**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

**Proposal for building an ozone module for STICS**

First, we present the way the impact of ozone (O<sub>3</sub>) was already introduced into new or existing models (Kobayashi, 1997; AFRCWHEAT2-O<sub>3</sub> with Ewert and Porter, 2000; Van Oijen et al., 2004 and CERES-O<sub>3</sub> model with Lebard, 2005). Second, we discuss the way those approaches feed the conceptual framework of the new ozone module for the STICS model.

### 1. **Presentation of existing modelling approaches for O<sub>3</sub> effects on crop growth and development**

For every approaches, we detail the way (i) the O<sub>3</sub> influx into the plant, (ii) the O<sub>3</sub> inhibition of photosynthesis and (iii) the O<sub>3</sub> acceleration of leaf senescence, are calculated.

#### a. *Kobayashi, 1997*

##### i. O<sub>3</sub> inflow

The O<sub>3</sub> inflow is not actually calculated. The model consider a **daily damaging O<sub>3</sub> concentration** [O<sub>3</sub>](d)<sup>1</sup> that is calculated as the excess of O<sub>3</sub> concentration beyond a background O<sub>3</sub> concentration under which there is no damage P<sub>-</sub>[O<sub>3,b</sub>]<sup>2</sup>:

$$[O_3](d) = [O_{3,a}](d) - P_{-}[O_{3,b}] \quad (1)$$

##### ii. O<sub>3</sub> effect on photosynthesis

The daily radiation use efficiency RUE(d) is reduced by a factor accounting for the daily damaging O<sub>3</sub> concentration [O<sub>3</sub>](d) previously calculated (eq.1). This reducing factor also depends on the sensitivity of the crop to O<sub>3</sub>, varying with the phenology, P<sub>pi</sub>.

$$RUE_{O_3}(d) = (1 - P_{pi} \cdot [O_3](d)) \cdot RUE(d) \quad (2)$$

With P<sub>pi</sub> = P<sub>pveg</sub> during vegetative growth, and P<sub>pi</sub> = P<sub>prep</sub> during reproductive growth. P<sub>pveg</sub> is assumed to be lower than P<sub>prep</sub>, considering that the O<sub>3</sub> impact on photosynthesis is much greater during reproductive growth.

##### iii. O<sub>3</sub> effect on senescence

The natural senescence rate P<sub>α<sub>r</sub></sub> is increased by a factor accounting for the daily damaging O<sub>3</sub> concentration [O<sub>3</sub>](d) previously calculated (eq.1). This factor also depends on the sensitivity of the crop to O<sub>3</sub> during reproductive growth, P<sub>p<sub>rep</sub></sub>. The daily LAI is thus calculated after having reached its maximum (LAI<sub>max</sub>):

$$LAI(d) = LAI_{max} - P_{\alpha_r} \sum_{LAI_{max}day}^{Harvest\ day} (1 + P_{p_{rep}} \cdot [O_3](d)) \quad (3)$$

#### b. *Ewert and Porter with AFRCWHEAT2-O<sub>3</sub>, 2000*

##### i. O<sub>3</sub> inflow

The **instantaneous O<sub>3</sub> uptake rate** O<sub>3,up</sub> is calculated according to the stomatal conductance for O<sub>3</sub> which is the stomatal conductance for CO<sub>2</sub> g<sub>sc</sub> corrected for the differences in the diffusivities of CO<sub>2</sub> and O<sub>3</sub> in the air with the ratio P<sub>f<sub>DO3</sub></sub> (Laisk et al., 1989):

$$O_{3,up} = [O_{3,a}] \cdot g_{sc} \cdot P_{f_{DO3}} \quad (4)$$

<sup>1</sup> All parameters and variables are listed in annex 1

<sup>2</sup> All parameters, supposed to remain constant are preceded by "P<sub>-</sub>"

ii. O<sub>3</sub> effect on photosynthesis

The short-term O<sub>3</sub> inhibition on photosynthesis is simulated through an O<sub>3</sub> dose effect factor  $f_{O_3,s}(d)$  (see eq.5 below) taking into account that:

- the short-term photosynthesis inhibition  $f_{O_3,s}(d)$  depends on the damage caused by O<sub>3</sub> during the current AND the previous hours  $f_{O_3,s}(h)$  and  $f_{O_3,s}(h-1)$  respectively (eq.5);
- there is a dose threshold under which there is no damage ( $P_{\gamma 1}/P_{\gamma 2}$  in eq.6);
- the recovery from O<sub>3</sub> damage depends on leaf age according to the  $f_{LA}$  function (young leaves resist higher O<sub>3</sub> concentrations and can recover completely from O<sub>3</sub> damage within a period ranging from hours to a few days, Saxe 1991);

$$\begin{aligned} f_{O_3,s}(d) &= f_{O_3,s}(h) \cdot f_{O_3,s}(h-1) & \text{for } h = 2,3 \dots 24 \\ f_{O_3,s}(d) &= f_{O_3,s}(h) \cdot r_{O_3,s} & \text{for } h = 1 \end{aligned} \quad (5)$$

With:

$$f_{O_3,s}(h) = \begin{cases} 1 & \text{if } O_{3,up} \leq P_{\gamma 1}/P_{\gamma 2} \\ 1 + P_{\gamma 1} - P_{\gamma 2} \cdot O_{3,up} & \text{if } P_{\gamma 1}/P_{\gamma 2} < O_{3,up} < \frac{1+P_{\gamma 1}}{P_{\gamma 2}} \\ 0 & \text{if } O_{3,up} \geq \frac{1+P_{\gamma 1}}{P_{\gamma 2}} \end{cases} \quad (6)$$

And:

$$r_{O_3,s} = f_{O_3,s}(d-1) + [f_{O_3,s}(h-1)] \cdot f_{LA} \quad (7)$$

Where  $r_{O_3,s}$  corresponds to the incomplete recovery from O<sub>3</sub> damage of the previous day (considering that repair of ozone damage during the night was not sufficient);

And where  $f_{LA}$  is a factor accounting for leaf age, with values between 0 and 1;  $f_{LA}$  equals to 1 before emergence, decreases linearly with the age of the leaf (°C.day) and falls to zero when the leaf is dead. Thus before emergence  $r_{O_3,s} = 1$  and for mature leaves there is quite no repair during the night ( $r_{O_3,s} \approx f_{O_3,s}(d-1)$ ) (figure 1).

Finally this short-term photosynthesis inhibition factor  $f_{O_3,s}(d)$  reduces the Rubisco-limited rate of photosynthesis  $A_c$  (simulated at hourly steps as in the biochemical model of photosynthesis developed by Farquhar et al., 1980 and von Caemmerer & Farquhar, 1981):

$$A_{c,O_3} = A_c \cdot f_{O_3,s}(d) \cdot f_{LS} \quad (8)$$

The  $f_{LS}$  term in eq.8 is a senescence factor taking into account the natural decrease of the Rubisco-limited rate of photosynthesis with leaf senescence. As O<sub>3</sub> is assumed to accelerate senescence, this  $f_{LS}$  term is detailed below.

iii. O<sub>3</sub> effect on senescence

O<sub>3</sub> is assumed to accelerate the rate of senescence by reducing leaf life-span  $t_{l,ma}$  through a long-term O<sub>3</sub> impact factor  $f_{O_3,l}$  calculated as a function of accumulated ozone uptake (till the leaf age  $t_l$ ):

$$\begin{aligned} f_{O_3,l} &= 1 - P_{\gamma 3} \int_0^{t_l} O_{3,up} dt \\ t_{l,ma} &= (t_{l,ep} + t_{l,se}) \cdot f_{O_3,l} \end{aligned} \quad (10)$$

Where  $t_{l,ma}$  is the life-span of a mature leaf, corresponding to the thermal time from sowing to fully expanded leaf stage ( $t_{l,ep}$ ) plus the thermal time during which the leaf is senescing  $t_{l,se}$ .  $O_3$  is thus also assumed to bring forward the onset of senescence ( $t_{l,se}=0.33t_{l,ma}$ , Porter, 1984).

Finally, the factor  $f_{LS}$  accounting for the effect of senescence on the Rubisco-limited rate of photosynthesis  $A_c$ , is calculated taking into account the effect of accumulated ozone uptake (eq.11)

$$f_{LS} = \begin{cases} 1 & \text{before the fully expanded leaf stage} \\ 1 - \frac{a_l - t_{l,ep}}{t_{l,ma}/f_{O_3,l} - t_{l,ep}} & \text{for } t_{l,em} < a_l < t_l \\ 0 & \text{for } a_l \geq t_l \end{cases} \quad (11)$$

Where  $a_l$  is the leaf age ( $^{\circ}\text{Cday}$ ) and  $t_l$  is the leaf life-span ( $^{\circ}\text{Cday}$ )

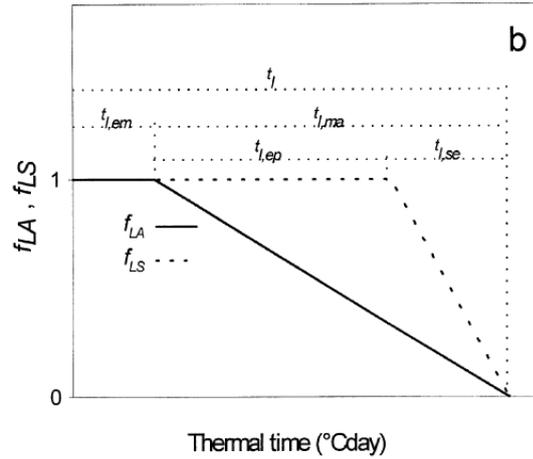

Figure 1:  $f_{LA}$  and  $f_{LS}$  factors versus the thermal time (from Ewert & Porter, 2000)

### c. Van Oijen et al., 2004

#### i. $O_3$ inflow

The **daily damaging  $O_3$  uptake**  $QO_{3,up}$  is calculated according to the canopy stomatal conductance for  $CO_2$  and  $O_3$   $g_s$ , the photoperiod average of ambient ozone concentration  $[O_{3,aph}]$ , and taking into account that part of the flux that is detoxified by inert plant material (cell walls) and by biochemical detoxification mechanisms  $P_{f_{detox}}$ :

$$QO_{3,up} = [O_{3,aph}] \cdot g_s \cdot (1 - P_{f_{detox}}) \quad (12)$$

#### ii. $O_3$ effect on photosynthesis

The daily radiation use efficiency  $RUE(d)$  is reduced by a factor  $F_{O_3}(d)$  accounting for the daily photoperiod average of ambient ozone concentration  $[O_{3,aph}]$  (and not for the daily damaging  $O_3$  uptake previously calculated  $QO_{3,up}$  eq.12 !):

$$RUE_{O_3}(d) = RUE(d) \cdot F_{O_3}(d) \quad (13)$$

With:

$$F_{O_3}(d) = 1 - \frac{44 [O_{3,aph}] \cdot P_{f_{detox}} \cdot P_{c_{detox}}}{30 (C_a - C_i)} - f_{lv} \cdot P_{f_{repair}} \quad (14)$$

Where the ratio 44/30 is the ratio of carbon contents of  $CO_2$  (12/44) and  $CH_2O$  (12/30),  $f_{lv}$  is the fraction of produced assimilates that is allocated to leaf growth and maintenance,  $f_{repair}$  is the fraction of assimilates allocated to leaves that is used in

repair,  $P_{Cdetox}$  is the cost coefficient of detoxification,  $C_a$  is ambient  $CO_2$  concentration,  $C_i$  is the leaf internal  $CO_2$  concentration (supposed to be equal to  $0.7 C_a$ ).

iii.  $O_3$  effect on senescence

Nothing is proposed by the authors to deal with the  $O_3$  impact on senescence.

d. *Lebard with CERES-O3, 2005*

i.  $O_3$  inflow

The **damaging instantaneous  $O_3$  uptake rate within the leaf layer II**  $O_{3,up,ll}$  is calculated according to the stomatal conductance for  $O_3$ ,  $g_{O_3}$ , the ambient ozone concentration near leaf surface in the leaf layer II,  $[O_{3,a,ll}]$ , and taking into account that a part of the flux is detoxified accordingly to the leaf age:

$$O_{3,up,ll} = ([O_{3,a,ll}] - P_{Kd} \cdot Facsen) \cdot g_{O_3} \cdot 10^{-12} \quad (15)$$

Where  $Kd \cdot g_{O_3} \cdot Facsen$  corresponds to the instantaneous detoxified flux in layer II, and  $Kd \cdot Facsen$  is a threshold concentration above which  $O_3$  impacts the crop growth. This threshold evolves according to the leaf senescence which is estimated through to ratio between the actual leaf photosynthesis activity and the maximal (before senescence) leaf photosynthesis activity:

$$Facsen = \frac{V_{cmax}}{P_{Vcmaxopt}} \quad (16)$$

A **damaging cumulative amount of  $O_3$**  is then calculated (t in second):

$$CO_{3,up,ll} = \int_0^t O_{3,up,ll} \cdot 3600 \cdot dt \quad (17)$$

ii.  $O_3$  effect on photosynthesis

The maximum rate of carboxylation  $V_{cmax}$  is reduced according to the damaging cumulative amount of  $O_3$ ,  $CO_{3,up,ll}$  (eq.17):

$$V_{cmax,O_3} = V_{cmax} - P_{Ki} \cdot 10^{-3} \cdot CO_{3,up,ll} \quad (18)$$

Where  $P_{Ki}$  is an  $O_3$  impact coefficient.

The Rubisco amount is also reduced by the damaging instantaneous  $O_3$  uptake rate within the leaf layer II  $O_{3,up,ll}$  calculated as described above (eq.15)

$$\partial RU = -P_{Ki} \cdot [RU] \cdot O_{3,up,ll} + \partial RU_{remobilisation} \quad (19)$$

Where  $\delta RU$  is the variation of the stock of Rubisco,  $P_{Ki}$  is an impact coefficient ( $= 302 s^{-1}$ ),  $[RU]$  is the remaining amount of Rubisco, and  $\delta RU_{remobilisation}$  is the reduction of the stock of Rubisco because of remobilization.

This formalism allows simulating the cumulative effect of  $O_3$  as well as the dose effect on the photosynthesis response to the cumulative effect (Fig.2).

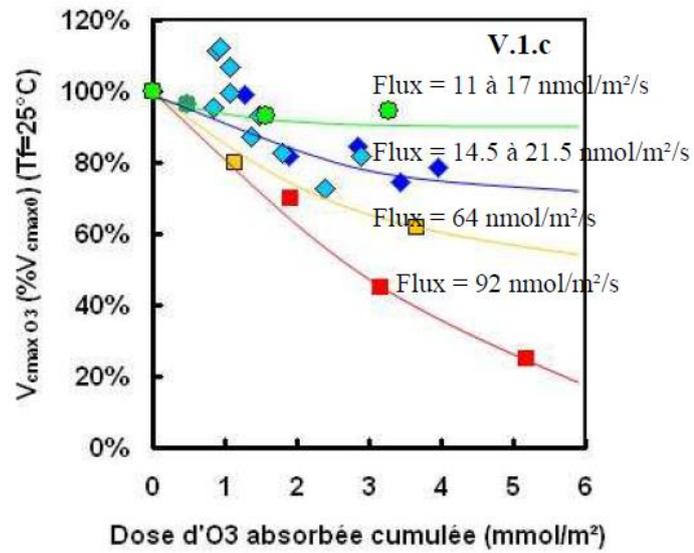

Figure 2: Maximum carboxylation rate versus cumulative O<sub>3</sub> uptake and according to the average O<sub>3</sub> inflow (from Lebard, 2005, Fig. V.1.c Chap. V.)

iii. O<sub>3</sub> effect on senescence

Nothing is proposed by the author to deal with the O<sub>3</sub> impact on senescence.

Furthermore, the author developed a formalism about the O<sub>3</sub> impact on leaf nitrogen content.

e. *Synthesis on about threshold effect, detoxification and repair mechanisms, and time scales which are considered in the previous modelling approaches.*

## 2. Conceptual framework of the future STICS O<sub>3</sub> module

In order to build an O<sub>3</sub> module pluggable to STICS, it's necessary to choose formalisms using input variables that can be provided by STICS (or at less calculated from STICS state variables). As STICS assesses daily canopy resistances for CO<sub>2</sub> exchanges through a resistive approach (Fig. 3), and simulates a daily net photosynthesis according to an integrative approach without downscaling to the biochemical processes such as in the FvCB model, we propose the following formalisms in line with van Oijen et al. (2004) and Lebart (2005).

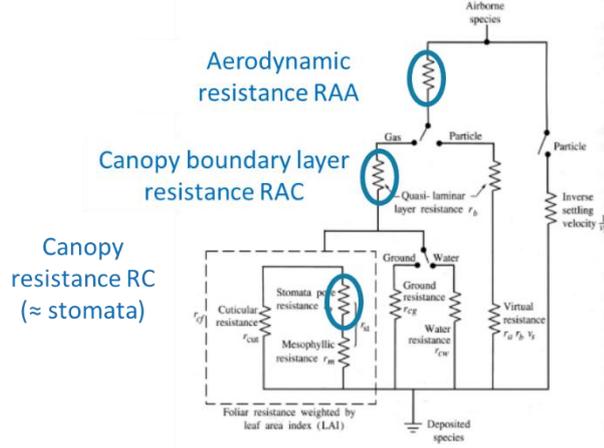

Figure 3: Canopy resistances as calculated by STICS (from Brisson et al., 2009)

### a. O<sub>3</sub> inflow

In line with van Oijen et al. (2004), the **daily damaging O<sub>3</sub> uptake**  $QO_{3,up}$  ( $\text{nmol} \cdot \text{m}^{-2} \cdot \text{ground} \cdot \text{day}^{-1}$ ) is calculated according to the canopy resistance for O<sub>3</sub> (the inverse of canopy conductance for O<sub>3</sub>), the photoperiod average of ambient ozone concentration  $[O_{3,aph}]$  ( $\text{nmol} \cdot \text{m}^{-2} \cdot \text{ground} \cdot \text{s}^{-1}$ ), and taking into account that part of the flux that is instantaneously detoxified  $P_{f_{detox}}$  (eq. 20). The canopy resistance for O<sub>3</sub> is the canopy resistance for CO<sub>2</sub>  $RT$  ( $\text{sm}^{-1}$ ) corrected for the differences in the diffusivities of CO<sub>2</sub> and O<sub>3</sub> in the air with the ratio  $P_{kdifO_3}$  (eq. 20). Two options were implemented, considering only the stomatal resistance  $rc$  (1<sup>st</sup> option) which is the greater contribution, or alternatively all resistances (2<sup>nd</sup> option) i.e. aerodynamic resistance  $raa$ , canopy boundary layer resistance  $rac$  and stomatal resistance  $rc$  (eq. 21):

$$QO_{3,up}(d) = 1/RT(d) \cdot [O_{3,aph}] \cdot P_{kdifO_3} \cdot (1 - P_{f_{detox}}) \cdot photoperiod \cdot 3600 \quad (20)$$

$$\text{Where} \quad RT(d) = \begin{cases} rc(d) & \text{if option 1} \\ rc(d) + rac(d) + raa(d) & \text{if option 2} \end{cases} \quad (21)$$

The **damaging cumulative amount of O<sub>3</sub>**  $CO_{3,up}$  ( $\text{mmol O}_3 \cdot \text{m}^{-2} \cdot \text{ground}$ ) is thus equal to:

$$CO_{3,up}(d) = \int_{em}^d QO_{3,up}(i) \cdot 10^{-6} \quad (22)$$

### b. O<sub>3</sub> impact on photosynthesis

In line with Lebard (2005), we consider the cumulative effect of O<sub>3</sub> on photosynthesis, as well as the dose effect on the photosynthesis response to the cumulative effect. We apply Lebard approach (eq.18, fig.2) to the maximum value of the radiation use efficiency  $EB_{MAX}$  (eq. 23, Fig. 4):

$$\frac{EBMAX_{O_3}(d)}{EBMAX(d)} = 1 - \left(1 - \exp(-f_{FO_3} \cdot CO_{3,up}(d))\right) \quad (23)$$

With :

$$f_{FO_3} = P\_kdose_{O_3} \cdot FO_{3,up}(d) \quad (24)$$

Where:

$$FO_{3,up} = QO_{3,up} / (\text{photoperiod} \cdot 3600) \quad (25)$$

EBMAXO<sub>3</sub> is the maximum radiation use efficiency under O<sub>3</sub> effect (g biomass.MJ<sup>-1</sup>) while EBMAX is the maximum radiation use efficiency without O<sub>3</sub> effect. CO<sub>3,up</sub> as calculated in eq.22, represents the cumulative amount of O<sub>3</sub> uptake, whereas f<sub>FO<sub>3</sub></sub> is the O<sub>3</sub> dose effect factor on photosynthesis response to the cumulative effect of O<sub>3</sub>. f<sub>FO<sub>3</sub></sub> is calculated from FO<sub>3,up</sub> (eq.24) i.e. the instantaneous average of O<sub>3</sub> inflow calculated from the daily damaging O<sub>3</sub> uptake QO<sub>3,up</sub> (eq.25). P\_kdose<sub>O<sub>3</sub></sub> is a coefficient supposed to be constant.

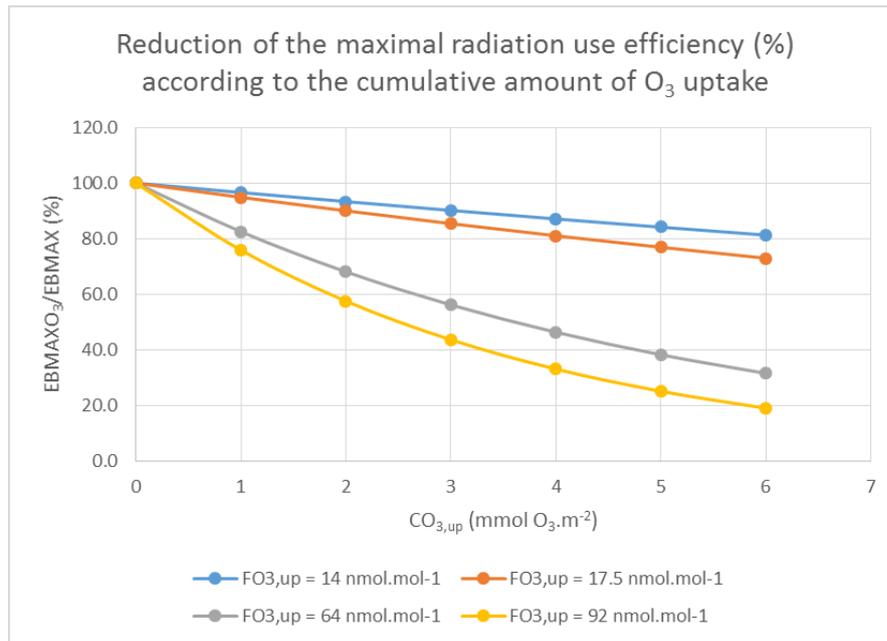

Figure 4: Relation between the reduction of the maximum radiation use efficiency and the cumulative amount of O<sub>3</sub> uptake, according to the inflow intensity

### 3. Parameterization, evaluation and perspectives of the STICS O<sub>3</sub> module

Parameters of the O<sub>3</sub> module should now be estimated:

- The ratio of diffusion rates **P\_kdifO<sub>3</sub>** is fixed at 0.93 when considering only the stomatal resistance (1<sup>st</sup> option), according to Ewert and Porter (2000). When considering all resistances (2<sup>nd</sup> option) i.e. aerodynamic resistance r<sub>aa</sub>, canopy boundary layer resistance r<sub>ac</sub> and stomatal resistance r<sub>c</sub>, we should estimate a diffusion ratio for each of them: the diffusion ratio for aerodynamic resistance could be fixed at 1 (A. Olioso, com. Pers.), and the diffusion ratio for boundary layer resistance should be found in the literature.
- The instantaneous detoxified fraction of O<sub>3</sub> flux **P\_f<sub>detox</sub>** is fixed at 0.9 according to van Oijen et al. (2004).
- The coefficient for the O<sub>3</sub> dose effect factor calculation **P\_kdose<sub>O<sub>3</sub></sub>** is estimated from the V<sub>cmaxO<sub>3</sub></sub>/V<sub>cmax</sub> curve by Lebard (2005) originally established with data from Lebard (2005), Farage et al. (1991) and Cardoso Vilhena et al. (2004) (see Lebard, 2005, Figure V.1). The optimized value of P\_kdose<sub>O<sub>3</sub></sub> is thus fixed at 3.10<sup>-3</sup>.

The O<sub>3</sub> module should be evaluated, and parameters estimated more accurately, according to data found in the literature (such as Farage et al., 1991, Ewert et al., 1999; Cardoso Vilhena et al., 2004 and Lebard, 2005) and from the ozone experiments conducted by Danish colleagues in Roskilde University and DTU within the Climate CAFÉ project (Hansen et al., 2019).

Finally, the effect of leaf age on the detoxification efficiency could be introduced into the module, by transforming the  $P_{f_{detox}}$  parameter into a variable evolving with leaf age. Last, the effect of O<sub>3</sub> on senescence has to be formalized.

[O <sub>3,a</sub> ]	Input variable	Instantaneous O <sub>3</sub> concentration at the leaf surface	ppb or nmol.mol <sup>-1</sup>		4	Ewert&Porter, 2000	hourly average
g <sub>s,c</sub>	Input variable	Stomatal conductance for CO <sub>2</sub>	mol.m <sup>-2</sup> .s <sup>-1</sup>		4	Ewert&Porter, 2000	hourly
P_fO <sub>3</sub>	Parameter	ratio of diffusion rates for O <sub>3</sub> and CO <sub>2</sub>	-	0.93	4	Ewert&Porter, 2000	
f <sub>O<sub>3,s</sub></sub> (d)	Output variable	short-term O <sub>3</sub> dose effect factor [0,1] inhibiting photosynthesis and accounting for the damage caused during the current and previous hours	-		5	Ewert&Porter, 2000	hourly
f <sub>O<sub>3,s</sub></sub> (h)	Output variable	short-term O <sub>3</sub> dose effect factor [0,1] accounting for the damage caused during the current hour	-		5	Ewert&Porter, 2000	hourly
P_γ1	Parameter	O <sub>3</sub> short-term damage coefficient	-	0.06	6	Ewert&Porter, 2000	
P_γ2	Parameter	O <sub>3</sub> short-term damage coefficient	(nmol.m <sup>-2</sup> .s <sup>-1</sup> ) <sup>-1</sup>	0.0045	6	Ewert&Porter, 2000	
P_γ3	Parameter	O <sub>3</sub> long-term damage coefficient	(nmol.m <sup>-2</sup> .s <sup>-1</sup> ) <sup>-1</sup>	0.5	10	Ewert&Porter, 2000	
A <sub>c,O<sub>3</sub></sub>	Output variable	Rubisco-limited rate of carboxylation (during photosynthesis) reduced by O <sub>3</sub> effect	μmol.m <sup>-2</sup> .s <sup>-1</sup>		8	Ewert&Porter, 2000	instantaneous (second)
A <sub>c</sub>	Output variable	Rubisco-limited rate of carboxylation (during photosynthesis)	μmol.m <sup>-2</sup> .s <sup>-1</sup>		8	Ewert&Porter, 2000	instantaneous (second)
f <sub>LA</sub>	Output variable	factor accounting for leaf age [0,1]	-		7	Ewert&Porter, 2000	daily
f <sub>LS</sub>	Output variable	factor accounting for leaf senescence [0,1]	-		8, 11	Ewert&Porter, 2000	daily
t <sub>l,ma</sub>	Output variable	life-span of a mature leaf	°C.day		10, 11	Ewert&Porter, 2000	daily
t <sub>l,ep</sub>	Input variable	thermal time from sowing to fully expanded leaf stage	°C.day		10, 11	Ewert&Porter, 2000	daily
t <sub>l,em</sub>	Input variable	thermal time from sowing to emergence	°C.day		10, 11	Ewert&Porter, 2000	daily
t <sub>l,se</sub>	Input variable	thermal time during which the leaf is senescing	°C.day		10	Ewert&Porter, 2000	daily
f <sub>O<sub>3,l</sub></sub>	Output variable	long-term O <sub>3</sub> impact factor [0,1] accelerating senescence	-		10	Ewert&Porter, 2000	daily
t <sub>l</sub>	Output variable	life-span of the leaf	°C.day		10	Ewert&Porter, 2000	daily
a <sub>l</sub>	Output variable	leaf age	°C.day		11	Ewert&Porter, 2000	daily
P_fdetox	Parameter	detoxified fraction of O <sub>3</sub> flux	-	0.9	12	van Oijen et al., 2004	daily
QO <sub>3,up</sub>	Output variable	Daily damaging O <sub>3</sub> uptake rate (flux)	g O <sub>3</sub> .m <sup>-2</sup> ground.day <sup>-1</sup>		12	van Oijen et al., 2004	daily
g <sub>s</sub>	Input variable	Stomatal conductance for CO <sub>2</sub> and O <sub>3</sub> (supposed to be equal)	mol.m <sup>-2</sup> .s <sup>-1</sup>		12	van Oijen et al., 2004	instantaneous (second)
[O <sub>3,a,ph</sub> ]	Input variable	photoperiod average of ambient ozone concentration	ml O <sub>3</sub> .m <sup>-3</sup>		12	van Oijen et al., 2004	daily average
RUE(d)	Input variable	Daily radiation use efficiency with no O <sub>3</sub> impact	g biomass.MJ <sup>-1</sup>		13	van Oijen et al., 2004	daily
RUEO <sub>3</sub> (d)	Output variable	Daily radiation use efficiency reduced by O <sub>3</sub> impact	g biomass.MJ <sup>-1</sup>		13	van Oijen et al., 2004	daily
F <sub>O<sub>3</sub></sub> (d)	Output variable	O <sub>3</sub> effect factor [0,1] inhibiting photosynthesis	-		13	van Oijen et al., 2004	daily
P_cdetox	Parameter	cost coefficient of detoxification	g CH <sub>2</sub> O g <sup>-1</sup> detoxific	0.375	14	van Oijen et al., 2004	
f <sub>lv</sub>	Input variable	fraction of assimilates allocated to leaf growth and maintenance	g.g <sup>-1</sup>		14	van Oijen et al., 2004	daily
P_frepair	Parameter	fraction of assimilates allocated to leaves that is used in repair	g.g <sup>-1</sup>	0.05	14	van Oijen et al., 2004	
Ca	Input variable	ambient CO <sub>2</sub> concentration	ml CO <sub>2</sub> m <sup>-3</sup>		14	van Oijen et al., 2004	daily
Ci	Input variable	leaf internal CO <sub>2</sub> concentration	ml CO <sub>2</sub> m <sup>-3</sup>		14	van Oijen et al., 2004	daily
O <sub>3,up,ll</sub>	Output variable	Damaging instantaneous O <sub>3</sub> uptake rate within the leaf layer II (flux)	nmol.m <sup>-2</sup> .s <sup>-1</sup>		15	Lebard, 2005	instantaneous (second)
[O <sub>3,a,ll</sub> ]	Input variable	Instantaneous O <sub>3</sub> concentration at the leaf surface in leaf layer II	ppb or nmol.mol <sup>-1</sup>		15	Lebard, 2005	hourly average
P_Kd	Parameter	Coefficient of instantaneous detoxification and repair	ppb or nmol.mol <sup>-1</sup>	49.4	15	Lebard, 2005	
Facsen	Output variable	Factor of senescence effect on the threshold of damaging instantaneous O <sub>3</sub> uptake	-		15	Lebard, 2005	instantaneous (second)
V <sub>cmax,O<sub>3</sub></sub>	Output variable	Maximum rate of carboxylation reduced by absorbed O <sub>3</sub>	μmol.m <sup>-2</sup> leaf.s <sup>-1</sup>		18	Lebard, 2005	instantaneous (second)
V <sub>cmax</sub>	Output variable	Maximum rate of carboxylation	μmol.m <sup>-2</sup> leaf.s <sup>-1</sup>		16	Lebard, 2005	instantaneous (second)
P_V <sub>cmax,opt</sub>	Parameter	Maximum rate of carboxylation for an optimum nitrogen content in leaves	μmol.m <sup>-2</sup> leaf.s <sup>-1</sup>	95	16	Lebard, 2005	instantaneous (second)
CO <sub>3,up,ll</sub>	Output variable	Damaging cumulative amount of uptaken O <sub>3</sub>	mmol.m <sup>-2</sup> leaf		17	Lebard, 2005	over the crop season
P_Ki	Parameter	Coefficient of O <sub>3</sub> impact	s <sup>-1</sup>	302	18	Lebard, 2005	

## Annex 2: Table of Parameters, Input and Output variables of the STICS O3 module

Name	Input variable / Output variable / Parameter	Definition	Unit	Value (for parameters only)	Equation	Comment
QO <sub>3,up</sub>	Output variable	Daily damaging O <sub>3</sub> uptake	nmol O <sub>3</sub> .m <sup>-2</sup> ground.day <sup>-1</sup>		20	
RT	Input variable	Canopy resistance for CO <sub>2</sub>	(mol.m <sup>-2</sup> .s <sup>-1</sup> ) <sup>-1</sup>		20, 21	
[O <sub>3,amb</sub> ]	Input variable	photoperiod average of ambient ozone concentration	nmol.mol <sup>-1</sup> or ppb		20	
P <sub>_kdifO<sub>3</sub></sub>	Parameter	ratio of diffusion rates for O <sub>3</sub> and CO <sub>2</sub>	-	0.93	20	From Ewert & Porter (2000)
P <sub>_f<sub>detox</sub></sub>	Parameter	detoxified fraction of O <sub>3</sub> flux	-	0.9	20	From van Oijen et al. (2004)
photoperiod	Input variable	Daily interval period during which the plants are exposed to light	hour		20, 25	
RT	Input variable	Canopy resistance for CO <sub>2</sub>	(mol.m <sup>-2</sup> .s <sup>-1</sup> ) <sup>-1</sup>		21	
rc	Input variable	Stomatal resistance for CO <sub>2</sub>	(mol.m <sup>-2</sup> .s <sup>-1</sup> ) <sup>-1</sup>		21	
raa	Input variable	Aerodynamic resistance for CO <sub>2</sub>	(mol.m <sup>-2</sup> .s <sup>-1</sup> ) <sup>-1</sup>		21	
rac	Input variable	Boundary layer resistance for CO <sub>2</sub>	(mol.m <sup>-2</sup> .s <sup>-1</sup> ) <sup>-1</sup>		21	
CO <sub>3,up</sub>	Output variable	Damaging cumulative amount of O <sub>3</sub> uptake	mmol O <sub>3</sub> .m <sup>-2</sup> ground		22	
EBMAX <sub>O<sub>3</sub></sub>	Output variable	Maximum radiation use efficiency under O <sub>3</sub> effect	g biomass.MJ <sup>-1</sup>		23	
EBMAX	Input variable	Maximum radiation use efficiency without O <sub>3</sub>	g biomass.MJ <sup>-1</sup>		23	
fFO <sub>3</sub>	Output variable	O <sub>3</sub> dose effect factor on photosynthesis response to the cumulative effect of O <sub>3</sub>	(mmol O <sub>3</sub> .m <sup>-2</sup> ground) <sup>-1</sup>		23, 24	
P <sub>_kdoseO<sub>3</sub></sub>	Parameter	coefficient for the O <sub>3</sub> dose effect factor calculation	10 <sup>6</sup> .(nmol O <sub>3</sub> ) <sup>-1</sup> .m <sup>4</sup> ground.day	0.003	24	estimated from Lebard (2005) with data from Lebard (2005) and Farage et al. (1991) and Cardoso Vilhena et al. (2004)
FO <sub>3,up</sub>	Output variable	Instantaneous damaging O <sub>3</sub> uptake rate (flux)	nmol O <sub>3</sub> .m <sup>-2</sup> ground.s <sup>-1</sup>		25
