HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Pre-dispersal seed predation and reproductive strategy affect genetic diversity in expanding tree populations

Violette Doublet (INRA Avignon & Université de Montpellier)

Ecological and evolutionary processes involved in population expansions are key drivers of the ability of

organisms to colonize and persist in novel territories. Long-lived sessile organisms such as trees may be

more exposed species facing such colonization and adaptation issues. The environmental factors affecting

both reproductive and dispersal capacities, and more specifically biotic interactions, are acknowledged to

have a strong influence on expansion success, but their demo-genetic implications in expanding tree populations remain an understudied body of theory. Here, we contribute towards filling this gap using a

theoretical approach based on a mathematical model, to describe the impact of pre-dispersal seed predators on the spatio-temporal evolution of genetic structure within tree expanding populations displaying highly variable (masting species) or consistent (non-masting species) interannual seed production. Our theory shows that pre-dispersal seed predation induces an Allee effect at the front of

expansion that enables the maintenance of a higher tree genetic diversity, as compared to a situation where

the seed predators are absent. Interestingly, masting tends to buffer such seed predation-induced Allee

effect, which results in lower overall genetic diversity in the expanding population than in the non-masting

population. Furthermore, simulations also shows that these demo-genetic consequences of seed predation

are enhanced by fat-tailed distributions of seed dispersal. This theoretical approach provides novel insights

on the effects of biotic interactions on tree population dynamics, calling specifically for more consideration

of their demo-genetic implications in mechanistic and process-based approaches of expanding populations

in broader contexts.
