HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

LIGHT QUALITY (RED:FAR-RED RATIO) DOES NOT AFFECT THE PHOTOSYNTHESIS OF DEVELOPING LEAF IN WHITE CLOVER (*Trifolium repens* L.)

V. Héraud-Bron, C. Robin and A. Guckert.

In lower parts of a canopy, the foliage shade induces a drop of irradiance but also a decrease of the ratio between Red (R) and Far-Red (FR) wavelengths (Holmes and Smith, 1977). The red (660 nm) : far-red (730 nm) is perceived by the plant through the photoreceptor phytochrome. The photosynthesis of lowest leaves is obviously limited by the reduction of light intensity but the specific effects of low R:FR ratio on CO₂ fixation were little investigated particularly for a plagiotropic species like white clover (Sheehy *et al.*, 1983). This legume is mainly used as a component of mixed swards. The grass leaves overtop the lower parts of white clover (stolons, buds and young leaves) and the competition for light leads often to legume's decline (Soussana *et al.*, 1995).

In order to study the influence of R:FR ratio on photosynthetic activity of developing leaves, cuttings of white clover cv Huia were grown in a controlled environment under low irradiance ($110 \pm 40 \mu\text{mol}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$ in PAR range) in combination with two light quality treatments. For the -FR treatment, the background light was provided by halogen metal vapour lamps with a R:FR ratio of 2.4. For the +FR treatment, the R:FR ratio of background light was reduced up to 0.4 by FR light supplementation. As simulation of foliage shade occurring within a sward, we limited the FR lighting to the developing leaf before its emergence from apical bud until its unfolding by using far red light emitting diodes (Figure 1).

Figure 1 : Irradiation of developing leaves with FR diodes from the initiation within apical bud to the unfolding under +FR treatment. L, lead to power source ; C, collimator containing a FR diode ; BW, black wire holding up a FR diode ; WS, wire staple to avoid the irradiation of internode.

The results showed that low R:FR ratio does not affect the net CO₂ assimilation rate of unfolded leaf under growth irradiance (Table 1). The CO₂ fixation was neither limited by stomatal conductance nor by total carboxylase activity of Rubisco under FR lighting. Nevertheless, the measurements of chlorophyll a fluorescence showed that low R:FR ratio slightly decreased the photochemical quantum yield of PSII centers (parameter estimating the efficiency of the overall photosynthetic performance) without modification of apparent electron transport rate through PSII (Table 1). This reflects a decrease of the electron flow which is used by another process than CO₂ fixation, like photorespiration. Low R:FR ratio also reduced the chlorophyll a content without modification of chlorophyll b content (Table 1). This characterized an acclimation of thylakoid structure to foliage shade (Chow *et al.*, 1990).

Table 1 : A comparison of photosynthetic activities and components of developing leaf between -FR and +FR treatment. Values represent the mean of 9 replicates \pm SD. The significance of light quality effects (*p*) were determined by variance analysis (** *p* \leq 0.01 ; * *p* \leq 0.05 ; ns = not significant)

Parameters	-FR treatment	+FR treatment	<i>p</i>
Net CO ₂ assimilation rate ($\mu\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$)	4.7 (1.56)	4.9 (0.95)	ns
Stomatal conductance ($\text{mmol H}_2\text{O m}^{-2} \text{ s}^{-1}$)	96 (19.4)	90 (23.5)	ns
Total carboxylase activity of Rubisco ($\text{mmol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$)	208 (53.3)	185 (43.3)	ns
Photochemical quantum yield of PSII centers	0.75 (0.009)	0.73 (0.024)	**
Apparent electron transport rate through PSII ($\mu\text{mol e}^- \text{ m}^{-2} \text{ s}^{-1}$)	35.8 (5.40)	33.8 (5.64)	ns
Chlorophyll a content ($\mu\text{g cm}^{-2}$)	63.9 (9.76)	58.6 (10.21)	**
Chlorophyll b content ($\mu\text{g cm}^{-2}$)	11.7 (4.01)	9.3 (3.04)	ns

Conclusions : This study showed that low R:FR ratio does not determine the efficiency of CO₂ fixation under foliage shade. An other process of photosynthesis like photorespiration seems to be affected by light quality. This aspect remains to be investigated. We also confirmed that white clover is an intolerant shade species as regard to morphology but also about its chlorophyll content.
