Abstract

One aim of comparative neuroanatomy is to better understand brain function among species. It is tempting to try and explain brain differences throughout the animal kingdom by differences in adaptive behaviors as well as ecological factors.

Based on this idea, we explored, with MRI, the brain morphology of three species with different sociality and predator avoidance (Bongo, Java deer mouse and Maki Catta). Brains were collected after death of natural causes and MR-imaged. Brain and body weights were collected, and volumes of brain were estimated after MRI segmentation.

The brain-to-body weight ratio was close to 1 for the Java deer mouse (1.04%) and the maki catta (1.05%) but only 0.26% for the bongo. Encephalization quotients (EQ) were calculated using formulas defined for human (hEQ, constants 0.12 and 2/3; Cairó 2011, doi:10.3389/fnhum.2011.00108) and for dog (dEQ, constants 0.14 and 0.528; Saganuwan 2021, doi:10.1186/s13104-021-05638-0). Whatever the method, the Java deer mouse EQs were the smallest (hEQ=0.98; dEQ=0.88). The maki catta had a higher hEQ (1.23) than the bongo (1.14) whereas the order was reversed for the dEQ (maki catta dEQ=1.21; bongo dEQ=1.96). These values are coherent with the idea that EQ is higher in prey species using active predator avoidance (bongo) and in social species (bongo and maki catta).

Adaptative behaviors of specimen

BONGO
Tragelaphus eurycerus
Herbivore
Gregarious
Prey (vigilance in group, escape)

JAVA DEER MOUSE
Tragulus Javanicus
Herbivore
Solitary
Prey (hiding, fight)

MAKI CATTÀ
Lemur catta
Omnivore
Gregarious
Hierarchy
Prey (vigilance in group)

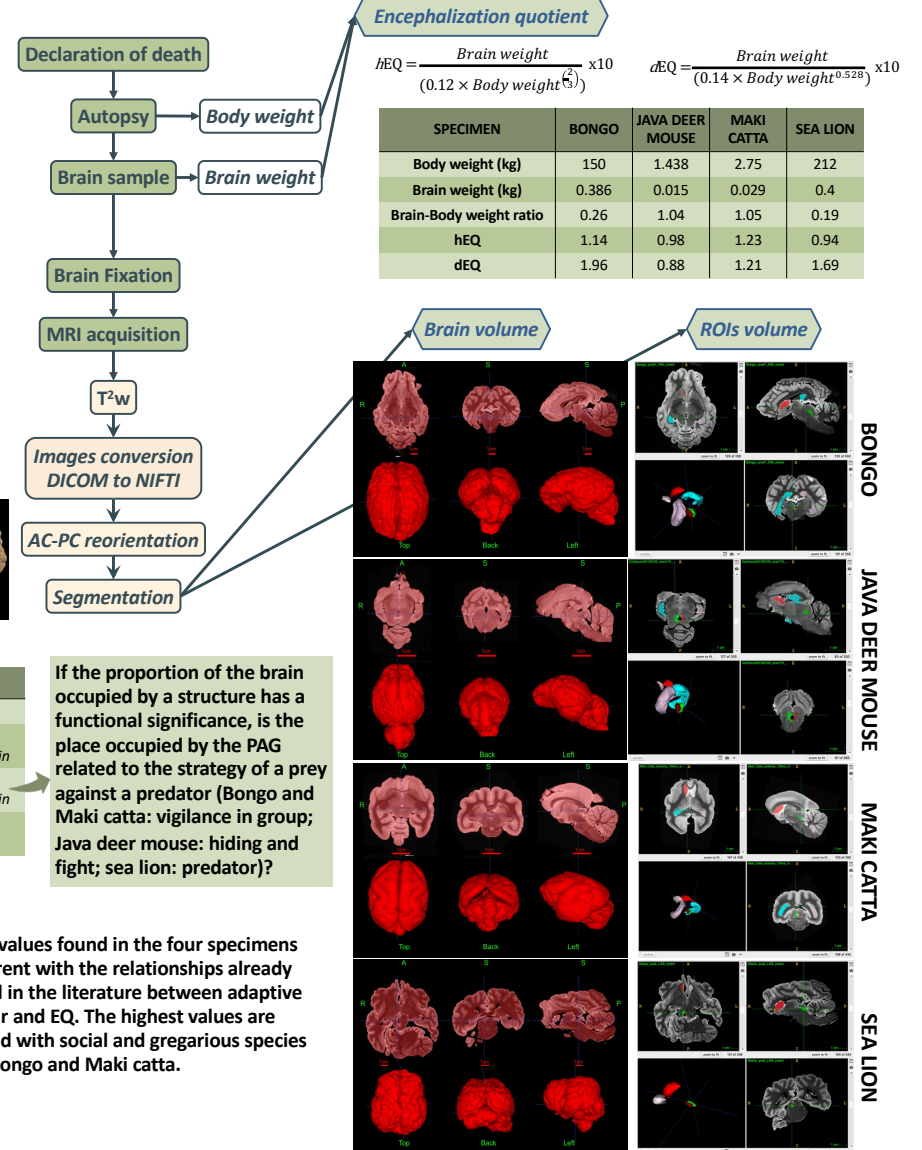

SEA LION
Zalophus californianus
Piscivore
Gregarious
Hierarchy
Predator (hunts alone, in group or in cooperation)

SPECIMEN	BONGO	JAVA DEER MOUSE	MAKI CATTÀ	SEA LION
Brain	353600	12080	25590	377800
Caudate nucleus	1988	63	398	4315
PAG	704	58	43	214
Hippocampus	6320	639	624	N.D.
	1.79% to the brain	5.29% to the brain	2.44% to the brain	

The ratio of brain to body weight of the studied specimens is consistent with the data previously described by Herculano-Houzel (2019).

The hQE values found in the four specimens are coherent with the relationships already proposed in the literature between adaptive behaviour and EQ. The highest values are associated with social and gregarious species such as Bongo and Maki catta.
