HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Sustainable hydrogen production from agro-industrial wastewater combining dark fermentation and microbial electrolysis

The aim of this work is the development of a feasible, cascade two-step BioH₂ production process from Organic Waste Streams (OWS), combining dark fermentation (DF) and Microbial Electrolysis (ME). Such coupling of DF and ME constitutes a technological cornerstone within the concept of an environmental biorefinery.

In this work, more than 20 different OWSs, were selected and collected from a wide range of industrial sectors (food, manufacturing, biofuel, wastewater treatment, among others). All the OWSs were fully characterized (i.e., total solids/volatile solids, COD, sugars, proteins, VFAs, organic acids, alcohols, N-tot, pH, density, electrical conductivity, nutrients, etc.) and tested for H₂ production by DF in batch reactors (pH 5.5, 37°C) using heat treated anaerobic sludge as inoculum. The fermentative metabolic patterns were analysed. Depending of the OWS the H₂ yield varied from 0 to 130 mLH₂/gCOD with acetate, butyrate and ethanol as main metabolic by-products. The H₂ recovered in DF was linearly correlated with the initial content of sugars and/or glycerol present in OWSs ($R^2 = 0.9$). The most promising OWSs DF effluents were selected on the basis of fermentative conversion efficiency (i.e., both H₂ and metabolic by-product accumulation) to further recover H₂ in ME cells. Such experiments are currently ongoing. They are conducted in two chambers (400 mL wV) potentiostatically controlled systems (anode applied potential + 0.2V vs SCE, pH 7, 37°C) using an electroactive biofilm as biocatalyst previously enriched from anaerobic sediments using acetate as carbon source. Preliminary results show satisfactory performances in terms of electrical current production, 600 ± 10 mA/m² (up to 34 A/m³_{reactor}), with a CE (Coulombic Efficiency) of about 30% and a biogas stream highly enriched in H₂ (60%).

These results showed that dark fermentation linked with ME is a feasible and highly promising option in order to maximize the conversion of OWSs into bioenergy.
