- Conclusion

The global cycle of carbon 2005-2006

(stocks in GtC, flux in GtC.an⁻¹, Canadell et al. 2007)

Sources: anthropogenic C Emissions: Land Use Change

Borneo, Courtesy: Viktor Boehm

Tropical deforestation

13 Million hectares each year

2000-2005

Tropical Americas 0.6 Pg C y⁻¹

Tropical Asia 0.6 Pg C y⁻¹

Tropical Africa 0.3 Pg C y⁻¹

1.5 Pg C y⁻¹

Anthropogenic C Emissions: Tropical Deforestation

Sources: anthropogenic C Emissions, fossil fuel

2006 Fossil Fuel: **8.4 Pg C**

[2006-Total Anthrop. Emissions: $8.4 + 1.5 = 9.9$ Pg]

1990 - 1999: **1.3% y^{-1}**

2000 - 2006: **3.3% y^{-1}**

Trajectory of Global Fossil Fuel Emissions

Anthropogenic perturbation of global carbon budget (1850-2006)

Sink: partition of anthropogenic carbon emissions

[2000-2006]

45% of all CO₂ emissions accumulated in the atmosphere

Atmosphere

The Airborne Fraction

The fraction of the annual anthropogenic emissions that remains in the atmosphere

55% were removed by natural sinks

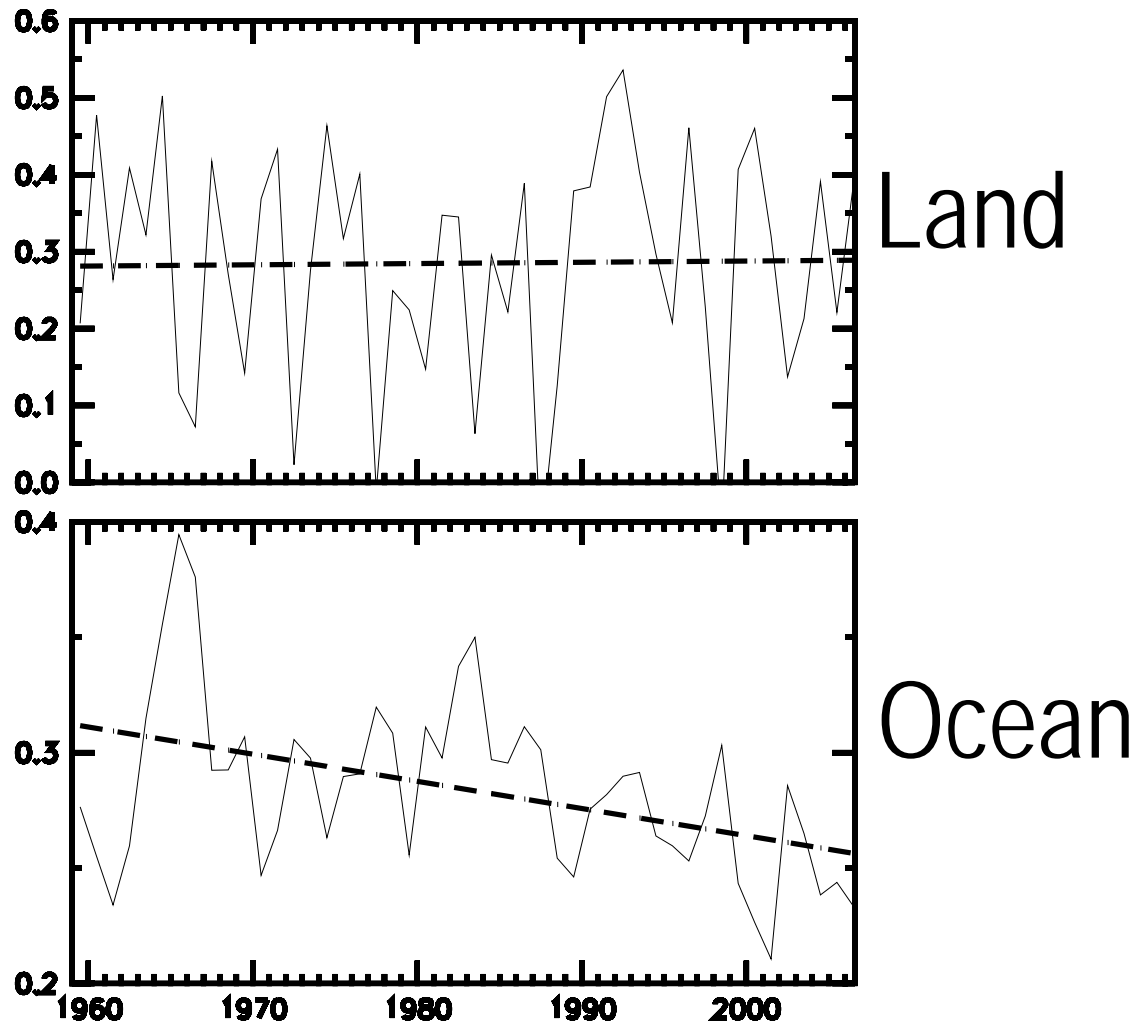

Ocean removes _ 24%

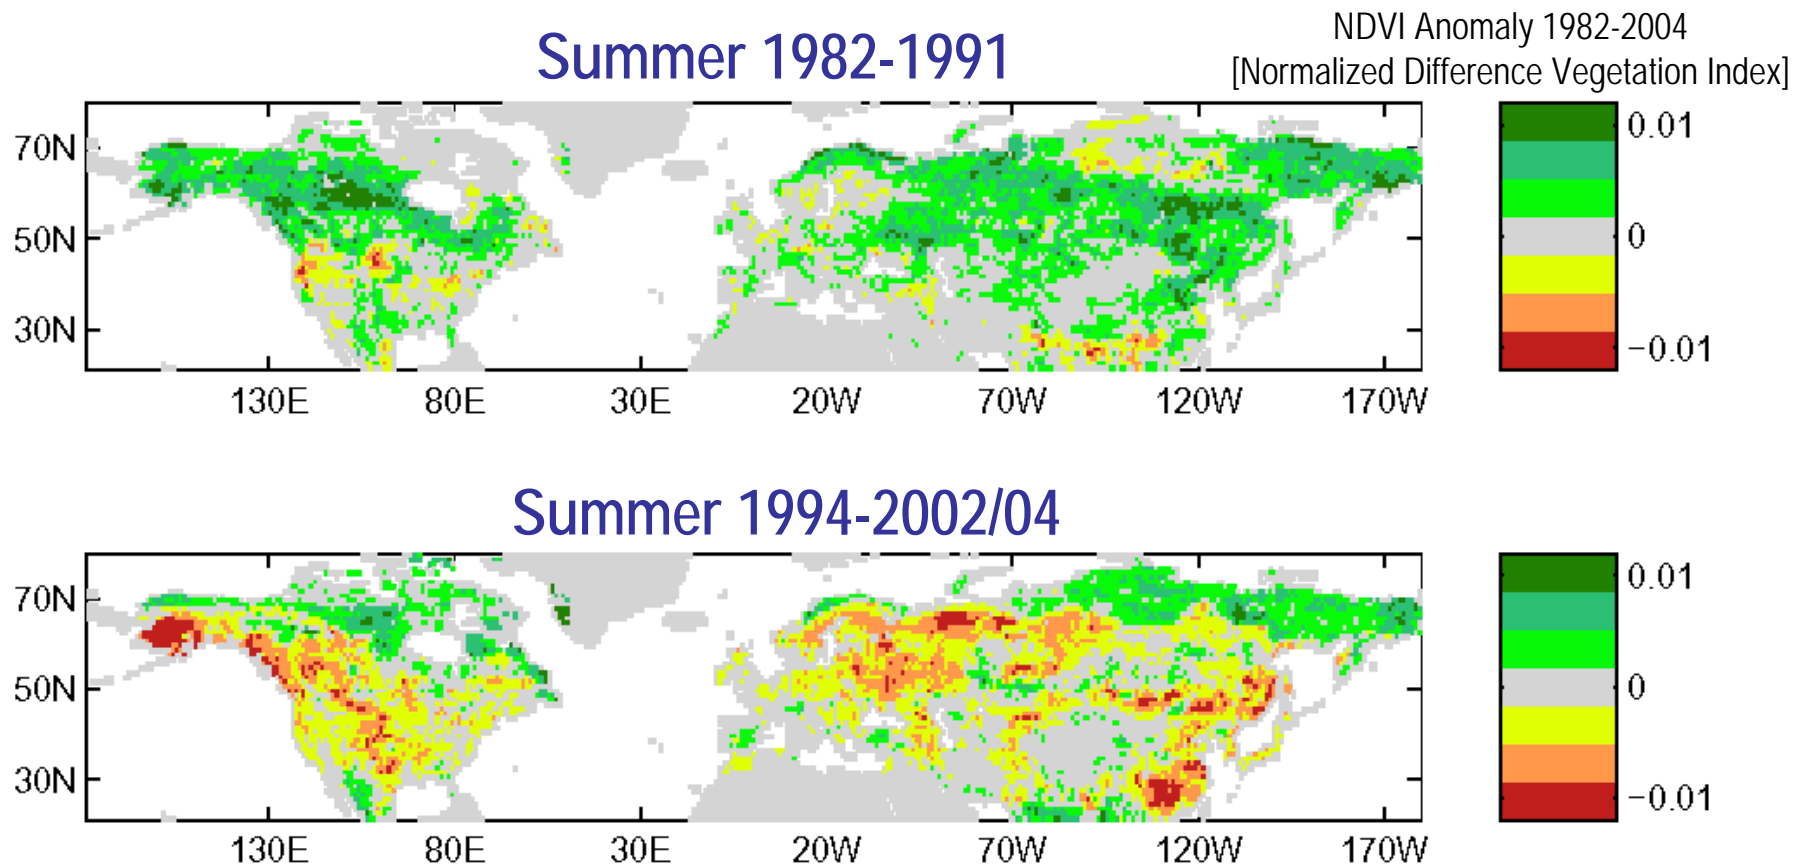

Land removes _ 30%

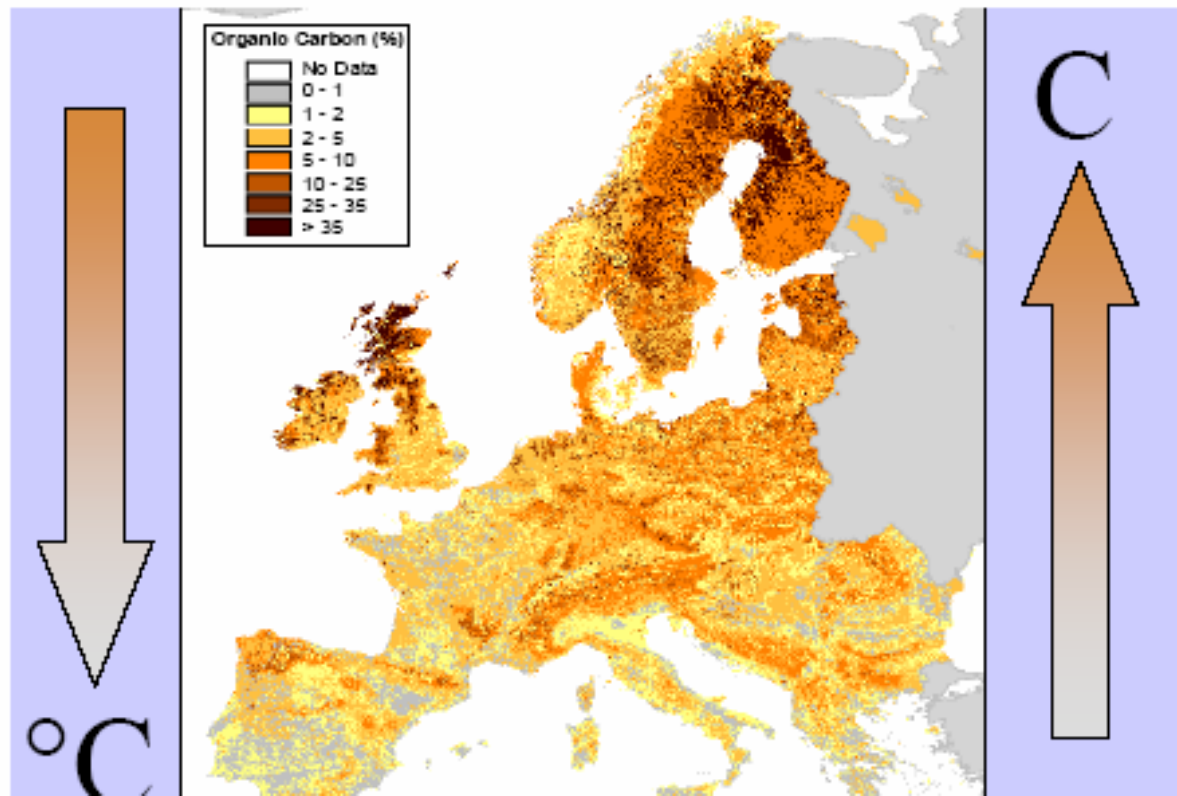

The Efficiency of Natural Sinks: Land and Ocean Fractions

A number of major droughts in mid-latitudes have contributed to the weakening of the growth rate of terrestrial carbon sinks in mid latitude regions.

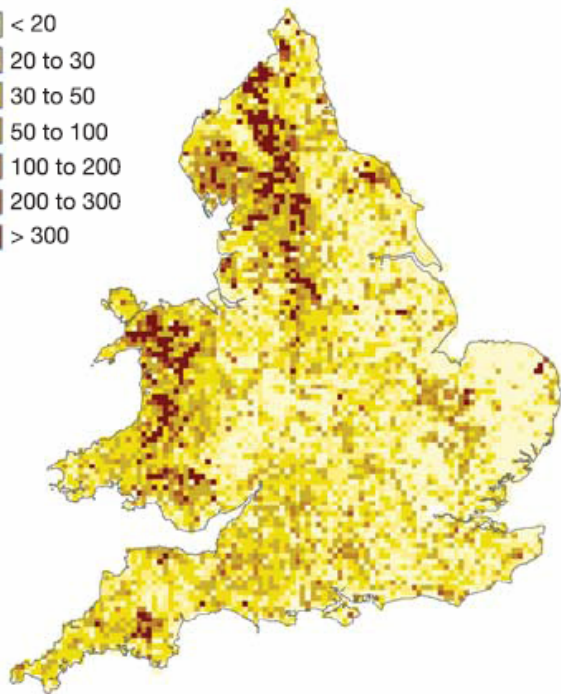

- Large carbon stocks in soil are found in cold and wet climate on acidic soils where microbial activity is constrained by lack of O₂, N, Heat, liquid water.
- These conditions are changing rapidly: soils are getting warmer and drier, and N enriched through acidic deposition → .../...

C storage
in soil is not
given on long term

a Original C_{org} ($g\ kg^{-1}$)

b Rate of change ($g\ kg^{-1}\ yr^{-1}$)

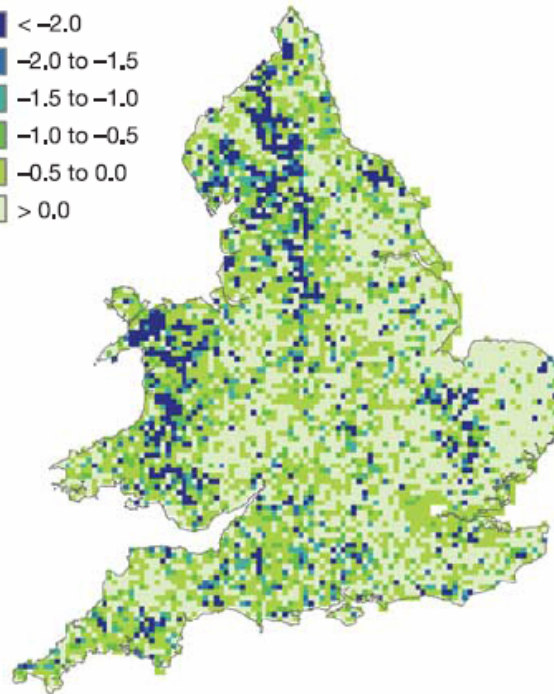

Figure 1 | Changes in soil organic carbon contents across England and Wales between 1978 and 2003. **a**, Carbon contents in the original samplings, and **b**, rates of change calculated from the changes over the different sampling intervals. Values at sites that were not resampled were calculated from their original organic carbon contents using equation (1). The changes were negative in all but 8% of the sites.

Bellamy et al.,
Nature 2006

Ex. : Soil have released from 0 to 100-150 $gC\ m^{-2}.an^{-1}$ in UK between 1978 and 2003

Disequilibrium in net atmospheric balance :

Year 2006
Atmospheric CO₂
concentration:
381 ppm
35% above pre-industrial

1970 – 1979: 1.3 ppm y⁻¹

1980 – 1989: 1.6 ppm y⁻¹

1990 – 1999: 1.5 ppm y⁻¹

2000 - 2006: **1.9 ppm y⁻¹**

>20 years	40	46	15

Table A1.From
IPCC Report on Good Practice
Guidance for Land Use,
Land-Use Change and Forestry

Note: Data are given in mean value and as range of possible values (in parentheses).

¹ The definition of forest types and examples by region are illustrated in Box 2 and Tables 5-1, p 5.7-5.8 of the *IPCC Guidelines* (1996).

Carbon cycle in terrestrial ecosystems : fluxes, pools and residence time (years)

Carbon sequestration in forest ecosystems: important definitions

Gross Primary Production

$$GPP = A - R_d$$

Net Primary Production

$$NPP = GPP - R_a - VOC$$

Net Ecosystem Exchange

$$NEE = GPP - R_a - VOC - R_h$$

Net Ecosystem production

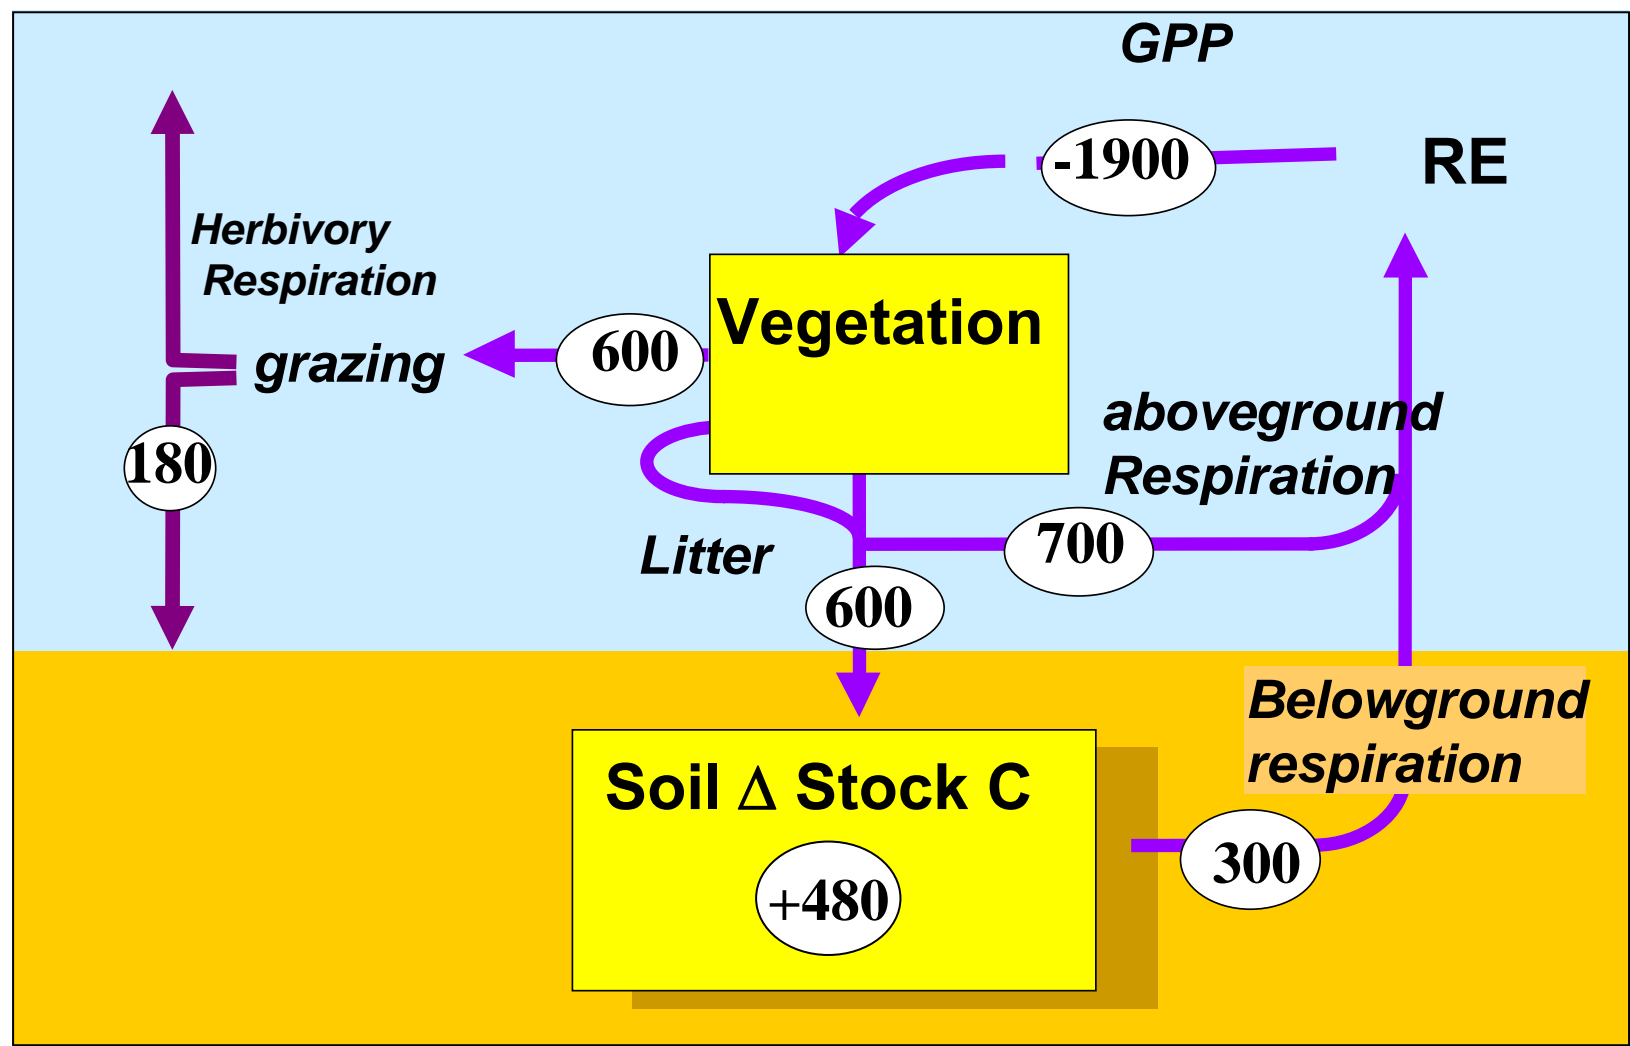

$$NEP = GPP - R_a - VOC - R_h - DOC - DIC$$

A Net Assimilation
R_d Day mitochondrial leaf respiration
R_a Autotrophic Respiration
R_h Heterotrophic Respiration

VOC Volatile Organic Carbon
DOC Dissolved Organic Carbon
DIC Dissolved Inorganic Carbon

Carbon cycle: grassland with grazing.

Annual balance of carbon (gC m⁻² an⁻¹)

Carbon balance of forest ecosystems.
 Synthesis from a database including 513 forest sites.

Table 3 Mean carbon fluxes, NPP components, sum of closure terms [$\Sigma(\delta\text{Flux}) = |\delta\text{GPP}| + |\delta\text{NPP}| + |\delta R_e| + |\delta R_a| + |\delta R_h|$] and their standard deviation for the different biomes. The SD refer to the variability surrounding the mean values

- Conclusion

How much carbon can we
sequester in forest and natural
ecosystems ?

Carbon removed by forestry practices: global estimates

Tableau 2. Estimations mondiales de la quantité potentielle de C stockée et conservée grâce aux pratiques de gestion forestière entre 1995 et 2050 (tiré de Brown *et al.* 1996).

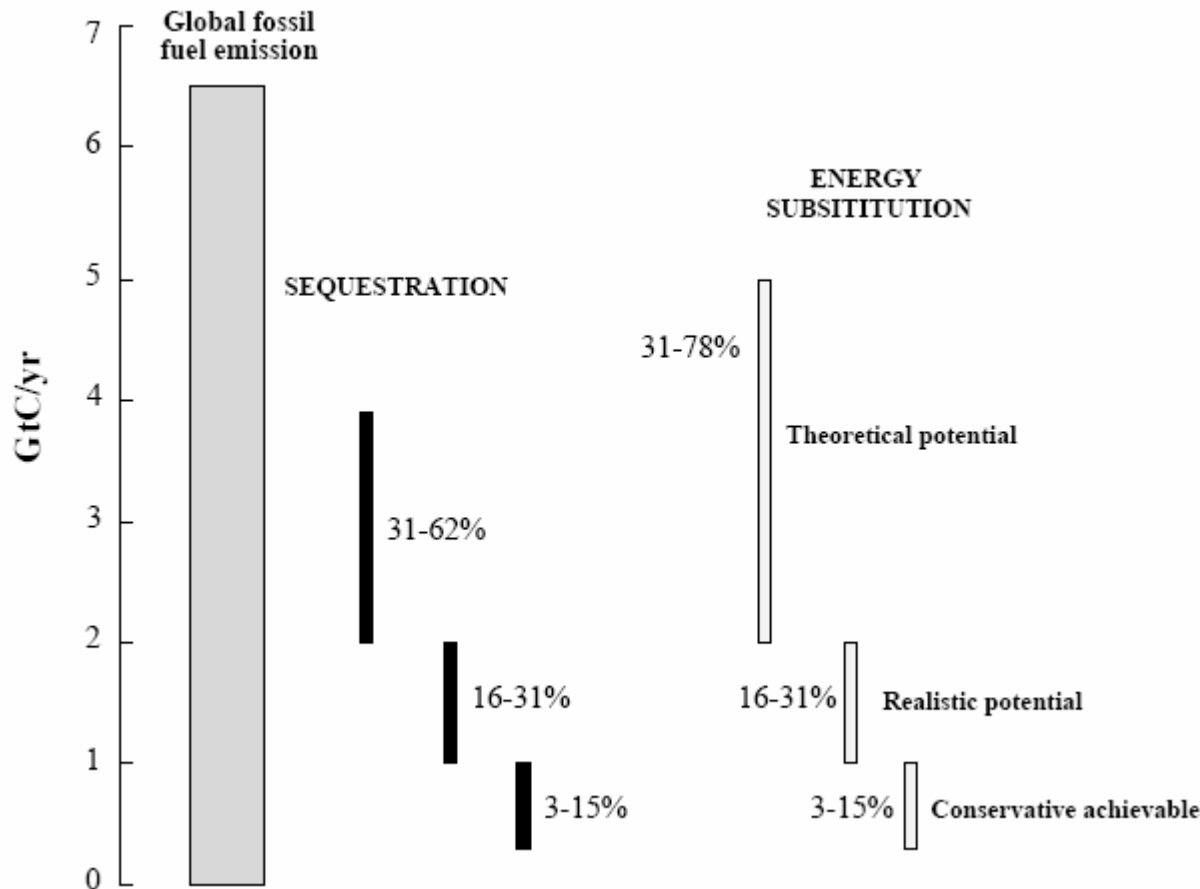

Latitudes	Pratique	Superficie (Mha)	C stocké et conservé (Pg)
Hautes	Afforestation	95,2 ¹	2,4
Moyennes	Afforestation	113	11,8
	Agroforestry	6,5	0,7
Basses	Afforestation	66,9	16,4
	Agroforestry	63,2	6,3
	Reforestation	217	11,5-28,7
	Avoided deforestation	138	10,8-20,8
	Total	700	60-87

¹ Comprend les forêt insuffisamment reboisées du Canada

² Comprend 25% additionnels de C dans la biomasse aérienne pour tenir compte de la biomasse souterraine (racines, litière et sol) (d'après les données de Nilsson et Schopfhauser, 1995 et Brown *et al.*, 1993b); la fourchette des valeurs est le résultat de l'emploi d'estimations faibles et élevées de la densité de carbone dans la biomasse dû à l'incertitude des estimations.

~Approximately 12% of fossil fuel emissions

Carbon removal potential of continental ecosystems

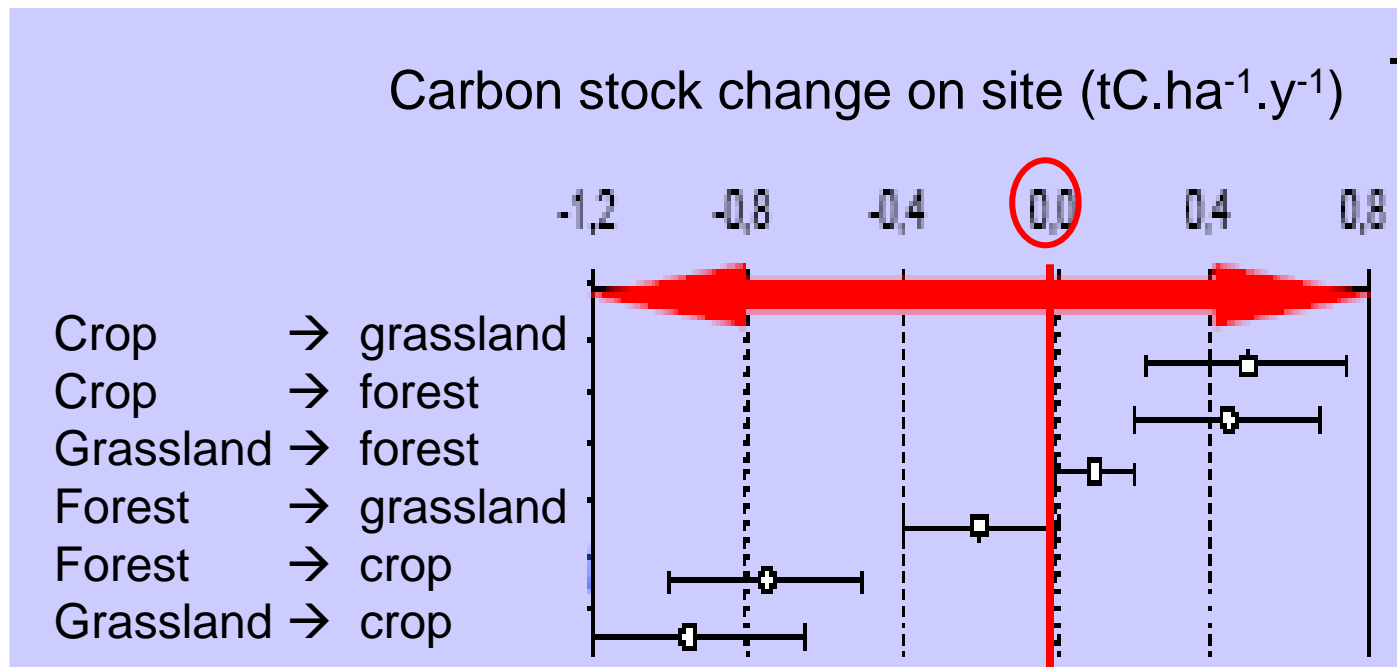

Energy production and carbon sequestration by continental ecosystems can offset 30- 60% of the global emissions (derived from Cannell, 2003).

How to proceed ?

→ land use changes

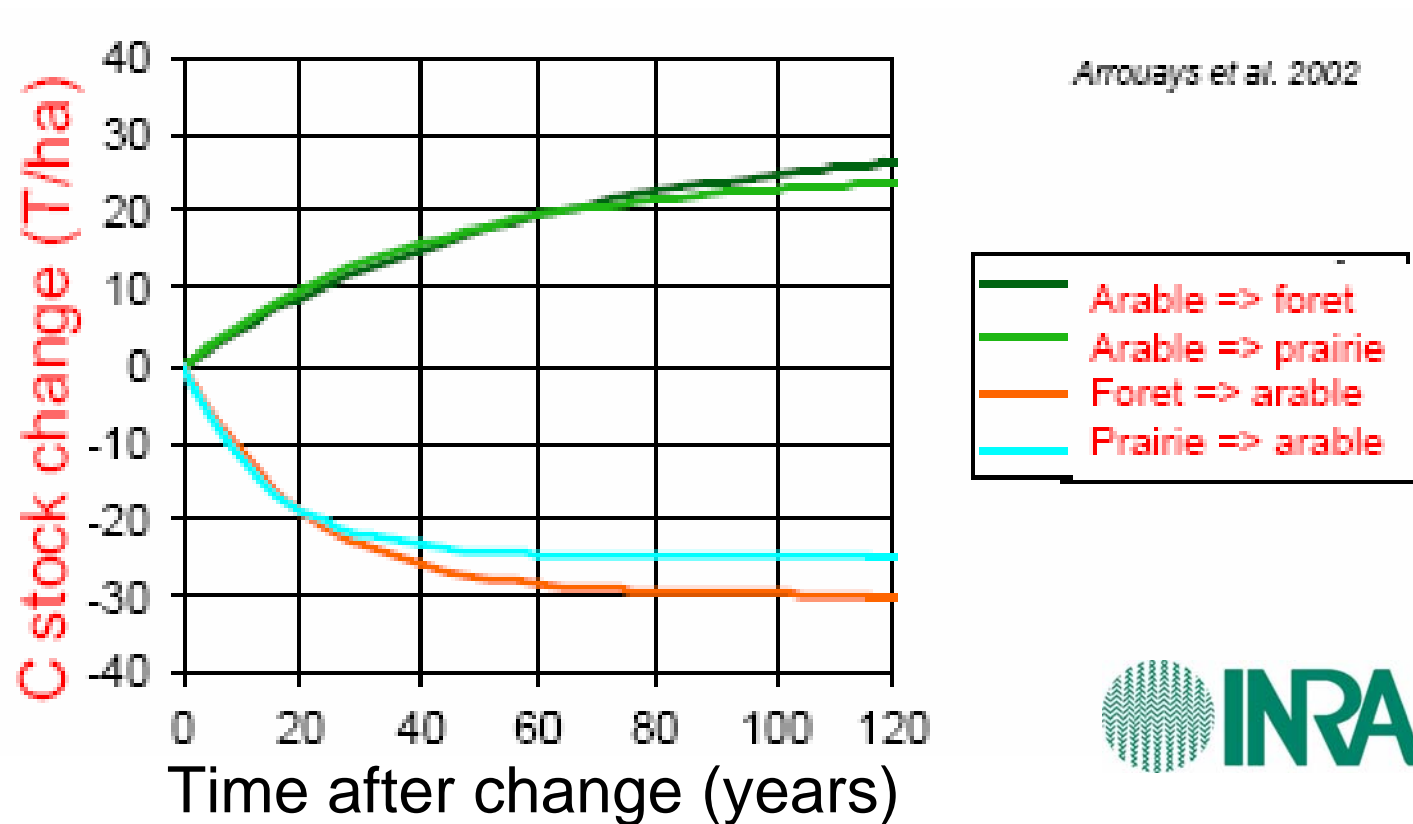

→ forest management for carbon sequestration

Conversion of crops, abandoned lands, ...into forests

(Values averaged over 20 years. Arrouays et al. INRA)

Land use change: effects on carbon stocks.

- hysteresis: carbon is lost faster than it is gained
- slow: steady values take a century to be reached
- Reforesting renders many additional services: soil protection, water quality, air quality, local climate

Forest management for carbon sequestration

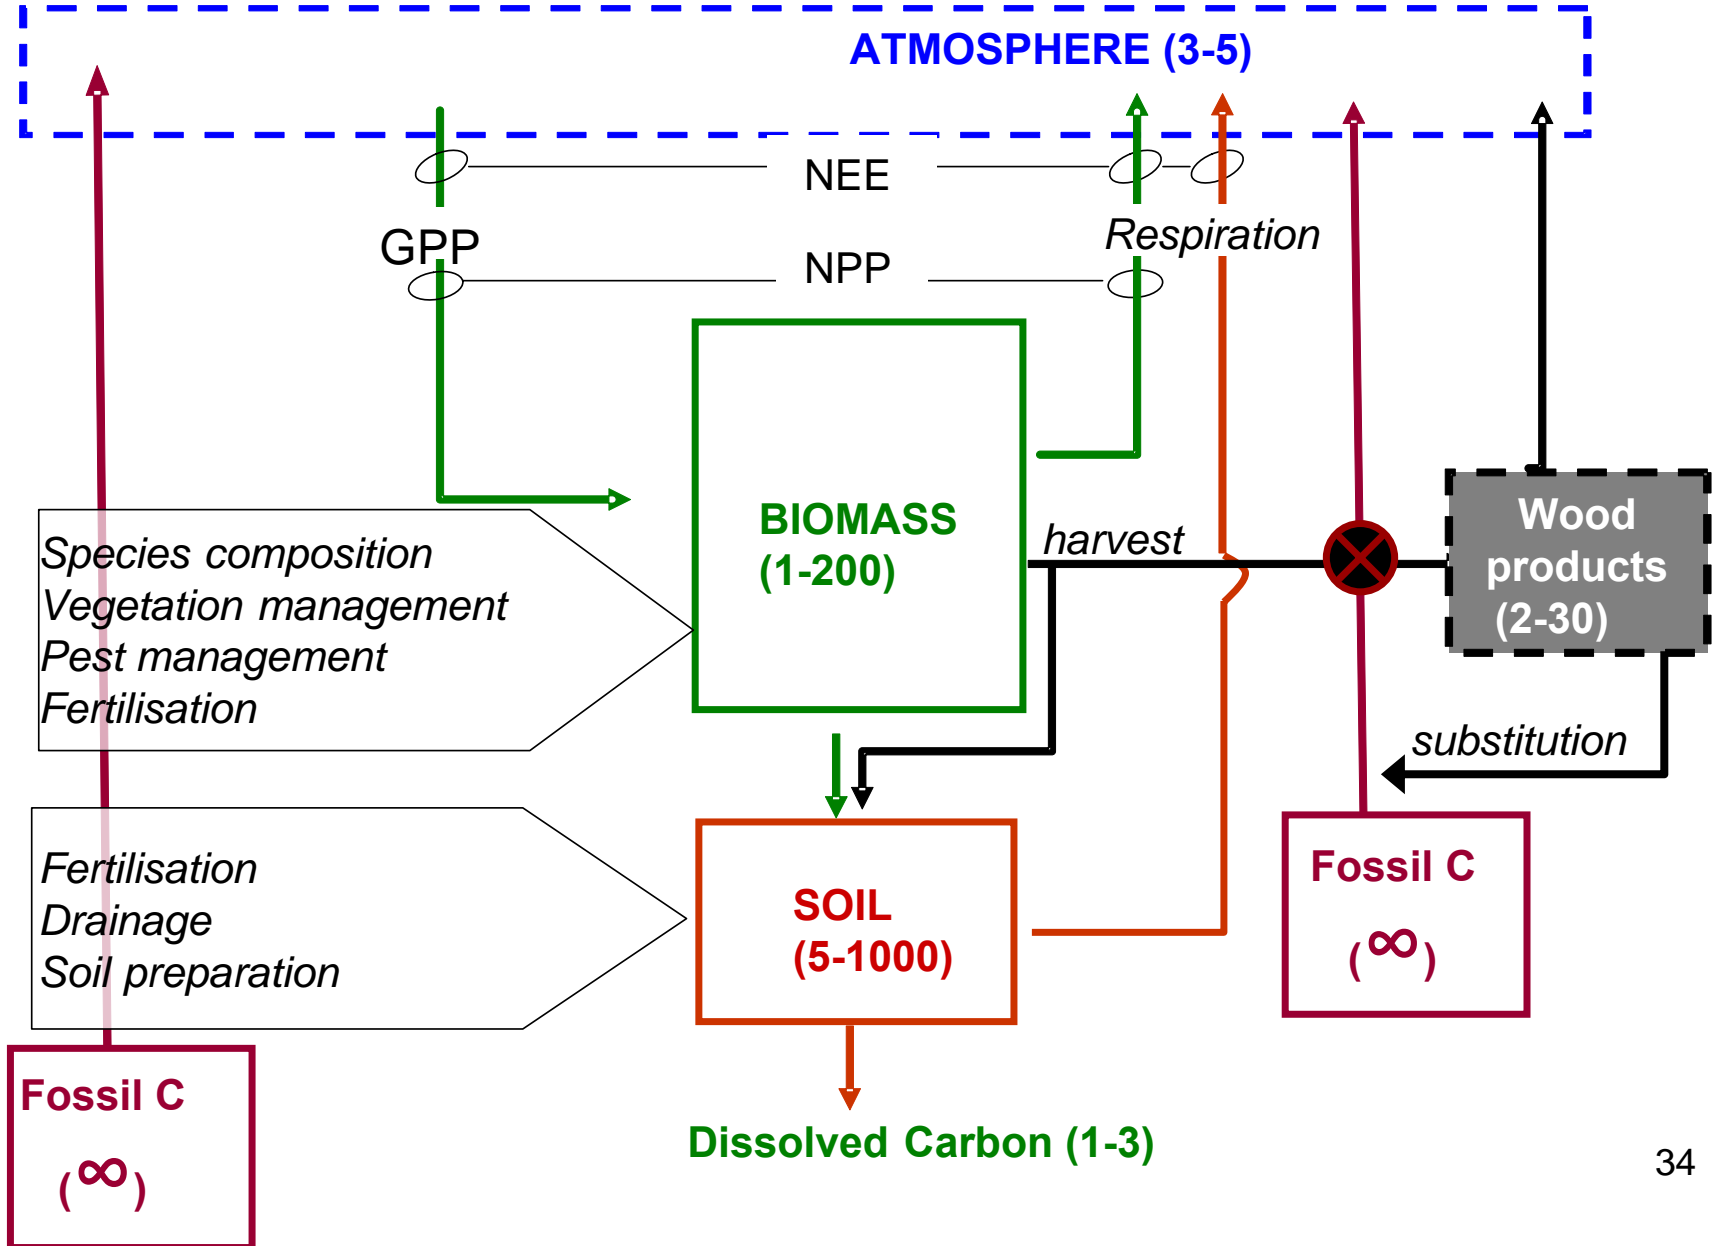

Assessment of impacts of forest management on carbon cycle: tentative framework

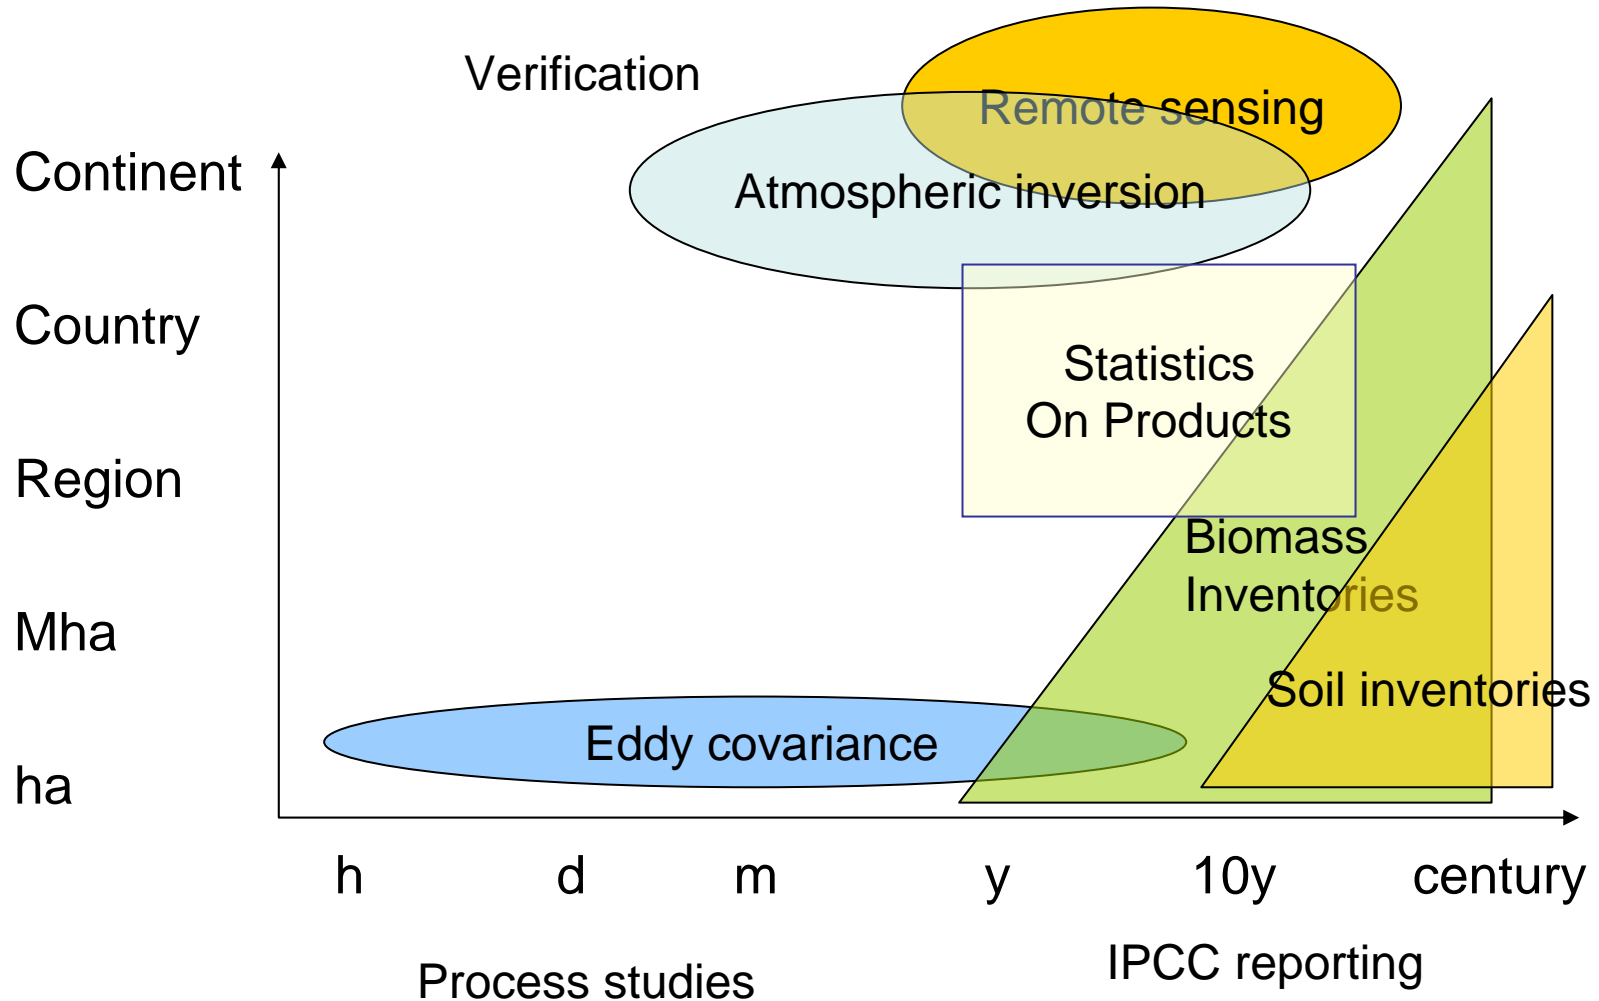

- Time scale: the entire life cycle including harvest
- Reference state: definition of a reference state: b.a.u., “nature”, state at a reference date (1990 for the Kyoto protocol)...
- Assessment of the only relative impact, i.e. stock change
- Completeness: Include additional carbon costs of forest operation, seedling, logging, drainage, transportation, transformation, product use and products replaced (concrete, steel, fossil fuel, others...)
- Consistent basis for calculation: unit land area (ha), unit production (ton biomass, cubic meter of roundwood,...)

Default simplified method: [Good Practice Guidance for Land Use and-Use Change and Forestry, IPCC 2003.](#)

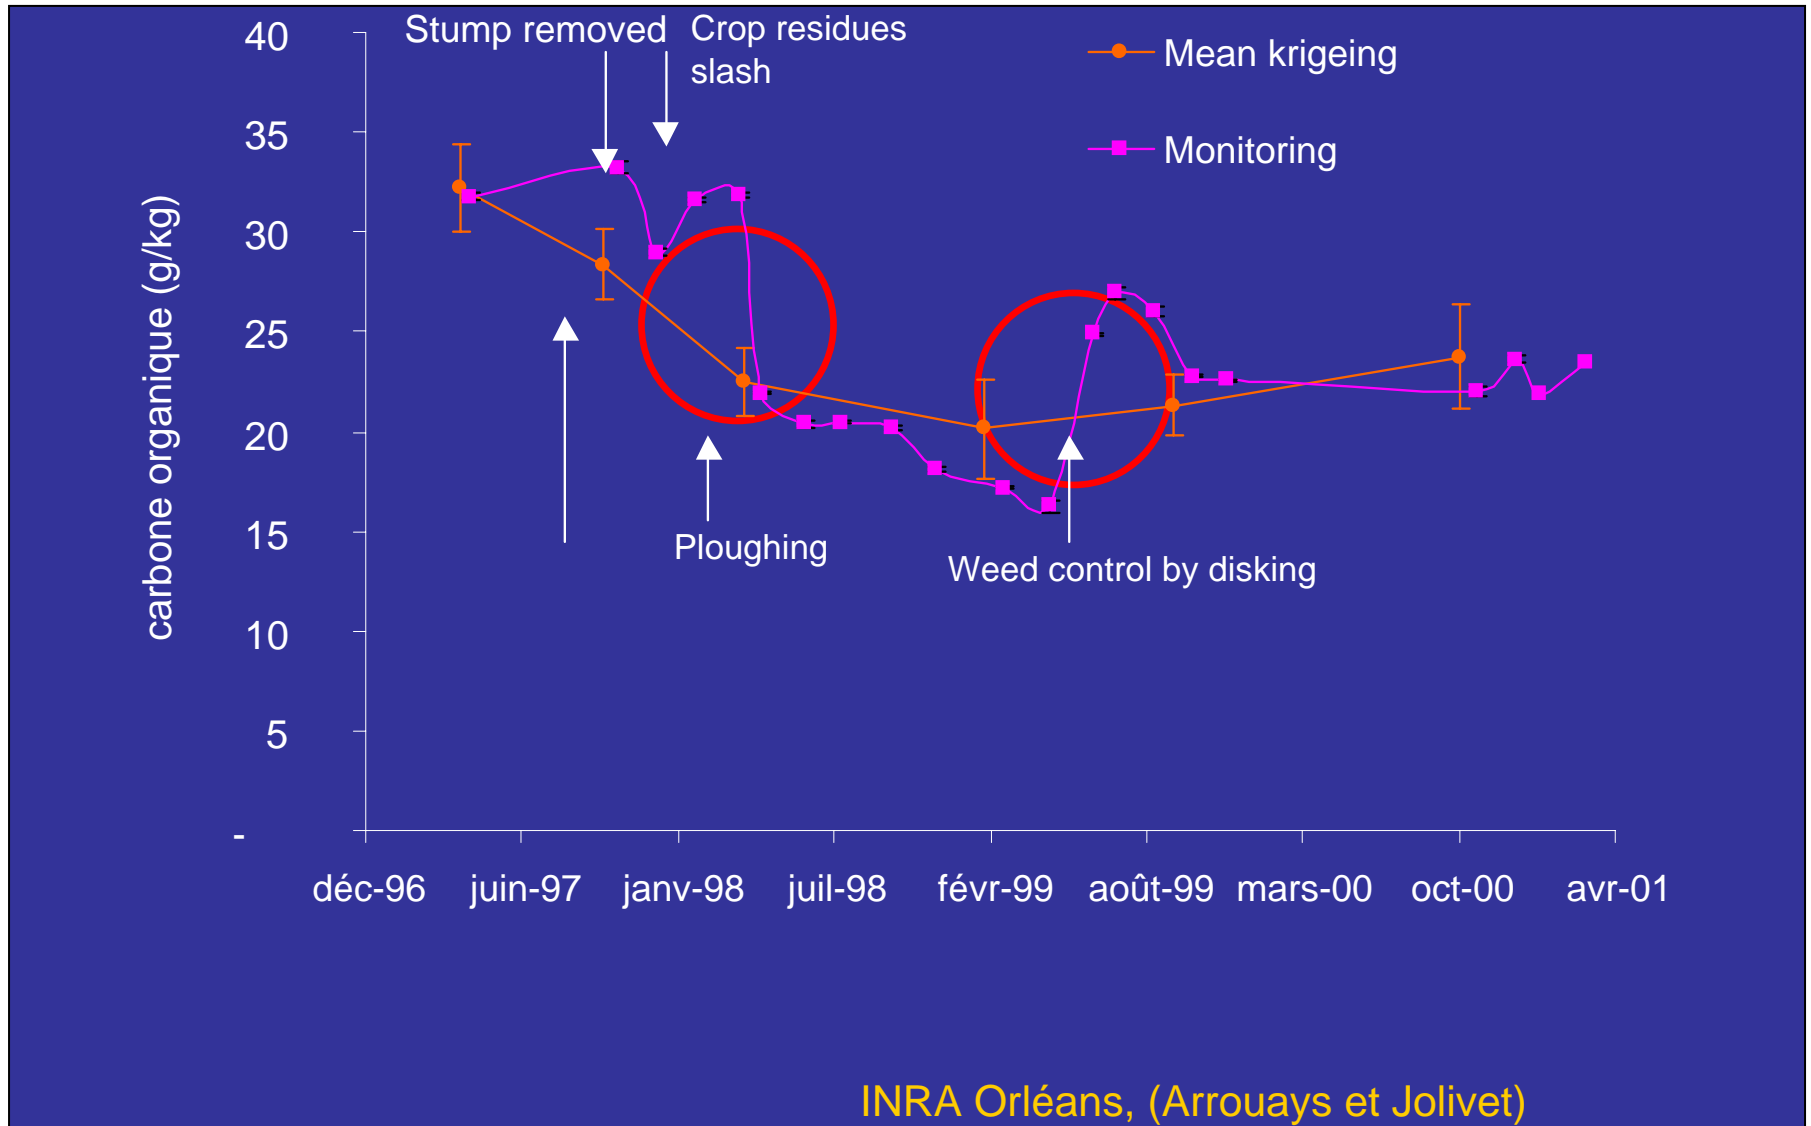

System boundary

Accounting and verifying: space and time resolution of C flux measurement methods

Forest operations example: soil carbon stock is primarily affected by mechanical disturbances (ploughing).

Forest operation impacts: qualitative assessment

(Hyvonen et al. 2007 *New Phytol.*)

Table 2 Qualitative effects on average carbon stocks of management operation in managed forests over a rotation period compared with the rotation period prior to management (modified from Freeman *et al.*, 2005)

Management measure	Soil C stock	Biomass C stock	Ecosystem C stock
Stand initiation phase			
Prescribed burning*	Decreasing	Decreasing, neutral or increasing	Decreasing, neutral or increasing
Drainage of peatlandst	Decreasing	Increasing	Decreasing, neutral or increasing
Site preparation method‡

Increased rotation length††	Decreasing, neutral or increasing	Increasing	Increasing
Harvesting method‡‡	Decreasing, neutral or increasing	Decreasing, neutral or increasing	Decreasing, neutral or increasing

The carbon cost of forest operations :E.

Sonne 2006, *J of Environm. Quality*

- Life cycle analysis
 - CO₂, CH₄, N₂O accounted
 - “Upstream” and on site costs accounted
 - 408 management alternatives analysed
 - Douglas fir, Washington and Oregon.
-
- “Downstream” costs not accounted
 - Units: land are (ha) and wood volume (m³), time frame 50yr, units a CO₂ eq.

Estimate of carbon cost of management operations

Table 8. Contribution of each unit process to greenhouse gas (GHG) emissions.

	GHG emissions	Percent contribution [†]
	Mg CO ₂ e [‡] ha ⁻¹ , except where specified	%
P + 1§	0.022	<1
1 + 1	0.027	<1
Large plug	0.01	<1
<u>Pile and burn</u>	4.0	32
Chemical site preparation	0.12	1
Transportation: 1 + 1, P + 1	0.05	<1
Transportation: large plug	0.15	1
<u>Fertilization</u>	1.9	15
Herbicide treatment	0.15	1
<u>Harvesting (including CT and PCT)¶</u>	5.9	51

[†] Based on P + 1, pile and burn, fertilization, herbicide, and harvesting 747 m³ timber.

[‡] Carbon dioxide equivalents.

[§] Seedling emissions are based on 1236 seedlings ha⁻¹.

[¶] Emissions are based on 700 m³ harvested timber. CT, commercial thinning; PCT, pre-commercial thinning.

Estimate of carbon cost of scenario alternatives

Table 6. Direct emissions contribution to global warming impact (normalized to 50 yr). And distribution among main GHG

Rotation age† yr	carbon dioxide equivalents (CO ₂ e) ha ⁻¹	Emissions		
		CO ₂	N ₂ O	CH ₄
		%		
30	11.1	57	31	12
40	10.9	66	24	10
50	9.9	72	19	8
60	8.9	73	19	8

Shorter rotations emit more carbon per unit area

N fertilisation is a major source of global warming through N₂O
(Crutzen P.J. et al., 2007)

Table 9. Greenhouse gas (GHG) emissions per 100 m³ harvested timber by rotation age.

Scenario	Rotation age (yr)			
	30	40	50	60
	———— Mg CO ₂ e† 100 m ⁻³ ————			
865_CT‡_fert	2.47	1.59	1.59	1.34

Management increases the NPP share to the wood

C balance over the rotation

Stock (gC.m⁻²)

C Stock Trees

(gC.m⁻²)

Humus and soil

C Flux

(gC.m⁻².yr⁻¹)

- shortens life cycle
- amplifies NEP and NPP
- increase the fraction of harvest biomass (timber)
- but depletes carbon stock in soil and biomass

Summary: management keeps forest younger

- shortens life cycle
- amplifies NEP and NPP
- increase the fraction of harvest biomass (timber)
- but depletes carbon stock in soil and biomass
- has a higher cost in carbon for forest operation (up to 12.5%)

(Pine plantation, SW Fance)

(Rimu Forest SW NZ)

Should we produce.....or store carbon ?

- The carbon cycle updated 2007, natural and human- disturbed.
- Its terrestrial component
 - Generic scheme and important definitions
 - Land use types
 - Geographical distribution
- Managing carbon in “natural” ecosystems
 - Land use changes
 - Forest operations
 - Forest scenario alternatives
- Beyond carbon, managing the overall climate impacts
 - Carbon free greenhouse gases (N_2O , O_3)
 - Energy Balance: heat flux, evaporation
 - Global warming potential
- Diversity
- Conclusion

Accounting for all atmospheric impacts: GHG, energy balance,

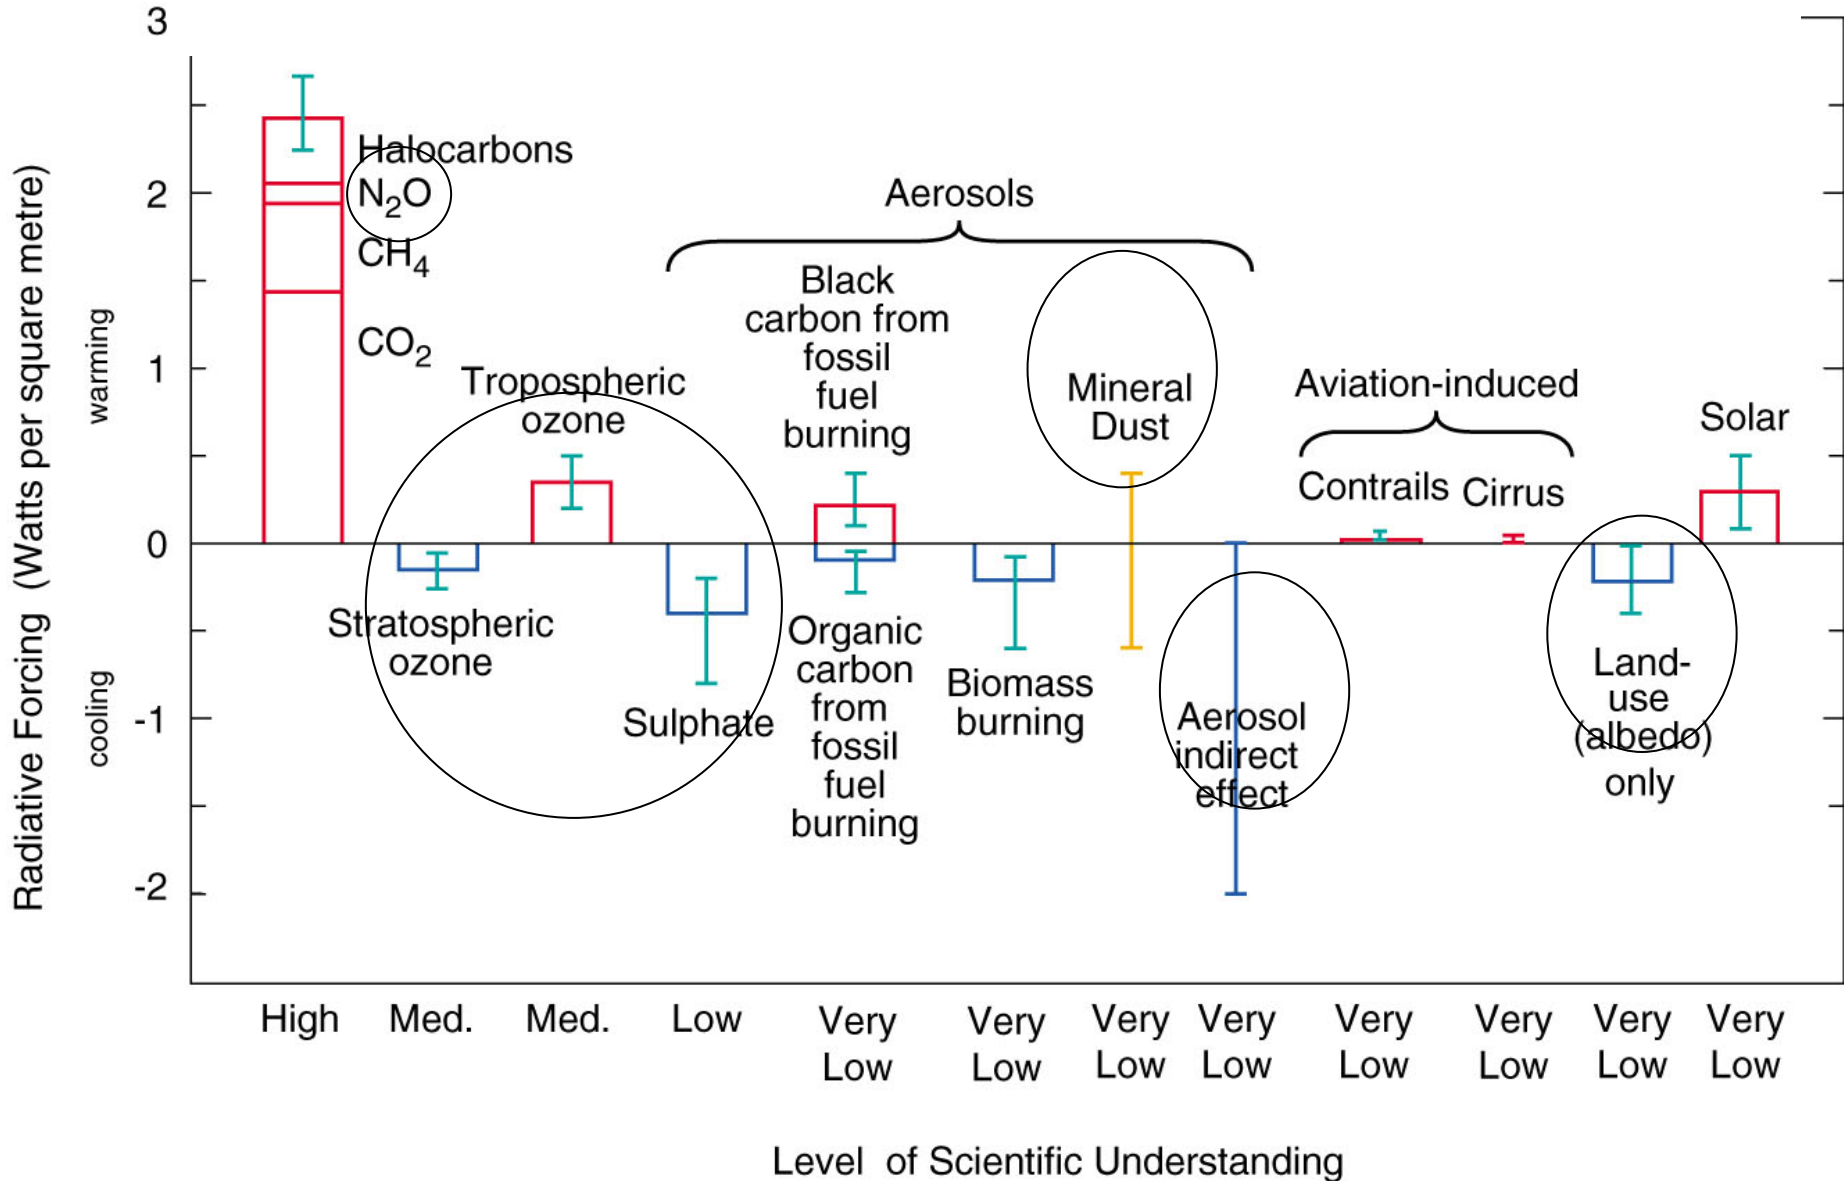

Shortwave radiation (solar)

Longwave radiation (terrestrial)

Carbon is only a (large) part of the story :

GLOBAL WARMING POTENTIAL

- A measure of how the energy balance of the earth-atmosphere system is influenced when factors such as GHG concentration, surface albedo or heat flux emitted by vegetation are altered.
- Unit $W \cdot m^{-2}$
- Allows to compare different alternatives and should be used for estimating climate impacts of terrestrial ecosystems

Other greenhouse gases involved in forestry

	Estimated lifetime in the atmosphere (years)	Global Warming potential relative to CO ₂		
		integration time (years)		
		20	100	500
CO ₂		1	1	1
CH ₄	10	63	21	9
N ₂ O	150	270	290	190

Accounting for GHG and energy balance (albedo only !)
 Change in the global warming index as compared with standard
 management scenario (M)

	total C. stock	Fossil C. saved	Albedo	Total
20 y				
FI	0.24	-0.11	-0.01	+0.12
UM	-0.22	0.11	0.01	-0.10
50 y				
FI	0.24	-0.27	-0.01	-0.04
UM	-0.22	0.27	0.01	+0.06

- Importance of the time scale
- « ghg » effect > albedo
- Production is better in fertile sites

- The carbon cycle updated 2007, natural and human- disturbed.
- Its terrestrial component
 - Generic scheme and important definitions
 - Land use types
 - Geographical distribution
- Managing carbon in “natural” ecosystems
 - Land use changes
 - Forest operations
 - Forest scenario alternatives
- Beyond carbon, managing the overall climate impacts
 - Carbon free greenhouse gases (N_2O , O_3)
 - Energy Balance: heat flux, evaporation
 - Global warming potential

• Diversity

• Conclusion

Species composition: single or multiple species stands ?

Not so much literature on forest

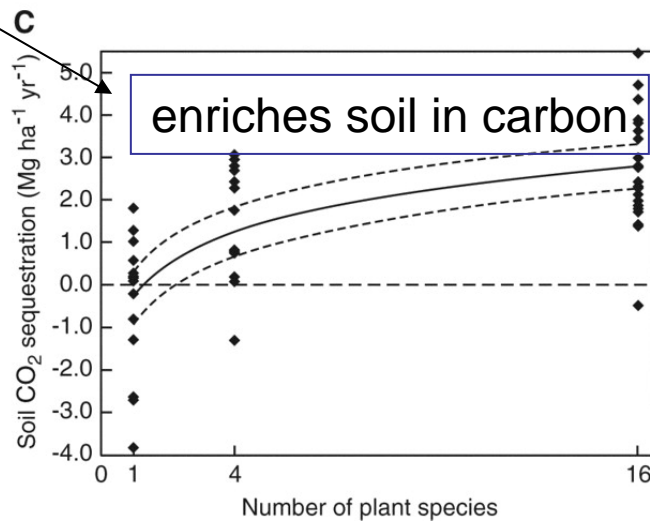

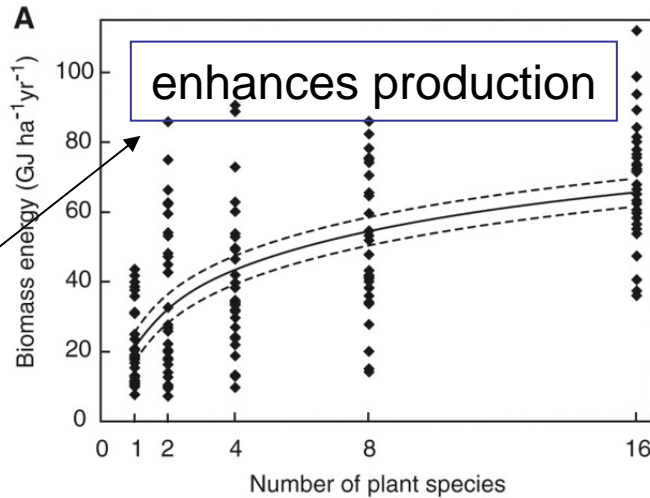

→Answers from grasslands

D. Tilman et al., Science 314, 1598 -1600 (2006)

Species composition: single or multiple species stands ?

Effects of plant diversity on biomass energy yield and CO₂ sequestration for low-input perennial grasslands

Diversity

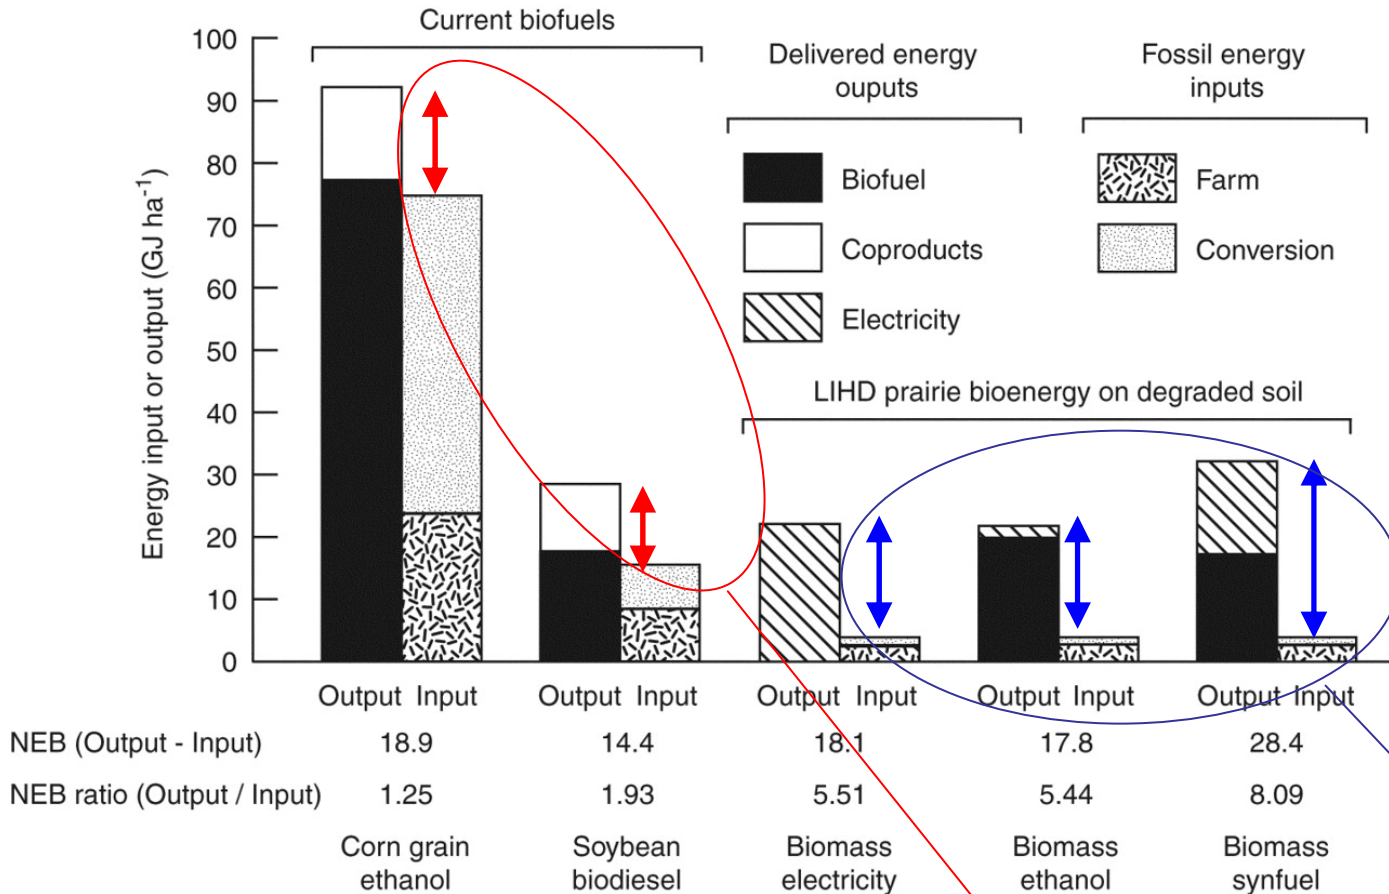

D. Tilman et al., Science 314, 1598 -1600 (2006)

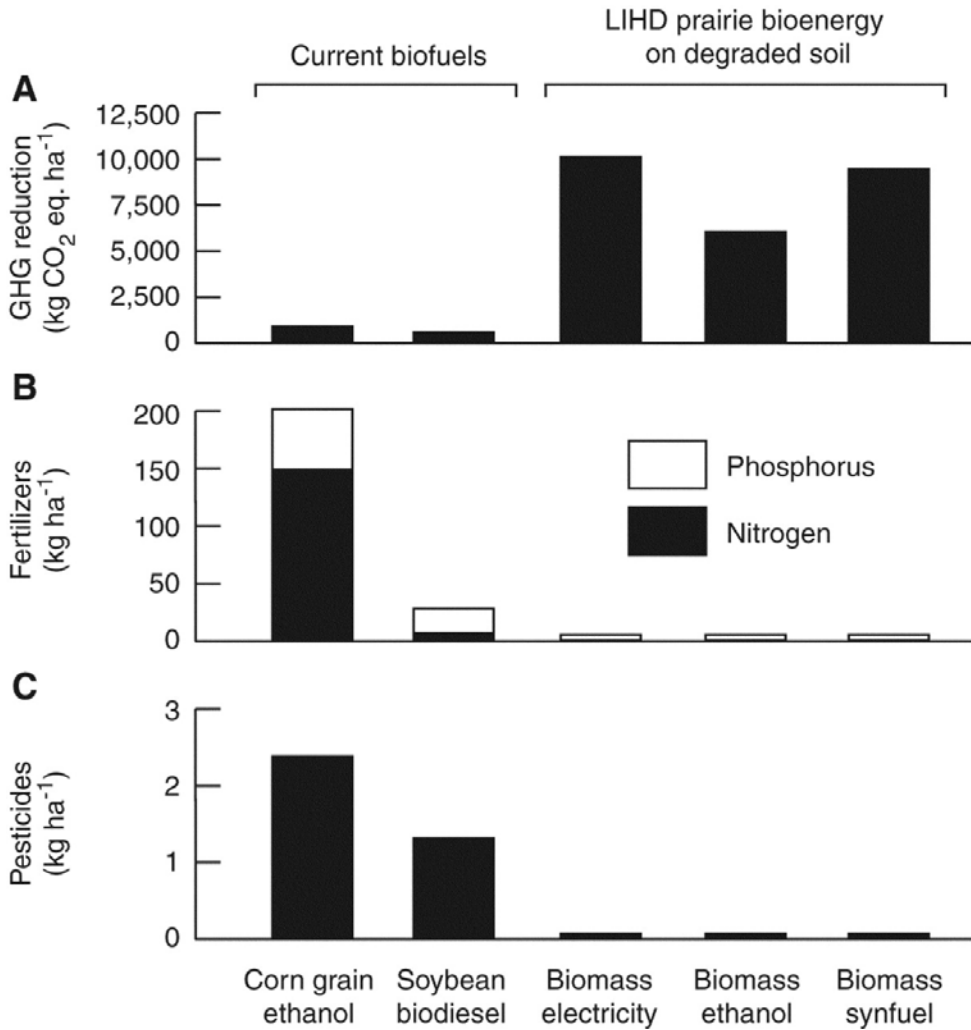

Species composition: single or multiple species stands ?

Net Energy Balance for two food-based biofuels (current biofuels) grown on fertile soils and for LIHD biofuels from agriculturally degraded soil

The net energy balance of “natural” biodiverse grasslands overtakes the **maize and soybean crops.**

Environmental effects of bioenergy sources

Highest GHG reduction

low cost in fertilisers

and phytocides

D. Tilman et al., Science 314, 1598 -1600 (2006)

Environmental effects of bioenergy sources

Tilman's study puts forward the hypothesis that, from the atmospheric point of view, low input high diversity alternatives may overcompete monospecific crops with high input

The question is open and Tilman's work has been discussed.

Using natural ecosystem functions for increasing resource capture (N, light, CO₂, water) at the expense of fossil carbon expensive fertilisers and phytocide must be considered.

Diversity may also enhance ecosystem resilience and adaptive capacity, a major issue for forest managers in a rapidly changing world.

D. Tilman et al., *Science* 314, 1598 -1600 (2006)

• Summary

Summary : a forest ideotype for climate

1. Site

- No tillage, minimize soil work
- Increase productivity (NPP): site remediation, soil improvement

2. Stand

- permanent cover (albedo)
- uneven aged stands
- Mitigate climate impacts: LAI control, understorey control,
- target the adaptative potential to changing climate , 2 options:
 - intra- and inter-species diversity, multi-aged canopy
 - short rotation

Summary: a forest ideotype for climate

3. Regional management

- Mitigate the impact of climate change: ex. continuous forest cover, increases species diversity, ..

- Allocate forest functions according to site conditions:

rich and deep soils	→	high production with low input
poor soil ...	→	conservation / protection and carbon storage <i>in situ</i> .

- Lengthen the residence time of carbon : promote long lived wood products (house, furniture, ...)

- Maximise fossil fuel substitution

Conclusions
