously inhibit XOD activity in serum(P<0.05). Then carrageen-induced mice paw edema model was employed for the anti-inflammatory activity of graveobioside A. The result showed each dose group of graveobioside A possessed most activities against inflammation. The rat acute feet swelling induced by sodium urate was often used to test compounds effects on gouty arthritis. The middle and high dose group of graveobioside A had significant activity compared to the model group (P<0.01). Therefore, graveobioside A had potential activity to treat gout and gouty arthritis

NON-COMMUNICABLE DISEASES AND ITS PREVENTION IN CHINA

[1]Ma, Guan-Sheng; [2]Zhang, Na.

[1]PhD.Department of Nutrition and Food Hygiene. School of Public Health. Peking University. China.; [2]National Institute for Nutrition and Health. Chinese Center for Disease Control and Prevention. China.

Along with the rapid development of social and economic, transitions in diseases pattern has been changed from infectious diseases to the non-communicable diseases (NCDs). In 2012, the mortality rate of NCDs among Chinese residents was 533/100 000, accounting for 86.6% of the total deaths. Cardio-cerebrovascular disease, cancer and chronic respiratory disease were the main cause of death, accounting for 79.4% of total deaths. The prevalence of overweight and obesity in adults aged 18 and over were 30.1% and 11.9%, respectively, while that for children aged 6~17 year olds were 9.6% and 6.4%, respectively. The prevalence of hypertension in adults aged 18 and over was 25.2 % and the prevalence of diabetes was 9.7%. According to the results of the national cancer registration in 2013 in China, the incidence of cancer was 235/100 000. It is indicated that unhealthy lifestyle including unhealthy dietary

pattern, smoking, excessive drinking, inadequate physical activity and the extension of sedentary time, and psychosocial stress was the main risk factors for the epidemic of NCDs. The epidemic of NCDs brings serious burden to economy. In 2003, the direct economic burden of five major chronic diseases (coronary heart disease, stroke, hypertension, cancer and diabetes) was 151.422 billion RMB; in 2010, the direct economic burden of five major chronic diseases was 211.436 billion RMB, accounting for 10.6% of the total health expenditure. It is estimated that the cost of cardiovascular disease, cancer, chronic respiratory disease, diabetes, and mental health will total 191 trillion RMB for the period 2012-2030. The preventive interventions of NCDs are highly cost-beneficial. Economic analysis showed that the comprehensive intervention, dietary intervention and physical activity intervention for obesity could avoid the loss of productivity equivalent to 314144.8 RMB, 31738.6 RMB, and 16391.6 RMB, respectively; and medical expenses equivalent to 37448.1 RMB, 3357.0 RMB, and 2486.0 RMB, respectively. In order to control the epidemic of NCDs, the Action Plan of control and prevention of NCDs has been issued in 2012. The Action Plan of Health China 2030 has been launched in 2016. The cost-effective and cost-beneficial measures have been identified and implemented.

OMICS BASED STUDY ON N-3 PUFA IN THE PREVENTION AND TREATMENT OF TYPE 2 DIABETES IN ASIAN

[1]Zheng, Jusheng; [2]Li, Duo.

[1]Career Development Fellow. University of Cambridge.; [2]PhD. Professor. Department of Food Science and Nutrition. Zhejiang University. China.

Background and Objectives: The interaction of genomics and metabolomics with omega-3 fatty acids among the Asian type 2 diabetic patients is not clear. We aimed to investigate the interaction between genes and omega-3 fatty acids for type 2 diabetes risk and for glycemic traits among type 2 diabetic patients. In addition, we aimed to examine the response of metabolomics profiles to omega-3 fatty acid intervention.

Methods: We conducted a case-control study involving 622 type 2 diabetic patients and 293 healthy controls, and a double-blinded randomized controlled trial among 185 type 2 diabetic patients for omega-3 supplements over 6 months. Among these participants, we genotypes several type 2 diabetes-related genetic variants to examine the interaction between omega-3 fatty acids and these genetic variants for type 2 diabetes in the case-control study and for glycemic traits in the trial. In addition, we examine the effect of omega-3 fatty acid intervention on the metabolomics profiles in a subset of the patients.

Results: In the case-control study, we found significant interaction between a genetic risk score generated from 9 type 2 diabetes-related genetic variants, with the inverse association between erythrocyte alpha-linolenic acid and type 2 diabetes only observed in those with low genetic risk. In addition, PEPD variant interacts with total erythrocyte omega-3 fatty acids for type 2 diabetes risk, with the genetic risk of PEPD variant being abolished in high omega-3 fatty acid group. In the randomised trial, we did not detect similar gene-fatty acid interaction pattern as in the case-control study. In the metabolomics analyses of the trial, we identified a most significant biomarker of omega-3 fatty acid supplements: 3-carboxy-4-methyl-5-propyl-2-furanpropanoate, a furan fatty acid metabolite. Change of this metabolite is positively correlated with change of serum eicosapentaenoic acid and docosahexaenoic acid, but negatively correlated with change of serum triglycerides.

Conclusions: Both genomics and metabolomics approaches could help advance our understanding about the role of omega-3 fatty acids in type 2 diabetes prevention and treatment.

SSS_144/1033

EARLY DETECTION OF MALNUTRITION IN THE FACILITY AND COMMUNITY SETTING FOR IMPROVED HEALTH AND ECONOMIC OUTCOMES

IMPROVING HEALTH OUTCOMES: EARLY DETECTION OF MALNUTRITION UTILIZING VALIDATED TOOLS

Correia, Isabel.

MD, PhD. Universidade Federal de Minas Gerais. Brazil.

Background and Objectives: Effective implementation of nutrition care plays a key role in achieving improved patient outcomes. Malnutrition negatively affects the patient evolution in terms of higher morbidity, mortality, re-admissions, prolonged hospitalizations and costs. Increased medical awareness regarding the impact of nutritional status on patient outcomes is essential. Malnourished patients cost more than patients with similar diseases who are well-nourished, demonstrating an independent and additive effect of malnutrition on negative outcomes. When malnutrition is identified and interventions are implemented, use of medical care and resulting costs decrease. Therefore, early use of screening and assessment tools (at hospital admission) to identify risk factors, establish a diagnosis of malnutrition and enable effective treatment is fundamental to provide the highest quality of care and improve patient outcomes. Methods: An estimated 30-50% of hospitalized adult patients are malnourished in the U.S. and internationally based on a combination of malnutrition screening and assessment studies. Yet, research indicates that the diagnosis/identification rate remains low with only 3.2% of adult patients are discharged with an International Classification of Diseases, Ninth Revision (ICD-9) malnutrition diagnostic code. Screening and assessment are different processes, the former should identify risk factors and the latter provides diagnosis. Both serve essential roles in creating a inter-disciplinary patient care plan. Results: A triangulation of indices is necessary to determine nutrition status. Weight loss in the last six months and decreased food intake are included in many of the various tools. Both are simple, easily available, do not require use of additional devices, can be provided by the patient or any member of the family and are related to morbidity and mortality in different populations. There are more sophisticated measurements including computed tomography and functional tools, particularly in cancer units, that when available can be added to increase accuracy. Conclusions: Dissemination and implementation of simple, validated tools that can be utilized in a variety of global healthcare settings, to early and accurately assess risk for and identify the presence of malnutrition is fundamental to improving patient and system level health outcomes.

CREATING A REPLICABLE MODEL OF NUTRITION CARE EXCELLENCE IN THE CLINICAL SETTING

Pinzon Espitia, Olga Lucia.

Nutritionist. PhD Candidate. National University of Colombia. Méderi. Colombia.

Background and Objectives: Optimal quality of care is a must for all healthcare institutions across the world. Nutritional care processes must be a priority for hospitals, thus supporting their implementation in clinical outcomes. This is why the conception of nutritional care processes allows hospitalized patients experiencing superior results.

Considering the current approach of healthcare models, it is of utmost important to generate strategies that allow healthcare systems improve their process performance by integrating nutritional management into their patients' clinical care. A comprehensive model responds to the nutritional needs of hospitalized patients under the superior concept of generating value.

Objective: To develop a model of hospital nutritional care that allows minimizing malnutrition related risks, optimizing care processes and improving clinical outcomes of hospitalized patients.

Methods: A systematic review of literature on hospital nutritional care models informed the construction of a new nutritional model in 2016, which was consulted and validated with feedback from 10 participating hospitals.

Results: Publications related to nutritional quality standards have focused on methods of measuring the activities of nutrition processes, thus making it necessary to propose a model of easy duplication and validation in different scenarios of clinical practice. The model aims to promote good practices for clinics delivering nutritional interventions based on set criteria of excellence. Using existing literature on nutritional care models for inpatients and subsequent fieldwork, four lines of patient care plans were proposed: 1. Identification of nutritional risk; 2. Intervention and follow-up; 3. Exchange doors: path of patient care to ensure continuity of treatment; and 4. Education and generation of culture of nutritional care to the patient, caregiver, family and organization.

Quality standards were established to demonstrate the applicability of the model considering the need for organizations to evaluate the impact on their clinical results, ,inform the construction of models aimed at being differentiators through creation of value for the patients, and lead organizations to be centers focused on excellence.

Conclusions: The construction of the new model of care allows the achievement of processes of healthcare of superior value in order to bring hospital nutrition to sites of relevance previously not considered.

Keywords: Nutrition Therapy, Quality of Health Care.

REDUCING THE ECONOMIC BURDEN OF DISEASE-ASSOCIATED MALNUTRITION THROUGH TARGETED INTERVENTIONS ACROSS THE CONTINUUM OF CARE

Sriram, Krishnan

Abbott Nutrition. Chicago. IL. USA.

Background and objectives: Disease-associated malnutrition costs health care systems across the globe billions of US dollars annually. This is a result of the direct and indirect costs associated primarily with higher rates of health care resource utilization by malnourished patients compared to their well-nourished counterparts. Nutrition interventions can be effective in terms of alleviating the burden of malnutrition and improving patient outcomes. Increasingly more real-world, pragmatic study designs such as quality improvement programs (QIPs) are used to study nutrition care improvements for malnourished patients across the continuum of care.

Objectives of the presentation include 1) brief overview of economic burden of disease-associated malnutrition; 2) review studies implementing effective research methods used to study nutrition interventions and their impact on patient health and economic outcomes; and 3) discuss key pragmatic studies targeting inpatients and community-dwelling malnourished adults.

Methods: Review of real-world, pragmatic research studies implemented in both US and ex-US countries aiming to assess the impact of nutrition-focused interventions on health and economic outcomes of malnourished hospitalized patients and community-dwelling adults.

Results: Report the results of different pragmatic research studies assessing the effectiveness of nutrition interventions on patient outcomes including significant reductions in 30-day unplanned readmissions, hospital length of stay, and health care costs.

Conclusions: Unplanned 30-day readmissions, length of stay, and healthcare costs among malnourished inpatients and community-dwelling adults can be significantly decreased through nutrition-focused pragmatic programs that include comprehensive screening of patients for malnutrition, prompt administration of oral nutrition supplements, and education of malnourished patients in both hospital and community settings. Real-world, pragmatic study designs are effective methods of generating data that can inform effective decision making in the optimization of nutrition care for malnourished adults across the continuum of care.

ADVANCING CLINICAL QUALITY IMPROVE-MENT PROGRAMS: A DATA DRIVEN APPROACH TO CAPTURE THE COST OF MALNUTRITION

Ruiz, Alvaro.

MD. MSc. FACP. Department of Internal Medicine and Department of Clinical Epidemiology. School of Medicine. Pontificia Universidad Javeriana. Bogota. Colombia.

Background and Objectives: Nutrition deterioration or malnutrition risk among hospitalized patients is associated with increased complications, hospital stays and readmissions, which can lead to increased healthcare costs and resource utilization. Malnutrition risk, however, is not easy to detect unless actively searched and hospitals are concerned about the costs associated with the screening process. While different screening tools are available for hospitals to use, the Malnutrition Screening Tool (MST), which is a validated and easy to use tool has been shown to be the most valid and reliable tool for the identification of malnutrition in hospitalized patients.

Presentation objectives include 1) Brief review of studies evaluating hospital-associated malnutrition prevalence of up to 69%; 2) Presentation of a real-world cohort study aiming to evaluate malnutrition screening rates in four Colombian hospitals and report readmission rates and direct costs differences between patients with positive and negative MST results; 3) Presentation of descriptive results of a pilot study including MST screening rates, positive frequencies, and readmission rates; and 4) Discussion of study implications to highlight the importance of formal malnutrition screening programs and nutrition-focused interventions for malnourished hospitalized patients.

Methods: Review of previously published malnutrition studies and detailed overview of a cohort study in four Colombian tertiary care centers aiming to assess malnutrition screening rates, incidence of positive MST results, readmission rates and direct cost differences between malnourished and non-malnourished patients with acute myocardial infarction, community acquired pneumonia, chronic obstructive pulmonary disease and heart failure.

Results: Descriptive results (i.e., demographics and frequency of screening and of positive MST results) and comparative results in terms of length of stay, readmission and cost differences for malnourished versus non-malnourished patients participating in the real-world cohort study and the pilot ongoing study will be reported.

Conclusions: Healthcare costs of malnourished hospitalized patients are significantly higher than their well-nourished counterparts resulting primarily from prolonged hospitalizations and readmissions. The MST can be effectively used for identification of malnourished Colombian patients in need of nutrition-focused interventions. We will report findings of two studies suggesting that identification of malnourished patients can lead to improved health and economic outcomes for patients and hospitals.

SSS_144/20

ADDRESSING TODAY'S NUTRITION AND PUBLIC HEALTH CHALLENGES WITH FOOD TECHNOLOGY INNOVATIONS

INNOVATION IN INGREDIENT TECHNOLOGY TO ADDRESS NUTRITION, HEALTH, AND CONSUMER NEEDS

[1]*Canene-Adams, Kirstie;* [2]*Spence, Lisa;* [3]*Karnik, Kavita.*

[1]PhD. Senior Scientist. Global Nutrition. Tate & Lyle. USA;
[2]PhD. RD. Principal Scientist Global Nutrition. Tate & Lyle. USA;
[3]M.Med.Sci. PhD. Director Global Nutrition. Tate & Lyle PLC. United Kingdom.

Ingredient and food technology can produce practical, functional solutions to help people meet dietary recommendations and address some of the world's most significant public health-related challenges. To combat the rise of obesity and diet-related chronic diseases, global health and nutrition authorities have called for an "all sector approach" to encourage diets reduced in total calories, sodium, added sugars and with increased dietary fibre content to deliver adequate amounts of essential nutrients. Research shows that taste remains the most important attribute in food choice, reinforcing the need for new strategic solutions to improve the quality of the diet. Food technology is essential in the global effort to improve public health while delivering the great tasting foods and beverages that consumers expect. New technologies and innovative ingredient solutions are helping to address fibre and protein enrichments as well as sodium, added sugars and calorie reduction in foods and beverages. In addition, a number of added fibres also provide additional health benefits such as laxation, favorable glycemic response, and improved calcium absorption and bone calcium retention.

Investment in nutrition research and innovation has allowed ingredient manufacturers to work closely with food and beverage manufacturers, to deliver healthy options without compromising taste and texture.

FOOD TECHNOLOGY AND INGREDIENT INNOVATIONS: POTENTIAL IMPACT FROM A PUBLIC HEALTH PERSPECTIVE

Ferruzzi, Mario.

Professor. Plants for Human Health Institute. North Carolina State University. Kannapolis NC. USA.

Addressing public health challenges requires a healthful food supply that provides diverse options for consumers to meet dietary guidance and nutritional needs. This notion must include consideration of the consumer's preferences for taste, quality and price within the modern food environment. With delivery of positive nutritional attributes increasingly becoming an important component in consumer choice of food, the potential to mix messages on consumer perception of factors impacting nutrition and health has grown. It is therefore critical to continue to foster collaborations between food science and nutrition disciplines that lead to development of consumer foods that are aligned to key principles of existing dietary guidance policies. To achieve this goal, advances in food and ingredient technology have been a critical tool for product researchers allowing for development and promotion of a diverse array of quality products that can fit within the lifestyles of a broad consumer base and align with existing dietary guidance. This lecture will focus on describing the manner in which food science and technology is a translational tool for nutrition science and policy. We will describe the existence of collaborations between these disciplines leading to innovations that can help consumers reach the aspirations of dietary guidance. Examples of food science and technology creating new and innovative nutrient dense food options for consumers and the continued progress on reducing nutritional limiters will be provided, including reduction strategies for added sugars, saturated fats and sodium in processed foods which have provided options for consumers to align to a healthy eating pattern. These examples of existing alignment will be balanced with the continued efforts that are required within the context of promoting constructive dialogue which can promote better consumer food options.

SSS_144/1005
EMERGING SCIENCE ON BIOACTIVES AND WHOLE GRAINS

THE ROLE OF BIOACTIVE COMPOUNDS IN WHOLE GRAINS: POTENTIAL BENEFITS FOR HUMAN HEALTH

Korczak, Renne.

PhD. RD. LD. Department of Food Science and Nutrition. University of Minnesota. US.

Epidemiologic research has consistently identified beneficial associations between consumption of whole grains and whole grain foods and lower prevalence of a number of chronic diseases. New research is also pointing towards the prebiotic effect of whole grains on the human gut microbiota, indicating a potential benefit for digestive health.

While whole grains and whole grain foods provide major sources of carbohydrates, protein, B- vitamins, minerals and phytochemicals, they also contain extra nutritional elements known as bioactives. According to the National Institute of Health (NIH), dietary bioactive components are defined as compounds that are constituents in foods, other than those needed to meet basic nutritional needs which are responsible for changes in health status.

The major bioactives found in whole-grains are phenolic compounds including phytosterols, dietary fibers (beta-glucan), lignans, alkylresorcinols, phytic acid, γ-oryzanols, avenanthramides, cinamic acid, ferulic acid, inositols and betaine. Currently, no recommended intake levels for dietary bioactive components have been established, but it is well understood that the majority of bioactive compounds of whole-grains are present in the bran and germ fraction of cereal-grains.

To date, scientific researchers understand that bioactives may elicit health benefits through multifactorial physiological mechanisms. Potential mechanisms include antioxidant activity, mediation of hormones and inflammation, enhancement of the immune system, and facilitation of substance transit through the digestive tract. The additive and synergistic effects of the biologically active compounds within whole grains and whole grain foods may be responsible for their health benefits.

The objectives of this session are to provide an overview of bioactive components found within all whole grains and describe the potential impact of dietary bioactives on human chronic disease states or conditions such as type 2 diabetes, obesity, cardiovascular disease, cancer and digestive health. An open discussion of the need for recommended intake levels for bioactives will also be included during this session.

Keywords: Whole grains, bioactives, oats, health benefits, recommended intake levels

OATS. MORE THAN JUST A FIBRE: THE ROLE OF UNIQUE BIOACTIVE AVENANTHRAMIDES

Sang, Shengmin.

PhD.Doctor.Laboratory for Functional Foods and Human Health Center for Excellence in Post-Harvest Technologies. North Carolina Agricultural and Technical State University North Carolina Research Campus 500 Laureate Way. Kannapolis. NC 28081. USA.

Oats (Avena sativa L.) have been cultivated for more than two thousand years in various regions throughout the world, and considered as a multifunctional crop nutritionally superior to many other unfortified cereals. They are commonly consumed as a whole grain and are known to provide healthy nutrients, such as proteins, unsaturated fatty acids, vitamins, and minerals, to humans. Numerous laboratory and clinical studies have demonstrated that consumption of oat-based products can lower serum cholesterol levels, reduce glucose uptake, decrease plasma insulin response, and prolong satiety. The beneficial nutritional properties of oats have attracted attention from scientific researchers and the general public, and have resulted in the food industry using oats as a food ingredient more extensively. Oats can be found in various food products, including breakfast cereals, beverages, bread and infant foods.

Oat is a good source of dietary soluble fibre especially β-glucan, which has outstanding functional and nutritional properties. β-Glucan has been considered as the major active component in oat for its positive impact on cholesterol and glucose disposition. However, the nutritional benefits of oats appear to go beyond fiber to bioactive phytochemicals with strong antioxidant and anti-inflammatory effects. Oats contain many bioactive phytochemicals, which are structurally diverse secondary metabolites synthesized by plants. The major phytochemicals in oats include carotenoids, vitamin E, phytosterols, saponins, phenolic acids, flavonoids, lignans, and avenanthramides (AVAs).

Among these phytochemicals, AVAs are phenolic compounds that are unique because they are found exclusively in oats and not in any other cereals. More than 25 AVA compounds have been identified since they were first isolated in the 1980s, with the most abundant being 2c, 2f and 2p. The total concentrations of AVAs in oat grains can reach up to 300 mg kg-1 based on literature reports. However, some processing can result in a decrease in total AVAs. Recently, AVAs have been reported to possess different bioactivities that may have a health benefit, such as antioxidant, anti-inflammatory, and cholesterol lowing activities.

The nutrition of oats appears to go beyond the benefits of fibre, to also include possible benefits of bioactives for their strong antioxidant and anti-inflammatory effects, suggesting intake of oats have the potential to contribute to prevention of some chronic diseases. However, the studies on the beneficial health effects of AVAs are still in their infancy. Additional health benefits of AVAs may yet be identified. Therefore, more research is needed in this area.

Keywords: Oats. fiber. phytochemicals. avenanthramides. health effect

FROM RESEARCH TO DIETARY RECOMMENDATIONS

Stolarza, Zulema.

Professor. MD. Nutrition and Diabetes Service of the Hospital Dr. Cesar Milstein. Argentina.

Whole grain oats are well-known for its many health benefits due to their nutrient-rich content, but mainly caused by the effect of β-glucan, its viscous soluble fiber which has been subject of research for a long time.

Since 1963, scientific research has shown evidence regarding soluble fiber and its lowering cholesterol properties to achieve a risk reduction on heart diseases when consumed with a healthy diet and a regular practice of physical activity.

The U.S. Food and Drug Administration (FDA) states that 3 g or more of β-glucan (oat soluble fiber) in conjunction with a diet low in saturated fat and cholesterol can reduce the risk of coronary heart disease; the American Heart Association also supports this statement. To achieve the heart health benefit, 56-150 g of whole grain oats can be consumed per day in form of oat bran, oat flakes, or in foods containing oats; e.g. ½ cup (40g) of oat flakes contain 2 g of β-glucan.

In regards to a glycemic response effect, the European Food Safety Authority (EFSA 2011) published an opinion allowing health claims for postprandial blood glucose response reduction when 4 g of β-glucans from oats for each 30 g of available carbohydrate should be consumed per meal.

Controlling appetite in order to adhere to dietary recommendations for weight loss /maintenance is necessary. Studies on the effect of oats on satiety have shown benefits at amounts of β-glucan ranging from 2.2g to 5.5g. Viscosity plays an important role in this effect, and then any processing could affect physicochemical process. This should be considered when we are looking for a satiety effect.

Besides soluble fiber, oats are also a source of insoluble fiber. A portion of 30g of oats contributes with approximately 10% of the daily value for fiber, which can be beneficial to achieve fiber recommendation. Both types of fiber are highly beneficial for digestive health.

Additionally, the nutrient content beyond fiber: unsaturated fatty acids, vitamin B complex and nutrients with antioxidant function make oats and oat containing products a great choice to improve breakfast quality.

Keywords: Oats, soluble fiber, health benefits, beta-glucan.

IS THERE A ROLE FOR DIETARY/FOOD SUPPLEMENTS IN NUTRITION AND HEALTH?

FROM CHALLENGES OF THE PAST TO OPPORTUNITIES OF THE FUTURE: EVOLUTION OF THE FIELD OF NUTRITION

Shao, Andrew.

Chair of the Scientific Council. International Alliance of Dietary/Food Supplement Associations. VP Global Nutrition Policy. Herbalife Nutrition.

The field of nutrition has evolved drastically over the past century. This has paralleled a shift in public health challenges from those related to communicable disease to lifestyle-related non-communicable disease. Nutrition scientists and policy makers are now faced with the dichotomous situation of malnutrition and obesity, with its associated comorbidities. In an attempt to control spiraling healthcare costs, societies' focus has shifted as well, to one aimed at prevention, and health maintenance and promotion. Nutrition research has in turn gone through a necessary evolution. Rapid advances in research and technology have led to important discoveries in the "omics" and microbiome. While these have greatly informed the understanding of the diet/lifestyle-chronic disease relationship, rates of chronic disease show no signs of abating in both developed and developing countries. This shortcoming may be due in part to the application of a reductionist approach, driven by a desire to understand what is responsible for nutritional effects down to the specific nutrient or molecule. This approach has necessarily expanded in recent years to become more holistic and multidisciplinary to better understand the role of nutrition in a broader context. Ultimately this approach will culminate in a full understanding of the dietary landscape – a web of interactions between nutritional, dietary, social, behavioral and environmental factors – and how it impacts health maintenance and promotion.

Keywords: Nutrition, non-communicable disease, dietary landscape, health promotion

DIETARY/FOOD SUPPLEMENTS IN HEALTH PROMOTION: ILLUSTRATIONS OF THE BENEFITS AND RISKS OF RESEARCH

Blumberg, Jeffrey.

PhD. Professor of Nutrition Science and Policy. Tufts University. USA.

A fundamental challenge in substantiating the benefits and risks of dietary/food supplements through research is the absence of a consensus regarding a framework for the scientific evidence. Can any degree of competent and reliable scientific evidence, including in vitro or animal models, be relied upon to provide supplement recommendations at a personal level or for public health? Is evidence derived from observational studies – such as cross-sectional, case-control, and/or cohort designs – sufficient to define these outcomes? Should one or more randomized clinical trials (RCTs) of any nutritional intervention be required before taking action to translate research results into the practice of nutrition care or public policy? As each of these research strategies has inherent strengths and limitations, must evidence be derived from two or more of these approaches to achieve sufficient scientific and regulatory agreement on the benefits and risks of dietary/food supplements and allow statements about health promotion and/or the reduction in risk of chronic disease? Should the breadth and depth of the evidence be dependent on the health claim allowed in communications via labeling and marketing? Despite the perception of RCTs in nutrition as the "gold standard" for determining causality, limitations common in their implementation often result a high risk of type II errors (i.e., false negatives – failures to detect an effect that is present); for example: absence of baseline and endpoint assessments of nutritional status; selection of a dose inappropriate to the response; too small a sample size or brief a duration for the intervention; designs ignorant of background dietary patterns; lack of relevant biomarkers of compliance and/or mechanisms of action; and confounding by issues such as health status, medication use, and non-intervention dietary components. These problems with RCTs often lead to results that contrast with evidence from experimental and observational studies. Thus, it is helpful to consider the options available in drawing conclusions when outcomes from RCTs and observational studies disagree: (i) the RCT is correct and the observational study is wrong; (ii) the observational study is correct and the RCT is wrong; (iii) both the RCT and observational study are wrong; and (iv) the RCT and observational study are both correct but, as designed and implemented, are asking different questions. It should be considered that the innate complexities of nutrient actions and interactions cannot always be adequately addressed through a single research design. In contrast to the use of RCTs within the context of a medical model, action to define the benefits and risks of essential nutrients and other dietary bioactive components provided as dietary foods/supplements should be taken at a level of confidence that is different from that needed in the evaluation of drug efficacy and safety in the treatment of disease.

REGULATION OF DIETARY/FOOD SUPPLE-MENTS: A GLOBAL OVERVIEW

Pettman, Simon.

International Alliance of Dietary/Food Supplement Associations IADSA.

There are three questions which are most commonly asked about regulation and food supplements: Are they regulated? Are they sufficiently regulated? And what is the future of regulation in this area?

Over the past 25 years the global supplement market as developed substantially and with that growth has come new regulation across the world. This regulation has in some cases responded to the market, in other cases defined the market. But despite it often being developed along national or regional lines the commonalities of this regulation across the world significantly outweigh the elements that are today not common.

When looking at the question of whether supplement products are sufficiently regulated, it is important to first look at the origins of legislation in this area and where it is today. It is then important to look at this in a national or regional context of the efficacy of the systems in place for control and enforcement of products and manufacturing. It is the total management system for supplements that defines whether the regulation is sufficient.

Looking forward, two of the major areas of future regulation are becoming the global priorities for regulatory bodies. How to fairly and consistently provide consumers with information about products; and how to regulate the use of botanicals in products? Ensuring the confidence of the regulatory, scientific and consumer communities in regulation in these and related areas will help define the next stage in the evolution of the supplement category.

Track 7: Food Culture Practices and Nutritional Education

GLOBAL FOOD VALUES IMPACT SURVEY: MEASURING HOW FOOD VALUES IMPACT THE POLICY AND REGULATORY LANDSCAPE

GLOBAL FOOD VALUES: PREDICTIONS AND THE IMPACT ON EMERGING FOOD VALUES FROM AROUND THE GLOBE

Pitman, Susan.

MA. RD. Founder. Executive Vice President. FoodMinds. USA.

Globally, the traditional primary value equation of food decisions and purchases: taste, price, and convenience, is evolving. Today, new food values beyond the product itself, including experience, social impact, environment, and transparency, are shaping how consumers view, and ultimately, make food purchase and health decisions. Food values are closely tied to human emotions and reflect gender, life stage and experiences, education, income, geographic location and culture. The impact of these new food values extends beyond the individual consumer—food and nutrition policies around the world reflect this evolving values. While science remains integral to policy development, policy decisions are no longer based solely on evidence-based data. Food and health policies are rapidly evolving to adapt to these new food values. Policies are emerging to encompass societal, environmental, experiential, safety, and health and wellbeing values that may, or may not be driven by science.

To understand the possible future impact of food values on the food and nutrition affairs landscape, FoodMinds embarked on an effort to construct and anticipate emerging values that are shaping consumer food decisions and behaviors as well as policy formulation flowing from shifts in these values. A first-of-its-kind prototype tool, the FoodMinds Food Values Factor AnalysisTM, informed by a survey conducted in over 15 countries in six continents using an interactive forecasting model to curate predictions from the global nutrition and food experts overlaid with market and modeling data, will be presented. The Analysis reveals a broad set of food values, which is comprised of several interrelated social, political, regulatory, agricultural and technological factors that are changing the way food is produced, distributed, marketed, regulated, sold and consumed. Importantly, these food values are emerging in different places around the globe and are being woven together in the flow of human migration and digital connectivity, including social media. Understanding the differences between these food values, level of impact and the relationships between them provides a deeper understanding of today's food and nutrition landscape, and can help to predict the future environment and policies that shape it.

REVIEW OF THE IMPACT OF EMERGING FOOD VALUE EQUATION ON POLICIES AROUND THE GLOBE – AND PREDICTIONS FOR THE FUTURE

Rowe, Sylvia.

President. SR Strategy. Adjunct Professor at the University of Massachusetts Amherst and Tufts Friedman School of Nutrition Science and Policy. USA.

Evidence-based policy has been the standard for major authoritative bodies, but in recent years, emerging food values are playing an impactful role in the global policy landscape. A decade ago, the impact of food as medicine, renewable energy and energy sources, risk, and ethics began to appear on the horizon as key factors of food development. These issues converge when using a food systems approach. The United Nations Food and Agriculture Organization (FAO) and the World Health Organization (FAO) assert the importance of food systems, which encompass all aspects of food from farm to fork, to promote healthy and sustainable diets in its Sustainable Development Goals, which broaden how policy makers consider food, nutrition and its impact on society.

Additionally, there is a call for a "One Health" conceptual approach from authoritative bodies such as the WHO and FAO, which ties together the health of humans, animals and the environment. This concept is practical in its application to non-communicable diseases, but more holistic in its application to food values, from local and sustainable food to animal welfare to worker safety and social justice. While food values can be analyzed as factors to delve into specific drivers of change, the totality of these factors can also predict how the food and nutrition landscape may change. These values inform the "One Health" concept as an approach to how we think about food, while concurrently reflecting how society is thinking about food.

Policies have begun to encompass societal, environmental, experiential, safety and health and wellbeing values that may or may not be driven by science. Policy levers to curb consumption of sugar, sugar sweetened beverages, and "junk food" are being encouraged, despite what some note as limited evidence. At a national level, the most recent United States Dietary Guidelines for Americans Committee proposed the inclusion of sustainable eating patterns as part of the 2015-2020 Dietary Guidelines for Americans, which were later excluded in the final policy due to lack of conclusive evidence on the association between sustainable eating patterns and health outcomes plus political pressure.

Science is the foundation of policy, but the complex, multifactorial issues of obesity and climate change in today's environment present challenges to our standard approach to addressing scientific evidence. "Public health rules" suggest that exploring a practice-based evidence approach grounded on natural or "real world experiments" versus an evidence-based approach, may be the new strategy going forward.

Another important part of the equation is how to effectively communicate science, as this impacts not only how the science is heard, but how decisions are made at the policy level. In an environment where multiple factors, beyond science affect global public health, science needs to be approached in a transdisciplinary manner.

FOOD CULTURE PRACTICES AND NUTRITIONAL EDUCATION

Guarita, Heloisa.

MS. Co-Founder. RGNutri. Brazil.

Latin America (LA) countries face, at the moment, a double burden of malnutrition. On one hand, even with the rates of stunting and wasting falling - although in different proportions among the LA countries -, the numbers of undernutrition parameters are still substantial. Among specific population groups, regions or even in low-income countries, there are low intakes of critical nutrients and food insecurity, which predisposes to micronutrient deficiency or, at least, to hidden hunger. On the other hand, overweight/obesity is increasing to alarming rates, as can be observed in Mexico, Venezuela, Chile and Uruguay, countries in which overweight already affects more than 60% of the population. In absolute numbers, the overweight/obesity has overcome undernutrition in almost all of the LA countries.

One of the most striking changes in food systems of LA countries is the displacement of dietary patterns based on meals and dishes prepared from unprocessed or minimally processed foods by those that are increasingly based on ultra-processed food and drink. The result is diets with excessive energy density, high in free sugars and unhealthy fats and salt, and low in dietary fiber that increase the risk of obesity and other diet-related non-communicable diseases (NCDs). This movement has a close relationship with the industrialization, urbanization and modernization processes, which have changed the dynamics of the families, the rhythm of life and lifestyle of the individuals.

As an answer to this epidemiological scenario, public health authorities are promoting positive changes in the dietary patterns of LA populations. For example, Ecuador, Chile, and Mexico have recently passed laws to promote Front-of-Package (FOP) in packaged foods. According to studies, the system with the most

favorable results in terms of healthy food choices and perception of healthfulness was the Multi-Traffic Light labeling system, and the summary system demonstrated the greatest impact on food reformulation. However, the LA region has specific characteristics that need to be considered when implementing any strategy regarding food labeling, such as mathematical and reading skills and education levels.

Brazil (2014) and Uruguay (2016) have launched new dietary Guidelines for its populations, both of which based its principles on a classification of food in the four categories: in natura, minimally processed, processed and ultra-processed; and a healthy diet must be based on the first two categories. PAHO has already adopted this classification, and affirms that "the proportion of ultra-processed products in food supplies can be seen as a measure of overall population diet quality".

Aware of its responsibility and role in public health, the food industry has moved to improve the nutritional quality of its products, either by reducing the sugar and sodium levels progressively or by prioritizing the elaboration of clean label products, among other actions.

As a result of health authority actions and increased access to information, there seems to be a population movement, albeit timid, to make more conscious food choices, prioritizing food with a better nutritional profile, and gradually regaining the habit of cooking at home.

HOW EVOLVING FOOD VALUES ARE DRIVING MAJOR POLICIES IN EUROPE

Azaïs-Braesco, Véronique.

PhD. Founder. VAB-nutrition. France.

Since the late 1990's, the value system around foods has significantly changed for European consumers. Price, taste and convenience remain major attributes, but a wide range of other concerns have emerged which result in an increasingly complex environment for all stakeholders to perform tasks such as providing, preparing, eating and regulating food. The survey carried out by FoodMinds helps us to better understand the link between changes in food values and changes in food policies and regulation.

A key learning of the survey is that economic considerations do not appear as major drivers of food choices as they used to be 50 years ago. In highly developed countries, cost concerns roughly rank as 8th rank out of 14 drivers. However, price is still believed to be important and the "tax" lever has been recently used in several European countries as a tool to orientate food consumption (e.g., tax on saturated fat in Denmark, on sweetened beverages

in France, etc.), especially in people with lower incomes, who are thought to be at highest risk of unbalanced diets and obesity. Results have often been mitigated, but not null, and the nutritional efficiency of taxes remains under discussion.

European consumers are paying increased attention to the nutritional content of their foods. Sugar is becoming the number one enemy, illustrated by new guidelines, such as in UK, where it is recommended that added sugar accounts for no more than 5% of daily energy; there are also by strong pressures from the European Union for manufacturers to significantly decrease the sugar content of processed foods and more generally to improve the nutritional quality of products. Consumer concerns about foods have also translated into food-labeling requirements, which have been answered, at least partially, by a 2011 European regulation which, harmonized nutrition information, and made detailed ingredient listing mandatory in all countries, including, country of origin for some.

The geographic and socio-demographic structures of the European population largely contribute to explain food behaviors, with a high proportion of working educated urban people with little time to buy food or cook, yet have concerns about food quality (see above) and often environmental worries, which are increasingly important in Europe. Although it does not (yet?) appear to be a major driver, the environmental dimension impacts many areas, including food. Organic or "reasoned farming" practices are encouraged by the European Union and in several countries, and measures are taken that promote local and/or organic supplies for school meals to limit pesticides intakes and green-house gas emissions. Emblematic of the fight against "industrial agriculture" has been the ban of genetically-modified organisms in 19 European countries in 2015.

This very short overview suggests that in Europe, food-related policies and the food consumer values are often connected, but not always strictly. This is probably a reassuring conclusion, as public policies should consider consumer interest, concerns and opinion, but should not been dictated by the latter two, nor should attempts at regulating which remains each one's area of freedom and free choice.

BREAD FOR HEALTH

BREAD AND THE MEDITERRANEAN DIET: A DUET FOR THE PREVENTION OF CHRONIC DISEASES

Gil, Ángel.

PhD. Prof. Department of Biochemistry and Molecular Biology. Institute of Nutrition and Food Technology. Centre of Biomedical Research. University of Granada. CIBERobn. Spain.

Wholegrain cereals are rich in nutrients and many phytochemical compounds, with recognised benefits for health, including dietary fibre, a number of phenolic compounds, lignans, vitamins and minerals and other bioactive components. Foods based on wholegrain cereals, including bread, play an important part in health and well-being. Thus, research consistently indicates that the regular consumption of wholegrain cereals reduces the risk of CVD, type 2 diabetes mellitus (DM2) and certain types of cancer, as well as several gastrointestinal pathologies.

The inclusion of different ingredients or the use of different baking technologies may modify the satiety response to bread, and aid in the control of food intake. We have performed a systematic search of randomized clinical trials on the effect of bread consumption on appetite ratings in humans. The inclusion of appropriate ingredients such as fiber, proteins, legumes, seaweeds and acids into breads and the use of specific technologies may result in the development of healthier breads that increase satiety and satiation, which may aid in the control of weight gain and benefit postprandial glycaemia. Indeed, we have investigated the appetite ratings and postprandial glucose, insulin, and gastrointestinal hormone responses related to hunger and satiety after the intake of a cereal-based bread contained a variety of cereal flours (wheat, oat, and spelt) and consisted of 22% dried fruits (figs, apricots, raisins, and prunes). It was also enriched with both fiber (7% from wheat cross-linked maltodextrins and pea) and protein (10–11% from wheat gluten and hydrolyzed wheat proteins). Consumption of that cereal-based bread contributed to appetite control by reducing hunger and enhancing satiety. In addition, consumption of this bread improved glycemic, insulinemic, and gastrointestinal hormone responses in healthy adults.

Additionally, we have carried out a study evaluating the glycaemic response, insulin response, appetite and gastrointestinal hormone responses, following the intake of the five most common breads consumed in Spain differing in their composition and manufacturing process. We did not find relevant differences in glycaemic index or insulinemic index within the breads. However, we found differences in glycaemic load among the tested breads, mainly in the wholemeal bread. We did not obtain relevant differences in either appetite ratings or gastrointestinal hormone responses between breads. Despite this, more emphasis on encouraging the consumption of different breads, specially whole wheat breads, should be made by national authorities in order to promote healthier and varied diets, and therefore, to establish healthy lifestyles.

GLUTEN INTRODUCTION AND THE RISK OF CELIAC DISEASE

Da Costa Ribeiro, Hugo.

Associate Professor of Pediatrics. Chief. Division of Pediatric Nutrology. General Coordinator of Fima Lifshitz Research Unit. Pediatric Nutrition Research Unit. Federal University of Bahia. Brazil.

Celiac disease (CD) is a unique disorder in which consumption of a specific food nutrient, namely gluten, in conjunction with genetic susceptibility, is essential for the development of na insidiously evolving autoimmune reaction affecting the gut and other organs.

CD is a permanent condition that affects approximately 1 to 3% of the general population in most parts of world except for population in which the HLA risk alleles (HLA-DQ2 and/or DQ8) are rare such as in South East Asia.

The only treatment currently available for CD is strict adherence of a GFD for life. There is evidence that diagnosed but untreated CD is associated with significant increase in morbidity and mortality. Prolonged adherence to a GFD may reduce this risk for both morbidity and mortality to the levels found in the general population.

Adherence to a GFD in children results in remission of the intestinal lesions and promotes better growth and bone mineral density. It is the task of health care professionals to monitor and advise patients about adhering to a GFD because compliance with a GFD is variable and may be as low as 40%.

Summary of Recommendation: The recommendations are based on findings in children genetically predisposed to developing CD, because the risk of inducing CD through a gluten-containing diet exclusively applies to persons carrying at least 1 of the coeliac risk alleles. The following recommendations are conditional due to the low quality of evidence, however, applicable to all infants, although it is recognized that they may not be relevant to approximately two thirds of the population.

Breast-feeding and CD

(1) Recommendations on BF should not be modified because of considerations regarding prevention of CD (low quality of evidence).

(2) Introducing gluten while the infant is being breast-fed cannot be recommended as a means of reducing the risk of developing CD (low quality of evidence). BF should, however, be promoted for its other well-established heath benefits.

Timing of Gluten Introduction

(1) Gluten can be introduced into the infant's diet between the ages of 4 and 12 completed months. The age of gluten introduction in infants in this age range does not seem to influence the absolute risk of developing CDA or CD during childhood (depending on the age, quality of evidence varies from very low to high quality of evidence).

Type of Gluten

(1) No recommendation can be made regarding the type of gluten to be used at introduction (very low quality of evidence).

Amount of Gluten

(1) Despite the optimal amounts of gluten to be introduced at weaning or the effects of different wheat preparations on the risks of developing CD and CDA have not been established, ESPGHAN suggests that consumption of large amounts of gluten should be discouraged during the first months after gluten introduction (very low quality of evidence).

POTENTIALLY HEALTH PROMOTING PHYTO-CHEMICALS OF THE BENZOXAZINOID GROUP ARE ABUNDANT IN CEREAL GRAINS AND FOOD PRODUCTS

[1]*Fomsgaard, Inge;* [2]*Krogh Steffensen, Stine;* [2]*Bahadur Adhikari, Khem;* [2]*Pedersen, Hans Albert;* [2]*Tanwir, Fariha;* [2]*Gregersen, Per L.*

[1]Associate Professor of Natural Product Chemistry and Environmental Chemistry. Dept. of Agroecology. Faculty of Science and Technology. Aarhus University, Denmark; [2]Dept. of Agroecology Faculty of Science and Technology Aarhus University, Denmark.

Proteins, carbohydrates and fat are large molecules that are necessary nutrients for growth and development; both for the human consumer and for the cereal crop itself. Small molecules, such as benzoxazinoids (BXs), lignans, phenolic compounds and alkylresorcinols are not needed for growth and development, but they often have interesting exploitable biological activities; - and they are present in cereal food products.

For a long time BXs were believed only to be present as defence compounds in the young cereal plants.

In 2008 we discovered that mature grains of rye and wheat contain BXs. Bread baked in our lab from rye or hydrothermally processed wheat showed to contain substantial amounts of BXs. The composition and quantity of BXs in food products depended much more on the food preparation process than on the cultivar. BXs were taken up by pigs, rats and humans after consuming rye-based food. BXs have a range of potential pharmacological properties, as reviewed by Adhikari et al (2015). When bacteria induce the production of inflammatory cytokines in innate immune cells, a previous diet high in BXs enhances this production, indicating an immune-modulating effect of the BXs. With a highly sensitive analytical method uptake of 6 BX compounds in human prostate tissue was documented after one week's high-BX diet.

Intake of BXs by humans, pigs and rats is not restricted to take place in experimental trials with specially produced food items. Our recent analyses of 25 commercial cereal food products, purchased in Danish supermarkets, showed concentrations of BXs from not detected to >500 µg/g dry weight. Most products high in rye content had high concentrations of BXs.

Based on the above, the possible health protecting effects of BXs should be in focus in future development of functional food products for humans and of feed for animals. Future research should cover: full characterization of BX structures; methods for easy isolation of pure compounds; fate of BXs in the body - occurrence in plasma and urine, and distribution to tissues; effect studies - not only registration of effects but understanding of mechanisms behind effects.

WHY JAPANESE CUISINE IS HEALTHY?

SYNERGISM IN UMAMI TASTE WHICH IS CENTRAL TO JAPANESE CUISINE 'WASHOKU'

Ninomiya, Kumiko.

PhD. Director. Non-Profit Organization Umami Information Center. Japan.

When we eat, we use all of our senses - sight, hearing, smell and touch – to form general judgments about our food. Taste however, is the most influential in determining how delicious a food is. Conventionally, it has been thought that our sense of taste is comprised of four basic or primary tastes, which cannot be replicated by mixing together any of the other primaries tastes, sweet, sour, salty and bitter. However, a further primary taste is now recognized: Umami. It is the lingering, pleasant taste one experiences when eating savory foods. Japanese cooking uses many umami rich foods, although it is a universal taste common in many foods.

Taking its name from Japanese, umami is a pleasant savory taste imparted by glutamate, a type of amino acid, and ribonucleotides, including inosinate and guanylate, which occur naturally in many foods including meat, fish, vegetables and dairy products. As the taste of umami itself is subtle and blends well with other tastes to expand and round out flavors, most people do not recognize umami when they encounter it, but it plays an important role in making food taste delicious.

Many chefs around the world gained much more awareness of umami by storing up tastes in preparation for creating new flavors. With the umami spectrum, they always find clear notes of umami in a good ripe tomato, aged Parmezan cheese or other fermented foods like miso and soy sauce, dried shiitake mushrooms, kombu, etc. Kombu is the indispensable material to cook Japanese soup stock 'dashi.' Taste of dashi is very subtle and delicate, but it brings out original taste of various vegetables and makes excellent harmony with other tastes. Further more, combination of glutamate and inosinate or guanylate enhances umami, more than 7 or 8 times higher than umami by single compounds. Once chefs understand synergistic mechanism by combination of different umami compounds, they successfully develop new dishes. It is possible to create a new dish which is built on the top of umami through a balanced mixture of the other four primary tastes. Having experiences of umami taste sensation in our mouth is crucial to understand exact meaning of this unique taste. Its taste quality is quite different from other four basic tastes. Everyone can easily imagine tastes of sweet, sour, salty and bitter. However, umami may not be noticed by some people without the experience being pointed out, because it is very subtle and overshadowed by other tastes.

In this presentation, I would like to let you understand what is umami and synergism between glutamate and inosinate or guanylate. Chef Takehiro Ohno's presentation and demonstration will deepen your knowledge on umami with experiences.

Keywords: Umami, Glutamate, Inosinate, Guanylate, Synergism

HEALTH MERITS IN THE JAPANESE CUISINE

Nishimura, Toshihide.

Ph. D.. Professor. Kagawa Nutrition University. Professor emeritus. Hiroshima University. Japan.

In 2013, Japanese Cuisine "WASHOKU" was registered on the Representative List of the Intangible Cultural Heritage of UNESCO. "WASHOKU" is defined as the "Traditional Dietary Cultures of the Japanese". Therefore, "WASHOKU" is a social practice based on an essential spirit of the Japanese, "respect for nature". It has four characteristics as follows; at first, ingredients used in WASHOKU are diverse, fresh and available in four distinct seasons such as spring, summer, autumn and winter. Next, since WASHOKU requires well-balanced and low-fat diets, it contributes to health. For example, fishes, soy beans, vegetables and so on, are widely used as materials for WASHOKU. The third point is that WASHOKU is associated with the beauty of nature in the presentation such as plates of dishes, decorating tables and rooms. Finally, WASHOKU has developed using traditional knowledge and customs closely associated with nature and in connection to annual events. Therefore, when Japanese people share a mealtime together, they enhance the bonds among family and community members.

The traditional Japanese Cuisine "WASHOKU" constitutes one soup and three dishes. In general, miso soup is the typical soup in WASHOKU and it is consumed at least once every day. Miso is made from soy beans via fermentation. Umami substances are added to miso soup as seasonings to enhance its flavor. One of the dishes constitutes cooked rice. The other two dishes are foods cooked using fresh materials such as fishes, seaweeds and vegetables. Since there are four seasons in Japan, fishes and vegetables are diverse and fresh. From science, we know that fishes contain some functional substances such as EPA and DHA, vegetables contain dietary fibers, many kinds of vitamins and minerals, and green tea contains polyphenols with antioxidant activities. Thus, the ingredients in WASHOKU contain functional compounds while being a low-fat diet.

The longevity of the Japanese was about fifty years old immediately after the Second World War. Then, it gradually increased and reached to 70 years old in 1980s, until the longevity of Japanese male and female became 80.8 and 87.1 years old, respectively, in 2016. The increase of the Japanese longevity is thought to be caused by the increase of animal foods and the decrease of carbohydrate as well as the development of medical techniques. Animal foods contain lots of protein with well-balanced essential free amino acids and fat. Recently, Japanese cancer center reported that the intake of animal foods decreased the risk of mortality by about 10 % related to the traditional Japanese Cuisine. Modern Japanese Cuisine "WASHOKU" consists on animal foods such as meats and milk products as well as fishes, soy beans and vegetables, leading

"WASHOKU" to become a more well-balanced diet and increasing the longevity of Japanese people.

In this presentation, I would like to introduce Japanese Cuisine "WASHOKU" and explain its merits in health.

BUILDING A HEALTHIER SOCIETY BY HELPING PEOPLE TO EAT WELL

THE 21ST CENTURY NUTRITIONAL CHALLENGES THAT FACES THE FOOD INDUSTRY

Tontisirin, Kraisid.

Professor and Senior Adviser. Institute of Nutrition. Mahidol University.

Since nutrition is a link between food and health regarding the fulfilment of dietary needs of energy, protein, vitamin, mineral and phytonutrients from food in human life course for good health and well-being, the 21 century nutritional challenges will have to aim for achieving food and nutrition security for all. Global nutrition situation compiled by FAO/WHO at the 2nd International Conference on Nutrition (ICN2) held at FAO in Rome in November 2014 indicated that 805 million people suffer from hunger; 161 million children under-five are stunted, 99 m. are underweight, and 51 m. are wasting; 2 billion people affected by micronutrient deficiencies; 43 m. children under five are overweight and obese; 500 m. people are obese with a rapidly increasing rates of diet related non-communicable diseases (NCDs); 3.4 m. people die each year due to overweight and obesity; and the cost of malnutrition is about 3.5 trillion USD per year. The commitments from ICN2 by member countries, UN agencies, civil societies and private sectors include eradicating hunger and prevent all forms of malnutrition, enhancing sustainable food systems, raising the profile of nutrition, ensuring healthy diets throughout the life course, and creating enabling environment for making informed choice. The ICN2 also endorsed the "Global Nutrition Targets 2025" from WHA Resolution by reduction of low birth weight, childhood stunting and wasting, anemia in women of reproductive age, no increase in childhood over weight, and increase in the rate of exclusive breast feeding rate. Framework for actions from ICN2 include sustainable, resilient food system for healthy diets; aligned health system providing universal coverage of essential nutrition actions; social protection and nutrition education; trade and investment for improved nutrition; safe and supportive environments for nutrition at all ages; and strengthen nutrition governance and accountability.

The UN General Assembly in 2015 adopted the 17 Sustainable Development Goals (SDGs) to be achieved by the year 2030. All SDGs are interrelated and complemented to other goals. For example SDG 2 "End hunger, achieve food security and improved nutrition and promote sustainable agriculture" will be related to SDG 1. Ending poverty, SDG 3. Good health and well-being, SDG 4. Quality education for all, SDG 5. Gender equality, SDG 6. Clean water and sanitation, SDG 9. Industry, innovation and infrastructure. SDG 12. Responsible consumption and production, SDG 13 Climate actions, and SDG 17. Revitalize the global partnership for sustainable development. It has been emphasized that a successful sustainable development agenda requires partnerships between governments, the private sector and civil society. These inclusive partnerships built upon principles and values, a shared vision, and shared goals that place people and the planet at the centre, are needed at the global, regional, national and local level.

Since food industries are key players in food systems which are fundamental and essential for human well-being and sustainable development, they should welcome and engage actively with other stakeholders for achieving global nutrition targets including controlling of the NCDs, and achieving the SDGs particularly goal 2 ending hunger and all form of malnutrition.

THE IMPORTANCE OF TASTE TO SUPPORT HEALTHY DIETS

Beauchamp, Gary.

PhD. Distinguish Member. Monell Chemical Senses Center.

The sense of taste plays a crucial role in food selection and utilization. Traditionally, this sense has encompassed a small set of primary or basic qualities, namely sweet, salty, sour and bitter. These primary qualities have been thought to exist to insure that an organism can identify and consume critical nutrients (e.g. simple sugars and sodium) and avoid potential toxins. In 1909, Kikunae Ikeda identified a potential additional primary taste which he proposed was involved in identifying amino acids and protein. This taste quality, now called umami, had as its primary stimulus the sodium salt of the amino acid glutamate, best known as MSG. Over the subsequent 100+ years, considerable evidence has supported Ikeda's original hypothesis that umami constitutes a fifth basic taste quality although one with significant differences from the other four. In the second part of this presentation, I will describe some of the history of umami taste development from the point of view of a researcher in the United States. Among the topics I will address are early studies of the importance of MSG in many food systems, the identification of specific receptors for umami compounds, human developmental studies, and studies on the functional significance of umami. I will also raise important questions about umami that remain to be investigated. Throughout I will emphasize the central role that the Ajinomoto company has had in fostering basic and clinical research on this topic.

SPORTS NUTRITION FOR ACTIVE LIFE-STYLE

Shimomura, Yoshiharu; Kitaura, Yasuyuki.

PhD. Nagoya University. Japan.

Branched-chain amino acids (BCAAs), leucine, isoleucine, and valine, are non-indispensable amino acids for humans. Recent studies have found that BCAAs, especially leucine, work as not only building blocks of proteins, but also regulators of protein metabolism. It is also known that BCAAs are used as energy source during exercise. Human skeletal muscle contains free BCAAs at the concentration of ~650 μM, which is similar to the plasma concentration. The plasma BCAA concentrations are rapidly elevated by BCAA supplementation and peak at ~30 min after ingestion. We examined effects of BCAA supplementation (0.1 g of BCAAs/kg BW) right before squat exercise (20 squat/set x 7 sets with 3 min interval between sets) on the delayed-onset muscle soreness using untrained young female subjects. Dextrin was used as a control in place of BCAAs. The subjects participated two trials (BCAAs and control) with ~3 months interval. The trials were conducted with a crossover and double-blind design. The results showed that BCAA supplementation significantly decreased the muscle soreness 2-3 days after exercise, suggesting that the amino acid supplementation improves the muscle conditions after exercise.

The BCAA catabolism is regulated by branched-chain alpha-ketoacid dehydrogenase (BCKDH), which is located at the second step in the catabolism. The BCKDH is regulated by covalent modification. BCKDH kinase (BDK) is responsible for inactivation by phosphorylation of the BCKDH. Skeletal muscle has the high BDK activity to inactivate the BCKDH, resulting in providing BCAAs for protein synthesis. However, exercise promotes BCAA oxidation by activation of BCKDH in skeletal muscle. We prepared mice with chronically low levels of BCAAs by muscle-specific deletion of BDK (muscle-specific BDK knockout (BDK-mKO) mice). We examined the role of BCAAs in the adaptability to exercise training using the mice. The endurance capacity was increased by the 2-week training program in both mice, but was significantly less in BDK-mKO mice than in control mice, suggesting that sufficient BCAAs are required for the animals to maximally adapt the exercise training. These findings suggest that BCAAs are useful as sports nutrition for acute and chronic exercise.

Keywords: BCAAs, delayed-onset muscle soreness, exercise training, skeletal muscle, BCAA catabolism

HOW THE AJINOMOTO FOUNDATION AP-PROACHES THE CHALLENGES OF NUTRITION SECURITY

Kuriwaki, Kei.

The Ajinomoto Foundation.

The Ajinomoto Foundation (TAF) was established by Ajinomoto Co., Inc. and certified as the Public Interest Incorporated Foundation by the Cabinet Office of Japan in 2017.

TAF took over 4 nutrition related social projects, formerly managed by Ajinomoto, and is making them more public-oriented, socially impactful and sustainable.

We believe nutrition is the base of Sustainability and even economic growth. Its goals are closely tied with 2030 Agenda/ SDGs, particularly Goal 2, 3, 5, 1, under partnership to "end all forms of malnutrition".

1. Ghana Nutrition Improvement Project "KOKO Plus"
-Target: 6-24m infants (1st 1000 days) in Ghana
-Means: Product/ Education

TAF acquired the right of "KOKO Plus" from Ajinomoto and is building the Social Business model. This supplement food satisfies nutritional needs for infants, fortifying traditional complementary food koko with energy, protein, an amino acid and micronutrients. It was developed through Ajinomoto's expertise of processed food and nutrition to be Acceptable, Accessible and Affordable. This attracted partners including Ghana Health Service, University of Ghana and INF as well as donors like JICA, USAID, WFP and GAIN.

"KOKO Plus" has been proved to improve the health status of infants (stunting and anemia) and is under the scaling up phase now.

2. AIN program
Target: 2-5 y children, adolescent girls and adults in developing countries
Means: Education/ Agriculture/ School Meal/Food Processing

TAF has took over the AIN (Ajinomoto International Nutrition network) program which started in 1999 as a grants for NGOs dedicated to the improvement of eating habits and nutrition. Since then, AIN has supported 74 projects in 14 countries. We collaborate with NGOs to change the lifestyle of individuals through power of knowledge, empowerment and self-efficacy as nutrition issues has been shifting from undernourishment to NCDs and DBM.

3. VINEP (Vietnam Nutrition system Establishment Project)
Target: Ministries/ Universities
Means: Education system/ Lobbying

Ajinomoto launched VINEP in 2011 with the National Institute of Nutrition (NIN), Vietnam to expand their education programs for nutritional infrastructure. As a milestone, a regulation specifying the status of "dietitian" was put into effect in 2015 (job code). Then "dietitian" became a nationally recognized profession. The 2nd milestone is the graduation of 1st class bachelors of nutrition from Hanoi Medical University in June 2017. TAF is further working with the Japan Dietetic Association and the Ministry of Health, Labor and Welfare to support NIN to create Nutrition

Standard so that dietitians can take an active part and become nutrition leaders in the country.

4. Support for reconstruction after disaster

Target: Elderly residents in disaster-struck areas

Means: Cooking Together & Eating Together with nutritionally balanced menu

In temporary housings in Tohoku since 6 years ago, nutrition-related problems have been detected; increased risk of diabetes and heart troubles, vitamin and mineral deficiency caused by lack of vegetables, reluctance to prepare food, and fewer opportunities for conversation due to the destruction of communities. Our solution to those is "Cooking together, Eating Together" events using tailor-made mobile cooking table and our original menus. Seniors enjoy the valuable opportunity to gather and enjoy conversation, which helps to prevent isolation, with "reduced salt, more vegetable" menus.

NUTRITIONAL REFORMULATION OF FOOD PRODUCTS – A KEY STRATEGY FOR IMPROVING FOOD SUPPLY IN LATIN AMERICA

FOOD POLICIES AND REFORMULATION OF FOODS IN CANADA

[1]Labbe, Mary; [2]Ahmed, Mavra; [3]Arcand, JoAnne; [2]Schermel, Alyssa.

[1]PhD. Earle W McHenry Professor and Chair. Dept of Nutritional Sciences. University of Toronto. Canada; [2]MSc. Department of Nutritional Sciences, University of Toronto. Canada; [3]RD. PhD. Assistant Professor. Faculty of Health Sciences. University of Ontario Institute of Technology. Canada.

The prevalence of overweight and obesity in Canada has increased 2.5 fold over the past 25 years [1]. Unhealthy diets are a major contributor to overweight and obesity, key risk factors for non-communicable diseases (NCDs) [2]. WHO has indicated the widespread production and marketing of energy-dense, nutrient poor foods and beverages high in fat, sugar and sodium as important contributors to obesity and NCDs [2]. As a result, public health initiatives at the nutrient level (e.g. labelling, advertising restrictions and reformulation) have been proposed as complementary strategies to improve diets. Nutrient profiling is the science of classifying or ranking foods according to their nutritional composition for reasons related to preventing disease and promoting health [3]. Thus programs such as front of pack labelling and setting reformulation targets require nutrient profiling systems that can be used in a transparent manner to define 'healthier' or 'less healthy' products for such programs.

In Canada, reformulation approaches included publishing sodium reduction benchmark targets for packaged foods in 2012 (as part of the national sodium reduction strategy) and earlier voluntary trans fatty acids (TFAs) limits which also encouraged substitution with unsaturated fats. Recently, Health Canada released their Healthy Eating Strategy which included a number of efforts including front-of-pack labelling, restrictions on marketing to children, and regulations eliminating partially hydrogenated oils. However, the potential for these approaches to be successful relies in part, on reformulation efforts by industry and public monitoring of the food supply.

The University of Toronto Food Label Information Program (FLIP) is a branded nutrition composition database of ~26,000 unique food and beverage products that began in 2010. Data includes national and private-label brand foods from the 4 largest Canadian grocery chains, accounting for approximately 75% of food retail sales. FLIP allows for an effective monitoring of the impact of reformulation efforts on the Canadian food supply over

time. We have utilized FLIP to comprehensively assess changes in sodium and trans fat levels in packaged foods sold in Canada from 2010 to 2013.

Analyses using the FLIP database to assess changes in sodium levels indicated that 16.2% of the food categories had significant reductions in sodium levels, with significant improvements seen in imitation seafood, condiments, breakfast cereals, canned vegetables/legumes, plain chips, hot cereals, meat analogues, canned condensed soup, and sausages and wieners. However, these analyses were done at year 3, mid-way through the 6-year target goals, and over 80% of the food supply had not yet made significant progress [4]. In contrast, impressive improvements were seen in elimination of trans fat, where 97% of products were meeting the TFAs limits within 7 years [5]. With the recent announcement of a front-of-pack labelling system in Canada (i.e. Warning Signs) and other programs, examination of the Canadian food supply in relation to these policy changes will be important to monitor industry reformulation progress in meeting healthy eating goals.

NUTRIENT PROFILING FOR PRODUCT REFORMULATION: THE BENEFIT FOR THE CONSUMER

[1]Masset, Gabriel; [2]Lehmann, Undine; [3]Mathias, Kevin; [4]Vlassopoulos, Antonis; [5]Gressier, Mathilde.

[1]PhD. Consumer Science & Applied Nutrition. Nestlé Research Center. Lausanne. Switzerland.; [2]PhD. Nutrient Profiling group leader. Consumer Science & Applied Nutrition. Nestlé Research Center. Lausanne. Switzerland.; [3]PhD. Dietary Recommendations. Nestlé Research Center. Lausanne. Switzerland.; [4]PhD. Consumer Science & Applied Nutrition. Nestlé Research Center. Lausanne. Switzerland.; [5]Consumer Science & Applied Nutrition. Nestlé Research Center. Lausanne. Switzerland.

Public health initiatives aimed at improving the nutritional content of food and beverages are regarded by WHO and other health authorities as an effective means to improve the health of the global population. Examples of countrywide initiatives include the UK responsibility deal (2011) with sodium as the primary target, the Health Canada guidance for the food industry (2012), and the recent United States FDA proposal (2016). In Latin America, several governments have proposed or implemented such approaches, such as the "Menos Sal Más Vida" initiative in Argentina, and the Brazilian Sodium initiative (2011). All of these approaches put the reformulation of food and beverages at the center of the public health nutrition agenda in addition to nutritional education and behavioral change initiatives.

To implement reformulation, manufacturers need guidance. Nutrient profiling (NP), the science of categorizing foods based on their nutrient composition, has emerged as an essential tool to guide reformulation and other nutrition policies. NP systems should be adapted to their specific purposes as it is challenging to design one system that can equally address all policies and purposes, e.g. reformulation and labelling.

In the symposium, we will present the principles and the validation process of the Nestlé Nutritional Profiling System (NNPS) that has been specifically designed for reformulation. The NNPS is a category-specific NP system which provides nutritional targets per serving for 7 to 10 nutrients, depending on the category; all nutrient targets need to be met to obtain an NNPS Pass status [1]. The system has been implemented since 2005 and is now used in all countries in which Nestlé operates (191 in 2016). The NNPS was recently shown to be able to identify more nutritious options within food and beverage categories [2], and a modeling study highlighted that potential reformulations following NNPS standards could improve nutritional intakes of the US and French populations [3]. These studies also identified some potential limitations of reformulation and the NNPS to address nutrition gaps, for example to act mainly on nutrients to limit but only with limited extend on nutrients to encourage [3]. New approaches for NNPS evolution that e.g. address this point and provide more holistic food and beverage product development guidance will be discussed.

In order to achieve its maximum potential and modify the food environment in a beneficial manner, reformulation should be implemented by the entire food sector. Multi-stakeholder partnerships including governments, food industry, retailers and consumer associations that will state concrete time-bound objectives accompanied by an independent monitoring system are the potential solution. Further, reformulation per se will not address the whole nutrition gap that exists in many countries, and there is a need to combine reformulation with other public health initiatives in more integrated frameworks.

FOOD REFORMULATION: A PUBLIC HEALTH AND ECONOMIC PERSPECTIVE

Soler, Louis-Georges.

PhD. Economist. INRA. Paris. France.

To address public health issues related to poor dietary habits, governments and public health agencies have been implementing policies intended to promote preventive behaviors thanks to information campaigns and food product labeling. Reviews of these policies show that they have some positive impact that, however, remains small, at least in the medium term. In addition, some of these policies are suspected to increase health inequalities, with less-educated individuals responding less to information policy. Given the modest impact of information-based policies, public health agencies are now considering other policies to modify the market environment to facilitate healthier food choices, even by non health-sensitive consumers. A broad range of instruments have been considered, from price policies to nutrition-related standards.

Policies focused on food quality are intended to facilitate healthy choices by consumers, even those who are not fully informed about the links between food consumption and health. Decreasing the salt and fat content in foods and increasing the whole grain content are good examples of food composition changes being made to address health-related issues. In this context, public health agencies urge the food industry to favor a better food environment through changes in the quality and variety of foods and through changes in advertising and marketing, and some governments are partnering with the food industry and the retail sector to generate changes on the supply side.

Are policies focused on the supply side more promising than policies focused on consumers? Which public health benefit can we expect from their implementation? Are market incentives sufficient to induce voluntary changes by firms or is public regulation of food quality needed to reach public health objectives?

To deal with these questions, we will first review the results of modeling-based articles to estimate the potential public health impact of changes in the nutritional quality of foods. We will suggest that the improvement of the nutritional quality of foods may induce significant health benefits even in the absence of changes in consumers' diet patterns. Although food reformulation alone would not be sufficient to dramatically reduce the prevalence of chronic diseases related to food consumption, it can play an important role in that direction.

Second, we will review the initiatives currently implemented by the food industry and assess their impact on consumers' intakes by using data collected in France. We will show that voluntary commitments made by firms are sometimes significant, but the final impact on consumers is still modest because the number of committed firms and the market shares of reformulated food remain limited.

Third, we will discuss what we can expect from self-regulation vs. public regulation of food quality. Although voluntary commitments could offer potential cost savings for regulators and firms, their success depends on several conditions that we will identify. Among them, we will insist on the need to favor collective agreements at the food industry level and the availability of monitoring tools to quantify and control their implementation.
