Submitted on 5 Jun 2020

HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

3.1 Introduction

List of Contributors	xii
Woodhead Publishing Series in Food Science, Technology and Nutrition	xv
Preface	xxvii

Part One Food Flavor Release in Humans

1 Retention and release of taste and aroma compounds from the food matrix during mastication and ingestion	3
<i>Elisabeth Guichard, Christian Salle</i>	3
1.1 Introduction	3
1.2 Flavor compounds	3
1.3 Interactions between flavor compounds and food matrix	7
1.4 Release of flavor compounds during the in-mouth process as a function of oral physiology	10
1.5 Modeling in vivo flavor release	14
1.6 Conclusions	16
References	17
2 How amniotic fluid shapes early odor-guided responses to colostrum and milk (and more)	23
<i>Benoist Schaal</i>	23
2.1 Amniotic fluid, colostrum, and milk are olfactorily attractive to newborns	24
2.2 Evidence for transnatal chemosensory continuity	25
2.3 Physiological bases and chemical evidence for transnatal chemosensory continuity	27
2.4 Transnatal olfactory continuity-related predictions	33
2.5 Conclusion: more predictions, contradictions, and other inclusive adaptive options	41
Acknowledgments	43

3.1 Introduction

Odors are very complex stimuli which are mainly raised by mixtures of odorant chemical compounds displaying different degrees of volatility. The volatility is directly related to a substance's vapor pressure^a at a given temperature; substances with higher vapor pressure vaporizing more readily than a substance with a lower vapor pressure. Thus, for a given combination of odorant molecules, the compounds compete with each other for constituting the gaseous phase, this competition depending on both individual volatility properties and ratios in which the compounds are present. Altogether, this will result in a unique and precise fragrance of an odor item. The quasi infinite variety of odorant compounds and their combinations, combined with the wide range of their volatility properties, imply that the olfactory system must be thus highly adaptable to new items, and highly sensitive.

In addition to having to face limitless and constantly moving stimuli, the peripheral olfactory system needs to regenerate. Indeed, in the nose, the sensory neurons are directly in contact with the exterior, and can be damaged by thermal or chemical aggressions. Such an exposure is compensated by the fact that these neurons are continuously and cyclically renewed during the course of life (Graziadei, 1973). Lastly, the olfactory system must be operating very early in the organism's life, since it intervenes in numerous survival behaviors like predator avoidance, the bonding of the young to the mother, and foraging behavior which starts at birth by the nipple search.

The olfactory system per se comprises three main levels, namely the olfactory epithelium (OE, peripheral level), the olfactory bulb (OB, first central relay), and the piriform cortex (PC, main cortical level). As a phylogenetically very ancient system, the olfactory system developed various and adaptive strategies to face the world of odors, and it can analyze and encode them as either juxtapositions of odorant elements (elemental coding), or as constructions (olfactory gestalts = synthetic coding), or both, as a function of the physiological needs or motivational events.

In this chapter, the peripheral odor processing steps will be not described according to their chronological order. Indeed, the normal time frame for the operational steps, for

^aVapor pressure. In a closed container, molecules from a volatile liquid escape the liquid phase and become vapor. These gaseous molecules strike the wall of the container, exerting what's known as vapor pressure. Vapor pressure is directly proportional to temperature. Increasing temperature will increase the ratio of gas:liquid molecules, thereby increasing vapor pressure.
