15 Running title: Oviduct fluid and polyspermy in goat embryos

16 **ABSTRACT**

17 The present study determined i) the presence of proteins (oviduct-specific glycoprotein,  
18 OVGPI; heat shock protein-70A, HSPA1A; heat shock protein-A8, HSPA8; annexin A1,  
19 ANXA1; annexin A5, ANXA5; and myosin-9, MYH9) known to be involved in early  
20 reproduction in the oviduct fluid (OF) of anestrous goats; and ii) the functional effect of OF  
21 during IVF on polyspermy modulation and embryonic development. *In vitro*-matured oocytes  
22 were co-cultured with spermatozoa ( $1.0, 2.0, \text{ or } 4.0 \times 10^6$  cells/mL) for 18 h in SOF medium  
23 supplemented with 5  $\mu\text{g/mL}$  of heparin, 4  $\mu\text{g/mL}$  gentamicin, and 10% estrus sheep serum  
24 (CTRL1, CTRL2, and CTRL4 groups) or the same medium plus 10% OF (OF1, OF2, and  
25 OF4 groups) obtained from anestrus goats. The analysis of OF by western blotting confirmed  
26 the presence of the six proteins tested for. The increase in sperm concentration had no effect  
27 ( $P > 0.05$ ) on the penetration rate in any group; however, monospermy rate decreased as  
28 sperm concentration was increased in both OF and CTRL. Regardless of the concentration  
29 used, when data were pooled, OF supplementation improved ( $P < 0.05$ ) monospermy and  
30 tended ( $P = 0.057$ ) to enhance IVF efficiency. Additionally, IVF efficiency was higher  
31 ( $P < 0.05$ ) in OF1 than in OF4 [ $60 \pm 13$  vs  $37 \pm 5\%$ ]. The development capacity was not  
32 affected ( $P > 0.05$ ) by the sperm concentration and OF treatment, and the average values were  
33 cleavage ( $72 \pm 2.6\%$ ), blastocyst ( $37 \pm 3.0\%$ ), blastocyst in relation to the cleaved ( $51 \pm$   
34  $4.8\%$ ), hatched ( $62 \pm 1.2\%$ ), and number of cells per blastocyst ( $174 \pm 1.8\%$ ). In conclusion,  
35 the six proteins analyzed are present in the OF of anestrous goats, and the supplementation of  
36 this OF during IVF may modulate the polyspermy incidence and enhance IVF efficiency,  
37 especially when  $1 \times 10^6$  sperm per mL is used.

40

## 41 **1. Introduction**

42 In most mammalian, gamete transport, final sperm capacitation, fertilization, and early  
43 embryo development are reproductive events that occur in the oviduct lumen [1]. In this  
44 microenvironment, gametes and early embryos are immersed in the oviduct fluid (OF), which  
45 is a mixture of plasma exudate, epithelial cell secretion, and follicular fluid released during  
46 ovulation [2]. In addition to metabolic components such as glucose, lactate, pyruvate, and  
47 amino acids, OF contains a wide variety of proteins which contribute to the success of early  
48 reproductive events [3]. Extracellular vesicles (EVs), including microvesicles and exosomes,  
49 are present in OF and play a fundamental role in the dialogue of oviduct epithelial cells with  
50 gametes/embryos [4,5]. Analyses of transcripts from oviduct epithelial cells [6] and protein  
51 composition [7] suggest that the composition of OF is dynamic and changes according to the  
52 concentration of sex steroid hormones such as  $17\beta$ -estradiol (E2) and progesterone (P4),  
53 during the estrous cycle.

54 In sheep expressing spontaneous estrus, 624 proteins were identified in the OF, among  
55 which 280 were found to be differentially expressed throughout the estrous cycle, with 64  
56 (23%) being more abundant at estrus and 17 (6%) at luteal phase [8]. Among the proteins in  
57 abundance at estrus, the oviduct glycoprotein-1 (OVGP1) has a role during the fertilization  
58 and interacts with heat shock protein (HSP) family members, such as HSPA8 and HSPA1A,  
59 and in the zona pellucida (ZP) hardening of the oocyte [9]. HSPA8 sperm exposure enhanced  
60 the sperm survival in boars and bulls and improved monospermy in pigs [10]. Annexins (*i.e.*,  
61 ANXA1 and ANXA5) are oviduct sperm-binding proteins involved with the sperm reservoir  
62 formation. This mechanism keeps the sperm viable near the site of fertilization, controlling  
63 the number of sperm cells arriving around the oocyte, and may intrinsically reduce the risk of  
64 polyspermy [4,11]. Myosin-9 (MYH9) has been identified as an important sperm-interacting  
65 protein with a possible role in sperm capacitation around fertilization. It acts by forming

66 complexes with other proteins of the OF (*e.g.*, OVGP1) before interacting with the sperm  
67 surface [12].

68 In IVF, oocyte polyspermic penetration is a common problem observed in several  
69 species, including goats [13–16]. It leads to embryo development failure and consequently a  
70 reduction in IVF efficiency. High rates of polyspermy have been observed in prepuberal  
71 (~48%) [17] and adult goats (~34%) [13]. Studies of different species have already  
72 demonstrated that IVF medium supplementations or gametes treatment with OF or EVs  
73 extracted from OF could promote gametes viability, fertilization rate, and embryo production  
74 [18–20]. One of the benefits of using OF in *in vitro* systems is that it enhances monospermic  
75 penetrations, possibly through inducing ZP hardening [9,14,21]. An improvement of cleavage  
76 and blastocyst rates was also reported using OVGP1 purified from OF in a goat IVF protocol  
77 [20]. OF effects on gametes were observed when using heterologous co-incubation systems,  
78 such as ram sperm/bovine OF [18] and oocytes from several species (cows, sheep, goats,  
79 pigs, rats, rabbits, and humans) with OF from different species [22].

80 There is no information about the OF proteome in goats, and only OVGP1 has been  
81 reported in the literature [20,23,24]. Proteome studies in bovine [25] and ovine [8] showed  
82 some similarities of OF protein expression profile throughout the estrous cycle. The follicular  
83 phase (late or pre-ovulatory) is related with high E2 concentration, which is the major  
84 modulator of the OF proteins involved in the gamete interactions and fertilization [5,26,27].  
85 In small ruminants under temperate climate conditions, the seasonal anestrus compromises  
86 natural reproduction, although follicular waves and steroid production are maintained [28].  
87 Thus, based on this evidence, a study that determines the protein profile and role of OF from  
88 anestrus females seems sound. Therefore, the present study was designed to i) determine the  
89 presence of proteins involved in the fertilization process (OVGP1, ANXA1, ANAX5,

90 HSPA8, HSPA1A, and MYH9) in the OF of goats in anestrus; and ii) assess the functional  
91 effect of this fluid during IVF on polyspermy and embryo development.

92

## 93 **2. Materials and Methods**

94 The study was performed at Unité de Physiologie de la Reproduction et des  
95 Comportements in Nouzilly, France (47°22'N and 00°41'E), during the non-breeding season  
96 (June to September) [29,30]. Chemicals were purchased from the Sigma Chemical Co. (Saint  
97 Louis, MO, USA), except where otherwise indicated.

98

### 99 *2.1. Experimental design*

100 The goat oviducts and ovaries used during the study were obtained at a local  
101 slaughterhouse. In June, the flushing containing OF was centrifuged, aliquoted, and stored at -  
102 80 °C. From early July to early September, a sample was used to determine the presence of  
103 important proteins by western blotting [4]. Over six runs 1,576 COCs were used and  
104 submitted to *in vitro* maturation (IVM), followed by co-culture with three different sperm  
105 concentrations (1.0, 2.0, and 4.0 x 10<sup>6</sup> cells/mL) in IVF medium supplemented with 10%  
106 oviduct flushing, corresponding to ± 10% OF (OF1, OF2, and OF4) or without (CTRL1,  
107 CTRL2, and CTRL4). After IVM, the COCs were allocated to the following groups: CTRL1  
108 (n=259), CTRL2 (n=270), and CTRL4 (n=254); and OF1 (n=261), OF2 (n=266), and OF4  
109 (n=266) for the IVF. After IVF, a part of the presumptive zygotes (n=628) was denuded,  
110 fixed, stained, and used to evaluate polyspermy, while the others (n=914) were cultured until  
111 day 8 to evaluate development.

112

### 113 *2.2. OF recovery*

114 Genital tracts and the attached ovaries were transported to the laboratory in individual  
115 bottles (dry) in a thermos box at 30 °C within 2–3 h of collection. The estrous cycle phase was  
116 assessed by ovarian morphology, according to Camp et al. [31]. The absence of corpus luteum  
117 (CL) and preovulatory follicles, characterizing acyclicity, was observed throughout the  
118 experiment. Consequently, all the oviducts and ovaries used were classified as being in  
119 seasonal anestrous. Oviducts were dissected free of surrounding tissues: A needle coupled to a  
120 1 mL syringe was inserted into the infundibulum and 500 µL of IVF medium were slowly and  
121 carefully injected into the oviduct lumen. A manual descendent (from ampulla to isthmus)  
122 pressure was applied to collect the flushing. The oviductal flushing of the pair of oviducts  
123 from each female was recovered in a falcon tube of 15 mL and centrifuged at  $300 \times g$  for 15  
124 min at room temperature to remove the cells. The supernatant was transferred into a new tube  
125 (FALCON white lid) and centrifuged at  $12,000 \times g$  for 15 min at 4 °C to remove cellular  
126 debris and apoptotic bodies. Clarified OF was stored at -80 °C until use. Before use, a pool of  
127 samples from three females was prepared, aliquoted, and frozen for use throughout the  
128 experiment.

129

### 130 2.3 Western blotting

131 Proteins were selected based on the previous identification of oviduct proteins with  
132 known reproductive roles in bovine [4,32] and porcine [14,19] species. Therefore, bovine and  
133 porcine OF were used as positive control in western blots (WB). For each species, an OF pool  
134 from three animals was used. OF samples were diluted in reducing Laemmli loading buffer  
135 (2x buffer; composition: 125 mM Tris, 20% glycerol, 4% sodium dodecyl sulfate, and 10%  
136 tris (2-carboxyethyl)phosphine), followed by vortexing, heating in a water bath at 95 °C for 5  
137 min and being centrifuged at  $12,000 g$  for 5 min. Proteins were separated by sodium dodecyl  
138 sulfate polyacrylamide using a 10% polyacrylamide gel containing 40 µg of proteins per lane

139 at 180 V for 45 min [33]. After separation, proteins were transferred onto nitrocellulose  
140 membranes (Bio-Rad, 1704271) over 30 min up to 1.0 A and 25 V using semi-liquid  
141 Transblot® Turbo™ System (Bio-Rad). After transfer, membranes were washed with distilled  
142 water and blocked with Tris-buffered saline solution containing Tween 20 (0.5% w/v; TBST),  
143 supplemented with lyophilized low-fat milk (5% w/v; TBST-milk) for 2 h at room  
144 temperature. Then, membranes were incubated with primary antibodies overnight at 4 °C,  
145 washed four times in TBST, and incubated with IRDye® Fluorescent secondary antibodies for  
146 45 min at 37 °C in the dark, both under gentle agitation. The protein bands were revealed with  
147 UV light exposure, and images were digitalized using Odyssey CLx Near-Infrared  
148 Fluorescence Imaging System (LICOR), in triplicate. The primary antibodies used for  
149 immunoblotting detection were anti-oviduct-specific glycoprotein (OVGP1; Santa Cruz  
150 Biotechnology, sc-377267); anti-annexin A1 and A5 (ANXA1 and 5; Santa Cruz  
151 Biotechnology); anti-heat-shock protein 70 (HSP1A1; Stressgen, SPA-810); anti-myosin  
152 heavy chain 9 (MYH9-H40, Santa Cruz Biotechnology, sc-98978); and Anti-Hsc70 (HSPA8;  
153 Abcam, ab65170). Secondary antibodies were IRDye® 800CW anti-Rabbit IgG and IRDye®  
154 680RD anti-Mouse IgG (1:10000; LICOR).

155

#### 156 *2.4. Cumulus-oocyte complexes (COCs) recovery*

157 Slaughterhouse ovaries from adult goats were collected and transported to the  
158 laboratory in a thermos box containing saline solution (0.9% NaCl) at 30 °C within 4 h of  
159 collection. Ovaries were washed with fresh saline solution at 30 °C and the stage of estrous  
160 cycle was classified. Oocytes were aspirated from all visible follicles between 2 and 6 mm in  
161 diameter with an 18-ga short bevel needle connected to a Falcon tube under controlled  
162 vacuum (30 mm Hg). The collection tubes had been previously filled with 3 mL of HEPES-  
163 buffered TCM 199 supplemented with 10 IU/mL heparin (Choay; Glaxo Wellcome

164 Production, Notre Dame de Bondeville, France), 4 µg/mL gentamicin (G1272), and 1 mg/mL  
165 BSA (A 9647).

166

#### 167 2.5. *In vitro maturation*

168 COCs were isolated under stereomicroscope (Nikon Corporation, Japan) and screened  
169 by morphology. Only COCs surrounded by at least one complete layer of unexpanded  
170 cumulus cells and finely granulated oocyte cytoplasm were used for IVM; the rest were  
171 discarded [34]. COCs were washed four times in four-well petri dishes (Nunc, Roskilde,  
172 Denmark) containing 500 µL of TCM 199 (M4530) supplemented with gentamicin (4  
173 µg/mL). Then, 40 to 50 COC groups were transferred into another four-well petri dish  
174 containing 500 µL of TCM199 supplemented with 10 ng/mL EGF and 100 µM cysteamine,  
175 and incubated for 22 h at 38.8 °C in a humidified atmosphere of 5% CO<sub>2</sub> in air.

176

#### 177 2.6. *Semen preparation and in vitro fertilization*

178 For each replicate used in the experiments, two straws of frozen semen (frozen at the  
179 same time) from the same batch and from the same two bucks were thawed (37 °C for 30 s)  
180 and pooled. Motile sperm were separated by centrifugation (15 min at 700 × g) on 3 mL of  
181 Percoll (Pharmacia, Uppsala, Sweden), discontinuous density gradient (45/90%). The sperm  
182 pellet was washed by centrifugation (100 × g for 5 min) in 600 µL of IVF-Hepes medium that  
183 consisted of synthetic oviduct fluid [SOF; 107.7 mM NaCl, 7.16 mM KCl, 1.19 mM  
184 KH<sub>2</sub>PO<sub>4</sub>, 1.71 mM CaCl<sub>2</sub>, 0.49 mM MgCl<sub>2</sub>, 25.07 mM NaHCO<sub>3</sub>, 3.3 mM Na lactate,  
185 0.3 mM Na pyruvate, 1.3 µg/mL phenol red, 1 mM glutamine, 3% essential (M-6766), 1%  
186 nonessential (B-7145) amino acids, and 0.3% BSA fraction V; pH = 7.3; 280 mOsm]  
187 supplemented with 2.4 mg/mL Hepes (H3375), and 4 µg/mL gentamicin. The sperm pellet  
188 was resuspended in IVF medium (described below).

189 After maturation, the COCs were washed once in 500  $\mu$ L of IVF medium and  
190 transferred into the fertilization well containing 250  $\mu$ L of medium. Sperm suspension was  
191 diluted in IVF medium to reach final concentrations of 1.0, 2.0, or 4.0  $\times 10^6$  cells/mL by  
192 adding 250  $\mu$ L to IVF wells. The IVF medium consisted in SOF (already described)  
193 containing 10% of heat inactivated estrus sheep serum (ESS), 5  $\mu$ g/mL heparin (Calbiochem  
194 375095) and 4  $\mu$ g/mL gentamicin (control groups; CTRL1, CTRL2 and CTRL4) or this same  
195 medium supplemented with 10% of OF (OF groups; OF1, OF2, and OF4). Sperm and COCs  
196 (40 to 50/well) were co-incubated for 18 h at 38.8  $^{\circ}$ C in a humidified atmosphere of 5% CO<sub>2</sub>  
197 in air.

198

### 199 *2.7. Assessment of fertilization*

200 The presumptive zygotes reserved for evaluation of polyspermy (approximately 40%  
201 of the initial number of inseminated COCs) from each group were transferred within a 10  $\mu$ L  
202 droplet onto a grease-free slide and dried at room temperature. They were then fixed in 100%  
203 ethanol for at least 3 h. After drying, structures were stained in 1  $\mu$ g/mL Hoechst 33342  
204 fluorochrome (stains all nuclei) in Vectashield mounting medium (Vector Labs, Burlingame,  
205 CA, USA), and overlaid with a cover slip sealed with nail varnish. Slides were stored at 4  $^{\circ}$ C  
206 until they were examined using epifluorescence microscopy to evaluate fertilization. Zygotes  
207 with three or more pronuclei (or decondensing sperm heads) were considered polyspermic.

208

### 209 *2.8. In vitro development (IVD)*

210 After IVF, the zygotes were placed into 15 mL Falcon tubes containing 2 mL of  
211 washing medium (SOF; 2.4 mg/mL Hepes and 2  $\mu$ L/mL BSA) and vortexed for 2 min to  
212 remove cumulus cells. The presumptive zygotes were recovered in 35 mm petri plates,  
213 washed four times in culture medium (SOF; supplemented with 3 mg/mL BSA), and reserved

214 for evaluation of polyspermy or transferred in groups of maximum 25 into four-well petri  
215 dishes containing 25  $\mu\text{L}$  (1  $\mu\text{L}/\text{structure}$ ) drops of culture medium covered with 700  $\mu\text{L}$   
216 mineral oil. The presumptive zygotes were cultured for 8 days at 38.8  $^{\circ}\text{C}$  in a humidified  
217 atmosphere of 5%  $\text{O}_2$ , 5%  $\text{CO}_2$ , and 90%  $\text{N}_2$ . At 48 h post-insemination (PI), the drops were  
218 supplemented with 10% fetal calf serum (FCS). On day 8, all blastocysts were washed,  
219 spotted onto microscopy slides, fixed in ethanol 100% for 3 h, dried, and stained with Hoechst  
220 (1  $\mu\text{g}/\text{mL}$ ) to count their total cell number under epifluorescence microscope.

221

## 222 2.9. Statistical analyses

223 The efficiency of development was evaluated (1) as the percentage of cleaved  
224 embryos 2 days PI and the percentage of blastocysts at 8 days PI, expressed (2) on the basis of  
225 the number of oocytes entering into IVD or (3) on the basis of the number of cleaved embryos  
226 at day 2. The following end points were assessed: penetration rate (penetrated zygotes/total  
227 oocytes  $\times$  100); monospermy rate (monospermic/penetrated zygotes  $\times$  100); and IVF  
228 efficiency (monospermic zygotes/total oocytes  $\times$  100). Data were tested for normality using  
229 the Kolmogorov-Smirnov test. Variables were compared by one-way ANOVA followed by  
230 Tukey test. Differences were considered significant when  $P < 0.05$  and tendency when  
231  $P < 0.10$ . Data are shown in mean  $\pm$  S.E.M.

232

## 233 3. Results

### 234 3.1. Western blotting

235 The analysis of candidate proteins confirmed the presence of the six proteins (OVGP1,  
236 ANXA1, ANXA5, HSPA1A, HSPA8, and MYH9) associated with reproductive functions in  
237 the OF obtained from goats in anestrus. The size of each protein observed in the goat sample

238 is compatible with the sizes observed in the bovine and swine samples used as positive  
239 controls (Fig. 1).

240

### 241 *3.2. Effect of OF on IVF outcomes*

242 When comparing OF with CTRL at the same sperm concentration (OF1 vs. CTRL1,  
243 OF2 vs. CTRL2, and OF4 vs. CTRL4, respectively), the fertilization parameters, such as  
244 penetration rate (Fig. 2A,  $P = 0.32$ ,  $P = 0.83$ ,  $P = 0.62$ ), monospermy rate (Fig. 2B,  $P = 0.14$ ,  
245  $P = 0.08$ ,  $P = 0.18$ ), and IVF efficiency (Fig. 2C,  $P = 0.11$ ,  $P = 0.55$ ,  $P = 0.15$ ), were similar.  
246 The increase in sperm concentration had no effect on the penetration rate (Fig. 2A) either for  
247 control ( $P = 0.82$ , CTRL1:  $67 \pm 11$ ; CTRL2:  $69 \pm 16$ , and CTRL4:  $72 \pm 15\%$ ) or OF groups ( $P$   
248  $= 0.74$ , OF1:  $74 \pm 13$ ; OF2:  $71 \pm 14$ , and OF4:  $67 \pm 17\%$ ). Regardless of the concentration  
249 used, when data were pooled, gametes exposure to OF during IVF improved ( $P = 0.04$ )  
250 monospermy and tended ( $P = 0.06$ ) to enhance IVF efficiency in terms of production of  
251 normally fertilized zygotes from total oocytes (Fig. 2D). In addition, IVF efficiency was  
252 greater ( $P = 0.002$ ) in OF1 than OF4 [ $60 \pm 13$  vs  $37 \pm 5\%$ ], with no effect ( $P = 0.11$ ) in the  
253 control groups [CTRL1:  $45 \pm 16$ ; CTRL2:  $46 \pm 13$ , and CTRL4:  $31 \pm 9\%$ ] (Fig. 2C). The  
254 monospermy rate decreased as sperm concentration was increased, in both OF and CTRL  
255 (Fig. 2B).

256

### 257 *3.3. Embryo development*

258 Gametes exposure to OF during IVF did not affect any parameter related to  
259 developmental competence, inferred by rates of cleavage ( $P = 0.63$ ,  $P = 0.61$ ,  $P = 0.94$ ),  
260 blastocysts in relation to oocytes ( $P = 0.75$ ,  $P = 0.85$ ,  $P = 0.94$ ), blastocysts in relation to  
261 cleaved embryos ( $P = 0.26$ ,  $P = 0.86$ ,  $P = 0.92$ ) and hatched blastocysts in relation to  
262 blastocysts ( $P = 0.99$ ,  $P = 0.83$ ,  $P = 0.89$ ), as well as the total number of cells per blastocyst ( $P$

263 = 0.94, P = 0.83, P = 0.89, Table 1). When comparing OF1 to OF4, there was a tendency (P =  
264 0.08) to favor OF1 in the blastocyst/cleaved oocytes parameter. When the data were pooled  
265 regardless of the treatment, average cleavage was  $72 \pm 2.6\%$ , blastocyst  $37 \pm 3.0\%$ , blastocyst  
266 in relation to cleaved  $51 \pm 4.8\%$ , hatched  $62 \pm 1.2\%$ , and total number of cells per blastocyst  
267  $174 \pm 1.8$ . Goat blastocysts are shown in Fig. 3.

268

#### 269 **4. Discussion**

270 To mimic physiological reproductive conditions *in vivo*, co-culture of  
271 gametes/embryos with oviduct epithelial cells, EVs (microvesicles and exosomes), and  
272 purified or integral OF proteins may represent the best models of *in vitro* systems [1].  
273 Interestingly, in this study we demonstrated that the main proteins (OVGP1, ANXA1,  
274 ANAX5, HSPA8, HSPA1A, and MYH9) involved in the fertilization process are present in  
275 the OF of anestrus goats. However, a moderate effect only was observed on fertilization  
276 parameters evaluated after the OF exposure of the gametes during IVF. Even though no  
277 differences were found when treatments using the same sperm concentrations (OF1 vs.  
278 CTRL1, OF2 vs. CTRL2, and OF4 vs. CTRL4) were compared, when data were pooled  
279 regardless of concentrations, the OF exposure significantly improved monospermy and tended  
280 to enhance IVF efficiency in terms of production of normally fertilized zygotes.

281 A comparison of the extreme concentrations within the same treatment (CTRL1 vs  
282 CTRL4 and OF1 vs OF4) revealed that penetration rate was not affected; however, a  
283 monospermy decrease was observed when  $4 \times 10^6$  sperm/mL was used in both (CTRL4 and  
284 OF4). These data partly diverge from those previously described in prepubertal goats [35],  
285 where penetration rate was enhanced when  $4 \times 10^6$  sperm/mL was used, but polyspermy was  
286 also increased. For adult goats, the standard sperm concentration used for IVF is between 1  
287 and  $2 \times 10^6$  sperm/mL [13,36], but  $4 \times 10^6$  sperm/mL has also been reported in the literature,

288 aiming to enhance oocyte penetration [20,37]. However, our data demonstrate that penetration  
289 was not affected by concentration and thus  $1 \times 10^6$  sperm/mL could be recommended for adult  
290 goat IVF.

291         Importantly, IVF efficiency was greater in OF1 than in OF4. Conversely, no effect  
292 was observed on the control (CTRL1 vs CTRL4). We believe that the effect observed in OF  
293 groups could be due to an enhancement of sperm quality. In this way, we recently  
294 demonstrated that bovine OF was able to enhance ram sperm motility for up to 4 h as well as  
295 rate of acrosome reaction after long (18–24 h) incubation periods without affecting sperm  
296 viability [18]. In addition, there was a tendency to favor OF1 in the rate of blastocyst in  
297 relation to the cleaved structures. This parameter is often associated with the quality of the  
298 oocyte and its capacity to sustain embryonic events until the maternal to zygotic transition,  
299 which occurs at 8-16 cells in goats [38]. However, in the current study, the oocytes were  
300 pooled at the beginning of the experiment, before the treatments were applied, and it is  
301 unlikely that this affected this parameter in any way. One aspect that may certainly not be  
302 overlooked is the possibility that the development of the polyspermic embryos was blocked  
303 before they reached the blastocyst stage [39]. When data were pooled regardless of sperm  
304 concentration, the OF total average (OF1+OF2+OF4) promoted a greater monospermy rate  
305 than the CTRL total average and tended to increase IVF efficiency. Overall, these data  
306 reinforce our hypothesis that the association of 10% OF and  $1.0 \times 10^6$  cells/mL sperm during  
307 IVF is the best combination to increase monospermy, obviously reducing polyspermy,  
308 improving IVF efficiency, and resulting in a lower number of embryos being blocked. Based  
309 on these data, we suggest that when OF is present, the IVF must be performed using a lower  
310 sperm concentration.

311         It is important to highlight that there were no significant differences in the comparison  
312 between treatments using the same sperm concentrations (OF1 vs. CTRL1, OF2 vs. CTRL2,

313 and OF4 vs. CTRL4). It should be emphasized that the OF was collected from anestrus goats.  
314 Considering the high influence of the season on small ruminant reproductive systems due to  
315 hormonal alterations [40], we suppose that this may have affected the overall protein  
316 concentrations and their role in the polyspermy modulation. The OF depends on the  
317 concentration of ovarian steroid hormones, which modulate the physiological and  
318 reproductive events that occur in the oviduct lumen [31]. During the estrous cycle,  
319 fluctuations of E2 and P4 concentrations induce changes in the epithelium of the oviduct and  
320 secretory function [2,3], which alter the proteomic and metabolomic profile of OF [4,30] to  
321 provide an optimal microenvironment for fertilization and early development. The practically  
322 constant concentrations of E2 during anestrus [28] may have modified the profile of proteins  
323 involved in the fertilization process, which were capable of exerting only a moderate control  
324 of polyspermy in the present study.

325         According to previous studies, throughout the estrous cycle the OF proteins OVGPI,  
326 HSPA8, HSPA1A, and MYH9 were most abundant at estrus in sheep showing a spontaneous  
327 cycle [8]. OVGPI and HSPA8 were also detected at luteal phase but in much lower quantities  
328 than during estrus [8]. In bovine, at ipsilateral to ovulation side, ANXA1 and MYH9 are most  
329 abundant in the pre- and post-ovulatory periods, respectively. OVGPI is overabundant in both  
330 pre- and post-ovulatory stages compared with mid-luteal, HSPA8 is more abundant in the pre-  
331 ovulatory stage, and there is no significant fluctuation in HSPA1A during the estrous cycle  
332 phases [25]. In heifers with induced estrus (synchronization by Ovsynch<sup>®</sup> protocol plus  
333 buserelin application) HSPA8, OVGPI, MHY9, and ANXA1 were among the 20 most  
334 abundant proteins [41].

335         OVGPI has been proposed as the main player in monospermy regulation, and ZP  
336 hardening could be the mechanism involved [7,13]. While in aquatic organisms a rapid  
337 depolarization of the oocyte plasma membrane prevents polyspermy within a few seconds, a

338 similar mechanism is still controversial in mammals even though a primary block to  
339 polyspermy, before the release of cortical granules, is also suspected. In mice and humans, the  
340 oocyte Juno membrane protein has been shown to play a role in polyspermy regulation before  
341 the cortical granule reaction [42]. Shortly after fertilization, Juno is released in the  
342 perivitelline space and binds to the Izumo partner of additional sperms, preventing their  
343 fusion to the oocyte membrane [43]. Juno and Izumo orthologs are found in most mammalian  
344 species, but their role in domestic species polyspermy regulation is yet to be explored.  
345 However, it has been shown that anti-Izumo antibodies can reduce fertilization in pigs [44].  
346 Nevertheless, the possible effect of OF on Juno-Izumo interactions needs to be investigated.

347         There is evidence in the literature that monospermy modulation in goats may be  
348 different to that in other species. Possibly, the OVGP1 has a concentration-dependent effect in  
349 goats, or it is only active in a short temporal window near ovulation, as occurs in swine [3].  
350 Besides OVGP1, MYH9 participates in the gamete-oviduct interaction process; OVGP1 may  
351 bind to spermatozoa and oocytes through the partner MYH9 by a non-glycosylated N-  
352 terminal conserved region [45]. It has been proposed that monospermic fertilization may be  
353 enhanced by the functional effects of OVGP1 and MYH9 via EVs, binding to the ZP, perhaps  
354 through modification of its carbohydrate and protein composition [11]. Additionally, EVs  
355 could bind to spermatozoa by annexins (e.g., ANXA1 and ANXA5), preventing a massive  
356 spermatozoa arrival at the oocyte and fertilization by apoptotic spermatozoa, leading to  
357 improvements in IVF efficiency [11]. In addition, OVGP1 and ANXA1 are amongst the most  
358 abundant embryo-interacting proteins from OF in 4-6 cells and morula stage embryos [46].

359         HSPA8 increases sperm viability *in vitro* and has been associated with the  
360 maintenance of sperm survival around ovulation [10]. HSPA1A is an EVs marker, an  
361 exosomal-specific protein present in 89% of proteomic studies [4,47], which confirms the  
362 presence of EVs in goats' OF used in our study. A study demonstrated that at adult oviduct,

363 the percentage of HSPA1A positive cells tended to decrease during estrus and increase during  
364 diestrus, and was associated with the rise of the percentage of estrogen receptor-positive cells.  
365 HSPA1A is an oviduct protein that is modulated differentially between oviduct regions, being  
366 more abundant in highly steroid-responsive regions, such as the infundibulum and ampulla.  
367 Moreover, HSPA1A-positive cells were found to be more abundant during rats in early  
368 pregnancy than in non-pregnant rats, suggesting they play a role in early embryo development  
369 [48].

370 Data in the literature support our speculation that the moderate OF effect seen in our  
371 study could be associated with the low steroid levels during the non-breeding season, which  
372 decreased the concentration of some OF proteins. The constant level of E2, with rare  
373 fluctuations in small ruminant females in anestrus [28,40], may indicate a moderate role of  
374 OF in monospermy modulation. Therefore, future studies aiming to compare the IVF effect of  
375 OF throughout the estrous cycle at breeding season might be of interest. In addition, the  
376 characterization of the protein profile of OF at different stages of the estrous cycle may be  
377 important for the identification of additional proteins that enhance the beneficial effect of OF  
378 on monospermic fertilization. Another possibility would be to supplement goat IVF medium  
379 with heterologous OF from a non-seasonal species (e.g., cows) as an alternative to reduce  
380 polyspermy in goat IVF.

381 In conclusion, the main proteins (OVGP1, ANXA1, ANAX5, HSPA8, HSPA1A, and  
382 MYH9) involved in the fertilization process are present in the OF of anestrus goats.  
383 Moreover, the OF supplementation in IVF during gametes co-culture may moderately  
384 modulate polyspermy incidence and enhance IVF efficiency, especially when  $1.0 \times 10^6$  sperm  
385 is used.

550

551 Table 1. Effect of adult anestrous goat oviduct fluid (OF) supplemented at IVF on *in vitro*  
 552 embryo production (IVP) system, considering different sperm concentrations at IVF. Mean  
 553  $\pm$  S.E.M.

Treatment	n	Cleavage (%)	Bl (%) <sup>#</sup>	Bl/cleaved (%) <sup>#</sup>	Hbl/total bl (%) <sup>#</sup>	Total cells (n) <sup>#</sup>
OF1 <sup>*</sup>	148	65 $\pm$ 7.1	41 $\pm$ 4.7	65 $\pm$ 8.1	64 $\pm$ 3.7	174 $\pm$ 11.5
CTRL1 <sup>**</sup>	154	71 $\pm$ 6.6	38 $\pm$ 6.5	54 $\pm$ 5.8	65 $\pm$ 8.6	175 $\pm$ 15.0
OF2 <sup>*</sup>	155	77 $\pm$ 1.7	39 $\pm$ 5.8	50 $\pm$ 7.6	59 $\pm$ 7.9	181 $\pm$ 11.6
CTRL2 <sup>**</sup>	156	72 $\pm$ 4.7	38 $\pm$ 4.3	52 $\pm$ 4.7	65 $\pm$ 8.7	177 $\pm$ 14.9
OF4 <sup>*</sup>	152	75 $\pm$ 6.5	33 $\pm$ 3.5	44 $\pm$ 1.9	59 $\pm$ 8.5	168 $\pm$ 12.1
CTRL4 <sup>**</sup>	149	74 $\pm$ 4.3	32 $\pm$ 5.7	43 $\pm$ 7.1	61 $\pm$ 13.9	170 $\pm$ 14.4
Total OF <sup>***</sup>	455	72 $\pm$ 3.3	38 $\pm$ 2.7	53 $\pm$ 4.2	61 $\pm$ 3.9	174 $\pm$ 3.8
Total CTRL <sup>***</sup>	459	72 $\pm$ 2.9	36 $\pm$ 3.1	50 $\pm$ 3.4	63 $\pm$ 5.8	174 $\pm$ 2.1

554 “n” represents the number of structures after IVF submitted to IVD

555 <sup>A,B</sup> differ within column between treatments (OF vs. CTRL) in the same sperm concentration

556 <sup>a,b</sup> differ within column among sperm concentrations (1 vs 2 vs 4) in the same treatment

557 <sup>C,D</sup> differ within column between the total averages (Total OF vs Total CTRL)

558 <sup>\*</sup> OF1, OF2 and OF4: IVF medium supplemented with 10% of OF and sperm concentration used at  
 559 IVF was 1.0, 2.0, and 4.0  $\times$  10<sup>6</sup> cell/mL

560 <sup>\*\*</sup> CTRL1, CTRL2, and CTRL4: no supplementation with OF, and sperm concentration used at IVF  
 561 was 1.0, 2.0, and 4.0  $\times$  10<sup>6</sup> cell/mL

562 <sup>\*\*\*</sup> Total average for OF (OF1, OF2, and OF4) and CTRL (CTRL1, CTRL2, and CTRL4) groups

563 <sup>#</sup>Bl: blastocyst, Hbl: hatched blastocyst, and Total cells: number of blastomeres per blastocyst  
 564 (n=22/group in three runs).

565 **Figure captions**

566 **Fig. 1.** Presence of proteins related to monospermy modulation in oviduct fluid (OF), such as  
567 annexin A1 (ANXA1), annexin A5 (ANXA5), anti-myosin heavy chain 9 (MYH9), anti-heat-  
568 shock protein 70 (HSPA1A), heat shock cognate protein 70 (HSPA8), and oviduct-specific  
569 glycoprotein (oviductin, OVGP1). Standard (St) and samples: bOF and sOF (bovine and  
570 swine oviduct fluid, positive controls), and gOF (goat oviduct fluid). The gOF was collected  
571 from goats in the anestrus season.

572

573 **Fig. 2.** Effect of goat oviduct fluid (OF) supplementation or not (Control: CTRL) at IVF with  
574 three sperm concentrations:  $1.0 \times 10^6$  (OF1 and CTRL1),  $2.0 \times 10^6$  (OF2 and CTRL2), and  
575  $4.0 \times 10^6$  (OF4 and CTRL4) on the goat IVF parameters. (A,D) Penetration rate; (B,D)  
576 monospermy/penetration rate; (C,D) IVF efficiency in terms of production of normally  
577 fertilized zygotes from total oocytes; (E) normal monospermic zygote containing two  
578 pronuclei; (F) polyspermic zygote containing three pronuclei plus a decondensed spermatozoa  
579 head under Hoechst stain. (A-D): each bar represents mean  $\pm$  SEM. For each group,  
580 approximately 628 presumed zygotes were evaluated. <sup>A,B</sup> differ between treatments (OF vs.  
581 CTRL) at the same sperm concentration (A-C); <sup>a,b</sup> differ among sperm concentrations (1 vs 2  
582 vs 4) in the same treatment; <sup>C,D</sup> differ between the total averages (Total OF vs Total CTRL).

583

584 **Fig. 3.** (A) Goat embryos at day 7 of culture produced from oocytes recovered in the non-  
585 breeding season (100 x); (B) Fresh blastocyst (400 x) and (C) Blastocyst stained with Hoechst  
586 (400 x).
