Abstract

Magnetic Resonance Imaging (MRI) is a non-invasive technique that requires the participant to be completely motionless. To date, MRI in awake and unrestrained animals has only been achieved with humans and dogs. For other species, alternative techniques such as anesthesia, restraint and/or sedation have been necessary. Anatomical and functional MRI studies with sheep have only been conducted under general anesthesia. This ensures the absence of movement and allows relatively long MRI experiments but it removes the non-invasive nature of the MRI technique (i.e., IV injections, intubation). Anesthesia can also be detrimental to health, disrupt neurovascular coupling and does not permit the study of higher-level cognition. Here, we present a proof-of-concept that sheep can be trained to perform a series of tasks, enabling them to voluntarily participate in MRI sessions without anesthesia or restraint. We describe a step-by-step training protocol based on positive reinforcement (food and praise) that could be used as a basis for future neuroimaging research in sheep. This protocol details the two successive phases required for sheep to successfully achieve MRI acquisitions of their brain. By providing structural brain MRI images from 6 out of 10 sheep, we demonstrate the feasibility of our training protocol. This innovative training protocol paves the way for the possibility of conducting animal welfare-friendly functional MRI studies with sheep to investigate ovine cognition.

Introduction

Structural and functional MRI acquisitions require the individual to be completely immobile to prevent motion artifacts and obtain accurate images. Several strategies have been developed to limit motion during MRI acquisitions. For example, MRI can be performed under general anesthesia (e.g., Aksenov et al., 2015), without anesthesia but with restraint (e.g., Stefanacci et al., 1998), using sedatives (e.g., Behroozi et al., 2018) or without anesthesia or restraint (e.g., Andics et al., 2014).

For most species, MRI is conducted under general anesthesia (Aksenov et al., 2015; Lee et al., 2015; Sadagopan et al., 2015; Simchick et al., 2019; Zhou et al., 2016). This effective method ensures the absence of movement, allows relatively long MRI experiments and can be considered less stressful than for an awake, restrained animal. However, anesthesia can be detrimental to the health of the individual (DeLay, 2016) and modifies brain activity by disrupting neurovascular coupling (Aksenov et al., 2015; Gao et al., 2017). In addition, the use of general anesthesia is not compatible with the study of higher cognitive processes.

To overcome the negative effects of anesthesia, alternative methods to acquire MRI images without anesthesia have been developed. MRI studies have been carried out in awake but restrained animals such as non-human primates (e.g., Hung et al., 2015; Premereur et al., 2018; Stefanacci et al., 1998), birds (e.g., Behroozi et al., 2020), rodents (Tsurugizawa et al., 2012), pigs (Fang et al., 2006) and rabbits (Weiss et al., 2022). In this method, participants are often restrained by their heads with a surgically implanted device that is fixed to the experimental setup and/or enclosed in a restricted space. To limit the potential stress provoked by these constraints the animals are often habituated to them prior to the actual experiment (Hung et al., 2015; Tsurugizawa et al., 2012).

In recent years, a new method has emerged to perform completely awake, unrestrained brain imaging in dogs (without any medication i.e., anesthesia or sedation). The first acquisitions were successfully performed in the 2010s with fully awake, unrestrained dogs (Andics et al., 2014; Berns et al., 2012; Huber & Lamm, 2017; Jia et al., 2014; for review, see Thompkins et al., 2016). Importantly, this method refined the procedure of conducting MRI with dogs by removing the potentially negative

74 aspects of general anesthesia. Arguably, because the animal can choose to stop at any time this
75 method also further minimizes stress compared to an animal habituated to being restrained during
76 the acquisition. A detailed description of the steps required to implement this method with dogs was
77 provided by Strassberg and colleagues (2019) and Karl and colleagues (2020).

78 To our knowledge, structural and functional brain MRI studies with sheep have only been
79 conducted under general anesthesia (e.g., Barrière et al., 2019; Just et al., 2021; Lee et al., 2015; Love
80 et al., 2022; Nitzsche et al., 2015; Pieri et al., 2019; Schmidt et al., 2012). However, sheep are widely
81 used as an experimental model and contribute notably in neuroscience research (Banstola & Reynolds,
82 2022; Murray & Mitchell, 2022). *In vivo* methods such as electroencephalograms (EEG),
83 electromyography (EMG) and functional near infrared spectroscopy (fNIRS) have been used with fully
84 awake sheep, without any anesthesia (Chincarini et al., 2020; Nicol et al., 2016; Perentos et al., 2016).
85 EEG and electromyography (EMG) were used to detect rumination and eating (Nicol et al., 2016) and
86 fNIRS to assess the cerebral activity of freely moving sheep under different environmental conditions
87 (Chincarini et al., 2020).

88 Sheep are capable of learning a wide range of tasks involving various degrees of complexity.
89 For example, they can learn to discriminate between images of familiar conspecific faces displaying
90 different emotional states of neutral or negative valence (Bellegarde et al., 2017). They are also able
91 to discriminate “learned-familiar” faces from an unfamiliar one (Knolle et al., 2017). Using the cup task
92 and the tube task, Duffrene and colleagues (2022) showed that sheep can solve inferential conditions
93 based on deductive reasoning. Most studies of sheep cognition require a series of successive phases
94 to successfully achieve the task. In general, sheep are first familiarized with the experimenters to
95 facilitate handling. Then they are habituated to the experimental equipment before being trained on
96 the actual task to be achieved. Finally, the sheep perform the experiment they have been trained for.
97 The duration of the training varies from a few days to several weeks, depending on the complexity of
98 the task, the animal’s experience and potentially other factors. It is also possible that some
99 participants do not successfully complete the entire task during an experiment. For example, only 3

100 out of 10 sheep met all the criteria for the tube task (Duffrene et al., 2022); 13 out of 23 learned the
101 complete operant task of Greiveldinger and colleagues (2009); 16 out of 40 learned the task of
102 discriminating faces of familiar conspecifics displaying different emotional states of neutral or negative
103 valence (Bellegarde et al., 2017). However, these studies show that sheep can be trained to perform
104 a wide range of tasks. Thus, sheep may be good candidates for learning the behaviors required to
105 successfully complete brain MRI acquisitions voluntarily, without anesthesia.

106 In this article, we present a proof-of-concept that sheep can be trained to perform a series of
107 tasks, enabling them to achieve structural MRI acquisitions of their brains without anesthesia or
108 restraint. We provide a step-by-step training protocol based on positive reinforcement (food and
109 praise) that could be used as a basis for future research in sheep. This protocol details the successive
110 phases required for sheep to successfully complete a structural MRI acquisition of their brain.

111

112

Methods

113 Ethics

114 The study was approved by the local ethical committee for animal experimentation (CEEA VdL,
115 Tours, France, authorization #26807-2020080314491255v6). All methods were performed in
116 accordance with the European directive 2010/63/EU for animal protection and welfare used for
117 scientific purposes.

118

119 Animals

120 This study was conducted with Ile-de-France sheep born in early March 2022 at the “Unité
121 Expérimentale de Physiologie Animale de l’Orfrasière” (UEPAO, INRAE Val de Loire, France;
122 <https://doi.org/10.15454/1.5573896321728955E12>). Within the conventional breeding system of the
123 UEPAO, lambs stay with their mother until weaning at around 80 days of age. However, due to
124 excessive numbers in a litter, non-maternal ewes or health problems, some lambs need to be
125 separated from their mother and artificially reared. At which point they were placed in a single pen

126 equipped with an automatic milk feeder, straw and hay. After this separation, the lambs were trained
127 to drink formula-milk from rubber teats attached to the milk feeder (Förster Technik® TAP5-EZ2), first
128 every 3 hours and then once a day until they were capable of feeding themselves in this way. From 2
129 weeks after birth, lambs had access to feed pellets. However, regular consumption of the pellets only
130 began around the time of weaning (approximately 45 days after birth). At weaning, milk was
131 withdrawn and lambs were fed with a solid daily food diet of hay and pellets. From the flock of
132 artificially-reared lambs, 5 males and 5 females were selected to participate in the training protocol -
133 the MRI group. The 5 males were castrated before puberty (\approx 4 months after birth) to maintain a stable
134 mixed sex group and to avoid aggressive behaviors towards the trainers. The MRI group was housed
135 either in a sheepfold or outside in a field depending on the season/weather (Figure 1 A, B). In their
136 home pen (20.7 m²) of the sheepfold they had *ad libitum* access to water and mineralised salt, while
137 daily quantities of pellets and hay were distributed. The field (2020 m²) was equipped for an *ad libitum*
138 access to water and mineralised salt. The sheep could graze in the field but a supplement of hay and
139 pellets was also distributed. Toys (e.g., balls, plastic cubes hung in trees, traffic cones) and bales of
140 straw were placed in the field to enrich the environment (Figure 1 B, C).

164

165 **Trainers**

166 Four main trainers (2 men: SAL, DD; 2 women: CaP, CeP) implemented the training protocol.
167 None had any previous experience in animal training. Punctually, eight other people helped with the
168 training. During a training session at least two trainers were present. This was necessary for safety and
169 because the training was physically demanding. All trainers received safety training before being
170 permitted to enter the MRI room.

171

172 **Training philosophy**

173 Our training approach was based on positive reinforcement, a positive human-animal
174 relationship and voluntary cooperation of the animal. For positive reinforcement, we used food
175 reward, verbal encouragement, cuddling and stroking. After successful performance of a requested
176 behavior, the lambs were rewarded with one or a combination of these reinforcers depending on the

177 individual's preference. Food reward was also used to lure the sheep into conducting specific
178 behaviors. In general, our strategy was to adapt our training protocol to the performance of each
179 individual. Because of the differences in motivation between each individual of the MRI group, we did
180 not impose a specific delay for the learning of the required behaviors. Moreover, it was possible that
181 lambs did not cooperate during a training session. In which case, they were not forced to work and
182 training was stopped until the next session. We ensured that lambs were free to move, never tethered
183 to the MRI table and could leave the training session at any time. Sheep are a very gregarious species
184 that will display extreme signs of distress if isolated from the flock. For this reason we initially planned
185 to always train one sheep in the presence of at least one other. However, unlike in the case of dogs
186 (Andics et al., 2014) our attempts to train with more than one sheep at a time proved problematic.
187 The sheep tended to interact with each other. Therefore, we finally chose to train and acquire data
188 with one individual at a time. To do so we habituated them to not feel isolated from the group when
189 they were in the presence of a trainer.

190 **MRI Group selection**

191 For two weeks after the lambs were separated from their mother, two trainers (CaP, SAL)
192 spent approximately 2 hours with them in the single pen twice a day, seven days a week. The main
193 aims of this phase were to familiarize lambs to humans and to select the ten individuals of the MRI
194 group. Initially, the trainers sat almost passively in the single pen waiting for the lambs to interact with
195 them. Over the next few days the trainers increased from passively to actively interacting by placing a
196 hand on their back, stroking their back, scratching under their neck or stomach etc. When the majority
197 of lambs were clearly comfortable with the presence of the trainers, a variety of objects were
198 introduced into the single pen: baby toys, foam and a ramp. These objects enriched the environment
199 and some were specifically chosen to begin introducing the behaviors to be learned during the 2
200 phases of the training protocol. The trainers encouraged the lambs to walk onto the ramp and also
201 placed the foam on, or gently wrapped it around, their head. Based on the positive interactions

202 expressed by individual lambs toward the trainers and their ease with the objects introduced into the
203 single pen, 10 lambs were selected and moved to the home pen (Figure 1). These 10 lambs (5 males:
204 Léonard, Ted, Tony, Joe and Jackson; 5 females: Brook, Maggie, Robin, Lily and Barnita) then
205 participated in the training protocol.

206 **Training protocol**

207 After selecting the 10 lambs of the MRI group, the training protocol was divided into 2 main
208 phases: 1) Learning MRI acquisition-related behaviors and; 2) Training in the real MRI room. Each
209 phase consisted of successive steps performed in the same order for each lamb (Table 1) but not
210 necessarily at the same time. We predicted that the noise produced by the MRI scanner could seriously
211 hinder the chance that sheep would be able to stay motionless inside the scanner. For this reason,
212 they were habituated to the sounds of the MRI scanner throughout the 2 phases of the protocol.
213 Initially, MRI sounds were occasionally played via a Bluetooth speaker (Bang & Olufsen Beosound A1
214 2nd generation) for about 5 minutes in the home pen to the entire MRI group. The volume of the sound
215 was gradually increased over time from 60 to 85 dB. Then, it was often the case that when an individual
216 began to achieve a particular training step we would have them perform it also in the presence of the
217 MRI sounds. Based on our observation that the lambs performed better in the morning than in the
218 afternoon, we chose to conduct the majority of our training sessions in the morning. In general a
219 session lasted approximately 10-20 minutes per individual.

220 ***Learning MRI acquisition-related behaviors (Phase 1)***

221 Phase 1 training sessions took place in the training pen (20.7 m²), which contained custom-
222 made mock MRI acquisition equipment (mock MRI scanner with ramp, Figure 2A, mock Radio
223 Frequency (RF) head coil, Figure 2B). The home pen and the training pen were adjacent and connected
224 by a gate. During the first week of training, the 10 lambs were trained together and could move freely

225 between the home and training pens. They were then trained in groups of 4 and were no longer
 226 allowed free access to the two pens. After 1 month of training, the 10 lambs were each trained alone.

227 During Phase 1, lambs were trained in MRI-related behaviors following 5 successive steps:
 228 climbing the ramp, lying down on the mock MRI table, staying still while the mock MRI table moved
 229 back and forth, being equipped with the mock RF head coil and waiting motionless for several minutes
 230 (Table 1, Figure 2, C-D). Phase 1 lasted approximately 5 months, during which the lambs were trained
 231 4 to 5 times a week.

232

 242 *on the moveable mock MRI table (dashed pink arrow), on a comfortable blue mat, in front of the mock*
 243 *MRI bore; D) Léonard waiting motionless with his head inside the mock RF head coil.*

244

245 In detail, for this phase of the training protocol, the mock MRI scanner and the mock RF coil
 246 were custom-made by the technical staff of the laboratory. The mock MRI scanner was built based on
 247 the dimensions of the real scanner and made of metal, wood and plastic. It consisted of a fixed base
 248 (length = 234 cm x width = 63 cm x height = 44 cm), a movable patient bed (length = 160 cm x
 249 width = 50 cm) and a mock bore (length = 141 cm x width = 73 cm x height = 142 cm). The mock
 250 patient bed had wheels that were inside rails, enabling it to be pushed in and out of the mock bore.

251 The spherical mock RF head coil (diameter: 24 cm; Figure 2B) was created using PVC plastic to mimic
252 our actual spherical 24-channel sheep's head coil (RAPID Biomedical GmbH, Rimpar, Germany, 1H
253 Phased Array for Sheep Brain P-H24LE-030-01808, Figure 3C). A ramp with a slip-resistant surface
254 (length = 140 cm x width = 63 cm x height = 51 cm, slope = 34%) was built to allow lambs to walk up
255 and down onto the patient table. The height of the ramp was equivalent to the real MRI patient table
256 in its lowest position.

257 Lambs were trained using French verbal signals to indicate a desired behavior: "patte" for
258 learning to bend their front legs over their knees, "couché" for learning to bend their back legs and lie
259 down (step 2 in Table 1), and "pose" for learning to stay motionless. Sheep learned to stay in the lying
260 down position while table movements were initiated manually back and forth (step 3 in Table 1), to
261 move their head in the right position into the mock MRI bore (step 4 in Table 1). Foam padding was
262 placed between the head and mock RF coil to minimize head motion. At this time of the training
263 protocol, the lambs were trained to wait (step 5 in Table 1). The interval between posing the head
264 inside the coil and the reward was gradually increased (a few seconds at the beginning to 5 – 10
265 minutes at the end of this step). During this step, the lambs must be as motionless as possible to
266 express the behavior required during real MRI sessions.

274

275

276

277 **Table 1** *Behaviors of the Step-by-Step Training Protocol*

Training phase	Step	Training criterion
Learning MRI behaviors		
(Phase 1)	1	Climb a ramp to reach the mock MRI table
	2	Lie down on the mock MRI table
	3	Stay still on the moving mock MRI table
	4	Place head in the mock RF head coil
	5	Wait motionless with the head inside the mock coil (at least 5 min)
+	Habituation to the scanner noise (from 60 to 85 dB over sessions)	
Real MRI room		
(Phase 2)	1	Climb the ramp to reach the patient MRI table and lie down on the table
	2	Lie still while the table rises and lowers
	3	Headphones on the ears
	4	Place head in the real coil with foam to wedge their head
	5	Move forward to the center of the scanner bore
	6	Stay motionless inside the scanner bore with MRI sounds
+	Habituation to the scanner noise in the real MRI environment	

278

279

280

281

282

283 Training in the MRI room (Phase 2)

284 This phase of the training took place within the MRI room at the imaging platform PIXANIM
285 (Phénotypage par Imagerie in et ex vivo de l'Animal à la Molécule, [https://doi.org/10.17180/CQ4D-](https://doi.org/10.17180/CQ4D-DW26)
286 [DW26](https://doi.org/10.17180/CQ4D-DW26)). As the MRI was located approximately 500 meters from the animal facilities, sheep learned to
287 walk between their home pen and the imaging platform where they were housed together in a waiting
288 pen (surface: 15 m², Figure 3A) before and after a training session. At the end of each training session,
289 sheep walked back to their home pen. The aim of this training phase was for the sheep to implement
290 the learned MRI acquisition-related behaviors in the real MRI environment. The main differences
291 between the mock and the real MRI environments are the noise, the temperature, the light, the table
292 lifting up and down via a controlled step motor, the height of the table and meeting new people
293 working at the platform. Moreover, sheep had to acquire new skills such as accepting to wear
294 headphones, which were essential to protect their ears. They also had to remain motionless in the
295 MRI bore with all the equipment required for acquisition (headphones, thicker foam around the head,
296 etc.). This phase included six steps (Real MRI room phase, Table 1) during which the sheep were
297 trained 2 to 5 times a week for about 3 months.

298 The first training step was to express previously learned behaviors in the novel environment
299 of the MRI room: climb up the ramp and lay down on the patient MRI table (figure 3B). To facilitate
300 this step, the ramp used during phase 1 was placed alongside the patient table in its lowest position.
301 A plastic-covered foam mat was placed on the patient table to provide greater comfort, prevent
302 damage and make it easier to clean the table. The second step required the sheep to lie still while the
303 table automatically rose and lowered. Once the sheep were lying on the table in the raised position,
304 we put headphones (MR Confon, Magdeburg, Germany) on their ears (step 3 in Table 1). To maintain
305 the headphones in place, a headband was created with muslin tights. The next step (step 4 in Table 1)
306 was to use the real 24-channel head coil. For safety, the coil was attached to the table with straps
307 (Figure 3C), but sheep were free to place and remove their head from it at any time without injury to
308 them or damage to the coil. Once the sheep's head was well positioned in the center of the coil, foam

309 was placed around the snout to minimize motion (Figure 4A). These pieces of foam have been
310 specifically created to fit the shape of a sheep's snout. The number and thickness of the foam pieces
311 used depended on both the sheep's ability to keep their head motionless in the coil and their head
312 size. The sheep was then automatically moved forward to the center of the scanner bore (step 5 in
313 Table 1). Once the sheep was placed in the center of the bore, they were asked to stay motionless
314 (step 6 in Table 1). During step 6, the time between the moment the sheep was moved to the center
315 of the bore and the reward delivery was gradually increased (within and between sessions). The rate
316 of the interval increase was entirely dependent on the sheep. It is important to note the position of
317 trainers during this step. One trainer directly faced the sheep from the back of the bore while, at least,
318 one other was at the front of the bore with a hand placed on the sheep's back. Once sheep were
319 capable of lying motionless in the center of the bore for several minutes (2 – 4 minutes), MRI sounds
320 were played (volume from 60 to 85 dB). Once step 6 was completed, the sheep had successfully
321 learned all the behaviors required to perform MRI acquisitions.

332

333

334 Brain MRI acquisitions

335 During an awake MRI acquisition session, sheep were required to implement the MRI
336 acquisition-related behaviors that they had learned. Our proof-of-concept awake sheep MRI session
337 took approximately 5 minutes. MRI was conducted using a 3T Siemens Magnetom® Verio scanner
338 (maximum gradient amplitude of 45 mT/m). Data acquisition included an initial localizer scan (33
339 seconds) followed by a T1-weighted structural image of the whole brain (2 min 36) using a 3D
340 magnetization-prepared rapid gradient echo (MPRAGE) sequence (TR = 2200 ms, TE = 2.64 ms, flip
341 angle = 12°, 448 x 448 matrix and, FOV = 500 mm with a slice thickness of 1.12 mm resulting in an
342 isotropic 1.12 x 1.12 x 1.12 mm³ voxel size). Sheep were in a head first, prone position (Figure 4). Slices
343 were oriented sagittally to the sheep's brain with the phase-encoding direction ventro-dorsally.

Results

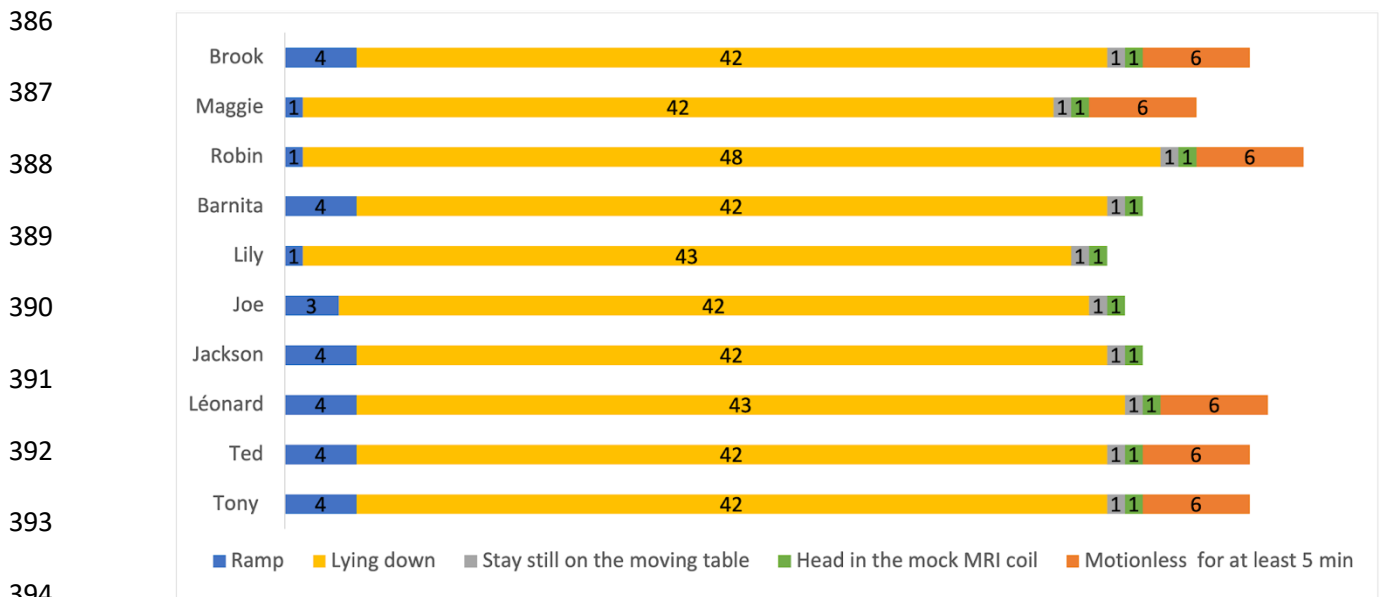

Group selection

From the artificially-reared lambs, the 10 selected were those that displayed the most positive interactions (strokes, food reward) with the trainers and the most ease with the MRI related objects. During the MRI group selection, all 10 lambs expressed a spontaneous preference for the trainers. Lambs approached the trainers and to a lesser extent other humans as soon as they were near the pen but they only sought contact with trainers. The gradual increase in the number of people working with them (4 main trainers and 8 other people) during the training protocol enabled all lambs to spontaneously approach unfamiliar people. Two months after the beginning of familiarization with the trainers, the 10 lambs showed this ability to generalize to all humans. At 2 – 3 weeks of age (mid-March 2022), all 5 females and 1 male (Joe) accepted to have a piece of foam held around their head. However, the 4 other lambs (Jackson, Léonard, Ted and Tony) didn't easily accept the foam around their head.

Learning MRI acquisition-related behaviors (Phase 1)

After selecting the MRI group, the mock MRI was set up and training sessions began in the training pen. The lambs came spontaneously into the training pen and quickly interacted with MRI-related equipment. Throughout the different steps of Phase 1, progress differed between the individuals (Figures 5). From the first training session with the ramp, Maggie, Robin and Lily walked up and down the ramp to receive a reward. It took 3 training sessions for Joe and 4 for Brook, Barnita, Jackson, Léonard, Ted and Tony to achieve this step. In 4 training sessions, all 10 lambs in the MRI group were capable of walking up and down the ramp to reach the mock MRI table.

385 **Figure 5**

395 *Number of training sessions for each individual (Brook, Maggie, Robin, Barnita, Lily, Joe, Jackson,*
 396 *Léonard, Ted, Tony) and for each step to be achieved during Phase 1. Note that the absence of the*
 397 *orange line for Barnita, Lily, Joe and Jackson indicates that this step was not successfully completed.*

399 Figure 5 shows that the “Lying down” behavior was the longest step of phase 1. During this
 400 step, which lasted approximately 2 months, the lambs learned to lie down on the table by first bending
 401 their front legs to follow a food lure, then their hind legs. The 10 lambs needed between 42 to 48
 402 training sessions to learn how to lie down on the mock MRI table by themselves, following the verbal
 403 signals corresponding to the requested behavior. Once the “Lying down” behavior was learned,
 404 forward and backward movements of the mock MRI table were initiated. No habituation was required,
 405 as from the first training session for this step, the lambs stayed still on the table while it was in motion.
 406 The mock RF head coil was introduced during the next training sessions. Once again, no habituation
 407 was required for this step. The lambs could be lured to place their head in the mock RF coil from the
 408 first training session with this equipment.

409 The last step of this phase of the training protocol consisted in teaching the lambs to wait
 410 motionless with their head in the mock RF coil for at least 5 minutes. Brook, Maggie, Robin, Léonard,

411 Ted, and Tony successfully achieved this step after 6 training sessions. The 4 other lambs of the MRI
412 group (Barnita, Lily, Joe, Jackson) are not yet capable of waiting motionless long enough with their
413 head in the mock RF coil. However, we decided to begin training in the real MRI environment with all
414 sheep, as it was evident that they were obedient and calm and that they would not harm themselves
415 or the MRI equipment.

416

417 **Training in the MRI room (Phase 2)**

418 For each training session in the MRI room, the 10 sheep had to walk from their home pen to the
419 imaging platform. Trips were conducted with the whole MRI group. The 10 sheep always walked
420 voluntarily between the imaging platform and their home pen. The first training session in the MRI
421 room took place from August 26, 2022 with Maggie, Robin and Ted (approximately 5 months old) to
422 October 26, 2022 with Barnita. From their first training session, each sheep entered the MRI room,
423 walked up the ramp and lay down on the MRI table (Figure 6). They did not show any stress reaction
424 (no vocalization, no defecation, relaxed, etc.). Except for Maggie, they all accepted that the patient
425 table was elevated to its highest position. Maggie accepted that the table was raised during the second
426 training session in the MRI room. These results suggest that the sheep generalized the MRI-related
427 behaviors learned during phase 1 to the real MRI environment of phase 2.

428 MRI acquisitions are extremely noisy, reaching sound pressure levels of up to 130 dB.
429 Headphones are placed over the sheep's ears to protect them from this noise. During the first training
430 session involving headphones, none of the 10 sheep displayed any negative reaction to wearing either
431 the headphones or the tight wrapped around their head to keep them in place.

432 The next step consisted of placing the head in the RF coil with foam between the coil and the
433 head to wedge them in and minimize head movements. Once again, no habituation was required for
434 this step. The sheep could be lured into placing their head inside the coil and accepted to have foam
435 placed around their heads from the first attempt. A single training session was then sufficient to know

436 that the sheep would remain lying down, with their head inside the coil until the table reached the
 437 center of the scanner bore.

438

440

449

450 *Number of training sessions for each individual (Brook, Maggie, Robin, Barnita, Lily, Joe, Jackson,*
 451 *Léonard, Ted, Tony) and for each step to be achieved during Phase 2. Note that the absence of the*
 452 *orange line for Barnita, Lily, Joe and Jackson indicates that this step was not successfully completed.*

453

454 The final step in this training protocol was to teach the sheep to stay motionless inside the
 455 scanner bore for several minutes, with their head inside the RF coil and listening to the MRI sounds.
 456 However, Barnita, Lily, Joe and Jackson have not yet reached the final step of phase 2 of the training
 457 protocol. They are still learning to stay motionless inside the scanner bore long enough for an
 458 acquisition. The other 6 sheep (3 females and 3 males) in the MRI group successfully achieved this
 459 step. Tony learned to stay motionless in the scanner bore for several minutes, with his head inside the
 460 RF coil, while listening to the MRI sounds in 10 training sessions, Robin and Brook in 11 training
 461 sessions, Léonard in 13 training sessions, Ted in 17 training sessions and Maggie in 18 training sessions.

462 Success in this final step for 6 of the sheep was marked by the acquisition of a T1-weighted
 463 structural image without the need for anesthesia or restraint after almost 9 months of training (Figure
 464 7, data accessible at: <https://zenodo.org/doi/10.5281/zenodo.10044453>). A video showing a
 465 successful acquisition can be viewed here, <https://zenodo.org/doi/10.5281/zenodo.10213970>. The
 466 resulting images are comparable to those obtained with the same sequence in sheep under general
 467 anesthesia (Figure 7).

 483 *awake-unrestrained sheep (Léonard, Maggie, Brook, Robin, Ted, Tony, Lily)*

484

485 It is important to note that the lambs were habituated to the sounds of the MRI scanner first
 486 in their home pen with the entire group, then alone during phases 1 and 2 of the training protocol. No
 487 specific reaction (withdrawal, attempt to flee, vocalizations, ear movements, etc.) was noticed when

488 the recorded MRI sounds were played in the different locations (i.e., home pen, training pen or MRI
489 room), or to the sounds of an actual acquisition.

490

491

Discussion

492 This study proposes a step-by-step training protocol, based on positive reinforcement, to
493 enable sheep to perform MRI acquisitions over several minutes without anesthesia or restraint. One
494 of the aims of this work was to refine the procedure of conducting MRI with sheep by removing the
495 potentially negative health effects of general anesthesia and to preserve neurovascular coupling,
496 which is disrupted by anesthetic agents (Aksenov et al., 2015). To date, T1-weighted structural images
497 have been acquired from 6 out of the 10 sheep in the MRI group. The resulting images are comparable
498 to those obtained in sheep under general anesthesia, demonstrating the feasibility of acquiring MRI
499 brain images without the use of anesthetic agents or physical restraint of the individual. Awake sheep
500 can remain as motionless as sheep under general anesthesia in a noisy and spatially enclosed MRI
501 environment. Using this training protocol, anesthesia-related side effects are avoided and cognitive
502 processes could be investigated in future fMRI studies with awake and unrestrained sheep.

503 This protocol was an ideal approach for teaching sheep the behaviors required to successfully
504 perform structural MRI acquisitions of their brain. Despite the time-consuming nature of the training
505 protocol, overall it was relatively straightforward to implement. As with dogs, we used a step-by-step
506 training protocol involving training with a mock MRI scanner to learn the MRI acquisition-related
507 behaviors, then implementing these behaviors during training sessions in the real MRI room (Karl et
508 al., 2020; Strassberg et al., 2019). Despite the differences in temperature, brightness and noise
509 between the MRI room and the training pen, the sheep easily transferred from the training pen to the
510 MRI room (i.e., a single training session for steps 1, 2, 3, 4, 5 in phase 2), and showed no negative
511 reaction. In this way, the sheep generalized the acquisition behaviors they had learned during the
512 phase 1 training pen sessions. Therefore, the training sessions in the real MRI environment really
513 began directly at the step, “staying motionless inside the scanner bore for several minutes, with their

514 head inside the RF coil". However, four sheep have not yet succeeded in this final step of phase 2,
515 which we highlight as a critical step in this training protocol.

516 MRI acquisitions require the individual to be completely immobile to prevent motion artifacts
517 and obtain accurate images. However, it is demanding for non-human and human animals alike to
518 remain motionless in a closed, noisy environment for several minutes (Enders et al., 2011; King et al.,
519 2005; Lukins et al., 1997). Teaching sheep to hold their heads motionless inside the enclosed sheep RF
520 coil was a critical step in this training protocol. Six sheep in the MRI group successfully achieved this
521 last step, enabling them to perform T1-weighted acquisitions. The 4 other sheep are still not yet able
522 to stay motionless long enough with their head inside the RF coil to perform an MRI acquisition. We
523 believe that there are at least three possible reasons for this. First, as it became clear that these 4
524 sheep were progressing slower than the 6 others, we began to spend less time training with them and
525 more time with the 6 other sheep. Second, perhaps our choice of training technique was less
526 appropriate for these 4 sheep and did not enable them to understand the instructions well enough to
527 successfully complete this step of the protocol. Recently, we have started to use the "clicker training"
528 technique (Skinner, 1951) with them and we have seen improved progress in their ability to stay
529 motionless. Third, it is also possible that they, and a certain proportion of sheep in general, will never
530 be capable of staying motionless long enough to acquire MRI data. However, we feel that this is the
531 least likely possibility and that with enough time and the correct technique the vast majority of sheep
532 will be capable of completing an MRI acquisition.

533 We also identified that the "lying down" behavior was a critical step for all the sheep in this
534 protocol. Initially, it was complicated to find a technique that could lie the sheep down. After
535 approximately twenty training sessions we discovered the appropriate technique (described in the
536 Method section). Then after another approximately twenty sessions, all ten sheep successfully
537 completed this step. Therefore, repeating this protocol with a new group of sheep would take less
538 time since we already have a well-developed technique to lie the sheep down (a video of this
539 technique can be viewed at <https://zenodo.org/doi/10.5281/zenodo.10213970>).

540 Our training protocol is based on positive reinforcement, with a social or a food reward for
541 each correctly performed behavior. Initially we tried different options of food reward (carrot, apple,
542 beet biscuits & pellets) to motivate the behavior. Lambs showed no real interest in apples, carrots
543 (used in Duffrene et al., 2022 with adults) or beet biscuits but only for pellets. These pellets are those
544 used in the daily diet and are the most suitable food reward for Ile-de-France sheep in a livestock
545 context. However, before weaning lambs were not motivated by solid food as they were fed
546 exclusively with a milk diet at that stage of development. Therefore, social rewards played an
547 important role in the beginning of the training protocol in particular. The sheep were very receptive
548 to praise and strokes from the first training sessions as they had experienced such positive interactions
549 from birth during the familiarization with trainers. The positive trainer–lamb relationship was essential
550 for the success of this training protocol. Indeed, in the context of our study (separation from the
551 mother, artificial rearing, positive interactions with trainers), the lambs considered trainers as
552 attachment figures (Guesdon et al., 2016; Tallet et al., 2005). Thus, they easily explored new
553 environments and objects and accepted to train without conspecifics but in the presence of trainers.
554 These observations suggest that trainers may be considered as congeners for the sheep. An open
555 question in this regard is whether it is necessary or not to build this positive trainer-lamb relationship
556 from birth.

557 In conclusion, we present a proof-of-concept that sheep can be trained to voluntarily perform
558 brain MRI acquisitions without anesthesia and without restraint. Our training protocol is perfectly
559 suited to teaching sheep the behaviors required for an MRI acquisition. It provides an animal welfare-
560 friendly protocol limiting any form of physical restraint by never tethering sheep to the MRI table and
561 allowing them to leave at any time during a session. The motivation of both sheep and trainers at
562 every step of this reward-based training ensured the success of the protocol. By acquiring T1-weighted
563 structural images with our MRI sheep group, a new species has joined the era of awake, unrestrained
564 neuroimaging.
