19 **ABSTRACT**

20 Interactions between embryo and endometrium at implantation are critical for the progression and the issue
21 of pregnancy. These reciprocal actions involve exchange of paracrine signals that govern implantation and
22 placentation. However, it remains unknown how these interactions between the conceptus and the
23 endometrium are coordinated at the level of an individual pregnancy. Under the hypothesis that gene
24 expression of endometrium is dependent on gene expression of extraembryonic tissues, we performed an
25 integrative analysis of transcriptome profiles of paired conceptuses and endometria obtained from
26 pregnancies initiated by artificial insemination. We quantified strong dependence ($|r|>0.95$, $eFDR<0.01$) in
27 transcript abundance of genes expressed in the extraembryonic tissues and genes expressed in the
28 endometrium. The profiles of connectivity revealed distinct co-expression patterns of extraembryonic
29 tissues with caruncular and intercaruncular areas of the endometrium. Notably, a subset of highly co-
30 expressed genes between conceptus ($n=229$) and caruncular areas of the endometrium ($n=218$, $r>0.9999$,
31 $eFDR<0.001$) revealed a blueprint of gene expression specific to each pregnancy. Functional analyses of
32 genes co-expressed between conceptus and endometrium revealed significantly enriched functional
33 modules with critical contribution for implantation and placentation, including “in utero embryonic
34 development”, “placenta development” and “regulation of transcription”. Functional modules were
35 remarkably specific to caruncular or intercaruncular areas of the endometrium. The quantitative and
36 functional association between genes expressed in conceptus and endometrium emphasize a coordinated
37 communication between these two entities in mammals. To our knowledge, we provide first evidence that
38 implantation in mammalian pregnancy relies on the ability of the conceptus and the endometrium to develop
39 a fine-tuned adaptive response characteristic of each pregnancy.

40 INTRODUCTION

41 In mammals, pregnancy recognition requires a tightly synchronized exchange of signals between the
42 competent embryo and the receptive endometrium. The initiation of this signaling is triggered by key factors
43 produced by the conceptus (1, 2) which are translated by the endometrial cells into actions that will condition
44 the trajectory of embryo development as well as progeny phenotype. In mammalian species, including
45 human, rodents and ruminants, the delicate balance in embryo-maternal communication is affected by the
46 way the embryos are generated (natural mating, artificial insemination, *in vitro* fertilization somatic cell
47 nuclear transfer) and by the sensor-driver properties of the endometrium defined by intrinsic maternal
48 factors (i.e.: maternal metabolism, ageing) and environmental perturbations (i.e.: pathogens, nutrition) (3-
49 5). The concept of sensor property applied to the mammalian endometrium was first proposed in a pioneer
50 paper as was suggested the notion of endometrial plasticity (6). This property was recently confirmed *in*
51 *vitro* with an aberrant responsiveness of human endometrial stromal cultured cells in the context of recurrent
52 pregnancy loss (7). Nevertheless, it remains unaddressed whether the mammalian endometrium is able to
53 develop an adaptive embryo-tailored response in a normal pregnancy.

54 In mammalian reproduction, sheep and cattle are research models that have relevantly contributed key
55 insights in the understanding of molecular and physiological pregnancy-associated mechanisms, including
56 the deciphering of embryo-endometrium interactions (8, 9). In the bovine species, by gestation days 7-8,
57 the blastocyst enters the uterine lumen. After hatching by days 8-9, the outer monolayer of trophoderm
58 cells establishes direct contact with the luminal epithelium of the endometrium (10). On gestation days 12-
59 13, the blastocyst is ovoid in shape (~2-5 mm) and transitions into a tubular shape by days 14-15. By day
60 ~15, rapidly proliferating trophoderm cells of the extra-embryonic tissues synthesize and release IFNT
61 (11-15), which is the major pregnancy recognition signal in ruminants (1, 9, 16, 17). The disrupted release
62 of the oxytocin-dependent pulses of prostaglandin F₂ alpha (18) allows maintenance of progesterone
63 production by a functional corpus luteum (18), which is critical for the establishment and progression of
64 pregnancy (1, 4, 9, 12, 14, 15, 19). IFNT actions include induction of numerous classical and non-classical
65 IFN-stimulated genes and stimulation of progesterone-induced genes that encode proteins involved in
66 conceptus elongation and implantation (4). IFNT-regulated genes have diverse actions in the endometrium

67 that are essential for conceptus survival and pregnancy establishment (12). Other paracrine signals such
68 as prostaglandins and cortisol have regulatory effects on conceptus elongation and endometrium
69 remodeling (20). More recently, the identification of potential ligand-receptor interactions between the
70 conceptus and endometrium (21) and the secretion of proteins and RNAs through exosomes (22, 23) have
71 expanded the field of possibilities by which the conceptus and endometrium interact prior to and during
72 implantation.

73 The cross-talk between the conceptus and the endometrium is associated with the expression and
74 regulation of a wealth of genes in each entity (24, 25). The nature of the conceptus modifies gene
75 expression of the endometrium in cattle (6, 26, 27) and decidualizing human endometrial stromal cells (28).
76 Similarly, the endometrium from dams with different fertility potentials (29) or metabolic status (30)
77 influences the gene expression of the conceptus. Despite the growing evidence of the interactions between
78 conceptus and endometrium at the level of gene regulation, the pathways and the functions that result from
79 this interaction have yet to be unveiled. Furthermore, the lack of integrated analysis between paired
80 conceptus and endometrium has made it challenging to advance our understanding of the functional
81 interactions between these two entities in normal pregnancies.

82 Here, we hypothesized that gene expression of extraembryonic tissue is not independent from gene
83 expression of endometrium. In the present study, we carried out an integrative analysis of transcriptome
84 profiles of paired conceptuses and endometria at the onset of implantation aiming at the identification of
85 regulatory pathways that have coordinated expression between the conceptus and endometrium in normal
86 pregnancies. Surprisingly, our results show that at gestation day 18 in cattle, several hundred genes have
87 an expression profile in conceptus and caruncular areas of the endometrium that is unique to each
88 pregnancy. Analyses of genes co-expressed between the conceptus and the paired-associated
89 endometrium revealed significantly enriched functional modules with critical contribution for implantation
90 and placentation. Our data provide evidence that successful implantation in mammalian pregnancy relies
91 on the ability of the endometrium to elicit a fine-tuned adaptive response to the conceptus.

92 **RESULTS**

93 **Data overview**

94 We analyzed the RNA-sequencing data that consisted of samples collected from five cattle pregnancies
95 terminated at gestation day 18 (GSE74152 (26)). The conceptus was dissected, and transcriptome data
96 was generated for extraembryonic tissue; whereas the endometrium was dissected into caruncular (gland-
97 free) and intercaruncular (containing endometrial glands) areas, and transcriptome data was generated
98 from both regions of the endometrium (Fig 1A). Therefore, the dataset analyzed was comprised of three
99 samples collected from each pregnancy: extraembryonic, caruncular, and intercaruncular tissues (Fig 1B).
100 Alignment of the sequences to the *Bos taurus* genome (UMD 3.1) resulted into an average of 22, 31.4, and
101 34.6 million uniquely mapped reads for extraembryonic (n = 5), caruncular (n = 5), and intercaruncular (n =
102 5) tissues, respectively. We quantified the transcript abundance of 9548, 13047, and 13051 genes in
103 extraembryonic, caruncular, and intercaruncular tissues, respectively (Fig 1C). Unsupervised clustering of
104 the samples based on their transcriptome data separated the samples obtained from the conceptus from
105 the endometrial samples and further distinguished caruncular from intercaruncular endometrial samples
106 (Fig 1D).

107

108 Fig 1. Transcriptome profiling of conceptus and endometrium collected from gestation day 18. (A)
109 Representative images of pregnant uterus and micrograph identifying the tissues from which RNA-seq data
110 were used in this study. (B) Data structure used in this study. Data on genome-wide transcript abundance
111 was obtained from extraembryonic tissue (EET) and endometrium (caruncular (CAR), intercaruncular
112 (ICAR) tissues) from five pregnant uteri. (C) Number of genes with transcript abundance quantified in each
113 sample. (D) Dimensionality reduction of the RNA-seq data for special visualization of the sample
114 distribution.

115

116 **Correlated gene expression between conceptus and endometrium**

117 The associated expression between two genes can be assessed by correlative metrics (31) within (32, 33)
118 or between tissues (33, 34). Thus, we calculated Pearson's coefficient of correlation (r (35)) to test whether
119 there is association between the transcript abundance of genes expressed in extraembryonic tissue and
120 endometrium (caruncular or intercaruncular tissues). We reasoned that under a null hypothesis, the
121 abundance of a gene expressed in extraembryonic tissue (G_j) would have no association with the
122 abundance of a gene expressed in endometrium (G_k , or G_l), for example: $H_0: r_{(G_j, G_k)} \approx 0$. On the other hand,
123 under the alternative hypothesis ($H_1: r_{(G_j, G_k)} \neq 0$), two genes display co-expression (35).

124 The distribution of correlation coefficients for all pairs of genes expressed in extraembryonic and caruncular
125 tissues averaged 0.13 (Fig 2A), and the equivalent distribution obtained for all pairs of genes expressed in
126 extraembryonic and intercaruncular tissues averaged 0.03 (Fig 2B). Both distributions deviated significantly
127 from a distribution obtained from shuffled data that disrupted the pairing of the conceptus and endometrium
128 ($P < 2.2 \cdot 10^{-16}$, S1 Fig). We calculated the empirical FDR (eFDR) and noted that absolute correlation coefficients
129 in both distributions were highly significant when greater than 0.95 (eFDR < 0.007 , S2 Fig, S1 Table). Of
130 note, S3 Fig and S4 Fig present examples of pairs of genes we identified with the highest positive and
131 negative correlation coefficients, which fit the alternative hypothesis ($H_1: r_{(G_j, G_k)} \neq 0$) and examples of pairs
132 of genes that show correlation coefficients close to zero fitting the null hypothesis ($H_0: r_{(G_j, G_k)} \approx 0$).

133

134 Fig 2. Co-expression analysis between extraembryonic tissue and endometrium. Distribution of the
135 correlation coefficients for genes expressed in extraembryonic (EET) and caruncular (CAR) tissues (A) or
136 intercaruncular (ICAR) tissues (B). (C) Number of genes expressed in either EET, CAR or ICAR that
137 participate in significant correlation connections involving conceptus and endometrium. (D) Tanglengram
138 of EET and CAR tissues formed by genes with strong co-expression. (E) Scatterplot of pairs of genes
139 expressed in EET and CAR with at least one gene involved in "mRNA processing" or "chromatin
140 organization". (F) Scatterplot of pairs of genes expressed in EET and CAR and highly correlated with at
141 least one gene involved in "RNA transport pathway".

142

143 Notably, all 9548 genes expressed in extraembryonic tissue were positively ($r > 0.95$) and negatively ($-$
144 $0.95 > r$) correlated with genes expressed in caruncular or intercaruncular tissues (Fig 1C). Eighty percent
145 and 95% of the genes expressed in caruncle tissues were negatively and positively correlated with genes
146 expressed in extraembryonic tissue. Similarly, 83% and 88% of the genes expressed in intercaruncular
147 tissues were negatively and positively correlated with genes expressed in extraembryonic tissue (Fig 1C).
148 The distribution of degrees of connectivity for significant correlations ($|r| > 0.95$, $eFDR < 0.01$) between
149 extraembryonic and caruncular tissues was not equivalent to the distribution observed between
150 extraembryonic and intercaruncular tissues ($P < 2.2 \cdot 10^{-16}$). The genes expressed in extraembryonic tissue
151 were significantly correlated with 295 genes expressed in caruncular tissues on average (median = 101).
152 Eleven genes were significantly correlated with over 2300 genes in caruncular tissues (i.e. *AREG*, *EGR1*,
153 *PEX3*, *GAN*, *S5A* Fig). The genes expressed in extraembryonic tissue were significantly correlated with
154 266 genes expressed in intercaruncular tissues on average (median = 252). Eight genes were significantly
155 correlated with over 750 genes in intercaruncular tissues (i.e.: *WNT5B*, *WNT7B*, *ROR2*, *DPEP1*, *GJB3*,
156 *S4B* Fig). These results strongly suggest different patterns of gene co-expression between extraembryonic
157 and caruncular or intercaruncular tissues.

158 We then examined if genes co-expressed in extraembryonic tissue and endometrium have expression
159 patterns that are unique to pregnancies. We identified 229 and 218 genes expressed in extraembryonic
160 and caruncular tissues, respectively ($|r| > 0.9999$, $eFDR < 0.001$, S1 Table), whose expression profiles
161 produced equivalent dendrograms for extraembryonic and caruncular tissues independently ($P = 0.008$,
162 Fig 2D). Functional investigation of these 441 genes identified significant enrichment in the biological
163 processes “mRNA processing” (*GEMIN6*, *PRPF4B*, *RBM39*, *SMNDC1*, *SUPT4H1*, *U2AF1L4*, $FDR = 0.13$,
164 Fig 2E), “chromatin organization” (*CDAN1*, *NUP133*, *SUPT4H1*, $FDR = 0.13$, Fig 2E), and “protein
165 autoubiquitination” (*CNOT4*, *MARCH5*, *UHRF1*). We also interrogated the KEGG pathways database and
166 identified an enrichment for the “RNA transport” pathway (*EIF4E*, *GEMIN6*, *KPNB1*, *MAGOHB*, *NUP133*,
167 *NUP54*, *PYM1*, *SEN2*, *SUMO1*, *THOC1*, $FDR = 0.06$, Fig 2F). We did not identify groups of genes co-
168 expressed in extraembryonic and intercaruncular tissues capable of producing dendrograms that mirrored

169 each other. These results demonstrate that genes highly co-expressed between extraembryonic and
170 caruncular tissues form a signature that independently distinguishes pregnancies in an equivalent manner.

171 **Visualization of co-expressed networks in extraembryonic tissue and endometrium**

172 Our analysis was not an exhaustive evaluation of all potential co-expression networks that exist between
173 conceptus and endometrium. Thus, we developed a web interface for dynamic and interactive data
174 visualization based on the co-expression analysis conducted in the present study (36, 37)
175 (https://biaselab.shinyapps.io/eet_endo/). The public access to this web application allows a user to
176 produce networks for genes of their choosing. Furthermore, each network is accompanied by supporting
177 data such as scatter plots and heatmaps of the gene expression values. The raw data and codes for
178 reproduction of this interface can be downloaded from a GitHub repository
179 (https://github.com/BiaseLab/eet_endo_gene_interaction).

180 **Functional networks between extraembryonic and caruncular tissues**

181 We investigated the transcriptome-wide interactions between extraembryonic and caruncular or
182 intercaruncular tissues independently. The clustering of genes based on co-expression is a powerful means
183 to understand coordinated gene functions (38), thus we used the matrix with correlation coefficients to
184 cluster extraembryonic, caruncular, and intercaruncular tissues independently.

185 The heatmap resultant of clustering the two datasets (extraembryonic and caruncular tissues) showed the
186 formation of an organized co-expression network between the genes expressed in extraembryonic and
187 caruncular tissues (Fig 3A). We identified 36 clusters formed by the genes expressed in extraembryonic
188 tissue that presented enrichment for several biological processes (FDR < 0.2, Fig 3B), where we identified
189 several genes expressed in extraembryonic tissue significantly co-expressed with genes expressed in
190 caruncular tissues (see S1 Data for a list of genes). For instance, 142 genes associated with regulation of
191 transcription were identified across clusters 1, 12, 30, 38, and 54. Eighty-two genes were associated with
192 signal transduction across clusters 1, 21, 27, and 71. Interestingly, 26 genes associated with “in utero
193 embryonic development” were identified in cluster 1.

194

195 Fig 3. Functional analysis of co-expressed genes between extraembryonic (EET) and caruncular (CAR)
196 tissues. (A) Heatmap produced by the correlation coefficients and independent clustering of EET and CAR.
197 (B) Gene ontology analysis of the cluster formed. Only significant coefficients of correlation are shown ($|r|$
198 > 0.95 , $eFDR < 0.01$). The colored bar on the right of the heatmap indicates clusters of genes expressed in
199 EET for which biological processes were significant. The colored bar on bottom of the heatmap indicates
200 clusters of genes expressed in caruncle for which biological processes were significant. The colored
201 squares at the bottom of the image identify the cluster number with the color observed on the bars. See S1
202 Data and S2 Data for details on the cluster identification, biological processes and genes. (C,D) Model of
203 functional co-expression networks possibly formed between EET and CAR.

204

205 The clustering of genes expressed in caruncular tissues according to their co-expression with
206 extraembryonic tissue genes resulted in the identification of 32 clusters presenting enrichment ($FDR < 0.2$)
207 for several Biological processes (Fig 3A, S2 Data). Among the genes forming significant co-expression with
208 extraembryonic tissue, we identified 96 genes in cluster 3 associated with “intracellular protein transport”,
209 as well as 111 and four genes associated with regulation of transcription in clusters 4 and 5, respectively.
210 Notably, ten genes on cluster 15 were associated with “defense response to virus”, and the annotated
211 genes are known to be stimulated by interferon-tau (*IFIT1*, *IFIT3*, *IFIT5*, *ISG15*, *MX1*, *MX2*, *OAS1Y*,
212 *RSAD2*, S2 Data).

213 Next, we intersected the results of gene ontology enrichment obtained from clustering extraembryonic and
214 caruncular tissues. We identified several biological processes on both datasets with co-expressing genes
215 expressed in extraembryonic and caruncular tissues (S3 Data). Based on the number of genes and
216 direction of connections, two pairs of biological processes are noteworthy. First, five genes associated with
217 “positive regulation of cell proliferation” in extraembryonic tissue form negative co-expression connections
218 ($\bar{x}_r = -0.96$, $n = 22$) with 14 genes associated with “regulation of transcription, DNA-templated” expressed
219 in caruncle (Fig 3C). Second, ten genes associated with “transmembrane transport” in extraembryonic

220 tissue form positive co-expression connections ($\bar{x}_r = 0.97$, $n = 22$) with 12 genes associated with “regulation
221 of transcription, DNA-templated” expressed in caruncle (Fig 3D). These results are coherent with a co-
222 expression between genes expressed in extraembryonic and caruncular tissues, with functional
223 implications to conceptus attachment and implantation.

224 **Functional networks between extraembryonic and intercaruncular tissues**

225 The independent clustering of the correlation coefficients obtained from the genes expressed in
226 extraembryonic and intercaruncular tissues also evidenced an organized co-expression network between
227 the two tissues (Fig 4A). Twelve clusters formed by genes expressed in the extraembryonic tissue
228 presented enrichment for biological processes (FDR < 0.2, Fig 4B, see S4 Data for a list of genes).
229 Interestingly, there were 85 and 27 genes associated with “mRNA processing” and “stem cell population
230 maintenance”, respectively on cluster 3. On cluster five, we identified 12 genes associated with “negative
231 regulation of cell proliferation” and seven genes associated with “regulation of receptor activity”. On cluster
232 eight, 5 genes were associated with “placenta development” (*ADA*, *CCNF*, *DLX3*, *PHLDA2*, *RXRA*). On
233 cluster 17, eight genes were associated with “regulation of transcription, DNA-templated”.

234

235 Fig 4. Functional analysis of co-expressed genes between extraembryonic (EET) and intercaruncular
236 (ICAR) tissues. (A) Heatmap produced by the correlation coefficients and independent clustering of EET
237 and ICAR. (b) Gene ontology analysis of the cluster formed. Only significant coefficients of correlation are
238 shown ($|r| > 0.95$, $eFDR < 0.01$). The colored bar on the right of the heatmap indicates clusters of genes
239 expressed in EET for which biological processes were significant. The colored bar on bottom of the heatmap
240 indicates clusters of genes expressed in intercaruncle for which biological processes were significant. The
241 colored squares at the bottom of the image identify the cluster number with the color observed on the bars.
242 See S4 Data and S5 Data for details on the cluster identification, biological processes and genes. (C,D)
243 Model of functional co-expression networks possibly formed between EET and ICAR. See S6 fig for an
244 enlarged version of panel C.

245

246 The clusters formed by intercaruncular genes co-expressed with extraembryonic tissue genes also
247 highlighted significant enrichment of biological processes (FDR < 0.2, Fig 4A, see S5 Data for a list of
248 genes). For instance, clusters one and six contained 145 and 63 genes associated with regulation of
249 transcription, respectively. Interestingly, on cluster two, there were 149, 23, 22, and 16 genes associated
250 with “oxidation-reduction process”, “cell redox homeostasis”, “electron transport chain”, and “tricarboxylic
251 acid cycle”. Cluster four contained 63 genes associated with “regulation of transcription”, and cluster seven
252 contained 11 genes associated with “fatty acid beta-oxidation”.

253 The intersection of the genes identified in enriched biological processes in clusters formed by
254 extraembryonic and intercaruncular tissues revealed several potential functional co-expression networks
255 between these two tissues (S6 Data). Notably, several of the intersecting categories involved processes
256 associated with regulation of transcription or oxidation-reduction on the intercaruncular side. For instance,
257 28 genes associated with “stem cell population maintenance” and expressed in extraembryonic tissue
258 presented positive co-expression ($\bar{x}_r = 0.97$, $n = 305$) with 83 genes associated with “regulation of
259 transcription” and expressed in intercaruncular tissues (Fig 4D). Five genes associated with “placenta
260 development” and expressed in extraembryonic tissue presented negative co-expression ($\bar{x}_r = -0.97$, $n =$
261 88) with 41 genes associated with “oxidation-reduction process” and expressed in intercaruncular tissues
262 (Fig 4E).

263 **DISCUSSION**

264 In mammals and particularly in the bovine species, a large body of gene expression data was produced at
265 various steps of early pregnancy derived from *in vitro* or *in vivo* produced embryos (6, 26, 27, 39), varied
266 physiological status of the dam (40), and fertility classified heifers (29). Altogether, results based on groups
267 analyses (conceptus or endometrium) have demonstrated different degrees of interactions between the
268 conceptus and endometrium at the initial phases of implantation. In the present study, our objective was to
269 shed light on the subtle interactions between the extraembryonic tissue of a conceptus and the endometrial
270 tissue of the uterus hosting this conceptus in normal pregnancy using paired co-expression analyses of

271 gene transcript abundances. Our analyses were carried out using biological material collected from the
272 single conceptus and the endometrium from the same pregnancy, a critical aspect to determine the cross-
273 talk during implantation at the level of one individual pregnant female.

274 Our analyses of transcriptome data from conceptus and endometrium pairs identified key signatures of
275 gene expression that are likely to be linked to the success of pregnancy recognition and implantation. A
276 large proportion of all genes quantified in extraembryonic tissue and endometrium have transcript
277 abundances that were not independent. Furthermore, the dependency observed for the abundance of
278 transcripts between extraembryonic tissue and endometrium varied with morphologically and
279 physiologically distinct areas of the endometrium, namely caruncular and intercaruncular tissues. For
280 instance, there were twice as many highly positive ($r > 0.95$) and approximately half the number of highly
281 negative ($r < -0.95$) co-expressing connections between extraembryonic and caruncular tissues compared
282 to extraembryonic and intercaruncular tissues. These results greatly expand previous findings that the
283 conceptus triggers distinct molecular responses in caruncular and intercaruncular tissues (6, 26, 41, 42).

284 During the elongation phase, the mural trophoblast proliferates rapidly (12, 25, 43) while maintaining its
285 pluripotency (44). This period of development is modulated by dynamic regulation of gene expression (43)
286 whereby metabolically active trophoblastic cells (45, 46) rely on the uptake of nutrients from the uterine
287 luminal fluid (47). Our results show that caruncular and intercaruncular tissues have an active role in the
288 programming of those functions, as several genes related with gene regulation, signal transduction, cellular
289 proliferation, maintenance of stem cell population, and transmembrane transport are also co-expressed
290 with genes expressed in the endometrium. The importance of gene co-regulation between extraembryonic
291 tissue and endometrium was further supported by the identification of 26 genes associated with “in utero
292 embryonic development” and five genes associated with “placenta development” co-regulated with genes
293 expressed in caruncle and intercaruncle, respectively.

294 Among the genes expressed in caruncular or intercaruncular tissues that were co-expressed with
295 extraembryonic tissues, it was noticeable that several genes were associated with regulation of gene
296 expression. This finding is in line with former publications reporting that the regulatory network needed for

297 endometrial remodeling (48) during attachment is conceptus-dependent. In the caruncular tissue, we
298 specifically identified 15 genes associated with “defense response to virus”, of which eight genes had their
299 expression modulated by interferon-tau, produced by the trophoblast between gestation days 9 and 25 (49).
300 This result provide additional knowledge on the biological actions of interferon-tau and other conceptus-
301 originated signaling on the remodeling of the caruncle (50).

302 Our findings identified genes with high levels of co-expression ($|r| > 0.9999$) between extraembryonic tissue
303 ($n = 229$) and endometrial caruncular tissues ($n = 218$) whose transcript profiles independently produced
304 equivalent discrimination of the pregnancies. Functional interrogation of these 444 genes revealed that
305 highly co-expressed genes between extraembryonic and caruncular tissues are involved in regulatory
306 functions at the chromatin, mRNA processing, and protein levels; which is a strong indication of a
307 coordinated reprogramming of tissues driven by multiple layers of cell regulation during the conceptus-
308 maternal recognition. These data prompt the need for additional investigation to better define the
309 coordinated interactions between extra-embryonic tissues and endometrium at the level of tissue layer
310 including luminal epithelium, stroma and glandular epithelium.

311 In the intercaruncular tissues, our analyses identified a list of genes related with “oxidation-reduction
312 process”, a finding consistent with a recent publication reporting that proteins associated with oxidation-
313 reduction are enriched in the uterine luminal fluid on gestation day 16 in cattle (51). Oxidative stress is a
314 consequence of altered oxidation-reduction state (52) and transcriptional regulation of factors involved in
315 the regulation of oxidative stress has been reported in the bovine endometrium during oestrous cycle and
316 early pregnancy (41, 53), Furthermore, a significant increase in oxidation-reduction potential was observed
317 in the endometrium of mice prior to implantation (54). The results show evidence that the maintenance of
318 oxidation-reduction status permissive to the conceptus health (55) and implantation is strongly linked to
319 genes regulated in the glandular area of the endometrium in cattle.

320 The analyses carried out in this study have provided novel insights into the molecular contribution of
321 extraembryonic, caruncular, and intercaruncular tissues to conceptus elongation, uterine receptivity, and
322 implantation, summarized in Fig 5. Gene products expressed by the extraembryonic tissue impact the

323 endometrial function by regulating diverse cell functions including oxidative stress, chromatin remodeling,
324 gene transcription, mRNA processing and translation. The endometrium also exerts key regulatory roles
325 on the extraembryonic tissue cells by modulating chromatin remodeling, gene transcription, cell
326 proliferation, translation, metabolism, and signaling (Fig 5). Collectively, our data have shown that
327 endometrial plasticity, a notion first suggested in cattle (6), allows unique adaptive and coordinated
328 conceptus-matched interactions at implantation in non-pathological pregnancies.

329

330 Fig 5. Working model of most prominent biological functions modulated by co-expression between
331 extraembryonic tissue and endometrium. The arrows indicate probable direction of interaction.

332

333 To our knowledge, this study presents the first analysis of paired conceptus and endometrium in a
334 mammalian species, using an integrative systems biology approach. Our results provide strong evidence
335 that implantation in mammalian pregnancy relies on the ability of the endometrium to elicit a fine-tuned
336 adaptive response to the conceptus in normal pregnancy. This finding opens new venues for the
337 development of strategies to improve term pregnancy rates when artificial reproductive technologies are
338 used. Since the endometrial response is embryo-specific, it would be valuable to develop approaches
339 aiming at selection of the competent embryo better suitable for the establishment of a successful cross-talk
340 with the recipient uterus of the female considered for transfer.

341 **MATERIAL AND METHODS**

342 All analytical procedures were carried out in R software (36). The files and codes for full reproducibility of
343 the results are listed on the S1 Code.

344 **Data analyzed and estimation of gene expression levels**

345 The appropriated approval from institutional committees of ethical oversight for animal use in research was
346 obtained as reported previously (26). Briefly, all five cattle gestations were initiated by artificial insemination
347 using semen from a single bull, and later terminated on gestation day 18 for sample collection. We analyzed
348 RNA-seq generated from samples obtained from cattle gestations interrupted at day 18 (n = 5, GSE74152).
349 The samples were extraembryonic tissue (n = 5), caruncle (n = 5), and intercaruncle (n = 5) regions from
350 the endometrium.

351 The reads were aligned to the bovine genome (*Bos taurus*, UMD 3.1) using STAR aligner (56). Reads that
352 aligned at one location of the genome with less than four mismatches were retained for elimination of
353 duplicates. Non-duplicated reads were used for estimation of fragments per kilobase per million reads
354 (FPKM) using Cufflinks (v.2.2.1 (57)) and Ensembl gene models (58). Genes were retained for downstream
355 analyses is FKPM > 1 in ≥ 4 samples. We employed the t-Distributed Stochastic Neighbor Embedding
356 approach (59) to assess the relatedness of the tissues.

357 **Calculation of correlation of gene expression between tissues**

358 Three samples were collected from the same pregnancy, thus the data structure (Fig 1B) allowed us to
359 quantify the association between genes expressed in extraembryonic tissue and endometrium (caruncular
360 and intercaruncular tissues). We utilized Pearson's coefficient of correlation due to its sensitivity to
361 outliers(60) to calculate $r_{(G_j, G_k)}$ and $r_{(G_j, G_l)}$, where G_j , G_k , and G_l , are the transcript abundance of a gene
362 expressed in extraembryonic tissue caruncle and intercaruncle respectively. Empirical FDR was calculated
363 by permuting the pregnancy index ($i = 1, \dots, 5$) for the extraembryonic tissue samples thereby breaking the
364 pairing of conceptus and endometrium obtained per pregnancy (100 permutations) and using the formulas
365 described elsewhere to calculate the proportion of resulting correlation resulted from the scrambled data
366 that was greater than a specific threshold (33, 61, 62).

367 **Testing the resemblance of two distance matrices**

368 We calculated distance matrices for extraembryonic tissue and caruncle passed on the Pearson's
369 coefficient of correlation of the expressed genes within tissues. The correlation matrix was subtracted from

370 one to obtain a distance matrix which was used as input for clustering using the method 'complete'. We
371 used the Mantel statistic test implemented in the 'mantel' package to assess the correlation between the
372 two dissimilarity matrices. The significance of the Mantel statistic was assessed by a permutation approach.

373 **Clustering of samples, heat maps, and network visualization**

374 We clustered samples using 'flashClust' package (63); we used the ComplexHeatmaps package (64) to
375 draw annotated heatmaps and Cytoscape software (65) to visualize the networks.

376 **Testing for enrichment of gene ontology terms or KEGG pathways**

377 We tested for enrichment of gene ontology (66) categories and KEGG pathways (67) using the 'goseq'
378 package (68). Subsets of genes were defined according to appropriate thresholds and defined as 'test
379 genes'; the genes expressed in the corresponding tissue were then used as background for the calculation
380 of significance values (69). Significance values were then adjusted for FDR according to the Benjamini and
381 Hochberg method (70).

382 **ACKNOWLEDGEMENTS**

383 The authors would like to thank the staff of INRA experimental units (Leudeville, France; Saint-Genes-
384 Champanelle, France; Nouzilly, France) for animal management as well as past and present members of
385 UMR BDR including Dr. H. Jammes, M. Guillomot, A Chaulot Talmon and Corinne Giraud-Delville for help
386 in sample collection and preparation.
