Pasta is a popular food which possesses interesting nutritional quality but may trigger allergic reaction in sensitized people. Many questions remain open for research area, including the relationship between pasta processing, pasta structure and resulting nutritional properties. The purpose of this study was to characterise the structure of pasta dried at different conditions and to relate it to the in vitro digestibility and allergenicity of proteins. Four drying profiles were studied: Low Temperature 55°C (LT), High Temperature 70°C(HT), Very High Temperature 90°C applied either from the beginning of the cycle, when the moisture content of spaghetti was high (20%) (VHT) or at the end of the drying cycle, when the moisture content of pasta was low (12%) (VHT_LM).

Methods

Proteins: Size Exclusion HPLC (SE-HPLC) after protein extraction with SDS (detergent), then with DTE (reducer) in dried and cooked pasta (Fig.1)

Microstructure: Confocal Laser Scanning Microscope of cross sectioned cooked pasta after protein staining with l-aescin acid (Fig. 2).

Protein digestibility : In vitro digestion of cooked pasta composed of a buccal phase (a-amylase, pH7), a gastric phase (pepsin, PH2) and an intestinal phase (pancreatin, pH7). Protein hydrolysis was evaluated by measuring the increase in free amine groups in protein extracts (Fig. 3).

Protein allergenicity : Juices from in vitro bucco-gastric or pancreatic digests were used to inhibit recognition of wheat proteins by IgE from a pool of allergic patients (table 1).

Fig.2: Example of CLSM images of LT cooked pasta at the central (A), intermediate(B) and external (C) zones of pasta strand.

⇒ Localisation effect: External zone: looser protein network with swollen starch granules: creation of a moisture gradient during cooking
⇒ Drying profile: LT ≠ other drying profiles

Allergenicity of Digests from Cooked Pasta

Table 1. Competitive ELISA with digestion juices from cooked pasta and a pool of sera from allergic patients to wheat. Percentage of inhibition obtained with digestion juices at the end of the gastric phase (5 minutes by a-amylase and 3 hours by pepsin) and at the end of the intestinal phase (end of gastric phase + 3 hours by pancreatin) are presented. Distinct letters by protein indicate significant difference between mean values (p<0.05).

⇒ Wheat fraction IgE reactive peptides from different wheat fractions are present in all tested digestion juices.

⇒ Digestion step: digests from gastric phase are richer in IgE reactive peptides than those from intestinal phase, difference depends on wheat fraction.

⇒ Drying process: compared to LT process, increasing the drying temperature led to a reduction in gastric digests and an increase in intestinal digests of IgE reactive peptides, specially for VHT_LM.

Protein digestibility in Cooked Pasta

⇒ Bucco-gastric phase
no significant effect of the drying profile (data not shown)

⇒ Intestinal phase
VHT_LM drying profile significantly decreased protein digestibility (by 10%) compared to other drying processes.

Fig.3: Mean degree of protein hydrolys in after 3 hour of intestinal phase.

VHT_LM decreased significantly protein digestibility (by 10 %) and increased allergenicity of intestinal digests. This could not be explained by a different protein spatial distribution at a microscopic level. VHT_LM cooked pasta presented a higher proportion a high molecular weight protein aggregates (data not shown) which may have contributed to this lower digestibility and higher allergenicity. Both gluten and soluble proteins seemed to be involved. It appears that applying VHT at the end of the drying cycle led to the formation of specific protein aggregates.
