16 Abstract:

17 Water ferns (Azolla spp.) are among the main important floating macrophytes used for 18 feeding farmed animals such as fish, because they have high growth potential and high 19 protein content. Nevertheless, their use as feed requires sustainable mass production, which 20 can be difficult to maintain in field conditions. We performed a first experiment to assess the 21 effects of shading and fertilization levels on the growth of Azolla filiculoides with 22 complementary information regarding the morphology and the chemical composition of the 23 plant cultivated under the different experimental conditions. Plants were cultivated in floating 24 50-L plastic drums at three fertilization levels ("no", "low" and "high") using an inorganic 25 multi-nutrient fertilizer rich in P (NPK = 1:2:1) and maintained under full natural light or 26 shaded by one of two different types of shading materials, transparent polyethylene sheet and 27 60% shade net, respectively. A second experiment was carried out to evaluate the effects of 28 grazing by the invasive golden apple snail *Pomacea canaliculata* on *A. filiculoides* previously 29 cultivated without addition of fertilizer (treatment "n") or in high fertilizer concentrations 30 (treatment "high"). Fertilization levels and shading materials significantly affected the growth 31 of Azolla. The highest productivity was reached using the highest fertilization level under 32 direct sunlight. Azolla produced in these culture conditions was preferentially grazed by snails 33 compared to Azolla cultivated without added fertilizer. Based on these findings, we make 34 recommendations regarding the best culture conditions for A. filiculoides in ponds for its use 35 as sustainable fish feed.

37 Keywords: Aquaculture, Floating macrophytes, Light, Nutrients, Productivity, Grazing

38 **1. Introduction**

39 Water fern species (Azolla spp.) are considered as the most economically important floating 40 aquatic macrophytes in the world (Brouwer et al., 2014; Kollah et al., 2016). Azolla spp. are 41 among the fastest growing plants and can reach very high growth rates via asexual 42 reproduction with a doubling time of only 2-5 days (Wagner, 1997; Sadeghi et al., 2013). 43 These aquatic fern species are native to Central and South America and western North 44 America (Sadeghi et al., 2013). Nevertheless, Azolla spp. are nowadays widely established in 45 freshwater ecosystems of temperate and tropical regions all over the world (Sadeghi et al., 46 2013), demonstrating high adaptability to various environmental conditions. This excellent 47 adaptability is explained by specific physiological characteristics.

48 Due to their symbiosis with nitrogen (N)-fixing microorganisms (diazotroph cyanobacteria 49 Nostoc (ex. Anabaena) azollae; Kahindi et al., 1997), Azolla growth is vigorous even in 50 natural N-limited conditions (Brouwer et al., 2017). Physiologically, the Azolla-Nostoc 51 complex is outstanding, because it can fix N at substantial rates - approximately the double of 52 Rhizobia living in the root nodules of soybean (Hung et al., 2013; Brouwer et al., 2017). The 53 two symbiotic organisms' light-harvesting pigments are complementary and can capture a 54 wide range of wavelengths of light (Wagner, 1997). These specific characteristics make 55 Azolla spp. very suitable for many uses in agriculture and aquaculture (Pabby et al., 2004; 56 Sithara and Kamalaveni, 2008; Kollah et al., 2016).

57 Beyond its high productivity, and according to the environmental conditions, *Azolla* spp. can 58 reach high protein contents (15-40% of its dry weight; Brouwer et al., 2018; Feedipedia, 59 2018; Slembrouck et al., 2018) and can therefore be a valuable alternative to costly fish meal 60 and soybean, especially in pond aquaculture systems (Datta, 2011; Gangadhar et al., 2015; 61 Das et al., 2018). *Azolla* may represent a valuable resource to meet the current challenge for 62 aquaculture: improvement in production to match the growing demand for aquatic products and in a sustainable manner. Thus, experiments carried out on many herbivorous or
omnivorous fish species have shown that reasonable inclusion rates (usually not exceeding
30%, Abdel-Tawwab, 2008; Datta, 2011; Das et al., 2018) of *Azolla* (fresh or dry form) in the
fish diet reduce production costs without affecting growth (for review, see Mosha, 2018).
However, this use requires continuous mass production, which is generally not yet common
on a large scale (Brouwer et al., 2018). Although, *Azolla* species have undeniable growth
capacities, many factors can affect the mass production of these macrophytes.

70 Nutrient availability is often considered as the main bottleneck in the production of Azolla. 71 Phosphorus (P) is a major nutrient limiting the growth of Azolla spp., as in many other 72 photoautotrophic aquatic organisms (Sadeghi et al., 2013; Temmink et al., 2018), because the 73 N₂-fixation rates are ensured by symbionts (Cary and Weerts, 1992; Kushari and Watanabe, 1991). In experimental conditions, 2 to 10 μ mol L⁻¹ P are reported for the sustainable growth 74 75 of Azolla (Subudhi and Watanabe, 1981; Kitoh and Shiomi, 1991; Temmink et al., 2018), but field observations suggest that higher concentrations are necessary (10 to 33 μ mol L⁻¹, 76 77 Sadeghi et al., 2013). Based on this information, P may be limiting for Azolla production even 78 in fertilized ponds used for fish production, where P concentrations are usually between 1-17 umol L⁻¹ (Green and Boyd, 1995; Pengseng and Boyd, 2011; Pouil et al., 2019). In addition, 79 80 temperature and light intensity are important climate variables determining Azolla growth 81 rates in the field (Sadeghi et al., 2013). Although different Azolla species or strains have 82 different temperature sensitivities (Uheda et al., 1999), the optimum temperature range for 83 Azolla growth is about 18-26°C (Sherief and James 1994; Hasan and Chakrabarti, 2009). 84 Furthermore, high temperatures (>35°C) are known to inhibit Azolla growth (Sadeghi et al., 85 2013). Light intensity affects Azolla photosynthetic activity, growth and N₂ fixation 86 (Watanabe, 1982; Pabby et al., 2003; Sagedhi et al., 2013). Although several experimental 87 studies showed a decrease of Azolla biomass under shading conditions (i.e. plants received 30

to 60% of full sunlight, Cary and Weerts, 1992; Abduh et al., 2017), slight shade (25-50% of full sunlight) can benefit *Azolla* mass production (Hasan and Chakrabarti, 2009). However, field investigations are missing to support this statement. In addition, light interacts with temperature in influencing the growth of *Azolla* species (Janes, 1998). Despite knowledge mainly gained through laboratory experiments, only few studies investigated the productivity of *Azolla* under field conditions (e.g. Brouwer et al., 2018).

94 The growth of *Azolla* can also be negatively affected by biological factors. Arthropods such 95 as Lepidoptera and Diptera, or crustaceans and gastropods can affect the growth of *Azolla* by 96 grazing (Sadeghi et al., 2013). The golden apple snail Pomacea canaliculata is a freshwater 97 gastropod, native to South America that has become a serious pest in Asian agriculture and is 98 included in the world's 100 worst invasive alien species (Lowe et al., 2000). These snails, 99 present in aquaculture ponds, are herbivorous and can feed on floating macrophytes such as 100 Azolla (Cruz et al., 2015). Golden apple snails have a strong negative effect on the biomass of 101 all macrophyte species in Asian wetlands (Carlsson and Brönmark, 2006) but, to our 102 knowledge, the potential effects of these snails on the production of Azolla in the field have 103 not been investigated.

104 We aimed to promote culture of Azolla in fish ponds as a potential alternative source of feed 105 for freshwater fish. Thus, the objectives of this study were to assess the combined effects of 106 fertilization levels and shading, considered among the main parameters for plant production, 107 on (1) productivity of Azolla filiculoides in a fish pond setting with complementary 108 information on chemical composition and morphology, and (2) on the grazing of Azolla 109 cultivated in two fertilizer conditions by the invasive golden apple snail P. canaliculata. We 110 hypothesized that the use of shading should support mass production of *Azolla* in fish ponds 111 by maintaining favourable light and temperature conditions while snails should cause non-112 negligible losses of plant production.

113 **2. Materials and Methods**

114 **2.1.** Experiment 1: Effects of shading materials and fertilization on *Azolla* production

115 A six-week field experiment was carried out to assess the response of A. filiculoides to several 116 culture conditions (3 fertilization levels x 3 light level conditions). The experiment was 117 performed from August to September 2018 during the dry season in an artificial pond (400 118 m^2 , depth 0.50 m) without fish. The pond was located in a fish farm of the village of Babakan (6°28'S; 106°42'E; altitude 125 m), district Bogor, West Java, Indonesia. The experimental 119 120 block design consisted of 27 plastic half drums (cut lengthwise; water volume: 50 L, water 121 depth: 0.25 m, surface: 0.5 m²), oriented east-west, partially immersed in the pond and 122 maintained in place with bamboo poles. Nine of these drums were covered by a 60% shade 123 net, nine by a transparent polyethylene sheet, and nine were exposed to direct sunlight without 124 any cover (control condition). Light intensity, water and air temperature were recorded 125 continuously throughout the experiment using data loggers (HOBO Pendant 126 Temperature/Light and HOBO Water Temperature Pro v2). Data loggers were placed in three 127 drums per light condition at 10 cm depth for water temperature and at 5 cm above the water 128 surface for air temperature and light intensity measurements.

129 The use of these low-cost and locally available shading materials resulted in a gradient of 130 shading between the different experimental conditions. Thus, Azolla cultivated under the 131 shade net and the transparent polyethylene sheet received 57% and 10% less light respectively 132 compared to the plants exposed to direct sunlight (Table 1). The nine drums of each condition 133 were filled with water from the pond (N: $33.5 \pm 15.0 \mu \text{mol } \text{L}^{-1}$, P: $5.8 \pm 3.6 \mu \text{mol } \text{L}^{-1}$, K: 31.7134 \pm 30.4 µmol L⁻¹). Commercial aqueous solutions of inorganic multi-nutrient fertilizer (Rosasol[®]-P hydroponic fertilizer with an NPK ratio of 1:2:1, see Table S1 for composition) 135 136 was used as nutrients source. Since P is the most limiting nutrient for Azolla growth, fertilizer was added to obtain concentrations of 2 µmol L⁻¹ of P (i.e., 3.2 and 1.5 µmol L⁻¹ of N and K 137

respectively; treatment "low") and 10 μ mol L⁻¹ of P (i.e., 16 and 7.5 μ mol L⁻¹ of N and K respectively; treatment "high"). The third series of drums was maintained without fertilizer and served as the control (treatment "no"). Each condition was triplicated.

141 Before starting the experiment, A. filiculoides maintained in an aquaculture pond was 142 acclimated to experimental conditions by inoculating 50 g fresh weight (FW) into the 50 L drums (i.e. 100 g FW m⁻² and surface cover of $\sim 20\%$). Plants were acclimated for 11 days 143 144 without harvesting to minimize P history effects (Temmink et al., 2018). During the 145 experiment, water in drums was changed 6 times per week. Azolla biomass was transferred in 146 a net and drum walls were cleaned during the water change. Fertilizer addition to the fresh 147 pond water was according to treatment, as described above. In order to check nutrient 148 concentrations, two times per week, water was sampled 30 min after the fertilizer addition 149 (300 mL per drum) and the operation was renewed the next day (i.e. 24 hours later) just 150 before to change again the water. This procedure allowed to keep nutrient concentrations in 151 water as constant as possible (at least 70% of N, P and K remained in the water after 24 h 152 whatever the experimental condition). Before adding fertilizer, water measurements were performed in each drum (08:00-10:00 AM, two times per week) to determine pH, dissolved 153 oxygen (DO, mg L^{-1}), temperature (T°C), and total dissolved solid matter (TDS, mg L^{-1}) 154 155 using a multi-parameter probe (HI 9829 Hanna).

Total plant biomass in each drum was determined at the beginning and at the end of the 11-d acclimation period and then one time per week during the 6-week experiment. Samples were rinsed, carefully drained and weighed (\pm 0.1g). After FW determination, a 50 g sample (100 g FW m⁻²) of *A. filiculoides* was returned into its original drum to avoid too high surface densities. Productivity (expressed as g FW m⁻² d⁻¹) was calculated as the total amount of *Azolla* harvested in each drum minus the initial seeding (50 g FW per drum). When productivity was negative (i.e. mortality of *Azolla*), plants from different stocks maintained under appropriate fertilizer and shading conditions were used to re-inoculate the drums.
Samples from each drum (each 10 g FW) were carefully weighted as described above and
were taken to determine dry weight (DW). The remaining samples were stored at -18°C for
further analyses.

167

168 **2.2. Experiment 2: Quantification of** *Azolla* ingestion by snails

169 The grazing of the invasive golden apple snail P. canaliculata on Azolla cultivated outdoors 170 was assessed at two extreme nutrient concentrations (treatments "no" and "high"). The experiment was carried out indoors (light: $<2 \mu$ mol PAR m⁻² s⁻¹) to prevent autogenic changes 171 172 Azolla biomass (i.e. changes in biomass caused by endogenous factors and not snail grazing). 173 The experimental set-up consisted of thirteen plastic buckets (6 L, 34 cm diameter) covered 174 with a 60% shade net to prevent snails from escaping. Twelve buckets were used to quantify 175 the ingestion of *Azolla* (from the treatments "no" and "high") by snails (n = 6 per condition) 176 and one basin served as the control, without snails (control). Water temperatures were 177 recorded continuously throughout the experiment using a data logger (HOBO Water 178 Temperature Pro v2) placed at the bottom of the bucket used as the control.

179 Twelve snails (FW: 20.1 \pm 3.2 g, shell length: 3.8 \pm 0.2 mm, shell width: 2.9 \pm 0.2 mm) were 180 randomly placed in the buckets (one snail per bucket) and acclimated for three days to the 181 experimental conditions. Buckets were filled with water from the pond (see Section 1.2.1). 182 During the acclimation period, each snail was fed with 10 g of fresh Azolla from treatments 183 "no" and "high". At the end of the acclimation period, 20 g of fresh Azolla coming from 184 treatments "no" or "high" was added to each bucket (n = 6 per treatment). After 24 h, the 185 remaining Azolla (i.e. non-ingested) was carefully drained, weighed and dried. The water was 186 changed at the same time. Measurements were repeated for four consecutive days using the 187 same procedure. At the end of the experiment, dry weight (DW) and the flesh-to-total FW ratio of each snail was determined. Thus, daily *Azolla* ingestion was calculated as the difference between quantity of *Azolla* added to the bucket and the quantity remaining (on a DW basis) and expressed as grams (DW) of *Azolla* eaten per gram of snail flesh (DW) per day.

192 The dietary preference of snails (FW: 18.0 ± 2.3 g, shell length: 3.8 ± 0.1 mm, shell width: 193 3.0 ± 0.2 mm) for one of the two *Azolla* growing conditions (treatments "no" and "high") was 194 also tested through a multiple-choice experiment. A floating plastic separation was placed in 195 three basins each containing one snail and 10 g each of Azolla coming from the treatments 196 "no" and "high" were introduced on either side of the plastic separation. As for the previous 197 experiment, another bucket served as the control without snail. After 72 h, the remaining 198 Azolla on each side was carefully drained and weighed, and the percentage of ingestion of 199 fresh Azolla was calculated.

200

201 **2.3. Sample analysis**

202 Total Kjeldahl nitrogen (TKN) in water was measured following the Indonesian National 203 Standard (SNI) 06-6989.52-2005 using Macro-Kjeldahl apparatus coupled with titration Total 204 N was then determined as the sum of TKN, NO₃⁻-N and NO₂⁻-N. Phosphorus (P) in water was 205 determined based on the procedures described in the SNI 06-6989.31-2005 adapted from 206 APHA 4500-PE (APHA, 2005). The chemical composition analyses were performed after the 207 11-d acclimation period (n = 1 per condition). Proximate analyses in Azolla samples were 208 performed following Cunniff (1999). Moisture was determined by weight loss upon drying at 209 105°C for 24 h. Crude protein was determined using the standard Kjeldahl procedure; lipid 210 content after acid hydrolysis was determined using the Weibull-Stoldt method; crude ash was 211 determined on residue after heating at 550°C for 4-5 h in a muffle furnace. Crude fibre was 212 determined as follows: macrophytes were extracted with 1.25% H₂SO₄ and 1.25% NaOH, 213 dried, weighed, incinerated and reweighed. Gross energy content was calculated using energy value coefficients of 9 kcal for crude fat and 4 kcal for crude protein and carbohydrates. For 214 215 total P and K determination, plant samples were weighed and digested in nitric acid for 20 216 min at 190°C. Measurements were then performed using an inductively-coupled plasma 217 optical emission spectrometer. Chlorophyll content of Azolla was measured after acetone 218 extraction by spectrophotometry. The absorbance was measured at wavelength of 663 nm and 219 645 nm. Calculation of chlorophyll levels was carried out based on Arnon's equation (Arnon, 220 1949).

221

222 **2.4. Data treatment and statistical analysis**

Prior to analysis, temperature data recorded in lux were converted to µmol PAR m⁻² s⁻¹ using
x54 as conversion factor (Thimijan and Heins, 1982). Because of non-normal distribution of
the data, statistical comparisons were done for the environmental parameters (air and water)
monitored under the different shading conditions using the non-parametric Kruskal-Wallis
and Siegel and Castellan tests (Siegel and Castellan, 1988).

A linear mixed model (LMM) was used to analyse differences in *Azolla* productivity at the nine experimental conditions (3 shading conditions x 3 fertilization levels). Shading materials and fertilizer conditions (with the interaction term) were considered as fixed effects in the model. The individual plastic drums in which *Azolla* grew were considered as random effects. Assumptions of normality and homoscedasticity were checked on residuals of the model. Contrast analysis was then performed as the mean separation procedure with a Bonferronicorrected p-value (α of 0.05/36 = 0.0014).

Analysis of covariance (ANCOVA) was then used to test for effects of light and other environmental covariables (air and water temperatures) on the productivity of *Azolla* cultivated at the three fertilization levels ("no", "low" and "high"). Quantities of ingested *Azolla* (from treatments "no" and "high") by snails (expressed as g g⁻¹ DW d⁻¹) and feed preferences (i.e. % of ingestion) were statistically compared using the non-parametric Mann-Whitney U test because of the non-normal distribution of the data.

The level of significance for ANCOVA and Mann-Whitney U test was set at $\alpha = 0.05$. All statistics were performed using R freeware version 3.3 (R Development Core Team, 2016). Unless otherwise stated, values shown are means \pm SD.

244

245 **3. Results**

246 3.1. Response of *A. filiculoides* to culture conditions

In our experiment, depending on the weather and the shading conditions (Table 1), we observed air and water temperatures ranging from 23 to 40°C and light intensity reached peaks of 278 μ mol m⁻² s⁻¹ (Fig. 2).

Fertilization levels and shading materials affected the growth of *Azolla* (Fig. 1). Overall, in the absence of added fertilizer, the productivity of *Azolla* was limited to 0.15 ± 0.73 g DW m⁻² d⁻¹ (n = 54) over the experiment and *Azolla* cultures collapsed in 43% of measurements performed (23 out of a total of 54). Conversely, the productivity of *Azolla* cultivated at a higher fertilizer level (treatment "high") reached 3.80 ± 1.44 g DW m⁻² d⁻¹ (n = 54) with doubling times of <1 d in some cases and no observed production collapse (Fig. 1).

Our LMM model indicated that both shading conditions (p < 0.001) and fertilizer levels (p = 0.001) affected the growth of *Azolla*. Significant interactions were found between the shading conditions and the fertilization treatment indicating that the effects of shading conditions are dependent of the fertilization level. Indeed, for the two lowest fertilizer addition treatments ("no" and "low"), productivity of *Azolla* was similar between the three shading conditions (t-ratio = 4.065-0.87, p = 0.016-0.992). Nevertheless, for the treatment "high", productivity of

Azolla was significantly lower (t-ratio = 6.521, p = 0.001) under the shade net (in average - 39%) and compared to the other shading conditions.

ANCOVA performed for the three fertilization levels ("no", "low" and "high") revealed that light intensity significantly affected *Azolla* productivity cultivated in the "high" fertilization condition (F = 16.805, p = 0.001) while there were positive significant effects of increasing air temperatures on productivity in the "low" and "high" fertilization conditions (F = 4.904, p = 0.044 and F = 13.422, p = 0.003 respectively) (Fig. 2).

269 We observed that morphology of A. *filiculoides* changed in response to different experimental 270 treatments. Visual aspect indicated that plants from the treatment "no" (no fertilizer added) were smaller and more fragile than those from the "low" and "high" fertilizer treatments 271 272 (lower breaking strength of the fronds). Furthermore, control plants turned brownish, whereas plants from treatments "low" and "high" stayed green (mg kg⁻¹ FW of chlorophyll 273 respectively, n = 3, Table 2). A slight difference (χ^2 = 6.057, p = 0.045) was observed in the 274 chlorophyll concentrations between the treatments "no" and "low" (343 ± 50 and 383 ± 23 275 mg kg⁻¹ FW of chlorophyll respectively, n = 3) and the treatment "high" (450 ± 17 mg kg⁻¹) 276 277 FW of chlorophyll, n = 3). Although the number of *Azolla* samples analysed was limited by 278 the low productivity in the treatment "no" (n = 1 per condition), the chemical composition 279 analyses indicated that, after the acclimation period, P and K concentrations increased with fertilizer concentrations from 121 to 331 and 616 to 1113 mg kg⁻¹ FW respectively, Table 2. 280

281

282 **3.2.** Impacts of the golden apple snail on *Azolla* production

During the experiments, no biomass change was observed in *Azolla* from both the treatment "no" and the treatment "high" maintained without snail (i.e. control condition). The consumption of *Azolla* by the golden apple snail *P. canaliculata* reached 0.06 \pm 0.04 g g⁻¹ DW d⁻¹ and 0.17 \pm 0.07 g DW g⁻¹ d⁻¹ when snails (n = 6 snails x 4 d) were fed on *Azolla* from the treatment "no" and the treatment "high" respectively (U = 536, p < 0.001, Fig. 3). These results were confirmed by estimation of the dietary preference of snails between *Azolla* from the treatments "no" and "high". When snails (n = 3) were able to choose between *Azolla* from the two fertilizer conditions, they slightly preferred (U = 9, p = 0.045) *Azolla* coming from the treatment "high" (79%, 80% and 88% of consumption after 72 h) to *Azolla* from treatment "no" (16%, 21% and 30% of consumption after 72 h).

293

294 **4. Discussion**

295 Some authors found that Azolla is able to grow in shade conditions (50% sunlight) and partial 296 shade may favour its growth in field conditions (see for review: Hasan and Chakrabarti, 2009) 297 contrasting with other experimental studies. Abduh et al. (2017) highlighted that Azolla 298 growth gradually decreased under shading conditions (up to 50% sunlight) while Cary and Weerts (1992) found that biomass yields of plants receiving 30% of greenhouse sunlight were 299 300 less than one-third those of plants receiving no shading. Nevertheless, comparisons between 301 studies are complex. Indeed, shading materials used are likely to affect not only the intensity 302 but also the spectrum of the light received. Although we did not measure light spectra, 303 another study performed on a large number of shading materials, revealed that the photon 304 irradiance is reduced at wavelengths from 260 to 500 nm (-42% for UVB: 280-315 nm, -30% 305 for UVA: 315-400 nm and -13% for blue: 400-500 nm) by polyethylene sheets (Kotilainen et 306 al., 2018). The same authors found that the light spectrum under 50-70% shade nets remained 307 similar to ambient sunlight spectrum. In this field experiment, we experimentally 308 demonstrated that there is no benefit of using such shading materials for Azolla growth in 309 field conditions suggesting that outdoor fish ponds may be an appropriate culture structures 310 for a mass production of *Azolla*.

311 The water fern A. *filiculoides* is known to be sensitive to air temperatures with optimal for 312 growth ranging from 20 to 30°C (Hasan and Chakrabarti, 2009; Sadeghi et al., 2013). In our 313 experiment, depending on the weather conditions and the shading materials used (Table 1), 314 we observed air temperatures ranging from 23 to 40°C. As for light intensity, increasing 315 temperatures had a positive effect on Azolla productivity, indicating that in our experimental 316 conditions high temperature was not a limiting factor for *Azolla* growth. Our results suggest 317 that light and temperature have positive effects on Azolla production within small-scale fish 318 farms in tropical environments.

319 The influences of temperature and light depended on fertilizer concentrations. In the absence 320 of added fertilizer (treatment "no"), light, air and water temperatures had no effect on growth. 321 In this condition, Azolla productivity was low and highly variable with regular production 322 collapses. There were significant positive linear relationships between the environmental 323 variables (light, air and water temperatures) and the productivity of Azolla cultivated at the 324 high fertilization level (treatment "high") and, to a lesser extent, for Azolla grown at the 325 intermediate fertilizer level (treatment "low"). Based on our results, we estimated, for Azolla, cultivated under direct sunlight and high fertilizer addition, yields of 30 ± 9 t DW ha⁻¹ year⁻¹. 326

In the present study, Azolla was harvested every week, and a minimum of 100 g m⁻² was 327 328 maintained in culture. As suggested by Brouwer et al. (2018), regular harvests of Azolla can 329 be used to maintain cultures in a linear growth phase and to obtain predictable and high 330 biomass yields. Our results confirm that the biomass production of Azolla depends on 331 fertilizer concentrations and presumably by P concentrations because this nutrient is the most limiting in Azolla culture (Subudhi and Watanabe, 1981; Kushari and Watanabe, 1991; 332 333 Temmink et al., 2018). Although production varied with environmental conditions (light and temperature), productivity remained high (median values: 44, 73 and 79 g FW m⁻² d⁻¹ for 334 Azolla maintained under a shade net, clear plastic or exposed to direct sunlight, respectively) 335

336 when plants were cultivated at high fertilizer concentrations (addition of 16, 10 and 7.5 μ mol 337 L⁻¹ of N, P and K respectively), regardless of the environmental conditions.

338 Here, we used an inorganic multi-nutrient fertilizer rich in P (NPK = 1:2:1, see Table S1). 339 Thus, other important nutrients for Azolla, such as iron (Fe), which may be limiting under 340 certain conditions and cause chlorosis (Temmink et al., 2018), were already incorporated in 341 the fertilizer. Although no visible evidence of Fe deficiency has been observed, it is possible 342 that other trace elements like Co, Cu, Mn, Mn and Zn required for Azolla growth, particularly 343 in relation with its nitrogen fixation metabolism (Sadeghi et al., 2013) might have been 344 limiting in the experimental condition without fertilizer. The use of multi-nutrient fertilizers mitigated the risk of trace element deficiency. Overall, Azolla cultivated under direct sunlight 345 346 and with a fertilization level equivalent to the "high" condition may presumably generate 6.9 ± 2.2 t protein ha⁻¹ year⁻¹, about three-fold higher than soybean (*Glycine max*) without arable 347 348 land use (Brouwer et al., 2018).

349 The morphology and chemical composition of A. filiculoides also changed in response to 350 different experimental treatments. We observed that plants from the control were smaller and 351 more fragile than those from the intermediate and high fertilizer treatments. Furthermore, 352 control plants turned brownish whereas plants from treatments "low" and "high" stayed 353 green. The chemical composition analyses indicated that P and K concentrations in plants 354 increased with fertilizer concentrations. Similar results were observed for crude protein (from 14 to 23% of DW) and energy content (from 8.7 to 10.9 MJ kg⁻¹ FW) while the fibre content 355 356 decreased from 21 to 15% of DW. These findings corroborate observations of Subudhi and 357 Watanabe (1981) on A. pinnata who found increased of N (from 2.78 to 4.53 % of DW) and P (from 0.03 to 0.11 % of DW) cultivated with 0, 1 and 2 µmol L⁻¹ of P additions. All together, 358 359 these results indicate that visual aspect of Azolla (size and colour) can be used as an indicator 360 of its health and its nutritional quality.

361 Previous studies have shown that the amino-acid profile of Azolla is suitable for fish feed (see 362 for review: Feedipedia, 2018). Given that the fibre content in Azolla cultivated under direct 363 sunlight was the lowest that we measured (13% of DW), we also suggest that the 364 recommended culture conditions can also improve the digestibility of Azolla for fish (Maina 365 et al., 2002). However, culture conditions (CO₂ concentrations) also affected the total 366 polyphenol content of Azolla, thereby affecting digestibility (Browner et al. 2018). In 367 addition, plant-based feed may contain other anti-nutritional factors such as anti-vitamins, 368 phytic acid protease inhibitors and tannins (Dersjant-Li, 2002; Drew et al., 2007). Such 369 factors were not considered in our study and more research is needed to confirm the effects of 370 the culture conditions on the concentrations of these compounds in Azolla.

371 Regarding the impacts of the golden apple snail on Azolla production, we found that snails 372 were able to ingest daily up to 38% of their body weight (FW) of Azolla, with a preference for 373 Azolla cultivated in high fertilization level. These results highlight the huge negative impact 374 of the presence of the golden apple snail on Azolla productivity. The average biomass of P. canaliculata has been estimated at 0.07 kg m⁻² (i.e. approx. 3-4 adult individuals m⁻²) in 375 376 Javanese aquaculture ponds (Pouil et al., 2019) which is in accordance with density observed 377 in Philippines rice paddies (i.e. 1-5 individuals m⁻², Cowie, 2002) although higher densities up to 150 individuals m⁻² have been reported (Halwart, 1994; Schnorbach, 1995). Based on this 378 379 finding, the yield loss of Azolla due to ingestion by snails can reach about 12.3 t DW ha⁻¹ year⁻¹ (i.e. 35% of the estimated average yield, see Section 3.2). Further large-scale 380 381 investigations are needed to confirm our findings.

Based on our observations, even maintaining *Azolla* in optimal conditions for production (direct sunlight and addition of fertilizer with high P concentration), does not overcome the risk of drastic drops in yields or even total loss of *Azolla* due to snails. The golden apple snail is able to select among macrophytes and prefers macrophytes species with high N and Ca

contents and low C:N ratios (Zhao et al., 2012). These facts may explain the preference of 386 387 snails for Azolla cultivated in optimal culture conditions (i.e. with the highest nutritional 388 content). Considering the high risk represented by snails in the mass culture of Azolla in 389 aquaculture ponds, we recommend (1) cultivating Azolla in snail-free ponds, (2) installing 390 protections (e.g. wire-mesh grills; Cowie, 2002) in association to snail predator fish such as 391 common carp (Sin, 2006) to prevent access of snails to ponds and/or (3) regularly trapping 392 snails (e.g. using baited traps), which are traditionally used for other purposes, such as feeding 393 poultry or certain fish (Cowie, 2002).

The present study demonstrates some important requirements for the mass production of *Azolla* in aquaculture ponds. This aquatic plant crop is potentially useful to improve sustainability of tropical pond aquaculture requiring a limited production surface with only few inputs and no nitrogen fertilizer. Potential yields are very promising compared to terrestrial crops. However, several practices must be optimised, especially regarding fertilization and risk of grazing by snails to maintain yields over time and sustain a mass production.

560

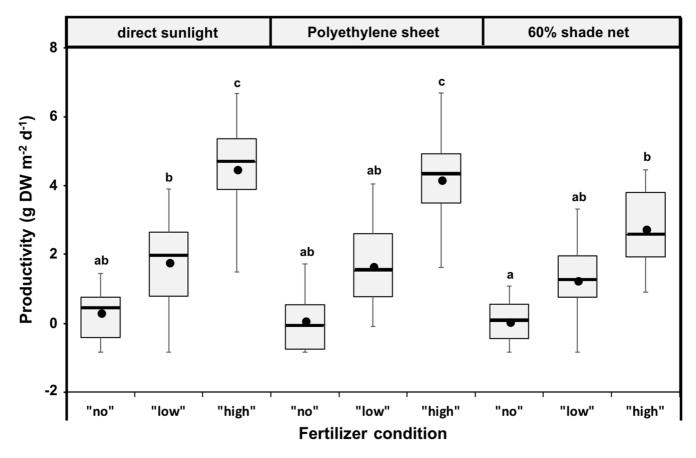

Figure 1. Productivity of *Azolla* (g FW m⁻² d⁻¹, n = 3 replicates x 6 weeks = 18 per treatment) cultivated at the three fertilization levels (treatments "no", "low" and "high") under three shading conditions: direct sunlight, polyethylene sheet and 60% shade net. Limits of the box indicate the first and the third quartiles. Whiskers indicate the maximum and minimum values, black lines and black dots indicate the median and mean values respectively. Different letters denote significant differences.

567

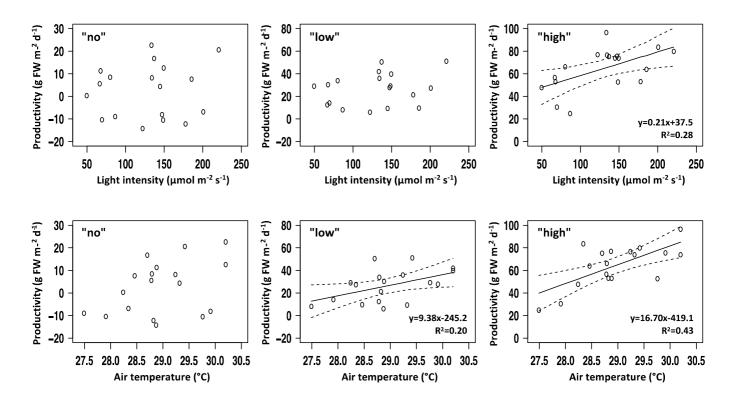

Figure 2. Relationships between light intensity (μ mol m⁻² s⁻¹), air temperature (°C) and average productivity (g FW m⁻² d⁻¹) of *Azolla* cultivated at the three fertilization levels (treatments "no", "low" and "high") under three shading conditions: direct sunlight, polyethylene sheet and 60% shade net. For light intensity and air temperature, data are the average values recorded during the 7 d before harvest. Regression lines are shown in black and the dotted lines indicate the upper and lower 95% confidence levels. Equations, determination coefficients (R²) and significance (p-values) are also given.

575

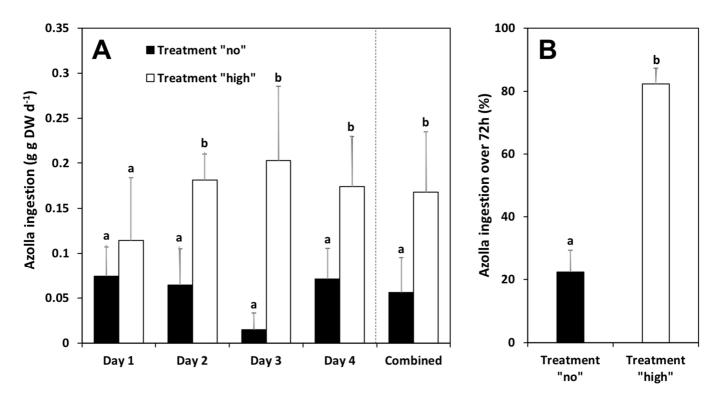

Figure 3. Daily ingestion (g g⁻¹ DW d⁻¹, n = 6 per day) of fresh *Azolla* cultivated at fertilization levels (treatments "no" and "high") by the golden apple snail (A) and feed preference (expressed as percentage of ingestion over 72 h, n = 3) between the two fertilization levels N0 and N2 (B). Data are means \pm SD. Letters denote significant differences.

581 Figure 1
