**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

### 10 **A global-level quantitative synthesis fills current knowledge gaps on the potential of agricultural** 11 **diversification on ecosystem services and the socio-economic benefits of rice.**

12

13 Agricultural expansion and intensification following the green revolution significantly contributed to food  
14 security in many regions of the world in the second half of the 20<sup>th</sup> century. However, all this intensification  
15 also resulted in habitat and biodiversity loss, soil and freshwater degradation, environmental pollution, and  
16 greenhouse gas emissions worldwide<sup>1,2</sup>. There is a great expectation in the society, especially from the  
17 governance systems, for designing, implementing and supporting crop management practices that can  
18 address tomorrow's needs of addressing global food security while minimizing negative impacts on the  
19 environment, worldwide. Despite several decades of research, the available empirical evidence on the  
20 potential of diversification on ecosystem service provisioning is widely scattered in scope, agronomic and  
21 geographic contexts, which is affected by the type and effectiveness of diversification strategy used<sup>3</sup>.  
22 However, for most staple crops, it is not known yet as to whether benefits due to agricultural diversification  
23 remain for specific regions, diversification practices, and crops.

24 Now writing in *Nature Food*, He et al<sup>5</sup> performed a quantitative synthesis of 40 years of research on global  
25 rice production to understand the effect of diversification practices on yields, economy, biodiversity, and  
26 ecosystem services of rice. By using a two-step method, the team performed a quantitative synthesis on the  
27 potential of agricultural diversification on environmental and socio-economic aspects of global rice  
28 production. First, they conducted a second-order meta-analysis showing that agricultural diversification can  
29 maintain soil fertility, nutrient cycling, carbon sequestration and yield. Then they used three individual first-  
30 order meta-analyses to close major research gaps on the effect of agricultural diversification on economy,  
31 biodiversity, and pest control. The study finds that agricultural diversification in rice production promotes  
32 win-win scenarios between yield and other ecosystem services in 81% of the investigated cases with an  
33 increased biodiversity by 40%, economic profitability by 26% and reduced crop damage due to pests by  
34 31%.

35 He et al.'s study also identified knowledge gaps in understanding the spatio-temporal effects of specific rice  
36 diversification practices and trade-offs. The study highlights how, despite several decades of research, data  
37 availability still limits our understanding of agricultural diversification effects on the socio-economy,  
38 environment, and potential trade-offs in staple food production. The current knowledge gaps are due to  
39 many different factors and one of them could be the lack of consistent framework and definition of

40 diversification in the scientific literature<sup>6</sup>. Therefore, the stakeholder community should work to build a clear  
41 framework and definition about agricultural diversification so that the produced primary knowledge can be  
42 easily retrieved and quantified for global policy initiatives and impact investment (**Figure 1**).

43 The consideration of economic analysis by He et al.'s study brings added value to the literature because  
44 economic viability is one of the key factors affecting a large scale adoption or non adoption of a given  
45 practice. Indeed, diversification has been reported as an economically viable alternative for farmers in  
46 diversified systems including in agroecological farming<sup>7</sup>. However, widespread adoption of diversified  
47 cropping practices needs to be supported by coupling technological advances with socio-cultural and policy  
48 changes. This can ultimately transform agri-food systems to address pressing climate, economic,  
49 environmental, health and social challenges<sup>8</sup>. This involves three major changes<sup>9-11</sup>: production and  
50 transfer/diffusion of evidence-based knowledge and innovation on the socio-economic and environmental  
51 sustainability of diversification practices at the scale of the whole agri-food system; identification of socio-  
52 technical lock-in that hinders adoption of diversification practices, and improved governance systems for  
53 coordination among stakeholders. These major changes will provide suitable conditions for farmers to  
54 locally tailor diversification practices based on location specific primary knowledge.

55 Awareness is raising in the 21<sup>st</sup> century among the stakeholder community in agriculture to design, re-  
56 design and implement new research and policy paradigms that allow building sustainable and resilient agri-  
57 food systems which is increasingly advocated by the society today. To this aim, an increasing number of  
58 papers in the literature calls for a paradigm shift in research and policy and propose different frameworks  
59 and strategies<sup>12,13</sup>. All this will require shifting paradigms toward valuing and promoting multifunctional  
60 agriculture at different spatio-temporal scales with a research agenda that untangles complex agricultural  
61 systems under current and future climate and land use changes. To this aim, we need far-sighted thinking  
62 that includes mixed crop-livestock and mixed livestock farming as part of agricultural diversification if we  
63 want to build sustainable and resilient agri-food systems (**Figure 1**).
