HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Root distributions and traits in a semi-arid agroforestry parkland dominated by *Faidherbia albida*: potential impacts on soil C and nutrient stocks?

The **objectives** of this study were:

- to assess the tree and crop root distribution and traits down to 150 cm deep in a Sub-Sahelian agroforestry parkland dominated by *Faidherbia albida* in Senegal
- to quantify the contribution of tree and crop root-derived C inputs to soil C stocks along the soil profile

And a same of the second

Methods

Experimental set-up of the pits (1m * 1m * 2m deep):

2 locations (under the tree and far (+30m) from the trunk)

x **5 soil layers** (0-10, 10-30, 30-50, 50-100, 100-150 cm)

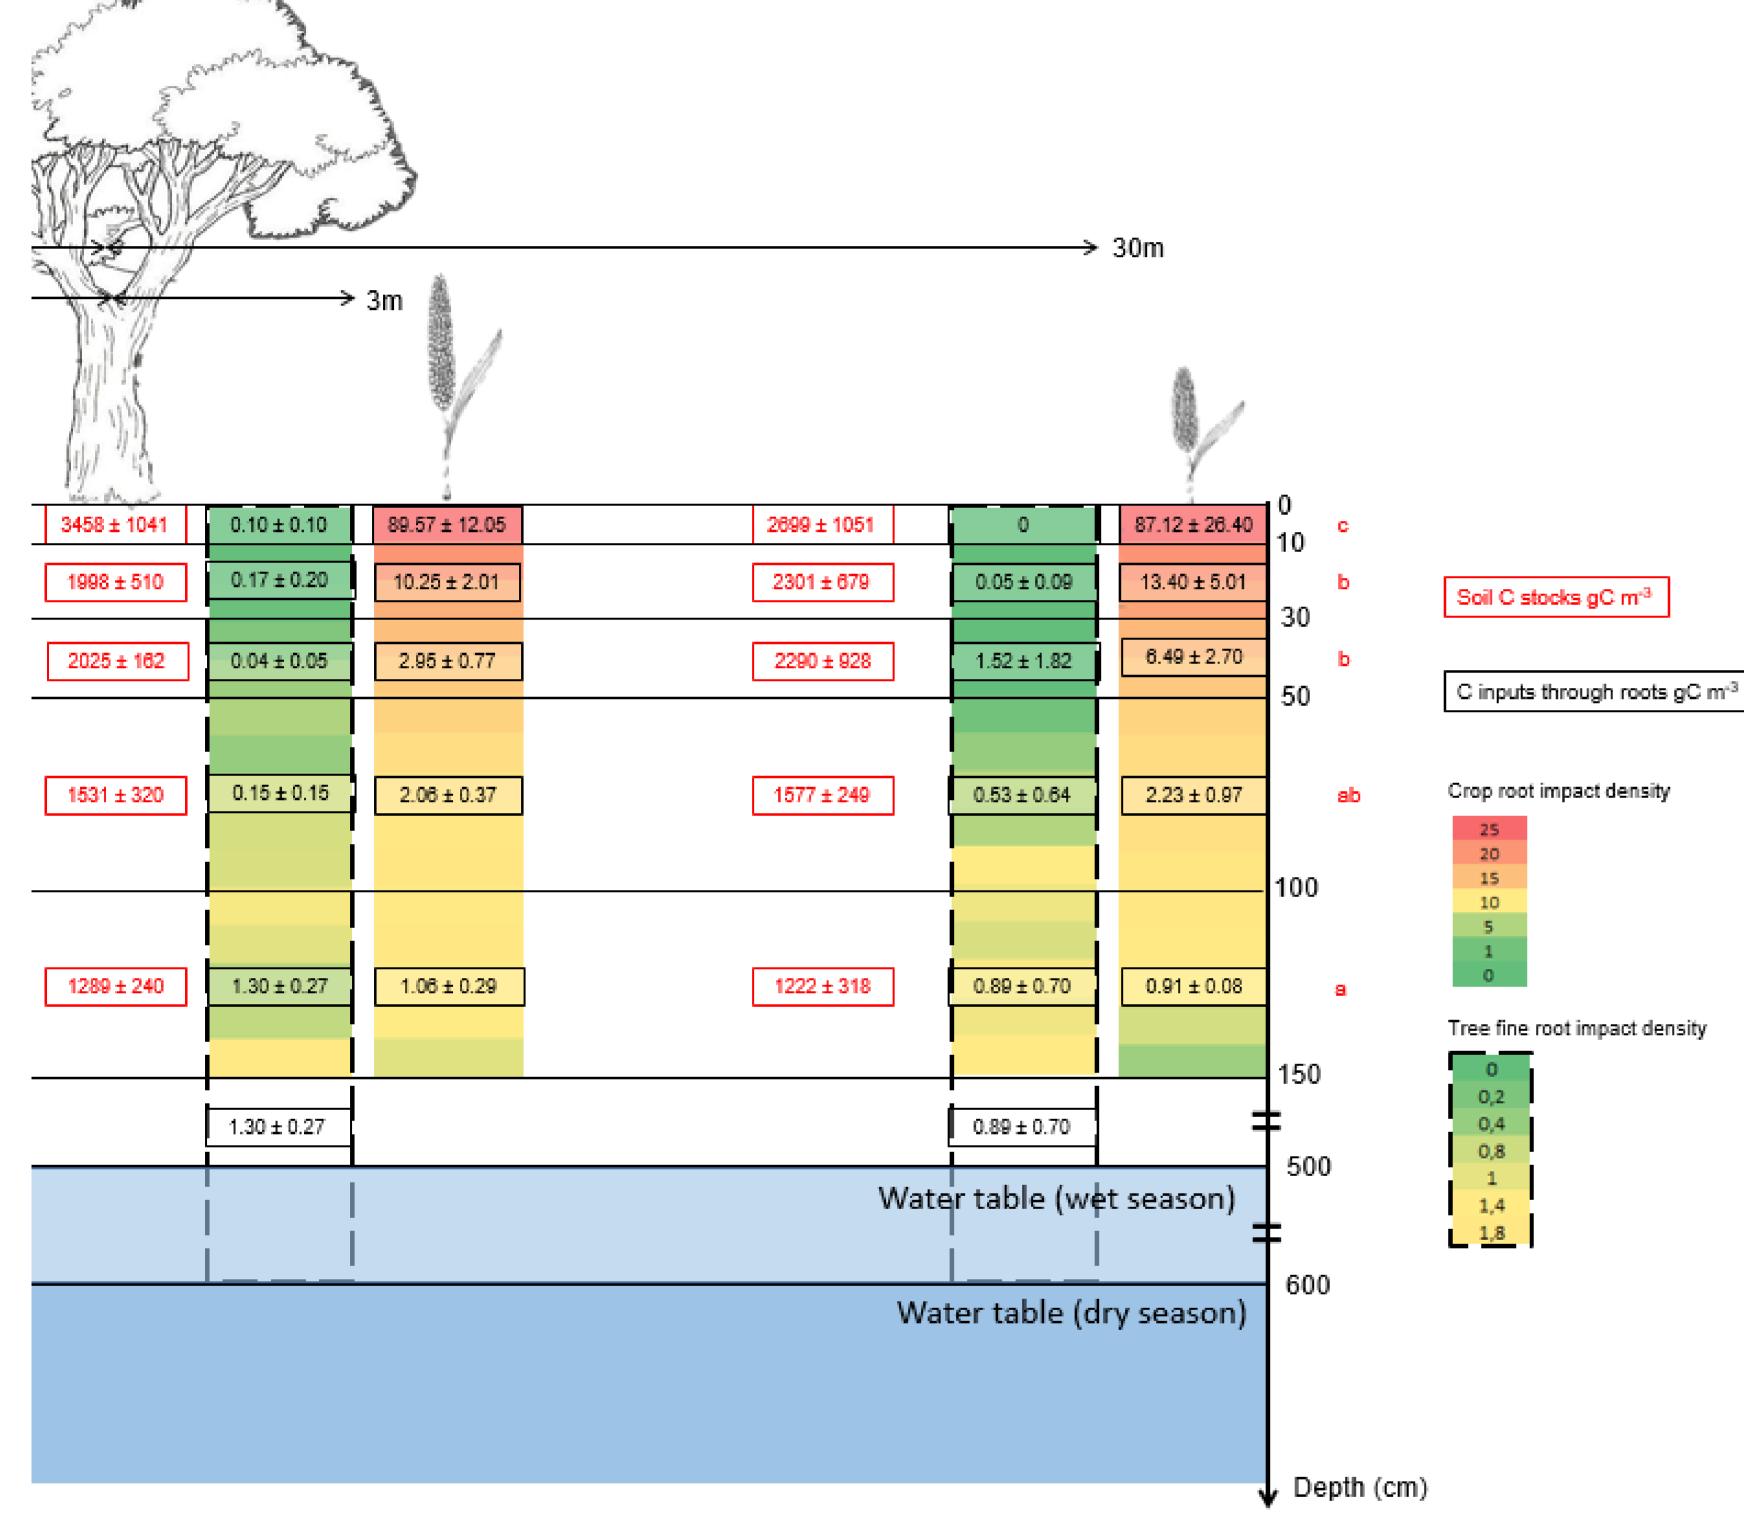

x 2 plant species (tree and annual crop)

x 2 rotations (2020: pearl millet and 2021: groundnut)

x 3 replicated trees

Root biomass density was measured by manual sorting from a large volume of soil (1m² x soil Root layer). mapping was assessed by counting the root impacts. Roots were sampled for functional chemical traits and composition analysis.

Results

Wet seasonDry season(july – october)(november – june)Crops growingNo cropTree defoliatedTree foliatedFig. 1 Faidherbia reversed

phenology across the seasons

Deep tree roots with low biomass density vs. shallow crop roots with high biomass density p-value = 6.31 × 10⁻³

 \rightarrow complementarity theory for associated plants (Van Noordwijk et al. 1996)

At 30cm deep, tree roots were found at +30m from the trunk, in higher quantity than under the tree p-value = 3.88 × 10⁻³

 \rightarrow compromise of the tree between water acquisition in deeper soil

Fig. 3 Annual root C inputs from tree and crop down to 6m deep, under and far from the tree. Gradients in colour are indicating tree and crop root impact density. Red and black framed figures are indicating soil C stocks and rootderived C inputs to soil respectively

Highlights

• Tree fine roots found at +30m of the trunk at 30 cm of depth: attesting the compromise between water and nutrient acquisition

 96% and 83% of the tree root C inputs are located below 100cm of depth under and far from the tree, respectively

 From the topsoil to the water table, the tree fine roots contribute to 27% (under) and 18% (far from tree) of the total annual root-derived C inputs to soil

layers during the dry season (Fig. 3) and nutrient acquisition in topsoil during the wet season \rightarrow plasticity of the perennial root

system (Zanetti et al., 2015)

Tree roots were found at 5m deep \rightarrow the annual root-derived C input was extrapolated from 100-150 to 100-500 cm of depth

The authors thank Ibou Diouf (Sob, Senegal) for technical support in root observations and Patricia Moulin (LAMA/IESOL, Senegal) for conducting all soil analyses, and Aline Personne, Nancy Rakotondrazafy and Didier Arnal from Eco&Sols for helping with the root processing and analyses.
