HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Recent advances with the integrated hydrological model of the Stampriet Transboundary Aquifer System (STAS)

The STAS is a very large transboundary aquifer system (100 000 km²) shared between Botswana, Namibia, and South Africa. It provides the only water resource in this otherwise arid region. As part of the GGRETA project, the UNESCO and local stakeholders have been promoting the development of a groundwater model for the assessment and the sustainable management of this shared resource. In this communication, we retrace recent progress and lessons learnt from this modelling endeavor. First, a detailed hydro stratigraphic study allowed us to refine the geometry of the STAS and in particular the position of its boundaries. This study also highlighted links between the STAS and the neighboring Central Kalahari Basin. To the south, a large complex of salt pans was identified as the regional outlet for the basin (Hakskeen, Koppieskraal, Uitsak pans). Second, although the isotope data for the basin were compiled in phase 1 of the GGRETA project, they have, to date, never been used as information for the STAS numerical model. Integration of environmental tracer data allowed the identification of key hydrological recharge, discharge, and aquifer exchange processes. In particular, the hydro chemical and isotopic synthesis highlighted the importance of surface and groundwater interaction, even in this arid environment. In turn, this led us to select an integrated hydrological model capable of simulating interaction between land surface (UZP) and groundwater (MODFLOW). A feasibility study showed there would be great benefits moving from a stand-alone model, which requires manual updating, to a state-of-the-art modelling platform that can be shared by all stakeholders and updated automatically with remote sensing data.
