HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

INTRODUCTION

Climate is changing towards more extreme precipitation patterns

	Dry period	Rewetting after dry period
SOIL	<ul style="list-style-type: none"> Decreased water saturation of pore spaces 	<ul style="list-style-type: none"> Increased saturation of pore spaces Breaking up of soil aggregates Release of trapped nutrients Increased respiration and release of greenhouse gases
MICROBES	<ul style="list-style-type: none"> Decreased mobility of microbes and nutrients Accumulation of intracellular osmolytes to prevent dehydration Increased number of dormant and resistant forms Increased fungal:bacterial ratio Decreased N and C cycling rates 	<ul style="list-style-type: none"> Increase in competitive and fast growing species Release of accumulated osmolytes to prevent cell lysis Increase in microbial activity including N and C cycling
PLANT	<ul style="list-style-type: none"> Reduced stomatal conductance to avoid water loss Decreased photosynthesis rate Access deeper water sources if possible 	<ul style="list-style-type: none"> Increased photosynthesis rate Resumed transfer of rhizodeposits to the soil

OBJECTIVES

Gain insight into the dynamics of the interactions involved in the coupling between water and N cycles, as affected by changes in precipitations patterns. A multidisciplinary approach is used to evaluate the response of soil microbial community, plant, and soil N cycle to repeated cycles of drying-rewetting patterns of contrasted frequency and magnitude.

FRAMEWORK

Fig. 1. Conceptual diagram of plant-soil interactions during and after a dry period. Arrow widths are proportional to flux rate.

¹⁸O Stable Isotope Probing (¹⁸O-SIP)

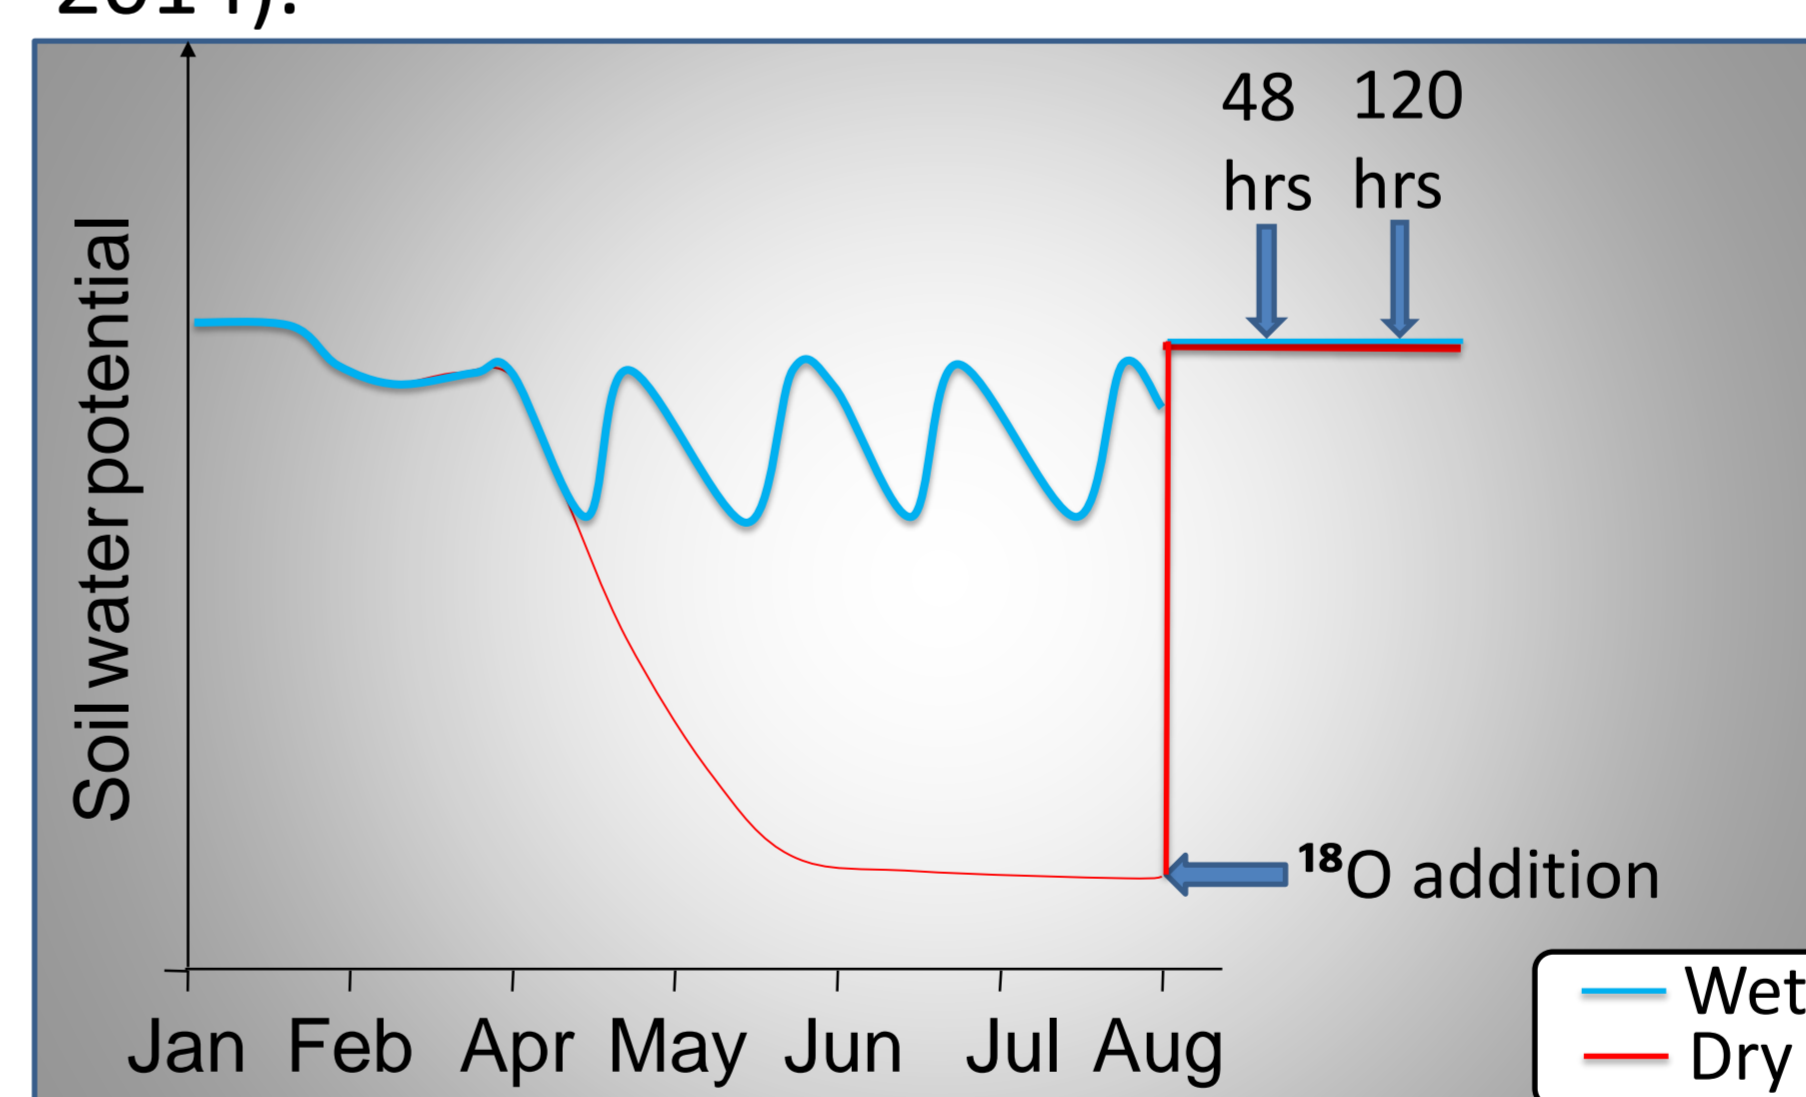

Capture the temporal dynamics of metabolically active soil microorganisms upon rewetting after contrasted water availability.

Aim

- Identify bacterial strategies
- Relate to soil N cycling and N₂O emissions

Principle

¹⁸O-labelled water allows identification of metabolically active communities in soil without the addition of external nutrient sources (Blazewicz et al. 2014).

Approach

- Isolate metabolically active community – SIP
- Identify community composition – sequencing
- Evaluate abundance of N cycling genes - qPCR

Fig. 2. Dynamics of soil water content in the precipitation pattern treatments and controlled wet-up (adapted from Barnard et al. 2015).

GREENHOUSE EXPERIMENT

Evaluate integrated response of system as a whole (plant, microbiota, soil) to rewetting after different precipitation regimes

Aim

- Establish fate of N by tracking ¹⁵N-NH₄ tracer as plants and microbes compete for resources
- Link to interaction between plant performance and soil microbial activity

Approach

- Soil microbial community: metagenomics, taxonomic diversity
- Plants: high throughput phenotyping platform
- Soil N cycling: nitrification, denitrification, N₂O efflux rate
