HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Preferred type of presentation

Poster presentation

Oral presentation

Environmental nitrogen and phosphorus supplies alters prevalence and competitive interactions among two plant viruses

Resource-ratio theory has widely been used to explain outcomes of competitive interactions between species in communities of plants and other free-living organisms. Yet, we have little empirical data on the effects of nutrient supplies on the interactions among microbial organisms that use plants as hosts. A framework for understanding the mechanisms governing the assembly of plant microbial communities would be an important advance because plants often host a diversity of micro-organisms, and interactions among co-occurring microbes can alter both host and microbe population dynamics. To better understand the effects of nutrient supplies to hosts on microbe interactions, we singly inoculated and co-inoculated plants of one annual crop species (*Avena sativa*, Poaceae) with two systemic and phloem-restricted virus species, barley yellow dwarf virus-PAV (BYDV-PAV, Luteoviridae) and cereal yellow dwarf virus-RPV (CYDV-RPV, Luteoviridae). Host plants were grown across a factorial combination of N and P supply rates. P addition lowered CYDV-RPV prevalence. N addition altered the interaction strength among viruses. The co-inoculation of BYDV-PAV lowered CYDV-RPV infection rate, but this antagonistic interaction only occurred at low nutrient supply rates and disappeared at high N supply rate. These results provide insights on how nutrient-host-virus interactions might drive microbe community composition and increase the risk of co-infection, especially in light of the global scale of human alterations of biochemical cycles.
