## CONTEXT AND OBJECTIVES

Forest soils host methanotrophic bacterial communities that make them a major methane sink worldwide. Soil compaction resulting from mechanization of forest operations is first affecting soil macroporosity, and thus gas and water transfer within the soil, leading to a reduced oxygenation of the soil. This reduction of gas diffusion is expected to promote methanogenesis in the deeper soil layer and to reduce the methanotrophic activity in the upper layers, leading thus to less CH<sub>4</sub> oxidation and more CH<sub>4</sub> production, affecting the overall soil CH<sub>4</sub> budget.

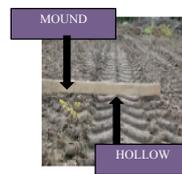

Objectives: Does the compaction reduce CH<sub>4</sub> uptake ?

What is the impact of compaction on the seasonal CH<sub>4</sub> variability (net fluxes and consumption/production)?

## II SITE DESCRIPTION

- Location: Azerailles Forest (NE of France)
- Precipitation : 950 mm /Mean annual temperature: 8.5°C
- afforested with 1600 sessile oak (*Quercus petraea* L.)/ha in 2007
- soil compacted in 2007 (treatments: control and compacted)
- In compacted treatment : 2 modalities defined by topography: hollow and mound
- soil type : luvisol
- soil texture : 50 cm of silty loam overlying a heavy clay

- bulk density ( $\rho_b$ ) increase with depth (Fig.1).  $\rho_b$  control <  $\rho_b$  compacted &  $\rho_b$  hollow >  $\rho_b$  mound in the upper layer

compaction of the soil in 2007 and due to the last passage of the truck, topographical variations (could reach 15-cm) leading to 2 modalities

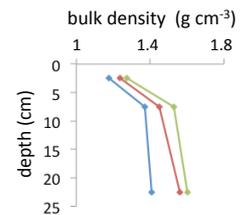

Fig.1: bulk density of the upper layers of the soil in the control (blue), hollow (red) and mound (green) modalities

## III MATERIALS AND METHOD

### SOIL GAS CONCENTRATIONS

- Gas-permeable tubes (Accurel PPV8/2) inserted horizontally at 0, 5, 10, 25 and 40 cm below the soil surface during early summer 2013.
- Air was collected sequentially with solenoid-valves and pumped to CH<sub>4</sub> analyzer (FGGA, LGR).
- 3-hour frequency measurement/depth/treatment

### SOIL FLUX

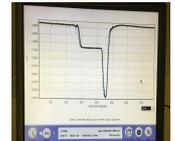

- 12 closed home-made-chambers (4 per treatment)
- opening/closing of chamber controlled by pneumatic cylinders.
- Frequency of measurement: 3h
- Air collected was analyzed with CH<sub>4</sub> analyzer (FFGA, LGR).

### SOIL TEMPERATURE AND WATER CONTENT

Temperature and soil water content devices (CS650 Campbell Sci.). 2 devices/treatment at following depths -10, -25 and -40 cm

soil efflux chamber

FGGA analyser

## IV RESULTS

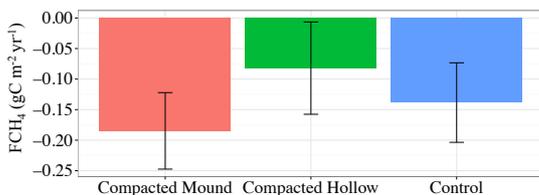

Fig.2: Cumulative CH<sub>4</sub> effluxes measured during one year from nov 2014 to nov 2015 for the 3 treatments. Cumuls are the mean of 4 chambers

**No significant difference in CH<sub>4</sub> uptake by the soil between treatments (Fig 2) but strong seasonal variations linked to variations in air filled porosity (fig 3&4)**

**When air filled porosity is high (low SWC), higher CH<sub>4</sub> uptake by the soil (Fig4)**

- ✓ CH<sub>4</sub> uptake is slightly higher in the compacted hollow when the air filled porosity is high
  - higher consumption of CH<sub>4</sub> in the compacted hollow => higher microbial biomass and/or lower limitation by water availability compared to the others treatments increases the methanotrophic activity in compacted hollow

**When air filled porosity is low (high SWC), CH<sub>4</sub> uptake by the soil is low (Fig 4) linked**

- ✓ to limitation of CH<sub>4</sub> diffusion
- ✓ and to production of CH<sub>4</sub> in deeper layers (Fig.5). This CH<sub>4</sub> is preferentially oxidised in upper layers as soils become only occasionally CH<sub>4</sub> source (Fig 3 & 5)

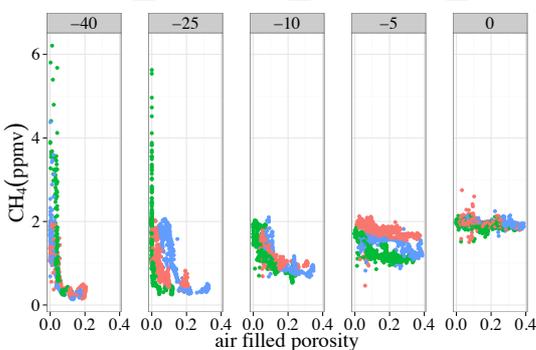

Fig.5: Relation between CH<sub>4</sub> concentrations and air filled porosity at each depth for the different treatments based on daily means.. Each depth is represented by a rectangle from the deeper in the left to the shallower in the right (depth are in cm).

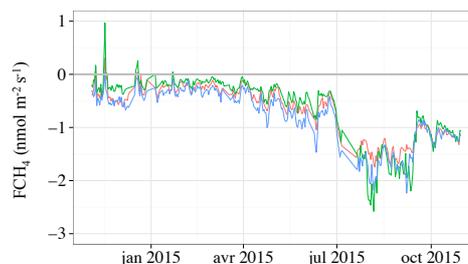

Fig.3: Time courses of daily averaged CH<sub>4</sub> effluxes from nov 2014 to nov 2015 for the 3 treatments

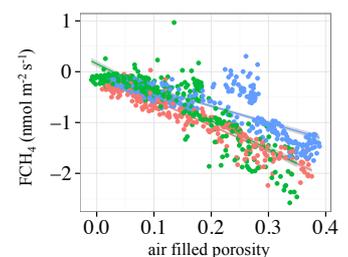

Fig.4: Correlations between CH<sub>4</sub> effluxes and air filled porosity measured at -5cm depth. Each point represents daily means of 4 chambers for FCH<sub>4</sub>

## V CONCLUSIONS

Compaction does not reduce significantly the yearly CH<sub>4</sub> uptake

But compaction increases the seasonal variations in the compacted hollow (increase uptake in summer / increase the production in depth in winter and reduce CH<sub>4</sub> uptake)

**Future works:** development of a flux-gradient approach model (AGU presentation n° B54A\_03 by Delogu, Friday afternoon for the method) and <sup>13</sup>CH<sub>4</sub> labelling in the field (i) to separate transport and biological production/consumption and (ii) to determine where the consumption takes place in the soil
