HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Early pedogenesis of a Technosol developing on iron industry deposits

Keywords : Technosol, iron industry settling pond, pedogenesis, rhizosphere

As a result of increasing soil anthropisation, large surface areas covered by anthropogenic materials are submitted to environmental factors (\textit{e.g.} climate, organisms). Pedogenesis of the developing Technosols is often characterized by an intense and rapid weathering (1, 2, 3). However, the nature, localization, and extent of the pedogenetic processes occurring in Technosols are still little known.

To assess the soil formation on purely anthropogenic parental materials, a former settling pond of iron industry sludge colonized by vegetation since \textit{ca.} 50 years was chosen. The soil is composed of contrasted layers, and an organic layer has developed at the surface (4, 5, 6). Composition, mineral and organic components and structure of the soil were studied as tracers of the material origin and indicators of early pedogenetic processes. Also, historical records regarding the industrial operations were analyzed. Twelve layers were sampled in the first two meters of the profile. Mineralogy was determined with XRD, IR, Mössbauer spectroscopy, SEM and TEM-EDS. Spectroscopic and molecular analyses were carried out on solvent extractable organic matter. Thin sections were prepared for some layers.

Results showed a stratification of the soil profile resulting from successive sludge supplies. Composition, mineralogy, and structure of the layers of the Technosol were derived from the industrial raw materials and processes. Elemental composition reflected the enrichment in volatile elements, and organic analyses the dumping of oil and combustion by-products. Part of the mineral phases was inherited from raw materials, and others resulted from the industrial processes (\textit{e.g.} high temperature...
Phases. Pedogenetic processes were obvious with the development of an organo-
miner horizon. In the deeper layers, analysis of microstructure and mineralogy
revealed physical (cracks, solute movements) and chemical processes (dissolution,
precipitation). These phenomena occurred primarily in cracks and at the interfaces
between two layers. Also, roots, which have colonized the whole profile, and
developed preferentially in these areas, have induced changes in their rhizosphere
(modification of porosity and metal extractability). In conclusion, the Technosol
results from successive steps of pedogenesis, driven firstly by drying-wetting cycles
and changes of physico-chemical conditions induced by the climatic factor, and
finally by biological processes in relation with root development.
