# The structure of the food matrix at different length scales drives the mechanism of digestion and the nutrient bioaccessibility and bioavailability

Dr Didier DUPONT, INRAE, STLO, Rennes, France

# Food and human health: the key role of digestion

Diet-related diseases ↑  
Prevent these pathologies rather than  
cure them

**Gut = interface between food and human body**

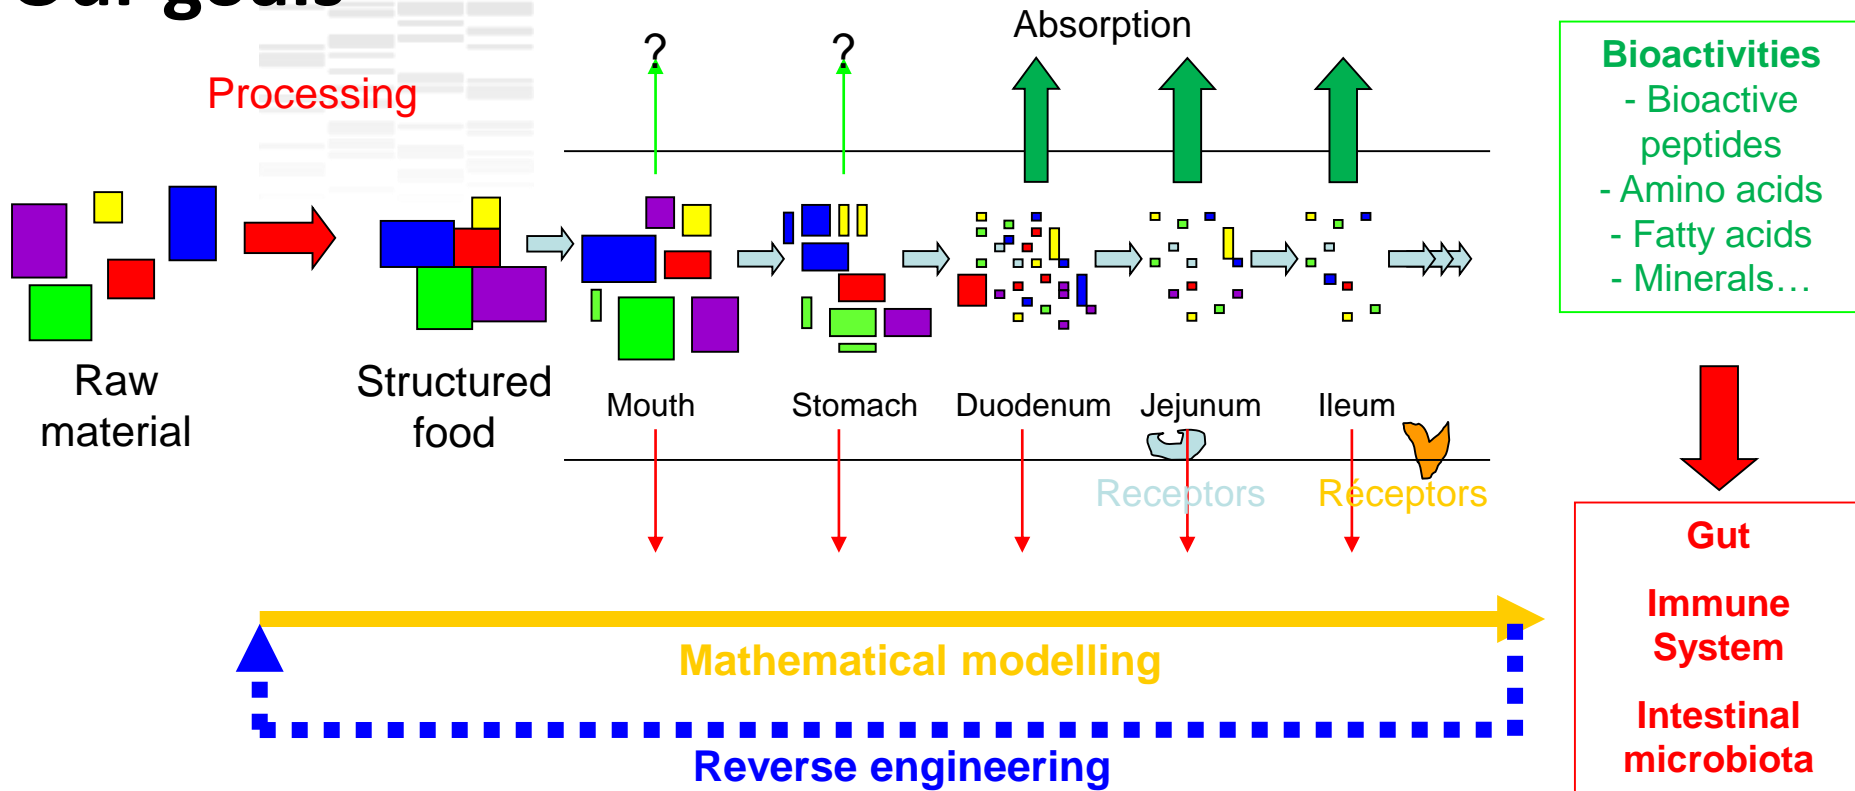

**Digestion releases food components that can have a beneficial or a deleterious effect on human health**

... but the mechanisms of food disintegration in the gastrointestinal tract remain unclear and the digestive process has been considered as a black box so far

**By increasing our knowledge on food digestion, we will increase our knowledge on the effect of food on human health**

# Our goals

Healthy Adult/ Infant / Elderly

- ☞ To understand the mechanisms of breakdown of food matrices and their constituents in the gut and identify the beneficial/deleterious food components released during digestion
- ☞ To determine the impact of the structure of food matrices on nutrient bioavailability
- ☞ To model these phenomena in order to develop a reverse engineering approach

# The digestive process

From Roger Lentle, Massey Univ. NZ

Gastric phase = a very complex but crucial step for the whole digestion process

# Models available at INRAE for simulating digestion

Non-encapsulated DHA oil

Encapsulated DHA oil

### Distribution of non-encapsulated and encapsulated DHA oil in omelets.

# Lipidomics allows to assess the bioaccessibility of DHA from different lipid species during digestion

Non-encapsulated DHA oil —■—

Encapsulated DHA oil —●—

The evolution DHA from different lipid species during digestion.

In gastric phase (pepsin and RGE):

- DHA oil was not hydrolyzed in gastric phase.

In intestinal phase (bile salt and pancreatin):

- Hydrolyzed TAG and released FFA encapsulation > unencapsulation

- Larger interaction area between DHA oil and pancreatic lipase made by emulsification (*Maljaars, 2012*).

- Around 10-25% and 40-70% of ingested TAG can be hydrolyzed in gastric and intestinal phase, respectively (*Bauer et al; Carriere et al., 1993*).

- Microbiota

# Microbiota by DHPLC

D7 & D28

D28

The composition/structure of the infant formula « orientates » the microbiota

More Proteobacteria with milk fat /  
More Firmicutes with plant oil

# What happens when they become older (140 d)?

If animals are submitted to a nutritional stress (high fat/sugar diet), some differences remain in:

- \* the microbiota composition
- \* the fecal metabolome with different metabolites (including propionate)
- \* the immune system with a reduced susceptibility to inflammation with milk lipids

# Conclusion

The structure/composition of food regulate the kinetics of protein digestion in the gastrointestinal tract and the release of amino acids in the bloodstream

Omic technologies (proteomics, peptidomics, lipidomics...) are great tools to identify the molecules that are released in the gut during digestion and assess the bioaccessibility of nutrients

Being able to design food structures for controlling the kinetics of hydrolysis of macronutrients will allow to obtain food particularly adapted to specific population

# Main objective: understanding the mechanisms of food digestion

- Develop new *in vitro*, *in vivo* and *in silico* digestion models including some for specific populations (infant, elderly)
- Harmonize the methodologies and propose guidelines for performing experiments
- Validate *in vitro* models towards *in vivo* data (animal and/or human)
- Identify the beneficial/deleterious components that are released in the gut during food digestion
- Determine the effect of the matrix structure on the bioavailability of food nutrients and bioactive molecules
