3/ Experimental study

4/ Concluding remarks

Why investigating the evaluation of Two-stage prospects?

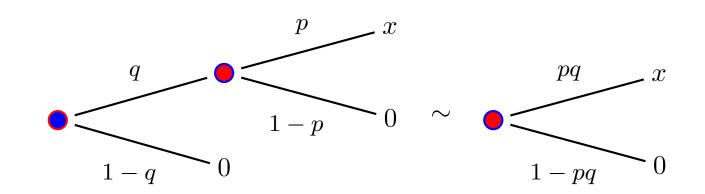

Table 1: compound risk and its reduced one-stage lottery

□ Rational Decision makers (DMs) reduce compound risks, represented by compound lotteries, into single stage lotteries by using the Reduction of compound prospects axiom (RCP).

 \Rightarrow Rational DMs should exhibit a perfect neutrality toward compound risk.

However...

Three observations on compound risk

- 1. Reduction of compound prospects have been descriptively challenged in many empirical investigations:
 - Bar Hillel (1973), Bernasconi & Loomes (1992), Budescu & Fisher (2001), Abdellaoui, Klibanoff & Placido (2014), Nebout & Dubois (2014)...
- 2. Following Becker & Brownson (1964) and Yates and Zukowski (1976), Segal (1987, 1990) represented ambiguous bets as two-stage prospects.
- 3. Prospect Theory (PT) is the most succesful descriptive model of decision making under risk and ambiguity.

 \Rightarrow Would it still be the case when dealing with attitudes toward two-stage prospects?

Theoretical and Empirical Background

Background: One-stage prospects

- $\Box \quad (x, p; y) \text{ denotes the one-stage } prospect \text{ resulting in outcome } x \\ \text{with probability } p \text{ and in outcome } y \text{ with probability } 1 p \text{ with } \\ x \ge y \ge 0.$
 - Probability p is generated using a known urn containing 100 balls numbered from 1 to 100, i.e. drawing a ball which has a number between 1 and $p \times 100$.
- \Box $(x, E_p; y)$ denotes the corresponding ambiguous prospect. The probability $P(E_p)$ is unknown to the DM.
 - We use an unknown containing 100 balls numbered from 1 to 100 in unknown proportions, i.e. drawing a ball which has a number between 1 and $p \times 100$. Symmetry arguments imply $P(E_p) = p$. (Chew & Sagi, 2006, 2008)

Background: Evaluation of one-stage prospects

□ Under Expected Utility (EU), prospects are evaluated as follows: EU(x, p; y) = pu(x) + (1 - p)u(y)

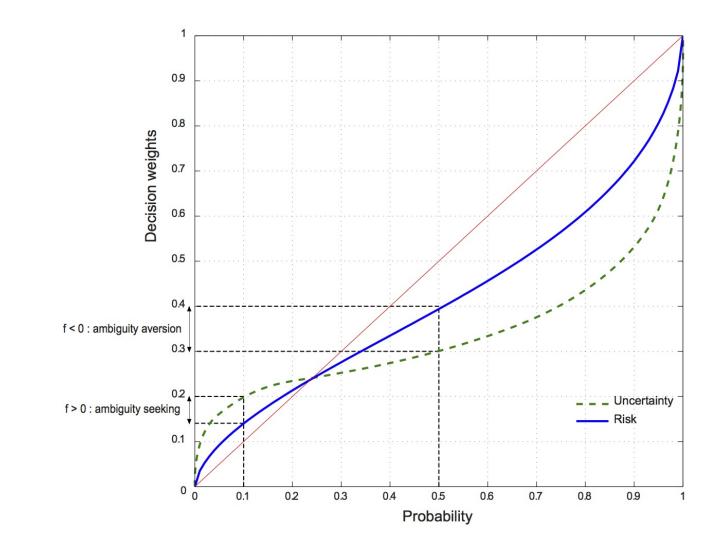

- Where u is the utility function (and a risk attitude index).
- Violations of EU popularized by Kahneman & Tversky.
- \Box Under Prospect Theory (PT), prospects are evaluated as follows in the gain domain:

$$PT(x, p; y) = w(p)u(x) + (1 - w(p))u(y)$$

- *u* is the utility function.
- w is the probability weighting function. w is strictly increasing and satisfies w(0) = 0 and w(1) = 1.

 \Rightarrow Many experimental evidence on RDU under risk and ambiguity.

Probability weighting under risk and ambiguity

 \Rightarrow Ambiguity increases **likelihood insensitivity.**

How to evaluate two-stage prospects?

20-23 July 2014

How to evaluate two-stage prospects?

 \Box Recursive Expected Utility without RCP (REU):

$$\Rightarrow \frac{1}{2} \times \phi \left[EU(P) \right] + \frac{1}{2} \times \phi \left[EU(Q) \right]$$

- Kreps & Porteus (1978) introduced this transformed EU functionnal to account for delayed resolution of uncertainty.
- Klibanof & al. (2005) used the same preference functional to model ambiguity. (Seo, 2009, Ergin & Gul (2008),...)

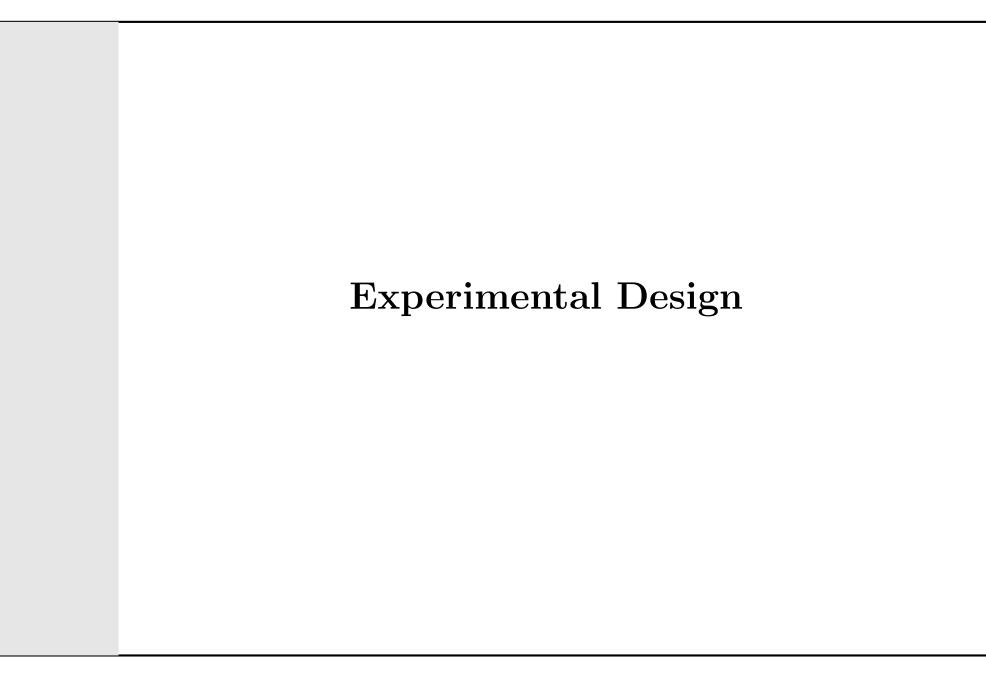

How to evaluate two-stage prospects?

 \Box Recursive Prospect Theory (RPT):

$$\Rightarrow \pi_1 \times \phi \left[PT(P) \right] + \pi_2 \times \phi \left[PT(Q) \right]$$

- Segal (1987) suggested this recursive form of RDU to model ambiguity attitudes through second-order probabilities.
- Abdellaoui & Zank (2014) provide the first axiomatization of this general form of Prospect Theory.

Experiment: outline

62 subjects:

- □ Parts 1 & 2: certainty equivalents for known and unknown Ellsberg urns $(2 \times 13 \text{ equivalents}).$
- □ Parts 3 & 4: matching probabilities for two-stage prospects $(2 \times 10 \text{ equivalents}).$
- \Box Payment: show up 10 euros + RIS (max 50 euros).
- \Box Individual interviews (about 45 minutes).

Under RPT, we aim to elicit the following functionals:

	Elicitation 1: Risk	Elicitation 2: Ambiguity
Attitudes towards	u	$ ilde{u}$
1-stage prospects	w	$ ilde{w}$
Attitudes towards		
2-stage prospects	w^*	$ ilde{w}^*$

	$c \sim$	(x, p; y) and \hat{c}	$\tilde{\epsilon} \sim (x, z)$	$E_p; y)$			$c_p \sim 0$	(x, p; y)	and \tilde{c}_{p}	$b_{p} \sim (x,$	$E_p; y)$	
\overline{x}	50	40	50	50	25	10	50	50	50	50	50	50	50
y	25	20	10	35	5	0	0	0	0	0	0	0	0
p	0.30	0.30	0.30	0.30	0.30	0.30	0.02	0.06	0.17	0.33	0.50	0.67	0.94
E_p	E_{30}	E_{30}	E_{30}	E_{30}	E_{30}	E_{30}	E_2	E_6	E_{17}	E_{33}	E_{50}	E_{67}	E_{94}

- \Box Under risk, we elicit c and c_p following Abdellaoui & al. (2008).
- $\Box \quad \text{Under ambiguity, we elicit } \tilde{c} \text{ and } \tilde{c}_p \text{ following Abdellaoui \& al.}$ (2011).
- \Rightarrow We can compare our results to these benchmark studies.

Model specification: TREU and REU

Using the equivalence revealed by the elicitation of the matching probability r:

 $((\bar{x},p),q) \sim (\bar{x},r)$

we infer the following equalities:

1. Under TREU, we have:

 $q \times p = r$

2. Under REU, we have:

 $q\times \phi(p)=\phi(r)$

Where ϕ is a transformation function.

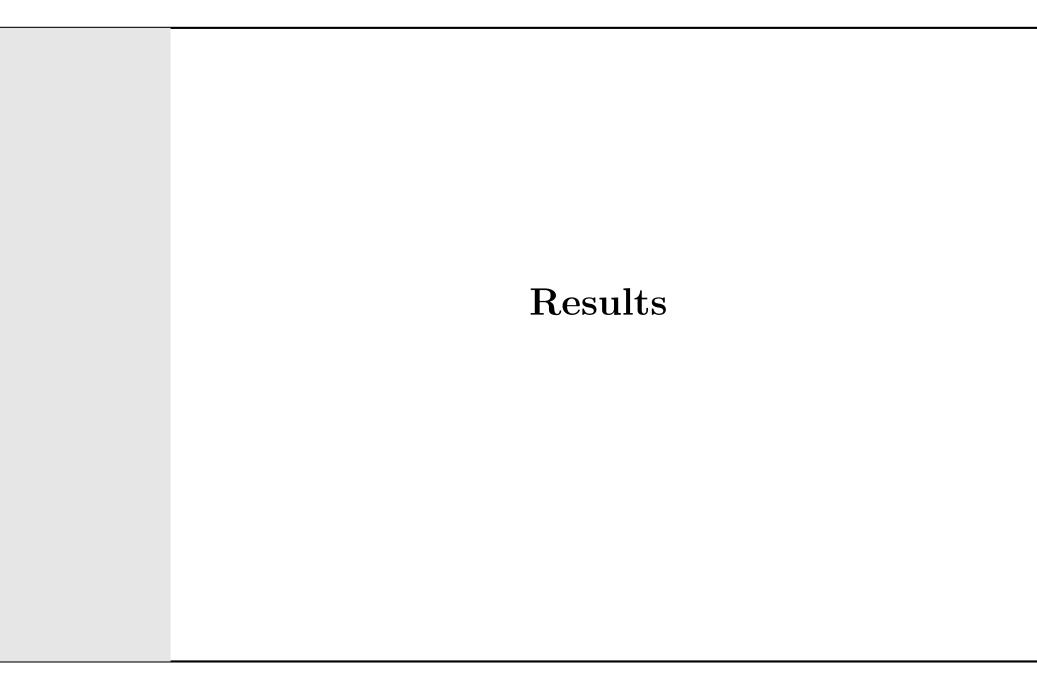

Parametric specification: $\phi(x) = x^{1/\theta}$.

\Box Under RPT, we have:

Setup	RPT-r	RPT-a
	RPT for "risk-risk"	RPT for "risk-ambiguity"
		$c \sim (x, p; y)$
One- stage	$c \sim (x, p; y)$	u(c) = w(p)u(x) + (1 - w(p))u(y)
Stage	u(c) = w(p)u(x) + (1 - w(p))u(y)	$\tilde{c} \sim (x, E_p; y)$
		$u(\tilde{c}) = \tilde{w}(p)u(x) + (1 - \tilde{w}(p))u(y)$
Two-	$((\bar{x}, p), q) \sim ((\bar{x}, m), 1)$	$((\bar{x}, E_p), q) \sim ((\bar{x}, \tilde{m}), 1)$
stage	$w(q)w^{\star}(p) = w^{\star}(\tilde{m})$	$w(q)\tilde{w}^{\star}(p) = w^{\star}(\tilde{m})$

\Box Parametric specifications:

$$u(x) = x^{\alpha}$$
 and $w(p) = exp(-(-ln(p)^{\gamma})^{\delta})$.

Results: RCP and TREU

<i>p</i>	q = 1/3		q = 2/3		
	$\#(\Delta\gtrless 0)$	t-test	$\#(\Delta \gtrless 0)$	<i>t</i> -test	
0.06	60/2	8.42**	48/14	2.12**	
0.17	38/24	3.65^{**}	27/35	-0.22^{ns}	
0.33	26/28	2.26^{*}	-	-	
0.50	39/23	3.39^{**}	24/38	-1.96^{*}	
0.75	-	-	24/25	0.33^{ns}	
0.94	27/35	0.69^{ns}	40/22	1.99^{**}	

Table 2: RCP $(\Delta = (r - pq)/pq)$

- □ RCP is globally violated, thus TREU is not descriptively valid for evaluating two-stage prospects.
- \Box Overall, we observe preference for the compound prospect, especially for q = 1/3.

Here, we present the descriptive statistics of the 3 OLS estimations of θ , assuming $\phi(x) = x^{1/\theta}$ under risk (i.e. only using the matching probabilities, r)

		Probability q	!
	1/3	2/3	$\{1/3, 2/3\}$
Mean	0.89	1.03	0.91
Median	0.90	0.98	0.91
Std	0.18	0.35	0.18
IQR	0.75 - 0.98	0.83 - 1.23	0.79 - 1.01

 $\Box \quad \text{At an aggregate level, } \phi \text{ is convex for } q = 1/3 \text{ but exhibits} \\ \text{linearity for } q = 2/3.$

□ Impact of probability q on the shape of function ϕ is confirmed by a paired *t*-test (p < 0.01).

 \Rightarrow Inconsistent with REU in which the probabilistic structure of the two-stage prospect should not impact the shape of ϕ .

Stage	func	param	Estimates			
			Mean	Median	Std	IQR
First	u	α	0.94	0.93	0.26	0.74-1.10
	w		1.06	1.07	0.32	0.85-1.22
		δ	0.62	0.61	0.20	0.48 - 0.77
Second -	$w_{1/3}^{*}$	$\gamma^*_{1/3}$	1.01	0.96	0.42	0.74-1.18
		$\delta^{*}_{1/3}$	1.20	1.15	0.29	1.03 - 1.35
	$w_{2/3}^*$	$\gamma_{2/3}^{*}$	1.66	1.63	0.52	1.25-2.04
		$\delta^*_{2/3}$	0.90	0.85	0.28	0.69-1.07

 \Box Function, w^* , depends on probability q. While it is close to linearity for q = 1/3, it is convex for q = 2/3.

 \Rightarrow Inverse than for REU but same problem (differences both for elevation and curvature between $w_{1/3}^*$ and $w_{2/3}^*$).

Results: RPT under risk

Additional results

- \Box Adding ambiguity (first and second stage) does not change our main results i.e.
 - Impact of probability q on the shape of function ϕ .
 - Stage dependent pwf.
 - Dependence of the second stage pwf on the first stage probability.
- $\hfill\square$ Benchmark results are found for the single stage pwf under risk and ambiguity.
- □ No association between RCP and ambiguity attitudes (\neq from Halevy, 2008 and Segal).

Concluding remarks

- 1. Recursive evaluation of two-stage prospects is more complex than allowed by any existing recursive model.
- 2. In Kreps and Porteus (or KMM) integral, function ϕ is sensitive to the first-stage probability of winning.
- 3. Second-stage probability weighting is very sensitive to the first-stage winning probability.

 \Rightarrow Abdellaoui & Zank (2014) first axiomatized a RPT model that could account for our experimental findings.

Thank you for your attention!
