15 **Abstract**

16 ZC3H11A is a stress-induced mRNA binding protein required for efficient growth of nuclear-

17 replicating viruses, while being dispensable for the viability of cultured human cells. The cellular

18 functions of ZC3H11A during embryo development are unknown. Here we report the generation

19 and phenotypic characterization of *Zc3h11a* knock-out mice. Heterozygous null *Zc3h11a* mice

20 were born at the expected frequency without distinguishable phenotypic differences compared

21 with wild-type. In contrast, homozygous null *Zc3h11a* mice were missing, indicating that *Zc3h11a*

22 is crucial for embryonic viability and survival. *Zc3h11a$^{-/-}$* embryos were detected at the expected

23 Mendelian ratios up to late preimplantation stage (E4.5). However, phenotypic characterization at

24 E6.5 revealed degeneration of *Zc3h11a$^{-/-}$* embryos, indicating developmental defects around the

25 time of implantation. Transcriptomic analyses documented a dysregulation of glycolysis and fatty

26 acid metabolic pathways in *Zc3h11a$^{-/-}$* embryos at E4.5. Proteomic analysis indicated a tight

27 interaction between ZC3H11A and mRNA-export proteins in embryonic stem cells. Furthermore,

28 CLIP-seq analysis demonstrated that ZC3H11A binds a subset of mRNA transcripts that are

29 critical for metabolic regulation of embryonic cells. Altogether, the results show that ZC3H11A is

30 participating in export and post-transcriptional regulation of selected mRNA transcripts required

31 to maintain metabolic processes in embryonic cells. While ZC3H11A is essential for the viability

32 of the early mouse embryo, inactivation of *Zc3h11a* expression in adult tissues using a conditional

33 knock-out did not lead to obvious phenotypic defects.

Introduction

The zinc finger CCCH domain-containing protein 11A (ZC3H11A) is a stress-induced mRNA-binding protein that is required for the efficient growth of several human nuclear replicating viruses, including human immunodeficiency virus (HIV-1), influenza A virus (IAV), human adenovirus (HAdV) and herpes simplex virus 1 (HSV-1) [1]. Proteomic studies on human cells have indicated that ZC3H11A is a component of the transcription-export (TREX) complex [2]. Functional studies indicated that ZC3H11A selectively export newly transcribed viral mRNAs to the cytoplasm during virus infection [1, 3]. Thereby, inactivation of ZC3H11A in human cells impaired the export of a subset of viral mRNA transcripts and resulted in a dramatic reduction in virus growth [1]. These important functions of ZC3H11A in the growth cycle of several human viruses makes ZC3H11A a potential target for development of an anti-viral therapy. The aim of the present study was to develop an animal model to study the molecular functions of ZC3H11A in prenatal and postnatal development.

The TREX complex serves a key function in nuclear mRNA export and consists of multiple conserved core subunits including ALYREF (RNA binding adaptor of TREX), UAP56 (DEAD-box type RNA helicase) and a stable subcomplex called THO, which in turn consists of at least six subunits [4, 5]. Proteomic studies using human cells have indicated that ZC3H11A is an auxiliary component of the TREX complex, but did not consider it as a core subunit of the TREX complex [6, 7]. THO proteins are conserved from yeast to human and play pivotal roles during embryo development, cell differentiation and cellular response to stimuli [8, 9]. It has been reported that the disruption of THO proteins, such as THOC1, THOC2 or THOC5, leads to early embryonic lethality [9–11]. The TREX complex controls the mRNA export in a selective manner, where individual TREX components appear to be required for export of distinct subsets of mRNAs [12].

57   For instance, THOC2 or THOC5 are required for the export of mRNAs essential for pluripotency

58   such as *Nanog*, *Sox2* and *Klf4* in mouse embryonic stem cells [9]. Despite several reports

59   characterizing the role of THO proteins during embryogenesis, the cellular function of ZC3H11A

60   during embryo development is unknown.

61   In the current study, we established *Zc3h11a* knock-out (KO) mouse models to study the

62   effect of *Zc3h11a* loss of function on embryo development. Our results identify ZC3H11A as a

63   fundamental protein required for early embryo growth. Disruption of ZC3H11A is homozygous

64   lethal and leads to complete failure of embryo development and survival. Using proteomic and

65   RNA-seq analyses, we show that the ZC3H11A protein interacts with TREX complex core

66   proteins in mouse embryonic stem cells. ZC3H11A is apparently an auxiliary factor participating

67   in export and post-transcription coordination of selected mRNA transcripts required to maintain

68   the metabolic processes in embryonic cells. Interestingly, *Zc3h11a* inactivation in adult mouse

69   tissues using an inducible mouse model showed that the ZC3H11A protein is dispensable for

70   postnatal tissue growth.

71
72   **Results**
73
74   ***Zc3h11a* inactivation in mice is lethal in the homozygous condition**

75   *Zc3h11a* is located on chromosome 1 in both human and mouse genomes and harbors the coding

76   sequence of another gene encoding the DNA-binding zinc-finger protein ZBED6 [13–18] (Figure

77   1A). We used two strategies to target the *Zc3h11a* coding exons without affecting *Zbed6*. The first

78   *Zc3h11a* mouse model was developed by targeting exon 3 using the CRISPR/cas9 system with

79   two guide RNAs flanking the targeted sequences. This resulted in both a deletion of 567 bp

80   including the entire exon 3 and a frameshift (Figure 1B). The second mouse model was developed

81   by inserting loxP sites flanking the coding sequence of exon 2 using homologous recombination

82   (Figure 1C). These loxP mice were crossed with mice expressing Cre recombinase in germ-line

83   (PGK-Cre), which resulted in a deletion of 1.5 kb containing exon 2 and removal of the zinc finger

84   domains of the encoded ZC3H11A protein (Figure 1C). For each model, heterozygous mice were

85   crossed and the offspring were genotyped. No $Zc3h11a^{-/-}$ mice were obtained from heterozygous

86   matings (Figure 1D and E), with the exception of one single homozygous $Zc3h11a^{-/-}$ female from

87   the loxP mouse model (1 out of 204 mice). When we crossed this KO female with $Zc3h11a^{+/-}$

88   males, 10 out of 10 progeny were heterozygous $Zc3h11a^{+/-}$. The probability to get this outcome if

89   both parents are heterozygous is $P=0.5^{10}=0.001$. The result confirms our interpretation that one

90   single homozygous KO survived and were fertile.

91

92   ***Zc3h11a* deletion results in embryonic degeneration**

93

94   In order to explore at what point ZC3H11A is essential for embryo survival, we collected and

95   genotyped embryos at different time points post $Zc3h11a^{+/-}$ X $Zc3h11a^{+/-}$ mating (Figure 2A).

96   The genotyping of embryos at embryonic day E4.5 prior to implantation revealed expected

97   Mendelian proportions (Figure 2A). However, a clear deviation from expected Mendelian

98   proportions was observed after implantation (Figure 2A, bottom panel). Remarkably, phenotyping

99   at E6.5 showed dramatic changes in the morphology of the $Zc3h11a^{-/-}$ embryos with a large degree

100   of tissue degeneration, whereas $Zc3h11a^{+/-}$ heterozygotes appeared morphologically

101   indistinguishable from the WT embryos (Figure 2B).

102

103   **ZC3H11A is highly expressed at early stages of embryonic development**

104   The lethal effect of *Zc3h11a* inactivation in mouse embryos encouraged us to explore the cellular

105   localization of ZC3H11A at early embryonic stages. We used immunofluorescence (IF) staining

106 to visualize the ZC3H11A protein and the nuclear speckles marker SRSF2 (SC35) for expression

107 profiling in mouse 2-cell and blastocyst stages. The IF analysis indicated that ZC3H11A was

108 expressed at a detectable level as early as the 2-cell stage, with clear nuclear localization (Figure

109 3A, top panel). The z-stack imaging of the blastocysts showed that ZC3H11A was expressed in

110 trophectoderm (Figure 3A, middle panel) as well as in inner cell mass (ICM) (Figure 3A, bottom

111 panel). The localization pattern of ZC3H11A in ICM was overlapping with the nuclear speckles

112 as indicated using the anti-SC35 antibody (Figure 3A and B). This subcellular localization of

113 ZC3H11A in mouse embryonic cells is similar to the ZC3H11A localization in human cell lines

114 [1]. Re-analyzing single cell RNA-seq data from Deng *et. al.* [19] revealed that *Zc3h11a* mRNA

115 is highly expressed in mouse embryos as early as the zygotic stage, indicating maternal

116 contribution (Figure 3C).

117

118 **Disrupted metabolic pathways in the *Zc3h11a$^{-/-}$* embryos**

119 The degeneration of *Zc3h11a $^{-/-}$* embryos during early embryo development (E6.5) encouraged us

120 to perform whole transcriptome analysis of stage E4.5 embryos to reveal the dysregulated

121 pathways that led to the degeneration of *Zc3h11a $^{-/-}$* embryos at E6.5. We collected embryos from

122 *Zc3h11a$^{+/-}$* X *Zc3h11a$^{+/-}$* matings and extracted the RNA from the embryonic part for sequencing

123 (Figure 4A, left). Principle component analysis (PCA) of RNA-seq data showed that Het

124 (*Zc3h11a$^{+/-}$*) and WT (*Zc3h11a$^{+/+}$*) embryos clustered together and apart from the KO (*Zc3h11a^{-}*

125 $^{/-}$) embryos (Figure 4A). This result is in agreement with the observed morphological similarity

126 between WT and Het embryos (Figure 2B). Furthermore, the differential expression (DE) analysis

127 between WT and Het did not detect any significant DE genes with FDR <0.05. Therefore, we

128 performed the DE analysis between KO embryos vs. WT and Het embryos that revealed 660 DE

129   genes (FDR <0.05) out of ~11,000 expressed genes (Table S1). Among these DE genes, 419 were

130   up-regulated and 241 were down-regulated in KO embryos (FDR <0.05). Next, we performed a

131   gene set enrichment analysis (GSEA) using the DE genes in KO embryos in order to further

132   explore the function of ZC3H11A. The GSEA of ranked DE genes in KO embryos using the

133   hallmark gene sets revealed a significant negative enrichment (FDR <0.05) of genes involved in

134   glycolysis, fatty acid metabolism pathways and epithelial-mesenchymal transition (EMT)

135   processes (Figures 4B-4D). The heatmaps present the expression of the subset of genes that

136   contributed the most to the indicated pathway enrichment among significantly down-regulated

137   genes in KO embryos (Figures 4B-4D). Among the key down-regulated genes, contributing to the

138   significant GSEA result, are lactate dehydrogenase A (*Ldha*), which has an essential role in

139   glycolysis, and disruption of *Ldha* causes congenital disorders of carbohydrate metabolism [20,

140   21]; enoyl-CoA hydratase and 3-hydroxyacyl CoA dehydrogenase (*Ehhadh*), which is involved in

141   fatty acid beta-oxidation using acyl-CoA oxidase [22, 23]; and dickkopf WNT signaling pathway

142   inhibitor 1 (*Dkk1*), which is involved in several processes including cell fate determination and

143   cell differentiation processes during embryogenesis [24]. On the other hand, the positively

144   enriched gene sets among up-regulated genes in the KO mice included genes in the P53 pathway

145   and autophagy process-related genes (Figures 5A, 5B and S1). This includes the up-regulation of

146   autophagy related 12 (*Atg12*) and microtubule-associated proteins 1A/1B light chain 3A

147   (*Map1lc3a*) genes (Figure 5E). MAP1LC3A is known as LC3A protein and is required for

148   autophagosome formation [25].

149   To get further insight on which cell type in blastocysts was most affected by *Zc3h11a*

150   inactivation, we explored the expression profile of the DE genes in *Zc3h11a*$^{-/-}$ embryos in

151   embryonic lineages (ICM and epiblast) and trophectoderm (TE). Using previously published

152   datasets of mouse gene expression (GSE76505 [26]), the ICM/TE ratio of expression was

153   computed for genes down-regulated and up-regulated in the KO embryos (FDR ≤0.05, fold change

154   ≥2). We also explored the expression of DE genes at earlier stages using gene expression dataset

155   (E-MTAB-2950) [27]. This showed that down-regulated genes in $Zc3h11a^{-/-}$ embryos are

156   primarily expressed in the ICM/early epiblast rather than trophectoderm (Figure 5C), while the

157   expression of the up-regulated genes is nearly equally present in ICM/early epiblast and TE (Figure

158   S2). The down-regulated genes in $Zc3h11a^{-/-}$ embryos with high expression in the ICM include:

159   *Ldha,* teratocarcinoma-derived growth factor (*Tdgf1, Cripto)*, growth differentiation factor 3

160   (*Gfd3),* phosphofructokinase (*Pfkp*) (Figure 5D). GDF3 is an analog of NODAL and uses TDGF1

161   as co-factor [28]. Both *Ldha*, *Pfkp, Pfkm* and *Pdk2* are down-regulated in $Zc3h11a^{-/-}$ embryos and

162   are involved in glycolysis and lactate production, as indicated in the GSEA (Figure 4). At peri-

163   implantation stages, there is a major metabolic switch from oxidative phosphorylation to anaerobic

164   glycolysis, with increased lactate production [29, 30]. *Cripto*/*Tdgf1* has been reported as an

165   essential factor regulating this metabolic switch [31]. That explains the GSEA results that show

166   that the down-regulated pathways mostly concern metabolic regulation processes. Altogether, this

167   strongly suggests that the primary consequence of ZC3H11A deficiency is in the ICM, due to

168   perturbed metabolic regulation. The enrichment of genes associated with autophagy and apoptosis-

169   related pathways (Figure 5A-5B) among the up-regulated genes in $Zc3h11a^{-/-}$ embryos could be

170   secondary effect caused by the metabolic stress encountered by the ICM cells [32, 33].

171

172   **ZC3H11A is associated with the RNA export machinery in embryonic stem cells**

173   In human somatic cells, ZC3H11A has been recently characterized as an RNA-export protein that

174   functions through its interaction with TREX complex proteins [1]. In order to identify its

175   interacting partners in embryonic cells and to investigate if ZC3H11A maintains its association

176   with the TREX complex in mouse embryonic stem cells (mESCs), we performed co-

177   immunoprecipitations (co-IPs) using anti-ZC3H11A, anti-THOC2 and anti-IgG antibodies

178   followed by mass spectrometry (MS) analyses (Figure 6A). Statistical analyses of detected MS

179   intensities from the biological replicates (n=4) revealed a number of proteins with statistically

180   significant interaction with ZC3H11A and THOC2 (Figure 6B). Proteins belonging to the TREX

181   complex and RNA export machinery are highlighted in bold. The log-fold change in protein

182   intensities in the ZC3H11A co-IP relative to the IgG co-IP is presented along with the adjusted *P*-

183   values (Figure 6C). The interaction between ZC3H11A and THOC2 was validated by a reciprocal

184   co-IP and western blot using mESCs (Figure 6D). The majority of the significant partners

185   interacting with ZC3H11A are part of the TREX complex and also showed significant enrichment

186   in the THOC2 co-IP, including THOC5, THOC7 (Figure 6E), THOC1 and THOC6 (Figure 6C).

187   ZC3H11A also interacts with other RNA-binding proteins that are required for RNA maturation,

188   such as polyadenylate-binding nuclear protein 1 (PABPN1) [34]; FYTTD1, which acts as an

189   adaptor for RNA helicase UAP56 [35]; and the RNA export adaptor ALYREF/THOC4 [36]

190   (Figure 6D and F). Notably, almost half of the ZC3H11A partners detected by co-IP were also

191   found in the THOC2 co-IP (Figure S3). These data indicate that ZC3H11A is an essential

192   component of the TREX complex that is known to play pivotal roles during embryogenesis and

193   for maintaining pluripotency of ESCs [9, 10]. Furthermore, the proteomic analysis identified

194   additional interacting partners, independent of the TREX complex, such as the RNA-binding

195   protein DDX18; the PRC2 components SUZ12 and JARID2; and the two zinc finger proteins

196   ZNF638 and ZFP57 (Figure 6G and S3B). DDX18 is an RNA binding protein that plays a crucial

197   role in pluripotency and self-renewal of embryonic stem cells [37].

198

ZC3H11A selectively binds mRNA transcripts in mESCs

200 Previous studies using human somatic cells indicated that ZC3H11A is an RNA-binding protein

201 that selectively binds subsets of mRNA upon stress or viral infection [1]. To study the RNA-

202 binding properties of ZC3H11A in embryonic cells, we performed UV-crosslinking of mESCs

203 followed by ZC3H11A immunoprecipitation (CLIP) and RNaseI treatment to isolate the RNA

204 protected by ZC3H11A. We used two anti-ZC3H11A antibodies to minimize any artifact caused

205 by antibodies, and anti-ALYREF and anti-IgG as positive and negative controls, respectively.

206 High-throughput sequencing of the RNA isolated by CLIP (CLIP-seq) revealed an almost

207 exclusive interaction between ZC3H11A and protein-coding mRNAs in mESCs (Figure S4A),

208 with a preference to bind 3'UTRs over the 5'UTRs (Figure 7A). The analysis of ZC3H11A CLIP-

209 seq peaks from the two ZC3H11A antibodies revealed a significant enrichment of short purine-

210 rich motifs (Figure 7B, top panel). Moreover, ZC3H11A exhibited strong binding to the

211 paraspeckle *Neat1* transcript (Figure S4B), similar to what has been observed in human somatic

212 cells [1]. Comparing the CLIP-seq ZC3H11A mRNA targets with genes that were significantly

213 down-regulated in RNA-seq data, we identified subsets of genes as putative direct targets of

214 ZC3H11A in mESCs (Figure 7B, bottom panel). The gene ontology analysis of these genes

215 suggested that they are involved in germ cell development and metabolic processes (Figure 7C).

216 These 29 genes were dramatically down-regulated in *Zc3h11a*$^{-/-}$ embryos (Figure 7D) and are

217 involved in cellular processes vital for embryonic development [38–41]. Putative direct targets

218 included the *Tdgf1,* nucleoporin 85 *(Nup85),* proliferation-associated protein 2G4 *(Pa2g4)* and gap

219 junction protein beta 3 *(Gjb3)* genes. The CLIP-seq analysis detected ZC3H11A binding sites at

220 the 3'UTR of these genes that were either overlapped with ALYREF binding sites (for *Tdgf1 and*

221   *Pa2g4*) or distinct from them in *Nup85* (Figure 7E). These results suggest a crucial role of

222   ZC3H11A in post-transcriptional processing and mRNA export of key genes in embryonic cells.

223

224   **ZC3H11A is required for *in vitro* derivation of ESCs.**

225   To further understand the role of ZC3H11A in the peri-implantation development and especially

226   its role in the pluripotent epiblast, twenty-five E3.5 blastocysts were recovered from matings

227   between heterozygous mice, and cultured *in vitro*. From these, 14 ESC lines were obtained but

228   none were homozygous KO (X^2=4.7, d.f.=1; *P*<0.05). This suggests that ZC3H11A is required for

229   establishing ESC *in vitro*.

230

231   **Mice with postnatal *Zc3h11a*-ablation are healthy and viable**

232   We developed an inducible *Zc3h11a*-KO model to assess the effect of *Zc3h11a* ablation

233   postnatally. Loxp-*Zc3h11a* mice were crossed with mice containing fusion of a mutated estrogen

234   receptor T2 and Cre recombinase (Cre-ER), allowing temporal control of floxed gene deletion

235   upon tamoxifen induction *in vivo* [42]. We generated a strain that is homozygous *Zc3h11a*-loxp

236   ($Zc3^{loxP/loxP}$) with one copy of Cre-ER (CRE.ER$^+$ Zc3$^{loxP/loxP}$) and crossed it with the original strain

237   ($Zc3^{loxP/loxP}$) lacking Cre-ER. The offspring were injected with tamoxifen at week 3-4 after birth

238   (Figure 8A). Genotyping of the tamoxifen-injected mice at week 6 using genomic DNA from tail

239   biopsies revealed a balanced ratio between WT and induced KO (iKO) due to the presence/absence

240   of Cre-ER (Figure 8B). By injecting CRE.ER$^+$ Zc3$^{loxP/loxP}$ mice with tamoxifen postnatally we

241   succeeded in achieving >90% reduction of *Zc3h11a* expression in multiple adult tissues including

242   bone marrow, liver and spleen (Figure 8C and D). The examination of tamoxifen-injected mice

243   were carried out at week 12 and involved histology staining of multiple organs including stomach,

244   pancreas, small and large intestine tissues. The histology phenotyping did not exhibit obvious

245   defects between the floxed (WT) and iKO adult mice (Figure 8E and S5). Furthermore, the

246   measurement of body weight, dissected kidney and spleen tissues from WT and inducible ZC3-

247   KO adult mice did not show significant differences (Figure 8F).

248

249   **Discussion**

250   ZC3H11A is important for the growth of nuclear replicating viruses, where viruses take advantage

251   of the ZC3H11A protein to facilitate the export of their mRNA transcripts into cytoplasm.

252   Thereby, ZC3H11A is considered a possible target for development of anti-viral therapy. Hence,

253   we developed ZC3H11A mouse models to study its physiological functions across developmental

254   stages. The current study reports that ZC3H11A is an essential protein required for the viability of

255   mouse embryos. Loss of function of ZC3H11A leads to developmental defects and embryo

256   degeneration at peri-implantation stages associated with dysregulation of metabolic pathways such

257   as glycolysis and fatty acid metabolic processes. Interestingly, the defects mainly originate from

258   the epiblast, as most of the down-regulated genes are expressed predominantly in this lineage.

259   Moreover, even though ZC3H11A is expressed in all cells of the blastocyst, *Tdgf1*, one of its key

260   down-regulated target genes is expressed specifically in the epiblast cells [31]. TDGF1 (also called

261   *Cripto*) is a membrane-bound protein, co-receptor for NODAL/GDF3 [43]. TDGF1 and NODAL

262   signaling play important roles during specification of the early lineages and maintenance of the

263   pluripotent epiblast at early post-implantation stages [43]. Interestingly it also controls the

264   metabolic switch occurring at the time of implantation in the mouse, when cells transit from a

265   OXPHOS based metabolism to a glycolytic one [29, 31, 44]. Our CLIP-seq analysis detected two

266   strong peaks for ZC3H11A binding at the 3' end of the *Tdgf1* mRNA in mESCs (Figure 7E).

267 Furthermore, ZC3H11A binds the 3' end of *Nup85* and *Pa2g4* mRNA transcripts (Figure 7E).

268 Both *Nup85* and *Pa2g4* were down-regulated in the KO embryos and play crucial roles in

269 embryonic development [38–41]. For instance, NUP85 is a core component of the nuclear pore

270 complex (NPC) proteins and is required for mRNA export and maintenance and assembly of the

271 NPC [40, 41, 45]. Loss of function studies showed that inactivation of the NPC proteins in mouse

272 models resulted in early embryonic lethality [46–48]. Recent phenotypic characterization of the

273 *Nup85* knock-out mouse model from the International Mouse Phenotyping Consortium

274 (www.mousephenotype.org, accessed 22 August 2022) [49] has indicated complete preweaning

275 lethality of *Nup85*$^{-/-}$ mice. Furthermore, the ErbB3 binding protein-1 gene (*Ebp1*/*Pa2g4*) is

276 implicated in regulating the proliferation and differentiation during developmental stages. The

277 *Pa2g4* knock-out mice exhibited growth retardation and were 30% smaller than wild-type mice

278 [50]. A recent study has reported more severe phenotypes in *Pa2g4*-deficient mice with death

279 between E13.5 and 15.5, massive apoptosis, and cessation of cell proliferation [38]. These putative

280 ZC3H11A targets identified by CLIP-seq are known to be critical for embryonic viability and

281 implicated in diverse cellular functions, disruption of their expression leads to embryonic

282 degeneration.

283 Another key down-regulated gene in KO embryos is *Ldha*, the enzyme that controls the

284 level of anaerobic glycolysis by catalyzing the transformation of pyruvate into lactate. Hence, in

285 KO embryos, the establishment of a more anaerobic glycolysis is impaired, which compromises

286 survival when the environment becomes more hypoxic as embryos implant. Upregulation of

287 autophagy as observed in KO embryos can be viewed as reaction to a suboptimal metabolic

288 environment [33]. Although KO embryos can survive up to E6.5, they have already undergone a

289 process of degeneration, as suggested by the upregulation of P53 mediated apoptotic pathway

290   already at E4.5. The transcriptomic analysis also indicated a significant dysregulation in the EMT

291   process (Figure 4C). The EMT process is fundamental for embryo development and takes place

292   during implantation of the embryo into the uterus and during early gastrulation, where embryo is

293   transformed from a single layer to three germ layers. Defects in EMT and subsequently in

294   gastrulation usually lead to a failure in embryonic development [51, 52].

295   The ZC3H11A protein exhibited strong interactions with members of the RNA-export

296   machinery in ESCs and the top interacting partners with ZC3H11A are members of the TREX

297   complex, including THO proteins (Figure 6). The enrichment analysis of interacting partners with

298   ZC3H11A showed significant enrichment of proteins involved in metabolism of RNA, mRNA 3'-

299   end processing and transport of mature transcript to cytoplasm (Figure S3A). These proteomics

300   results are in agreement with the analysis of the CLIP-seq of ZC3H1A in mESCs that revealed

301   preferential binding at 3'UTRs over the 5'UTRs of target transcripts (Figure 7A). It also supports

302   the model of action that ZC3H11A interacts with TREX-complex proteins and contribute to

303   efficient mRNA maturation and export of the target transcripts. In agreement with this model,

304   several studies have described the pivotal roles of the TREX-complex in the embryonic

305   development [9–11]. THO proteins such as THOC1, THOC2 and THOC5 play essential roles

306   during early development but in a different way than ZC3H11A, as their depletion affects

307   pluripotency establishment and maintenance [9, 10]. In contrast, ZC3H11A depletion does not

308   directly affect pluripotency maintenance. The fact that $Zc3h11a^{-/-}$ blastocysts did not give rise to

309   ESC lines in the present study may be due to the metabolic impairment rather than a defect in

310   pluripotency maintenance, as they all form outgrowth, in contrast to $Thoc1^{-/-}$ embryos [10].

311   Our results provide evidence that ZC3H11A is required for the post-transcriptional

312   regulation of genes that are crucial for the embryonic cell. In contrast to the severe phenotypes in

313   *Zc3h11a* germline KO embryos, *Zc3h11a* inactivation in the adult tissues did not cause obvious

314   defects. The phenotypic characterization of the inducible ZC3-KO adult mice indicated a

315   dispensable role for ZC3H11A in adult tissues and a single surviving *Zc3h11a*$^{-/-}$ female showed

316   no pathological conditions, were fertile and gave birth to 10 progeny from three litters.

317   Furthermore, complete inactivation of *Zc3h11a* in human and mouse cell lines did not lead to

318   significant effects on cell growth or viability [1, 3].

319

320

321   **Methods**

322   **Animal models**

323   All mice were group-housed with free access to food and water in the pathogen-free facilities of

324   Uppsala University and INRAE. All procedures described in this study were approved by the

325   Uppsala Ethical Committee on Animal Research (#17346/2017), following the rules and

326   regulations of the Swedish Animal Welfare Agency, and were in compliance with the European

327   Communities Council Directive of 22 September 2010 (2010/63/EU). All efforts were made to

328   minimize animal suffering and to reduce the number of animals used. The loxP *Zc3h11a* mouse

329   model was generated by homologous recombination in mouse C57BL/6 ES cells (Cyagen, USA).

330   The PGK-Cre mice expressing the Cre recombinase in the germ line [53] was obtained as gift from

331   Klas Kullander's lab (Uppsala University). The CRISPR/cas9 *Zc3h11a* mouse model was

332   purchased from the Mutant Mouse Resource & Research Centers (MMRRC, USA, Strain No:

333   043457-UCD). For inducible knock-out model, the mice containing fusion of a mutated estrogen

334   receptor T2 and Cre recombinase (Cre-ER) was ordered from The Jackson Laboratory (USA,

335   Strain No: 008463). Mice were genotyped (Tables S2) based on tail biopsies.

336

Collection of mouse embryos

337

338   The *Zc3h11a* heterozygous males and females were mated and the following day, the presence of

339   a vaginal plug was recorded. To determine the time of developmental lethality, females were

340   sacrificed at E6.5 and embryos dissected out from the decidual swellings. Their morphology was

341   recorded and each of them was then processed for genotyping. Samples for RNA-sequencing were

342   collected at peri-implantation stage (E4). These embryos were bisected using glass needles and

343   both parts were individually snap-frozen. The abembryonic part (mural TE) was used for

344   genotyping and the embryonic part (ICM and polar TE) for subsequent RNA extraction.

345

346   **RNA sequencing**

347   The collected embryonic ICM and polar TE (as described above) were used for RNA-seq library

348   preparation using the SMART-Seq HT Kit (Takara Bio USA, Inc.) following the manufacturer's

349   instructions.   Briefly, cDNA was generated using the oligo-dT primer to enrich for mRNA,

350   followed by the tagmentation of the cDNA (Illumina Nextera XT) to generate Illumina-compatible

351   RNA-seq libraries. The libraries were amplified by 12 PCR cycles and size-selected for an average

352   insert size of 150 bp and sequenced as 100 bp paired-end reads using Illumina Nova-Seq. Sequence

353   reads were mapped to the reference mouse genome (mm10) using STAR 2.5.1b [54] with

354   parameter --quantMode GeneCounts to generate read counts. The edgeR (Bioconductor package)

355   [55] was used to identify differentially expressed (DE) genes using gene models for mm10

356   downloaded from UCSC (www.genome.ucsc.edu). The abundance of gene expression was

357   calculated as count-per-million (CPM) reads. Genes with less than one CPM in at least three

358   samples were filtered out. The filtered libraries were normalized using the trimmed mean of M-

359   values (TMM) normalization method [56]. *P*-values were corrected for multiple testing using the

360   False Discovery Rate (FDR) approach. Gene set enrichment analyses (GSEA) were performed

361   using the fgsea R package [57]. Genes were ranked based on the fold-change and the datasets were

362   downloaded from the GSEA website (https://www.gsea-msigdb.org/gsea/).

363

364   **Immunoprecipitation**

365   Mouse embryonic stem cell line (mESC) was cultured on gelatin-coated plates and maintained in

366   Dulbecco's Modified Eagle Medium (DMEM) complemented with 10% heat-inactivated fetal

367   bovine serum, penicillin (0.2 U/mL), streptomycin (0.2 µg/mL) and L-glutamine (0.2 µg/mL)

368   (Gibco, Waltham, Massachusetts, United States) and supplemented with recombinant mouse

369   Leukemia Inhibitory Factor (LIF, 20 U/ml, Millipore). Cultured mESCs at 60% confluency were

370   washed with PBS twice before the preparation of total lysate. Total protein lysates were prepared

371   using Pierce IP lysis buffer (Thermo Fisher Scientific) supplemented with protease inhibitors

372   (Complete Ultra Tablets, Roche) and Pierce Universal Nuclease (Thermo Fisher Scientific). Lysate

373   was cleared by centrifugation at 20 x *g* for 10 min at 4°C, and incubated rotating end-over-end at

374   4°C with anti-IgG, anti-ZC3H11A or anti-THOC2 antibodies in Protein LoBind 2-ml tubes

375   (Eppendorf). Thereafter, 30 µg of Dynabeads Protein G (Thermo Fisher Scientific) was added to

376   each tube and incubated for 30 min at room temperature, followed by washing three times with

377   Pierce IP lysis buffer. The co-IP proteins were eluted from the magnetic beads by adding 50 µg of

378   elution buffer (5% SDS, 50mM TEAB, pH 7.55) and heat denaturation for 5 min at 90 °C. The

379   eluted co-IP proteins were used for western blot and Mass spectrometric analysis. co-IP

380   experiments were performed in four replicates.

381

Immunoblot analysis

Equal volumes (5 µg) of the prepared co-IPs were separated by SDS-PAGE (4–15%, Bio-Rad) and transferred to PVDF membranes (Millipore). StartingBlock buffer (Thermo Fisher Scientific) was used to block the membrane before the primary anti-ZC3H11A, anti-THOC2 or anti-ALYREF antibodies (1:1000) were added. Proteins were visualized and detected by the Odyssey system (LI-COR).

Protein clean-up and digestion

The co-IPs were cleaned up and prepared for mass spectrometry quantification using the S-Trap column method [58]. First, the eluted co-IPs were treated by TCEP (5 mM) to reduce disulfide bonds, followed by adding methyl methanethiosulfonate (MMTS) to a final concentration of 15 mM to alkylate cysteines. Thereafter, the lysate was acidified by adding phosphoric acid to a final concentration of 1.2%. The acidified lysate was added to an S-Trap microcolumn (Protifi, Huntington, NY) containing 300 µl of S-Trap buffer (90% MeOH, 100 mM TEAB, pH 7.5) and centrifuged at $4000 \times g$ for 2 min. The S-Trap microcolumn was washed twice with S-Trap buffer. The columns were transferred to new tubes and incubated with 10 ng/µL sequencing-grade trypsin (Promega) overnight at 37°C. The digested proteins were eluted by centrifugation at $4000 \times g$ for 1 min with 50 mM TEAB, 0.2% formic acid (FA), followed by 50% acetonitrile (ACN)/0.2% FA, and finally 80% ACN/0.1% FA. The eluted peptides were dried down in a vacuum centrifuge (ThermoSavant SPD SpeedVac, Thermo Fisher Scientific), and finally dissolved in 1% FA. Digested peptides were thereafter desalted by StageTips (Thermo Fisher Scientific) according to the manufacturer's instructions, and subsequently dissolved in 0.1% FA.

Liquid chromatography and mass spectrometry

405   The dissolved peptides were quantified by mass spectrometry as previously described [17].

406   Briefly, a Thermo Scientific EASY-nLC 1000 liquid chromatography system coupled with an

407   Acclaim PepMap 100 (2 cm x 75 μm, 3 μm particles, Thermo Fisher Scientific) pre-column in line

408   with an EASY-Spray PepMap RSLC C18 reversed phase column (50 cm x 75 μm, 2 μm particles,

409   Thermo Fisher Scientific) was utilized to fractionate the peptide samples. The eluted peptides were

410   analyzed on a Thermo Scientific Orbitrap Fusion Tribrid mass spectrometer, operated at a Top

411   Speed data-dependent acquisition scan mode, ion-transfer tube temperature of 275°C, and a spray

412   voltage of 2.0 kV.

413

414   **Mass spectrometric data analysis**

415   Data analysis of raw files was performed using MaxQuant software (version 1.6.4) and the

416   Andromeda search engine [59, 60], with the following parameters: cysteine methyl

417   methanethiosulfonate (MMTS) as a static modification and methionine oxidation and protein N-

418   terminal acetylation as variable modifications. First search peptide MS1 Orbitrap tolerance was

419   set to 20 ppm, and iontrap MS/MS tolerance was set to 0.5 Da. Peak lists were searched against

420   the UniProtKB/Swiss-Prot *Mus musculus* proteome database (UP000000589, version 2019-04-01)

421   with a maximum of two trypsin miscleavages per peptide. The MaxQuant contaminants database

422   was also utilized. A decoy search was made against the reversed database, with the peptide and

423   protein false discovery rates both set to 1%. Only proteins identified with at least two peptides of

424   at least 7 amino acids in length were considered reliable. The peptide output from MaxQuant was

425   filtered by removing reverse database hits, potential contaminants, and proteins only identified by

426   site (PTMs).

427   Intensity values were used to determine the protein abundance. First, proteins with missing

428 values in more than one replicate in at least one group were filtered out. Thereafter, the filtered

429 intensities were normalized using the variance stabilizing normalization (vsn) method [61] and

430 followed by the imputation of missing values with the deterministic minimal value approach

431 (MinDet) [62] to replace the missing values in the normalized intensities. The normalized

432 intensities were fitted to a linear model and the empirical Bayes moderated t-statistics and their

433 associated *P*-values were used to calculate the significance of differential enriched proteins [63,

434 64]. The *P*-values were adjusted for multiple testing using the Benjamini–Hochberg procedure

435 [65]. Proteomics data was visualized using the ggplot R-package and Cytoscape v3.8.2.

436

437 **Crosslinking immunoprecipitation sequencing (CLIP-seq)**

438 Cultured mESCs were cross-linked using a 254 nM UV crosslinker with an energy setting of 400

439 mJ/cm^2. The cross-linked cells were collected in ice-cold PBS with a cell scraper and aliquoted in

440 1.5 ml tubes (25 million cells/ml). The CLIP-seq library preparation was performed as indicated

441 [66]. Briefly, the total lysate was digested with RNase-I and immunoprecipitated with 10 µg of the

442 following antibodies: anti-ZC3H11A (HPA028526 and HPA028490, Atlas Antibodies), anti-

443 ALYREF (ab202894, Abcam) or anti-IgG (ab37415, Abcam). The IP-RNA complexes were

444 loaded on a 4–12% Bis-Tris (Bio-Rad) gel, transferred to a nitrocellulose membrane, and the bands

445 above 75 kDa for each lane were cut. Extracted RNA molecules from the membrane were used for

446 Illumina library construction as indicated [66]. CLIP-seq reads were trimmed out using

447 *trim_galore* with the criteria to remove reads with low quality and shorter than 15 bp. The trimmed

448 reads were aligned to the mouse reference genome mm10 using STAR aligner with end-to-end

449 options --alignEndsType EndToEnd. The CLAM workflow were used for peak calling and

450   counting the fold enrichment of IP vs IgG control [67]. The identified peaks with adjusted *P*-

451   value <0.01 were annotated to the mouse mm10 genome using the *peak_annotator* function from

452   CLAM. HOMER software was used for motif finding using the findMotifsGenome.pl script with

453   default parameters for RNA motifs [68].

454

455   **Quantitative RT-PCR**

456   Total RNA was extracted using the RNeasy Mini kit (Qiagen) and the samples were treated with

457   DNase I to eliminate genomic DNA. The High Capacity cDNA Reverse Transcription Kit

458   (Applied Biosystems) was used to generate cDNA from RNA. Quantitative PCR analysis was

459   performed in ABI MicroAmp Optical 384-well Reaction plates on an ABI 7900 real-time PCR

460   instrument using SYBR gene expression reagents (Applied Biosystems). The amplification and

461   detection of each gene was performed using forward and reverse primers for *Zc3h11a*, F:

462   TGCCTAATCAGGGAGAAGACTG, R: AGCTTCACAGTGACGGAATG and *Actb* as a

463   housekeeping gene F: CTAAGGCCAACCGTGAAAAG, R: ATCACAATGCCTGTGGTACG.

464

465   **Derivation of ESCs**

466   E3.5 blastocysts were collected from heterozygous matings. They were plated individually on a

467   layer of Mitomycine C inactivated mouse embryonic fibroblasts (feeder layer) in 4-well plates, in

468   naïve ESC medium. This medium was composed of Chemically Defined Medium (CDM)

469   supplemented with LIF (700 U/ml), PD0332552 (1 µM) and CHIR99201 (final 3 µM) (2i/Lif

470   CDM) [69]. After 4-5 days, the blastocysts have attached and outgrowths formed. Individual

471   outgrowths were dislodged from the feeders, dissociated in Tryple Select (Invitrogen) and the

472   single cell suspension was plated in 4-well plates on fresh feeders. ESC colonies appeared within

473   the following days and were individually picked, dissociated and replated on feeders in 2i/Lif

474   CDM. The procedure was repeated a few times, until stable expansion of the ESCs that allows

475   passaging using trypsin and removal of feeders, replaced by plate coating with gelatin 0.2% and

476   serum.

477

478   **Immunostaining of ZC3H11A on pre-implantation embryos**

479   Mouse CD1 embryos were collected at 4-cell (E1.5) and blastocyst (E3.5) stage in M2 medium

480   (Sigma) by oviduct and uterine flushing, respectively. They were fixed in 2% PFA for 20 min,

481   followed by permeabilization by 1% Triton-X100, for 30 min. Permeabilized samples were

482   blocked with 1% BSA in PBS for 40 min, followed by incubation with primary antibodies in 1%

483   BSA overnight at 4°C. The day after, samples were washed by PBS and incubated with the

484   fluorophore conjugated secondary antibodies (Jackson ImmunoResearch) for an hour at room

485   temperature. Samples were then washed and stained by DAPI for nuclei staining. Samples were

486   mounted in Vectashield mounting agent (Vectorlabs, H1000). Embryos were imaged by a Zeiss

487   LSM710 confocal microscope. Antibodies used were anti-SC35 (ab11826, Abcam, 1:250) and

488   anti-ZC3H11A (HPA028526, Atlas Antibodies, 1:300)

489

490   **Author contributions**

491   SY and LA conceived the study. SY performed experimental and bioinformatic analysis. AJ, VB

492   and JO performed experiments on embryos and ESC derivation with contribution from SY. SY

493   and ML performed mass spectrometry analysis. SY, AJ and LA wrote the paper with input from

494   ML. All authors approved the final version before submission.

Ethics statement

Animal procedures were carried out according to the rules and regulations of the Swedish Animal Welfare Agency and French national rules on Ethics and Animal Welfare in the Animal Facility; and were in compliance with the European Communities Council Directive of 22 September 2010 (2010/63/EU). This work was approved by the French Ministry of Higher Education, Research, and Innovation (n°15-55 &21-01) and the local Ethical Committee (INRAE Jouy-en-Josas Centre). The study was carried out in compliance with the ARRIVE guidelines.

520

Data availability

The mass spectrometry proteomics data have been deposited to the ProteomeXchange Consortium via the PRIDE partner repository with the accession numbers (to be added). The RNA-seq reads have been submitted to the sequence read archive (http://www.ncbi.nlm.nih.gov/sra) with the accession numbers (to be added).

608   **Supplementary information**

609

610   **Figure S1.** Heatmaps of the normalized expression of genes involved in the P53 pathway (A) and

611   in positive regulation of autophagy (B).

612

613   **Figure S2.** (A) Heatmap of up-regulated genes (A, left) and down-regulated genes (A, right) in

614   *Zc3h11a*$^{-/-}$ embryos (FDR <0.05) and their expression profile during embryonic stages as

615   indicated. Re-analyzed data from GSE76505 and E-MTAB-2950. (B) Violin plot of the relative

616   expression of inner cell mass (ICM)-related genes and trophectoderm (TE)-related genes

617   (ICM/TE) as detected among the down-regulated and up-regulated genes in *Zc3h11a*$^{-/-}$ embryos

618   (FDR <0.05).

619

620   **Figure S3.** (A, top) Chord diagram illustrating the overlap between the interacting partners

621   detected with ZC3H11A and THOC2 co-IPs. (A, bottom) GO analysis of the identified interacting

622   partners with ZC3H11A and THOC2 co-IPs in mESCs. (B) Network analysis of the identified

623   interacting partners with ZC3H11A and THOC2 based on co-IPs in mESCs. Blue lines represent

624   the interaction detected by our proteomics analysis, and gray lines represent the predicted

625   interaction from the STRING database.

626

627   **Figure S4**. (A) Genome-wide distribution of the ZC3H11A CLIP-seq peaks from mESCs across

628   different types of transcripts. (B) Visualization of CLIP-seq reads and their distribution over the

629   *Neat1* gene.

630

631   **Figure S5.** Histology staining of intestine, colon and stomach tissues from three WT and three

632   induced ZC3-KO adult mice.

633

634   **Table S1.** Differentially expressed genes in *Zc3h11a* knock-out (KO) E4.5 embryos.

635

636   **Table S2.** Sequences of PCR primers used for mouse genotyping.

637
