ABSTRACT

Animal venoms and other protein-based secretions that perform a variety of functions, from predation to defense, are highly complex cocktails of bioactive compounds. Gene duplication, accompanied by modification of the expression and/or function of one of the duplicates under the action of positive selection, followed by further duplication to produce multigene families of toxins is a well-documented process in venomous animals. This evolutionary model has been less described in parasitoid wasps, which use maternal fluids, including venom, to protect their eggs from encapsulation by the host immune system. Here, we evidence the convergent recruitment and accelerated evolution of two multigene families of RhoGAPs presumably involved in virulence in two unrelated parasitoid wasp species, *Leptopilina boulardi* (Figitidae) and *Venturia canescens* (Icheumonidae). In both species, these RhoGAPs are associated with vesicles that act as transport systems to deliver virulence factors, but are produced in different tissues: the venom gland in *Leptopilina* sp. and the ovarian calyx in *V. canescens*. We show that the gene encoding the cellular RacGAP1 is at the origin of the virulent RhoGAP families found in *Leptopilina* sp. and *V. canescens*. We also show that both RhoGAP families have undergone evolution under positive selection and that almost all of these RhoGAPs lost their GAP activity and GTPase binding ability due to mutations in key amino acids. These results suggest an accelerated evolution and functional diversification of these vesicle-associated RhoGAPs in the two phylogenetically distant parasitoid species. The potential new function(s) and the exact mechanism of action of these proteins in host cells remain to be elucidated.

Keywords: parasitoids, venom and other secretions, RhoGAP multigene family, evolution, gene duplication, positive selection

45 Gene duplication is recognized as an important evolutionary process because it drives functional
46 novelty (Chen et al., 2013; Long et al., 2013). In particular, the formation of multigene families by repeated
47 gene duplication is a widely studied evolutionary process in several groups of venomous animals (Fry et al.,
48 2009; Wong & Belov 2012; Casewell et al., 2013), but also in some parasites (Akhter et al., 2012; Arisue et
49 al., 2020). Such repeated duplication events of venomous or virulence protein-coding genes are often
50 accompanied by significant copy divergence through positive selection, allowing the acquisition of new
51 functions. In this work, we studied the process of accelerated evolution by duplication and divergence of
52 two multigene families encoding RhoGAPs presumably involved in virulence in two phylogenetically distant
53 parasitoid wasp species, *Leptopilina* species of the family Figitidae and *Venturia canescens* of the family
54 Ichneumonidae.

55 The development of parasitoid wasps occurs at the expense of another arthropod, whose tissues are
56 consumed by the parasitoid larvae, usually resulting in the host death (Godfray 1994). For endoparasitoids
57 that lay eggs inside the host body, the host immune defense against parasitoids is usually based on the
58 formation of a multicellular melanized capsule around the parasitoid egg, resulting in its death (Carton et
59 al., 2008). To escape encapsulation, parasitoids have evolved several strategies, the main one being the
60 injection of maternal fluids together with the egg into the host at the time of oviposition (Pennacchio &
61 Strand 2006; Poirié et al., 2009). These maternal fluids contain (i) proteins synthesized in the venom glands
62 (Asgari & Rivers 2010; Poirié et al., 2014), some of which, as in *Leptopilina*, can be associated with
63 extracellular vesicles called venosomes and allow their transport to the targeted immune cells (Gatti et al.,
64 2012; Wan et al., 2019), (ii) proteins synthesized in the ovarian calyx cells and associated with particles of
65 viral origin devoid of nucleic acid and named virus-like particles (VLPs) as in *V. canescens* (Reineke et al.,
66 2006; Gatti et al., 2012; Pichon et al., 2015), and (iii) polydnviruses (PDVs) integrated into the parasitoid
67 genome and found in some groups of parasitoids belonging to the families Braconidae and Ichneumonidae
68 (Drezen et al., 2014). Like VLPs, PDVs are synthesized in the ovarian calyx cells and are present in the
69 ovarian fluid along with the egg. These particles are unique in that they are formed by the integrated viral
70 machinery, but carry circular double-stranded DNA molecules that contain virulence genes that will be
71 expressed in the host cells (Drezen et al., 2014). The process of accelerated evolution by duplication and
72 divergence has been described for some of these virulence genes carried by PDVs, suggesting functional
73 diversification of the proteins produced (Serbielle et al., 2008; Serbielle et al., 2012; Jancek et al., 2013).

74 *Leptopilina boulardi* is a parasitoid wasp of *Drosophila* for which two lines have been well characterized
75 (Dubuffet et al., 2009). The ISm line of *L. boulardi* is highly virulent against *Drosophila melanogaster* but is
76 unable to develop in *Drosophila yakuba* whereas the ISy line can develop in both *Drosophila* species but its
77 success depends on the resistance/susceptibility of the host (Dubuffet et al., 2009). One of the most
78 abundant proteins in the venom of the *L. boulardi* ISm line belongs to the Rho GTPase activating protein
79 (RhoGAP) family and has been named LbGAP (Labrosse et al., 2005; Colinet et al., 2013). A LbGAP homolog
80 named LbGAPy is also present in the venom of the *L. boulardi* ISy line, but in lower amounts (Colinet et al.,
81 2010; Colinet et al., 2013). While RhoGAPs are usually intracellular proteins composed of several different
82 domains (Tcherkezian & Lamarche-Vane 2007), LbGAP and LbGAPy contain only one RhoGAP domain
83 preceded by a signal peptide that allows its secretion. LbGAP has been shown to be associated with and
84 transported by venosomes to target host hemocytes (Wan et al., 2019). LbGAP and LbGAPy specifically
85 interact with and inactivate two *Drosophila* Rho GTPases, Rac1 and Rac2 (Colinet et al., 2007; Colinet et al.,
86 2010), which are required for hemocyte proliferation in response to parasitism, hemocyte adhesion around
87 the parasitoid egg, or the formation of intercellular junctions necessary for the capsule formation (Williams
88 et al., 2005; Williams et al., 2006). Combined transcriptomic and proteomic analyses have identified eight
89 additional RhoGAP domain-containing venom proteins in addition to LbGAP and LbGAPy for both *L.*
90 *boulardi* lines, suggesting that a multigene family has derived from repeated duplication (Colinet et al.,
91 2013). One of these venom RhoGAPs, LbGAP2, has also been shown to be associated with venosomes in *L.*
92 *boulardi* ISm and to be released with LbGAP in host hemocytes (Wan et al., 2019). Interestingly, three
93 RhoGAP domain-containing venom proteins have also been identified in the closely related species
94 *Leptopilina heterotoma* (Colinet et al., 2013), suggesting that the recruitment of RhoGAPs in the venom
95 arsenal may have occurred before the separation of the two species.

96 *Leptopilina* venom RhoGAPs are not the only example of the possible use of a protein from this family
97 in parasitoid virulence (Reineke et al., 2006; Du et al., 2020). In the Ichneumonidae *V. canescens*, a RhoGAP
98 domain-containing protein known as VLP2 (named VcVLP2 in this paper) was found to be associated with
99 VLPs formed in the nucleus of ovarian calyx cells (Reineke et al., 2006; Pichon et al., 2015). VLPs, which
100 package proteic virulence factors wrapped into viral envelopes, are then released into the ovarian lumen
101 to associate with eggs and protect them from the host immune response by as yet unknown mechanisms
102 (Feddersen et al., 1986). These observations suggest convergent recruitment of proteins belonging to the
103 same family and injected into the host with the egg in two phylogenetically distant parasitoid species.

104 In this work, we showed that VcVLP2 in *V. canescens*, like LbGAP in *Leptopilina*, is not unique but is part
105 of a multigene family of virulent RhoGAPs associated with extracellular vesicles. RhoGAPs from different
106 organisms are grouped into distinct subfamilies based on similarities in RhoGAP domain sequence and
107 overall multi-domain organization (Tcherkezian & Lamarche-Vane 2007). Our analyses indicate that an
108 independent duplication of the RacGAP1 gene, a member of the large RhoGAP family, was the origin of the
109 virulent RhoGAP multigene families found in *Leptopilina* and *V. canescens*. We then performed
110 comparative analyses to understand the duplication events at the origin of these two multigene families.
111 Finally, we demonstrated evolution under positive selection for both RhoGAP multigene families in *L.*
112 *boulardi* and *V. canescens*, suggesting accelerated evolution and functional diversification.

113

Methods

114 Biological material

115 The origin of the *L. boulardi* isofemale lines ISm (Lbm; Gif stock number 431) and ISy (Lby; Gif stock
116 number 486) has been described previously (Dupas et al., 1998). Briefly, the ISy and ISm founding females
117 were collected in Brazzaville (Congo) and Nasrallah (Tunisia), respectively. The *L. heterotoma* strain (Lh; GIF
118 stock number 548) was collected in southern France (Gotheron). The Japanese strain of
119 *Leptopilina victoriana* (Lv), described in Novković et al., 2011, was provided by Pr. M. T. Kimura (Hokkaido
120 University, Japan). All parasitoid lines were reared on a susceptible *D. melanogaster* Nasrallah strain (Gif
121 stock number 1333) at 25 °C. After emergence, the wasps were maintained at 20 °C on agar medium
122 supplemented with honey. All experiments were performed on 5- to 10-day-old parasitoid females.

123 Phylogeny of members of the Cynipoidea superfamily

124 The phylogeny of selected members of the Cynipoidea superfamily was constructed using internal
125 transcribed spacer 2 (ITS2) sequences available at NCBI (Supplementary Table S1). Multiple sequence
126 alignment was performed using MAFFT with the --auto option (Kato & Standley 2013). Poorly aligned
127 regions were removed using trimAl with the -automated1 option (Capella-Gutierrez et al., 2009).
128 Phylogenetic analysis was performed using maximum likelihood (ML) with IQ-TREE (Minh et al., 2020).

129 Search for candidate venom RhoGAPs in *Leptopilina* transcriptomes

130 *L. victoriana* venom apparatus, corresponding to venom glands and associated reservoirs, were
131 dissected in Ringer's saline (KCl 182 mM; NaCl 46 mM; CaCl₂ 3 mM; Tris-HCl 10 mM). Total RNA was
132 extracted from 100 venom apparatus using TRIzol reagent (Invitrogen) followed by RNeasy Plus Micro Kit
133 (QIAGEN) according to the manufacturers' instructions. The quality of total RNA was checked using an
134 Agilent BioAnalyzer. Illumina RNASeq sequencing (HiSeq 2000, 2 × 75 pb) and trimming were performed
135 by Beckman Coulter Genomics. The raw data are available at NCBI under the BioProject ID PRJNA974978.
136 Sequence assembly was performed using the "RNASeq de novo assembly and abundance estimation with
137 Trinity and cdhit" workflow available on Galaxy at the BIPAA platform (<https://bipaa.genouest.org>).

138 *Leptopilina clavipes* (whole body), *Ganaspis* sp. G1 (female abdomen), *Andricus quercuscalicis* (whole
139 body) and *Synergus umbraculus* (whole body) transcriptomes were obtained from NCBI under accession
140 numbers GAXY00000000, GAIW00000000, GBNY00000000 and GBWA00000000, respectively. Coding
141 regions in the transcripts were identified and translated using TransDecoder (Haas et al., 2013), which is
142 available on the BIPAA Galaxy platform. Searches for RhoGAP domain-containing sequences in translated
143 coding sequences were performed using hmmsearch from the HMMER package (Eddy 2009) with the
144 RhoGAP (PF00620) HMM profile.

145 **Completion of *L. bouleari* and *L. heterotoma* venom RhoGAP sequences**

146 Venom apparatus, corresponding to venom glands and associated reservoirs, were dissected in Ringer's
147 saline. Total RNA was extracted from venom apparatus using the RNeasy Plus Micro Kit (QIAGEN) according
148 to the manufacturers' instructions. To obtain the full-length coding sequence of LbGAP1.3, LbGAP5,
149 LbGAPy6, LhGAP1 and LhGAP2, rapid amplification of cDNA ends (RACE) was performed using the SMART
150 RACE cDNA Amplification Kit (Clontech). For LhGAP3, 3' RACE could not be applied due to the presence of
151 poly(A) stretches in the sequence. LhGAP3-matching sequences were searched for in the transcriptome
152 assembly obtained by Goecks et al., 2013) from the abdomen of *L. heterotoma* females (GenBank accession
153 number GAJ000000000) using the command line NCBI-BLAST package (version 2.2.24). The resulting
154 complete LhGAP3 sequence was then verified by RT-PCR using the iScript cDNA Synthesis Kit (BioRad) and
155 the GoTaq DNA Polymerase (Promega), followed by direct sequencing of the amplified fragment. Geneious
156 software (Biomatters) was used for sequence editing and assembly.

157 **Obtention of *Leptopilina* RacGAP1 coding sequences**

158 A combination of RT-PCR and RACE using conserved and specific primers was used to clone the full-
159 length ORF sequence of *L. bouleari* and *L. heterotoma* RacGAP1. The amino acid sequence of *Nasonia*
160 *vitripennis* RacGAP1 (Supplementary Table S2) was used to search for similar sequences among
161 Hymenoptera species using BLASTP at NCBI (<http://www.ncbi.nlm.nih.gov/blast/>). A multiple sequence
162 alignment of the RacGAP1 amino acid sequences found in Hymenoptera was then performed using
163 MUSCLE (Edgar 2004). Two pairs of RacGAP1-specific degenerate primers were designed from the
164 identified conserved regions (Supplementary Figure S1). Total RNA was extracted from Lbm and Lh
165 individuals using the TRIzol reagent (Invitrogen), and RT-PCR experiments were performed using the
166 RacGAP1-specific degenerate primers. After direct sequencing of the amplified fragments, Lbm- and Lh-
167 specific primers were designed to complete the sequences obtained by RT-PCR and RACE (Supplementary
168 Figure S1). The coding sequences of *L. victoriae* and *L. clavipes* RacGAP1 were obtained by BLAST searches
169 in the corresponding transcriptomes using *L. bouleari* and *L. heterotoma* RacGAP1 sequences as queries.

170 **Obtention of the genomic sequences of *Leptopilina* venom RhoGAPs and RacGAP1**

171 The genomic sequences of *Leptopilina* venom RhoGAPs and RacGAP1 were obtained by BLAST and
172 Exonerate searches (Slater & Birney 2005) using the corresponding coding sequences as queries. *L. bouleari*
173 ISm, *L. bouleari* ISy, *L. heterotoma* and *L. clavipes* genome assemblies were obtained from NCBI under
174 accession numbers GCA_011634795.1, GCA_019393585.1, GCF_015476425.1 and GCA_001855655.1
175 respectively.

176 **Search for candidate *V. canescens* RhoGAP calyx sequences**

177 Coding regions were identified from the *V. canescens* calyx transcriptome published by Pichon et al.,
178 (2015) and translated into protein sequences using TransDecoder (Haas et al., 2013). The search for
179 RhoGAP domain-containing sequences was performed using hmmsearch from the HMMER package (Eddy
180 2009) with the RhoGAP (PF00620) HMM profile. The identified RhoGAP calyx sequences were used as a
181 database for Mascot to explore MS/MS data obtained from purified *V. canescens* VLPs (Pichon et al., 2015)
182 with a false discovery rate of 1%. Only proteins identified by two or more peptides were considered.

183 The *V. canescens* RacGAP1 coding sequence was obtained by BLAST searches in the *V. canescens* calyx
184 transcriptome using the *N. vitripennis* RacGAP1 sequence as query.

185 The *V. canescens* calyx RhoGAP and RacGAP1 genome sequences were obtained by BLAST and
186 Exonerate searches (Slater and Birney 2005) using the corresponding coding sequences as queries. The *V.*
187 *canescens* genome assembly was obtained from NCBI under accession number GCA_019457755.1.

188 **Identification of domains and motifs and prediction of subcellular localization**

189 The presence and position of signal peptide cleavage sites in the identified RhoGAP domain-containing
190 sequences were predicted using the SignalP server
191 (<https://services.healthtech.dtu.dk/service.php?SignalP>). The searches for domains and motifs were
192 performed using InterProScan 5 (Jones et al., 2014). Coiled-coil regions were predicted using COILS (Lucas
193 et al., 1991).

194 Prediction of protein subcellular localization and sorting signals for *Venturia* RacGAP1 and calyx
195 RhoGAPs was performed using the DeepLoc2 server ([https://services.healthtech.dtu.dk/services/DeepLoc-
196 2.0/](https://services.healthtech.dtu.dk/services/DeepLoc-2.0/)).

197 Nuclear localization for VcRacGAP1 and calyx RhoGAPs was also predicted using the following three
198 tools: NucPred (Brameier et al., 2007) was used to indicate whether a protein spends part of its time in the
199 nucleus (<https://nucpred.bioinfo.se/nucpred/>), LocTree3 (Goldberg et al., 2014) to provide subcellular
200 localization and Gene Ontology terms (<https://roslab.org/services/loctree3/>), and PSORT II (Nakai &
201 Horton 1999) to detect sorting signals and subcellular localization (<https://psort.hgc.jp/form2.html>).
202 PSORT II results corresponding to ER membrane retention signals and cleavage sites for mitochondrial
203 presequences were included as they may be associated with nuclear localization. Mitochondrial
204 presequences have no sequence homology but possess physical characteristics that allow them to interact
205 with the outer membranes of mitochondria and thus allow the targeting of proteins to the mitochondrial
206 matrix. Regarding mitochondrial targeting, it has been shown from plants to humans that some proteins
207 with mitochondrial presequences are dually targeted to mitochondria and the nucleus (Millar et al., 2006;
208 Mueller et al., 2004). Indeed, anchoring signals to the ER membrane are known to allow baculoviral
209 proteins to migrate to the inner nuclear membrane (Braunagel et al., 1996). Proteins forming VLPs in *V.*
210 *canescens* could thus follow the same pathways as their homologous proteins in baculoviruses, nudiviruses,
211 hytrosaviruses, and bracoviruses due to the conservation of this mechanism among these viruses belonging
212 to the order Lefavirales (Braunagel et al., 1996; Hong et al., 1997; Braunagel et al., 2004; Abd-Alla et al.,
213 2008; Bézier et al., 2009; Braunagel et al., 2009).

214 **Phylogeny of *Leptopilina venom* and *Venturia calyx* RhoGAPs**

215 Searches for *N. vitripennis* RhoGAP sequences were performed using BLASTP at NCBI
216 (<http://www.ncbi.nlm.nih.gov/blast/>) and hmmsearch from the HMMER package (Eddy 2009) with the
217 RhoGAP (PF00620) HMM profile on the *N. vitripennis* v1.2 proteome database (Rago et al., 2016).

218 Multiple amino acid sequence alignments were performed using MAFFT with the --auto option (Kato
219 and Standley 2013). For codon-based analysis of selection (see below), codon-based alignments of
220 complete coding sequences were performed using RevTrans
221 (<https://services.healthtech.dtu.dk/service.php?RevTrans>) with the amino acid alignments as templates.
222 Poorly aligned regions were removed using trimAl with the -automated1 option (Capella-Gutierrez et al.,
223 2009). Phylogenetic analyses were performed using maximum likelihood (ML) with IQ-TREE (Minh et al.,
224 2020). ModelFinder was used to select the best model selection for phylogeny (Kalyaanamoorthy et al.,
225 2017).

226 **Codon-based analysis of selection**

227 Codon-based alignments of complete coding sequences were performed with RevTrans using the
228 amino acid alignments as templates (see above). Phylogenetic analyses were performed using maximum
229 likelihood (ML) with PhyML (Guindon et al., 2010). Smart Model Selection was used to choose the best
230 model selection for the phylogeny (Lefort et al., 2017).

231 To detect evolutionary selective pressures acting on RhoGAP sequences, the ratios of non-synonymous
232 substitutions (dN) to synonymous substitutions (dS) were compared using different ML frameworks: the
233 CODEML program in the PAML (Phylogenetic Analysis by Maximum Likelihood) package (Yang 1997; Yang
234 2007), the HyPhy software implemented at <http://www.datamonkey.org/> (Delpont et al., 2010), and the
235 Selecton server (Stern et al., 2007) available at <http://selecton.tau.ac.il/index.html>.

236 Five different methods were used to detect codons under positive selection. In the first, codon
237 substitution models implemented in CodeML were applied to the codon-based alignment using the F3x4
238 frequency model. Two pairs of site models were used to determine whether some codons were under
239 positive selection: M1a (neutral) versus M2a (selection) and M7 (β) versus M8 (β & ω). The models were
240 compared using a likelihood ratio test (LRT) with 2 degrees of freedom to assess the significance of
241 detection of selection (Yang et al., 2000). Bayes Empirical Bayes (BEB) inference was then used to identify
242 amino acid sites with a posterior probability >95% of being under positive selection (Yang et al., 2005). We
243 then applied four other methods of detection of selection available in the HyPhy package: Single Likelihood
244 Ancestor Counting (SLAC), Fixed Effect Likelihood (FEL), Mixed Effects Model of Evolution (MEME) and Fast
245 Unbiased Bayesian Approximation (FUBAR) methods (Kosakovsky Pond & Frost 2005; Murrell et al., 2012;

246 Murrell et al., 2013). To eliminate false-positive detection, only codons identified by CodeML M2a and M8
247 and at least one of the other methods were considered under positive selection. Radical or conservative
248 replacements were then determined based on whether they involved a change in the physicochemical
249 properties of a given amino acid, such as charge or polarity (Zhang 2000).

250 Four different methods were used to detect codons under negative selection: the Selecton server using
251 the pair of site models M8a (β & $\omega=1$) versus M8 (β & ω), and the FEL, SLAC and FUBAR methods mentioned
252 above. Only codons identified by Selecton and at least one other method were considered under purifying
253 selection.

254 To identify specific lineages with a proportion of sites evolving under positive or purifying selection, we
255 performed branch-site REL analyses using the HyPhy package (Kosakovsky Pond et al., 2011). Unlike the
256 branch and branch-site lineage-specific models available in CodeML, branch-site REL does not require *a*
257 *priori* identification of foreground and background branches.

258 **Structural analysis**

259 Molecular modeling of VcVLP2 RhoGAP was performed using the Phyre server with default parameters
260 (<http://www.sbg.bio.ic.ac.uk/phyre2/>) (Kelley et al., 2015). The model with the highest confidence (100%)
261 and coverage (46%) was obtained using the crystal structure with PDB code 2OVJ as a template. Model
262 quality was evaluated using the QMEAN server (<http://swissmodel.expasy.org/qmean/>) (Benkert et al.,
263 2011). Briefly, the QMEAN score is a global reliability score with values ranging between 0 (lower accuracy)
264 and 1 (higher accuracy). The associated Z-score relates this QMEAN score to the scores of a non-redundant
265 set of high-resolution X-ray structures of similar size, with ideal values close to 0. Visualization of LbGAP
266 (Colinet et al., 2007) and VcVLP2 structures and mapping of sites under selection were performed using
267 PyMol (<http://sourceforge.net/projects/pymol/>). Secondary structure assignment was performed with the
268 DSSP program (Kabsch & Sander 1983). Accessible surface area (ASA) or solvent accessibility of amino acids
269 was predicted using the ASAView algorithm (Ahmad et al., 2004).

270 ***In vitro* mutagenesis**

271 The S76K, V124K, L137D, T143L, S150L, I185K, E200G, and V203R mutations were introduced into the
272 LbGAP cDNA using the QuickChange XL Site-Directed Mutagenesis Kit (Stratagene). The results of *in vitro*
273 mutagenesis were verified by sequencing.

274 **Yeast two-hybrid analysis**

275 Interactions between LbGAP and LbGAP mutants and mutated forms of *Drosophila* RhoA, Rac1, Rac2
276 and Cdc42 GTPases were individually examined by mating as previously described (Colinet et al., 2007).
277 The plasmids expressing the GTPase proteins were tested against the pGADT7-T control vector, which
278 encodes a fusion between the GAL4 activation domain and the SV40 large T-antigen. Reciprocally, plasmids
279 producing LbGAP and LbGAP mutants were tested against the pLex-Lamin control vector. Interactions
280 between LbGAP and the Rac1 and Rac2 GTPases were used as positive controls (Colinet et al., 2007).
281 Interactions were initially tested by spotting five-fold serial dilutions of cells on minimal medium lacking
282 histidine and supplemented with 3-amino-triazole at 0.5 mM to reduce the number of false positives. β -
283 galactosidase activity was then detected on plates (Fromont-Racine et al., 1997).

284 **Purification of Leptopilina venosomes and mass spectrometry analysis**

285 Twenty-five Lbm, Lby and Lh female venom apparatus were dissected, and the reservoirs were
286 separated from the gland and opened to release the venom content in 25 μ l of Ringer's solution
287 supplemented with a protease inhibitor cocktail (Sigma). The venom suspension was centrifuged at 500xg
288 for 5 min to remove the residual tissues, then centrifuged at 15,000xg for 10 min to separate the vesicular
289 fraction from the soluble venom proteins (supernatant fraction) (Wan et al., 2019). The vesicular fraction
290 was then washed twice by resuspension in 25 μ l of Ringer's solution followed by centrifugation at 15,000xg
291 for 10 min. The two samples were mixed with 4x Laemmli buffer containing β -mercaptoethanol (v/v) and
292 boiled for 5 min. Proteins were then separated on a 6–16% linear gradient SDS-PAGE and the gel was silver
293 stained as previously described (Colinet et al., 2013). Identification of proteins by nano-LC-tandem mass
294 spectrometry (MS/MS) was performed on bands excised from the gels as previously described (Colinet et
295 al., 2013). MS/MS data analysis was performed with Mascot software (<http://www.matrixscience.com>),

296 licensed in house using the full-length coding sequences of the *Leptopilina* venom RhoGAP sequences. Data
297 validation criteria were (i) one peptide with individual ion score greater than 50 or (ii) at least two peptides
298 of individual ion score greater than 20. The mascot score is calculated as $-10\log(p)$. The calculated FDR
299 (based on an automated decoy database search) was less than 1%. The mass spectrometry proteomics
300 data have been deposited to the ProteomeXchange Consortium via the PRIDE (Perez-Riverol et al., 2022)
301 partner repository with the dataset identifier PXD041695.

302 Results

303 **Leptopilina venom RhoGAPs probably emerged in the ancestor of the genus**

304 In the Figitidae, venom RhoGAPs have only been described for *L. boulardi* and *L. heterotoma* (Labrosse
305 et al., 2005; Colinet et al., 2013). A search for candidate homologs was performed in the transcriptomes of
306 *L. victoriae* and *L. clavipes*, two other *Leptopilina* species, *Gasnaspis* sp. G1, another member of the family
307 Figitidae, and *Andricus quercuscalicis* and *Synergus umbraculus*, two gall wasp species representatives of
308 the superfamily Cynipoidea outside of Figitidae (separated by approximately 50 Mya (Peters et al., 2017)).
309 The putative venom RhoGAPs were identified based on the presence of a signal peptide at the N-terminus
310 of the protein, followed by a RhoGAP domain (Table 1). Two transcript sequences encoding RhoGAP
311 domain-containing proteins predicted to be secreted were found in *L. victoriae* (LvGAP1 and LvGAP2) and
312 one in *L. clavipes* (LcGAP1), whereas none were found for *Gasnaspis* sp. G1, *A. quercuscalicis* and *S.*
313 *umbraculus* (Table 1 and Figure 1A). Our results therefore suggest that venom RhoGAPs are specific to the
314 genus *Leptopilina* although further taxon sampling would be required to fully support this hypothesis.

315 **Leptopilina venom RhoGAPs likely evolved from a single imperfect duplication of RacGAP1**

316 A phylogenetic analysis was performed to learn more about the evolutionary history of *Leptopilina*
317 venom RhoGAPs. The phylogeny was constructed based on the amino acid sequence of the RhoGAP
318 domain of these venom proteins and that of the 19 classical RhoGAPs we identified from the predicted
319 proteome of the jewel wasp *Nasonia vitripennis* (Supplementary Table S2). Prior to analysis, the coding
320 sequence was completed for two Lbm (LbGAP1.3 and LbGAP5), one Lby (LbGAPy6) and all three Lh venom
321 RhoGAPs. Two of the *Leptopilina* venom RhoGAPs, namely LhGAP3 and LcGAP1, were predicted to contain
322 two RhoGAP domains instead of one. Therefore, these two domains were separated for the analysis. The
323 resulting phylogeny identified NvRacGAP1 as the closest RhoGAP from *N. vitripennis* to all *Leptopilina*
324 venom RhoGAPs with confident support values (Figure 1B). Accordingly, the RhoGAP domain found in all
325 *Leptopilina* venom RhoGAPs was predicted to belong to the MgcRacGAP subfamily typically found in
326 RacGAP1-related proteins (Table 1).

327 The RacGAP1 coding sequence of *L. boulardi*, *L. heterotoma*, *L. victoriae* and *L. clavipes* was obtained
328 either by cloning and sequencing or by searching genomic data, and its domain organization was compared
329 with that of venom RhoGAPs (Figure 1C, Table 1 and Supplementary Figure S2). *Leptopilina* RacGAP1 has a
330 typical domain organization consisting of a coiled-coil region and a C1 motif (protein kinase C-like zinc
331 finger motif, a ~ 50 amino-acid cysteine-rich domain involved in phorbol ester/diacylglycerol and Zn²⁺
332 binding) followed by a RhoGAP domain (Tcherkezian & Lamarche-Vane 2007). A large part of the RacGAP1
333 sequence spanning the coiled-coil region and the C1 motif is replaced by the signal peptide in all *Leptopilina*
334 venom RhoGAPs (Figure 1C, Table 1 and Supplementary Figure S2). This suggests that a unique incomplete
335 duplication of the RacGAP1 gene occurred in the ancestor of the *Leptopilina* genus, resulting in a truncated
336 duplicate encoding a RhoGAP with an altered N-terminus.

337 To further investigate this duplication event and the possible origin of the signal peptide, the genomic
338 sequences of *L. boulardi*, *L. heterotoma* and *L. clavipes* venom RhoGAPs and RACGAP1 were obtained,
339 either by cloning and sequencing or by searching in genomic data, and compared (Supplementary Table
340 S2). The genomic sequence of *Leptopilina* RacGAP1 consists of 10 exons with a “CC region”, “C1 motif” and
341 “RhoGAP domain” encoded by exons 2 and 3, exons 5 and 6 and exons 7 and 8, respectively. The RhoGAP
342 domain is also encoded by two exons for venom RhoGAPs. These two exons are preceded by one to three
343 exons, with the signal peptide encoded by the first exon for most of them. Sequence comparisons revealed
344 similarities between venom RhoGAPs and *Leptopilina* RacGAP1 only for the sequence spanning the two
345 exons encoding the RhoGAP domain and part of the following one. No significant similarities were found
346 for the preceding exons at either the nucleotide or amino acid level (Supplementary Figure S3). This

347 supports the hypothesis of a partial duplication of the RacGAP1 gene in the ancestor of the *Leptopilina*
 348 genus, resulting in the loss of the sequence spanning exons 1 to 6, followed by further duplication of the
 349 ancestrally duplicated gene during the diversification of the genus *Leptopilina*.

350 The two consecutive RhoGAP domains found in LhGAP3 were grouped together with confident support
 351 values in the phylogenies (Figure 1B and Supplementary Figure S2). This suggests that a partial tandem
 352 duplication spanning exons 2 and 3 has occurred for this *L. heterotoma* venom RhoGAP. In contrast, the
 353 two RhoGAP domains found in LcGAP1 did not group together (Figure 1B and Supplementary Figure S2).
 354 However, the genomic sequence of LcGAP1 was not complete and we could not find the region
 355 corresponding to the second RhoGAP domain in the *L. clavipes* genome (Supplementary Table S3).
 356 Therefore, it is unclear whether the LcGAP1 coding sequence found in the transcriptome assembly is true
 357 or artificial.

358 **Table 1.** Motif and domain organization of *Leptopilina* venom RhoGAPs. The signal peptide was
 359 predicted using SignalP at CBS. The RhoGAP domain (PF00620) and the RacGAP1 domain
 360 (PTHR46199) were identified using InterProScan. Two successive RhoGAP domains were found in
 361 LhGAP3 and LcGAP1. Lbm: *L. boulardi* ISm ; Lby: *L. boulardi* ISy ; Lh: *L. heterotoma* ; Lc: *L. clavipes* ;
 362 Lv: *L. victoriae*.

Figure 1. Origin of *Leptopilina* venom RhoGAPs (A) Maximum-likelihood phylogenetic tree of selected members of the Cynipoidea superfamily. The phylogenetic tree was obtained with IQ-TREE using internal transcribed spacer 2 (ITS2) sequence and displayed as a cladogram. Species in red are those for which venom RhoGAPs were not found. No data were available for species in black. (B) Maximum-likelihood phylogenetic tree of *Leptopilina* venom RhoGAPs along with *N. vitripennis* classical RhoGAPs. The phylogenetic tree was obtained with IQ-TREE using the RhoGAP domain amino acid sequence and displayed as a cladogram. For A and B, numbers at corresponding nodes are bootstrap support values in percent (500 bootstrap replicates). Only bootstrap values greater than 70% are shown. *Leptopilina* venom RhoGAPs are highlighted in blue. (C) Comparison of protein domain organization between LbGAP, representative of most *Leptopilina* venom RhoGAPs, LhGAP3 and LcGAP1, the two venom RhoGAPs that contain two RhoGAP domains, and *Leptopilina* RacGAP1. C1: protein kinase C-like zinc finger motif, CC: coiled-coil region, MgcRacGAP: RhoGAP domain found in RacGAP1-related proteins, SP: signal peptide.

LbGAP and LbGAP2 have been shown to be associated with vesicles named venosomes produced in *L. boulandi* venom that transport them to *Drosophila* lamellocytes (Wan et al., 2019). Our next goal was to investigate whether *Leptopilina* venom RhoGAPs other than LbGAP and LbGAP2 could be associated with venosomes. Proteomic analysis was performed on the supernatant and vesicular fractions separated from the venom by centrifugation. Comparison of the electrophoretic profiles obtained on a 6-16% SDS-PAGE for *L. boulandi* ISm (Lbm), *L. boulandi* ISy (Lby) and *L. heterotoma* (Lh) revealed an important variation between both fractions for all three wasps (Figure 2). All the major bands on the electrophoretic patterns of Lbm, Lby and Lh supernatant and vesicular fractions, as well as several minor bands (35 bands in total for Lbm, 34 for Lby and 37 for Lh), were excised and tryptic peptides were analyzed by mass spectrometry. The coding sequences of *Leptopilina* venom RhoGAPs were used to perform Mascot searches on the mass spectrometry data obtained from both venom fractions. All *L. boulandi* and *L. heterotoma* venom RhoGAPs were detected in the vesicular fraction, where most of them were found to be enriched (Figure 2). We

391 could then hypothesize that they are associated with and transported by vesosomes to target *Drosophila*
 392 cells.

393

394 **Figure 2. Proteomic analysis of *Leptopilina* venom supernatant and vesicular fractions.** (A) The
 395 supernatant (S) and vesicular (V) fractions obtained from 25 Lbm, Lby and Lh venom reservoirs were
 396 separated on a 6-16% SDS-PAGE under reducing conditions and visualized by silver staining. Protein
 397 bands in which *Leptopilina* venom RhoGAPs were identified by mass spectrometry are numbered on
 398 the gel. Molecular weight standard positions are indicated on the left (kDa). (B) For each *Leptopilina*
 399 venom RhoGAP, length (number of amino acids), predicted Mw (kDa), bands in which specific
 400 peptides were found by mass spectrometry and number of total Mascot matches according to the S
 401 and V venom fractions are given. Numbers in bold correspond to the bands in which each RhoGAP
 402 was identified as the most abundant according to the number of Mascot matches.

403 **V. canescens calyx RhoGAPs probably evolved from two or more imperfect RacGAP1 duplication events**

404 Analysis of the *V. canescens* calyx transcriptome allowed the identification of a total of 13 RhoGAP
 405 domain-containing protein coding sequences, including VcVLP2 (Table 2). Matches with peptides obtained
 406 from a proteomic analysis of *V. canescens* VLPs (Pichon et al., 2015) were detected for all 13 calyx RhoGAPs,
 407 indicating that they are associated with VLPs (Table 2).

408 Similar to the *Leptopilina* venom RhoGAPs, the *V. canescens* calyx RhoGAPs contain a MgcRacGAP1
 409 domain (Table 2) and are closely related to NvRacGAP1 (Figure 3A). In contrast to the *Leptopilina* venom
 410 RhoGAPs, none of the *V. canescens* calyx proteins were predicted to be secreted. Most were predicted to
 411 be localized in the nucleus and/or to contain a nuclear localization signal (Supplementary Tables S4 and
 412 S5). The absence of a predicted nuclear localization signal for VcGAP7 may be explained by the incomplete
 413 coding sequence at the 5' end (Table 2). There is greater variation in domain organization for *V. canescens*
 414 calyx RhoGAPs compared to *Leptopilina* venom RhoGAPs (Figure 3B and Supplementary Figure S4). Eight
 415 *V. canescens* calyx RhoGAPs have retained the C1 motif. In addition, VcGAP12 still contains a CC region in
 416 the N-terminal part of the sequence although the total sequence length is shorter than RacGAP1 (Figure
 417 3B and Supplementary Figure S4).

418 **Table 2.** Motif and domain organization of *Venturia* calyx RhoGAP proteins associated with VLPs. The
 419 coiled-coil (CC) region was predicted using COILS (Lucas et al., 1991). The protein kinase C-like zinc
 420 finger (C1) motif (PS50081), the RhoGAP domain (PF00620) and the RacGAP1 domain (PTHR46199)
 421 were identified using InterProScan. Mascot 5: number of matches with peptides from purified *V.*
 422 *canescens* VLPs. ^aCoding sequence not complete at 5' end. ^bCoding sequence not complete at 3' end.

423

424 The genomic coding sequence of VcRacGAP1 was obtained by genomic data mining. It comprised 9
 425 exons with the CC region, C1 motif and RhoGAP domain encoded by exons 2 and 3, exons 5 and 6 and exon
 426 7, respectively (Supplementary Table S6). In contrast to *Leptopilina*, the RhoGAP domain is encoded by a
 427 single exon in *V. canescens* RacGAP1 as well as in all calyx RhoGAPs. Interestingly, the VcGAP12 gene is
 428 located close to the VcRacGAP1 gene on chromosome 3, but is three exons shorter, suggesting a recent
 429 incomplete duplication (Supplementary Table S6). In contrast, VcVLP2 and the other VcGAP genes are more
 430 widely distributed in the *V. canescens* genome (Supplementary Table S6). It is therefore possible that
 431 incomplete duplication events of the VcRacGAP1 gene, followed by further tandem and dispersed

432 duplication of the ancestrally duplicated genes, led to the current number of calyx RhoGAPs in *V. canescens*
 433 organized in several clusters comprising 2 or more genes in tandem arrays (Figure 3C).

434

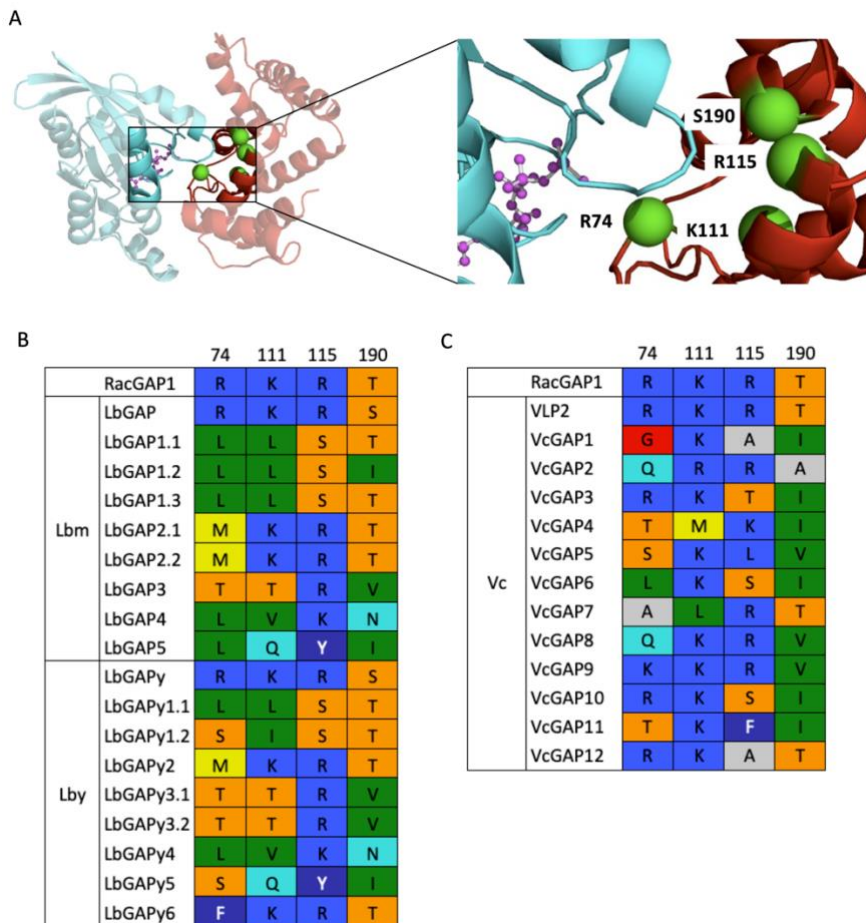

435

436 **Figure 3. Origin of *V. canescens* calyx RhoGAPs** (A) Maximum-likelihood phylogenetic tree of *V.*
 437 *canescens* calyx RhoGAPs along with *N. vitripennis* classical RhoGAPs. The phylogenetic tree was
 438 obtained with IQ-TREE using the RhoGAP domain amino acid sequence and displayed as a cladogram.
 439 Numbers at corresponding nodes are bootstrap support values in percent (500 bootstrap replicates).
 440 Only bootstrap values greater than 70% are shown. *V. canescens* calyx RhoGAPs are highlighted in
 441 blue. (B) Comparison of protein domain organization between *V. canescens* calyx RhoGAPs and *N.*
 442 *vitripennis* RacGAP1 using the RhoGAP domain as reference. The color code is as follows: purple for
 443 the coiled-coil region (CC), green for the protein kinase C-like zinc finger motif (C1) and blue for the
 444 RhoGAP domain. A (?) indicates that either the N- or C-terminal part of the sequence is unknown. (C)
 445 *V. canescens* chromosome map with the position of gene loci corresponding to RacGAP1 and calyx
 446 RhoGAPs visualized using chromoMap R package (Anand & Rodriguez Lopez 2022).

447

448 **Evidence of positive selection in *L. bouleari* venom and *V. canescens* calyx RhoGAP sequences**

449 In a previous work, we identified four amino acid residues involved in the interaction of LbGAP with
 450 Rho GTPases (Colinet et al., 2007), including the key arginine residue (R74 in LbGAP) required for the GAP
 451 catalytic activity (Figure 4A). The other 8 venom RhoGAP sequences found in *L. bouleari* lsm and lSy were
 452 all mutated at this arginine residue (Figure 4B). Most also contained mutations in one or more of the other
 453 three amino acids involved in Rho GTPase interaction (Figure 4B). Similarly, all *V. canescens* calyx RhoGAP
 454 sequences, except VcVLP2, are mutated in one or more of the sites essential for GAP activity and/or
 455 involved in the interaction with Rho GTPases (Figure 4C). These observations suggest that only LbGAP and
 456 its homolog LbGAPy in *L. bouleari* and VcVLP2 in *V. canescens* are functional as RhoGAPs.

457

458 **Figure 4. Mutations in the essential sites for GAP activity and/or involved in interaction with Rho**
 459 **GTPases** (A) Tertiary structure of LbGAP (red) in complex with Rac1 (blue) and the transition-state
 460 analogue GDP.AIF3 (modeled by homology for sequence spanning amino acid residues 51 to 216 in
 461 Colinet et al., 2007). The four sites essential for GAP activity and/or involved in interaction with
 462 RhoGTPases are colored green. (B) Amino acids found at the four sites essential for GAP activity
 463 and/or involved in the interaction with RhoGTPases for *Leptopilina* RacGAP1 and *L. bouleari* venom
 464 RhoGAP sequences. The numbering corresponds to the positions in the LbGAP sequence. (C) Amino
 465 acids at the four sites essential for GAP activity and/or involved in interaction with RhoGTPases for
 466 *V. canescens* RacGAP1 and calyx RhoGAP sequences. The numbering corresponds to the positions in
 467 the LbGAP sequence. In B and C, amino acids are colored according to their properties following the
 468 RasMol amino acid color scheme.

469 A search for positive selection was performed to detect possible functional divergence of *L. bouleari*
 470 venom and *V. canescens* calyx RhoGAP sequences. PAML codon-based models with (M2a and M8) and
 471 without (M1a and M7) selection were compared using likelihood ratio tests (LRTs). Both M1a/M2a and

472 M7/M8 comparisons resulted in the rejection of the null hypothesis suggesting that a fraction of codons in
473 RhoGAP sequences are under positive selection (Table 3).

474 **Table 3.** Positive selection analysis among sites using CodeML for *L. bouleardi* venom and *V. canescens*
475 calyx RhoGAP sequences. lnL is the log likelihood of the model. p-value is the result of likelihood ratio
476 tests (LRTs). Global ω is the estimate of the dN/dS ratio under the model (given as a weighted
477 average). Parameters ($\omega > 1$) are parameters estimates for a dN/dS ratio greater than 1.

478

<i>L. bouleardi</i>				
Model	lnL	p-value	Global ω	Parameters ($\omega > 1$)

479

480 Consistently, a total of 7 and 11 branches of the phylogenetic tree constructed with the *L. bouleardi*
481 venom and *V. canescens* calyx RhoGAP sequences, respectively, were detected by the REL branch-site test
482 as corresponding to lineages on which a subset of codons has evolved under positive selection (Figure 5A
483 and 6A). For *L. bouleardi*, 6 of the 7 lineages under positive selection were internal branches, indicating that
484 selection occurred primarily before the separation of the *L. bouleardi* Ism and ISy strains (Figure 5A).

485 The combined use of five different methods identified a total of 19 codons as candidates under positive
486 selection for the *L. bouleardi* venom RhoGAP sequences, most of which were found in the region
487 corresponding to the RhoGAP domain (Figure 5B). In contrast, only 4 amino acids were detected as evolving
488 under negative selection in the *L. bouleardi* venom RhoGAPs, respectively (Figure 5C). The leucine at position
489 9 in LbGAP is located in the signal peptide, demonstrating the importance of this region. The other three
490 amino acids in *L. bouleardi* and most of those in *V. canescens* under negative selection are buried in the
491 protein and are probably important for the structural stability (Figures 5D and 5E).

492 Interestingly, at least one radical change in charge and/or polarity of the corresponding amino acids
493 was found for all selected codons (Figure 5B). For example, the polar uncharged serine residue at position
494 76 in LbGAP was replaced by a negatively charged lysine residue in LbGAP4 (Figure 5B). Since radical
495 changes are more likely to modify protein function than conservative changes, this suggests that the
496 identified non-synonymous substitutions may be adaptive. Interestingly, the corresponding amino acids
497 are mostly exposed on the surface of the protein and therefore likely to interact with partners (Figures 5C
498 and 5D).

499 We therefore generated site-specific mutants of LbGAP for 8 of the 19 amino acids under positive
500 selection and compared their binding capabilities to Rho GTPases. Two-hybrid analysis revealed a lack of
501 interaction for five of the mutants, indicating that the corresponding amino acids are essential for
502 interaction with Rac GTPases (Table 4). On the other hand, the remaining three mutants were still able to
503 interact strongly with Rac1 and Rac2, suggesting that the corresponding amino acids are not involved in
504 the interaction with Rac GTPases (Table 4).

505 For the *V. canescens* calyx RhoGAP sequences, six amino acids were identified as candidates under
506 positive selection and 19 under negative selection (Figures 6B and 6C). Four of the amino acids under
507 positive selection are predicted to be exposed on the surface of the protein, indicating functional
508 diversification in relation to interaction with partners as in *L. bouleardi* (Figures 6D and 6E). Most of the
509 amino acids under negative selection are buried within the protein and are likely to be important for
510 structural stability (Figures 6D and 6E).

554

Discussion

555 **Independent convergent recruitment of vesicle-associated RhoGAP proteins in distantly related** 556 **parasitoid species**

557 The process of duplication of a gene encoding a protein usually involved in a key physiological process
558 whose function will be hijacked is a major mechanism of toxin recruitment (Fry et al., 2009; Wong & Belov
559 2012; Casewell et al., 2013). The results of phylogeny and domain analyses indicate that the *Leptopilina*
560 venom RhoGAPs and the calyx RhoGAPs found in *V. canescens* VLPs originated from duplication of the gene
561 encoding the cellular RacGAP1 in these species. This independent convergent recruitment may suggest a
562 similar function in virulence in these two evolutionarily distant parasitoid species. Consistently, our results
563 indicate that venom RhoGAPs in *L. bouleardi* and *L. heterotoma* and calyx RhoGAPs in *V. canescens* are
564 associated with extracellular vesicles, named venosomes and VLPs, respectively. While these two types of
565 vesicles have different tissue origins and formation mechanisms, *Leptopilina* venosomes and *V. canescens*
566 VLPs would act as transport systems to deliver virulent proteins, including RhoGAPs, into host hemocytes
567 to alter their function (Pichon et al., 2015; Wan et al., 2019). However, the role of RhoGAPs on host
568 hemocytes is still unclear or even unknown, although we have previously shown that LbGAP inactivates
569 Rac-like GTPases (Colinet et al., 2007), which are required for successful encapsulation of *Leptopilina* eggs
570 (Williams et al., 2005; Williams et al., 2006).

571 RacGAP1 is an intracellular multidomain protein consisting of a coiled-coil region followed by a C1 motif
572 (protein kinase C-like zinc finger motif) and a RhoGAP domain (Tcherkezian & Lamane-Vane 2007).
573 *Leptopilina* venom RhoGAPs, on the other hand, possess only a RhoGAP domain preceded by a secretory
574 signal peptide. Sequence comparisons at the genomic level support the hypothesis of a single partial
575 duplication of the RacGAP1 gene in the ancestor of the *Leptopilina* genus, resulting in the loss of a 5' portion
576 of the sequence encoding the coiled-coil region and the C1 motif, followed by the acquisition of the signal
577 peptide sequence. This initial evolutionary event would then have been followed by further duplication of
578 the ancestral duplicate gene throughout the diversification of the genus *Leptopilina*, leading to the current
579 number of venom RhoGAPs. A first hypothesis for the origin of the signal peptide would be that the loss of
580 part of the 5' coding sequence in the duplicate resulted in a new N-terminal end for the encoded protein
581 with signal peptide properties. Modification of the N-terminal end of the protein into a fully functional
582 signal peptide may have required some point mutations after partial duplication, as in the case of the
583 antifreeze protein of an Antarctic zoarcid fish (Deng et al., 2010). Another possibility is that the signal
584 peptide originated from a process of partial duplication with recruitment (Katju & Lynch 2006), in which a
585 "proto-peptide signal" coding sequence was acquired from the new genomic environment into which the
586 partial copy was integrated. Finally, it is also possible that the new 5' region of the duplicated copy results
587 from a chimeric duplication (Katju & Lynch 2006), e.g. from the partial duplication of another gene or by
588 exon shuffling (Vibrantovski et al., 2006). The acquisition of the signal peptide probably facilitated the
589 neofunctionalization of the venom RhoGAPs according to the evolutionary model of protein subcellular
590 relocalization (PSR) proposed by Byun McKay & Geeta (2007), according to which a modification of the N-
591 or C-terminal region of a protein can change its subcellular localization, by the loss or acquisition of a
592 specific localization signal, and enable it to acquire a new function.

593 In *V. canescens*, the N-terminal region of the calyx RhoGAPs is more variable in length, with some
594 proteins retaining the C1 motif upstream of the RhoGAP domain and one retaining a coiled-coil region
595 upstream of the C1 motif. Most of the *V. canescens* calyx RhoGAPs were predicted to contain a nuclear
596 localization signal, consistent with (i) the accumulation of VcVLP2 in the nucleus of the calyx cells prior to
597 its association with the virus-derived VLPs (Pichon et al., 2015) and (ii) our results from a proteomic analysis
598 indicating that all 13 calyx RhoGAPs are associated with VLPs. Human RacGAP1 has been described to
599 localize to the cytoplasm and nucleus (Mishima et al., 2002), suggesting that *V. canescens* calyx RhoGAPs
600 have retained the RacGAP1 nuclear localization signal, unlike *Leptopilina* venom RhoGAPs. One of the *V.*
601 *canescens* calyx RhoGAP genes is located close to the RacGAP1 gene in the genome, suggesting a recent
602 partial tandem duplication. The other genes, on the other hand, are scattered throughout the genome
603 suggesting that they originate from one or more older duplication events of the RacGAP1 gene. In contrast
604 to *Leptopilina*, it cannot be excluded that two or more partial duplication events of the RacGAP1-encoding
605 gene occurred in *V. canescens*, followed by further duplication of ancestral duplicates.

606 Accelerated evolution through duplication and divergence: pseudogenization and/or 607 neofunctionalization?

608 Our work revealed a significant divergence for the two multigene families of RhoGAPs in *L. boulardi*
609 and *V. canescens* compared to RacGAP1, illustrated by the presence of mutations on the arginine essential
610 for GAP activity and/or on one or more of the amino acids shown to be important, or even necessary, for
611 interaction with the Rac GTPases in all RhoGAPs except LbGAP (and its homolog LbGAPy) and VcVLP2. The
612 presence of mutations at key sites in the majority of *L. boulardi* venom and *V. canescens* calyx RhoGAPs
613 suggests a loss of function by pseudogenization. However, peptide matches were found in proteomic
614 analyses for each of these RhoGAPs, indicating that the corresponding genes are successfully transcribed
615 and translated. Furthermore, our results indicate that the ancestrally acquired secretory signal peptide, in
616 which we identified an amino acid under negative selection, is conserved in all *L. boulardi* RhoGAPs and
617 that most *V. canescens* RhoGAPs conserved the nuclear localization signal of RacGAP1. In addition, all
618 RhoGAPs retained the ability to associate with vesicles, namely venosomes in *L. boulardi* and VLPs in *V.*
619 *canescens*. Finally, we showed that several amino acids embedded in the protein structure evolved under
620 negative selection, suggesting that they are important for protein stability. Taken together, these
621 observations are not consistent with the hypothesis that any of the mutated RhoGAPs is undergoing a
622 pseudogenization process, although it cannot be excluded that this process is quite recent and could have
623 been initiated by the loss of the GAP active site.

624 An alternative hypothesis to pseudogenization would be functional diversification of the mutated
625 RhoGAPs independent of the Rho pathway. Indeed, we have evidenced an evolution under positive
626 selection for the majority of RhoGAPs in the two multigenic families. Most of the sites under positive
627 selection are located on the surface of the protein and are therefore likely to interact with partners. In
628 addition, directed mutagenesis and two-hybrid experiments in *L. boulardi* have shown that some of these
629 amino acids are not involved in the interaction with Rac GTPases. Although the majority of studies on the
630 RhoGAP domain concern the interaction with Rho GTPases, interactions with other proteins have also been
631 described (Ban et al., 2004; Xu et al., 2013), supporting the hypothesis of a neofunctionalization of the
632 mutated RhoGAPs. Further studies will be needed to determine which functions the mutated RhoGAPs
633 have acquired in relation to parasitism. Recently, a possible role has been proposed for one of the RhoGAPs
634 found in the venom of the ISy line of *L. boulardi* in the induction of reactive oxygen species (ROS) in the
635 central nervous system of *D. melanogaster* in the context of superparasitism avoidance (Chen et al., 2021).
636 However, ROS production is notably regulated by the GTPases Rac1 and Rac2 (Hobbs et al., 2014), whereas
637 this venom protein (named EsGAP1 in Chen et al., 2021 and corresponding to LbGAPy6 in our study) has
638 likely lost its RhoGAP activity due to a mutation on the arginine at position 74. Therefore, the mechanism
639 by which EsGAP1 would be involved in ROS induction is unclear.

640 Other potential viral factors involved in parasitic success have been described previously that are
641 encoded by large gene families and similarly correspond to truncated forms of cellular proteins that have
642 retained only a single conserved domain, such as protein tyrosine phosphatases (PTPs) or viral ankyrins (V-
643 ANKs) of bracoviruses. In the case of bracovirus PTPs, some are active as phosphatases, while others are
644 mutated in their catalytic site and have been shown to be inactive as PTPs (Provost et al., 2004). In the
645 latter case, as well as for V-ANK, it has been suggested that by binding to their target, they may act as
646 constitutive inhibitors of the function of the corresponding cellular protein (Provost et al., 2004;
647 Thoetkiattikul et al., 2005). Moreover, the model of adaptive evolution by competitive evolution of
648 duplicated gene copies (Francino 2005) predicts that after a first step in which different copies explore the
649 mutation space, once a protein with an optimal function is obtained, the other copies will begin to decay
650 and undergo pseudogenization. This can lead to intermediate situations where both functional and non-
651 functional proteins are produced, as observed for different virulence protein families of parasitoid wasps.
652 Some of the described features of *L. boulardi* and *V. canescens* RhoGAPs may suggest that a process of
653 competitive evolution is underway in *V. canescens* and *L. boulardi*, although our results are also consistent
654 with the hypothesis of a possible neofunctionalization of these vesicle-associated proteins as discussed
655 above.

656 In conclusion, we evidenced the independent convergent origin and accelerated evolution of a
657 multigene family of vesicle-associated RhoGAP proteins in two unrelated parasitic wasps. Strikingly, these
658 vesicles, which are similarly involved in parasitism, are produced in distinct organs: the venom apparatus
659 in *Leptopilina* and the ovarian calyx in *V. canescens*. In the case of *Leptopilina* RhoGAPs, the acquisition of

660 a secretory signal peptide after incomplete duplication of the RacGAP1 gene allowed secretion into the
661 venom where the vesicles are formed. *V. canescens* RhoGAPs, on the other hand, probably retained the
662 RacGAP1 nuclear localization signal, because it is in the nucleus of calyx cells that VLPs are formed. Another
663 striking point is that our results suggest a possible functional diversification of vesicle-associated RhoGAPs
664 in both species, with the exception of LbGAP in *L. bouleari* and VcVLP2 in *V. canescens*, which are probably
665 the only ones with RhoGAP activity. An open question would be whether all RhoGAPs are important for
666 parasite success, but by different mechanisms, independent of the Rho pathway or not, depending on
667 whether RhoGAPs are mutated or not.
668
