HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Abstract:

Agriculture is challenged by large scale issues, like impacts of land system changes on the preservation of environmental resources, urging agronomy to evolve. Landscape agronomy has been proposed as new perspective to address these issues (Benoît, Rizzo et al. 2012). It stressed the need for developing spatially-explicit modeling and assessment of agricultural activities at spatial levels encompassing the farm and its contexts. In line with this, we aimed at comparing two empirical studies whose common purpose was to characterize the landscape organization of agricultural land uses within a hydrological spatial framework. In particular, primary catchments were aggregated or segmented according to land use dynamics, stressing out the role of crops and meadows dynamics at different stream order levels (see Strahler, 1957). Both studies had thus to face difficulties at retrieving datasets to describe agriculture at wide spatial levels over long periods.

The first study assessed land use dynamics and their potential impact on water quality for the Meuse and Moselle watersheds (24,000 km², NE France). TerUti data (French Ministry of Agriculture) were analyzed at the primary catchment (hereafter PC) scale, as mapped by the Rhin-Meuse Water Agency (funding body and project partner). Return times of 11 land use classes, 9 of which agricultural, were described for each PC with a five-year window, sliding over the period 1981-2010. A preliminary data-mining using CarottAge (Mari & Le Ber 2006) oriented the successive analyses of land use trajectories, performed with R packages (Gabadinho et al. 2011, Housson et al. 2012). Hierarchical clustering on principal component was then used to aggregate the 16 PC on homogenous land use trajectories.

The second study aimed at generalizing a time-space clustering method based on hidden Markov models for the Yar PC (60 km², NW France). The method, currently implemented as

research software (ArpentAge, Mari et al. 2013), was originally developed to tackle detailed, yet highly work-demanding long-term surveys (Lazrak et al. 2009). Maps used to segment the Yar catchment derived from satellite images and distinguished 3 agricultural land uses, out of 6 total classes, over 12 successive years (Corgne, 2004). Such a coarse thematic resolution was due to limits in the remote sensing data interpretation. Despite that, major agricultural dynamics were unveiled, shedding new light on the role of agricultural activities in eutrophication issues that threaten this watershed.

In summary, both studies provided an example of advances in observational capabilities and modeling methods of landscape agronomy. More generally, they provided also insights in the land system architecture (Turner II et al. 2013). Indeed, eliciting the study of subtle (agricultural) land use changes by using watershed spatial elements can meet expectations of local and regional resource managers for decision-making spatially-explicit supports.
