HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Collections of Entomopathogenic Nematodes and Associated Bacteria for Biological Control of insect pests

Sylvie Pagès, Yascim Kamel, Aymeric Antoine-Lorquin, Jean-Claude Ogier, Sophie Gaudriault and Alain Givaudan

Since 1999, a collection of living entomopathogenic nematodes (EPNs) of *Steinernema* and *Heterorhabditis* genera has been maintained in the DGIMI laboratory, in Montpellier (France). This repository of EPN species, sourced from soils of international origin, is regularly updated with new isolates. Each new nematobacterial pair is characterized in terms of taxonomy, pathology on different insects and description of the associated microbiota. To ensure traceability, we have created a database for EPNs and associated bacteria, each isolate being characterized by a passport (origin, experimental results, bibliography...).

Methodology for reproducing infective juvenile (IJs) nematodes in laboratory before storage for several months

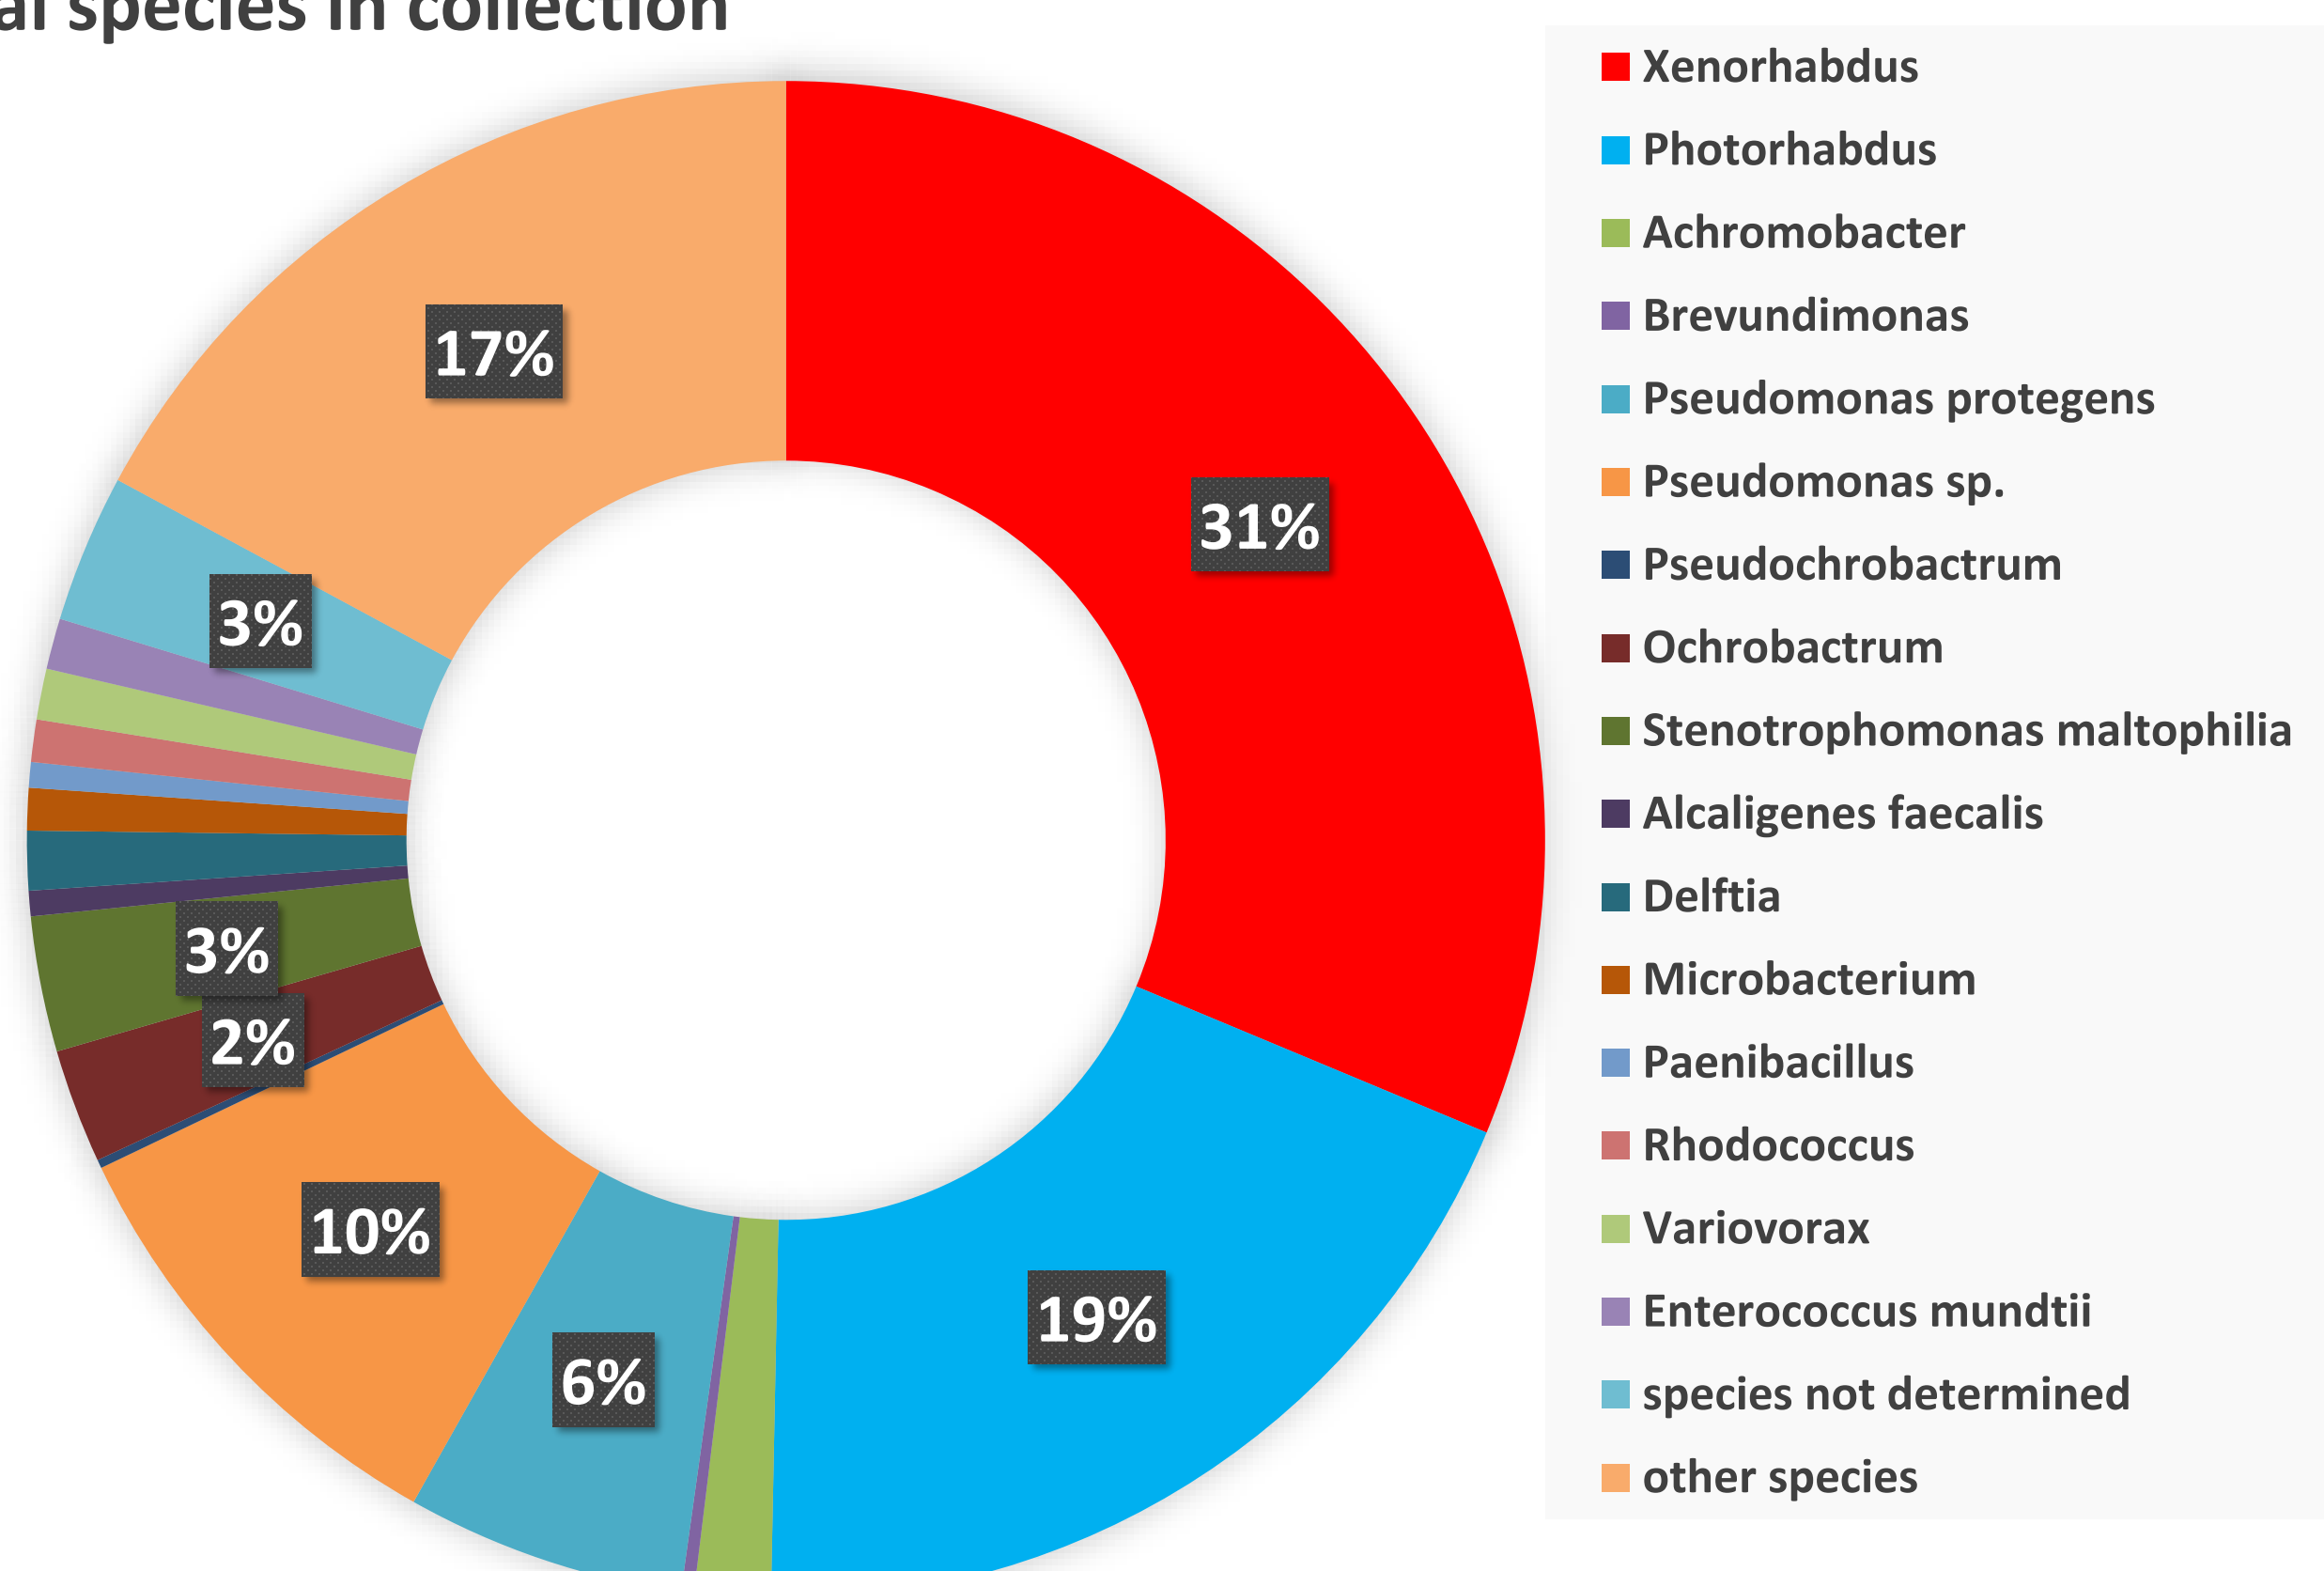

Geographical distribution of EPNs: EPN strains originate from France, as well as from across Europe and beyond, representing 15 countries. At present, 116 strains are kept alive in the laboratory. Each strain is renewed on larvae of insects (*Galleria mellonella*), every 4 to 9 months, depending of the specie, in order to preserve their pathogenicity.

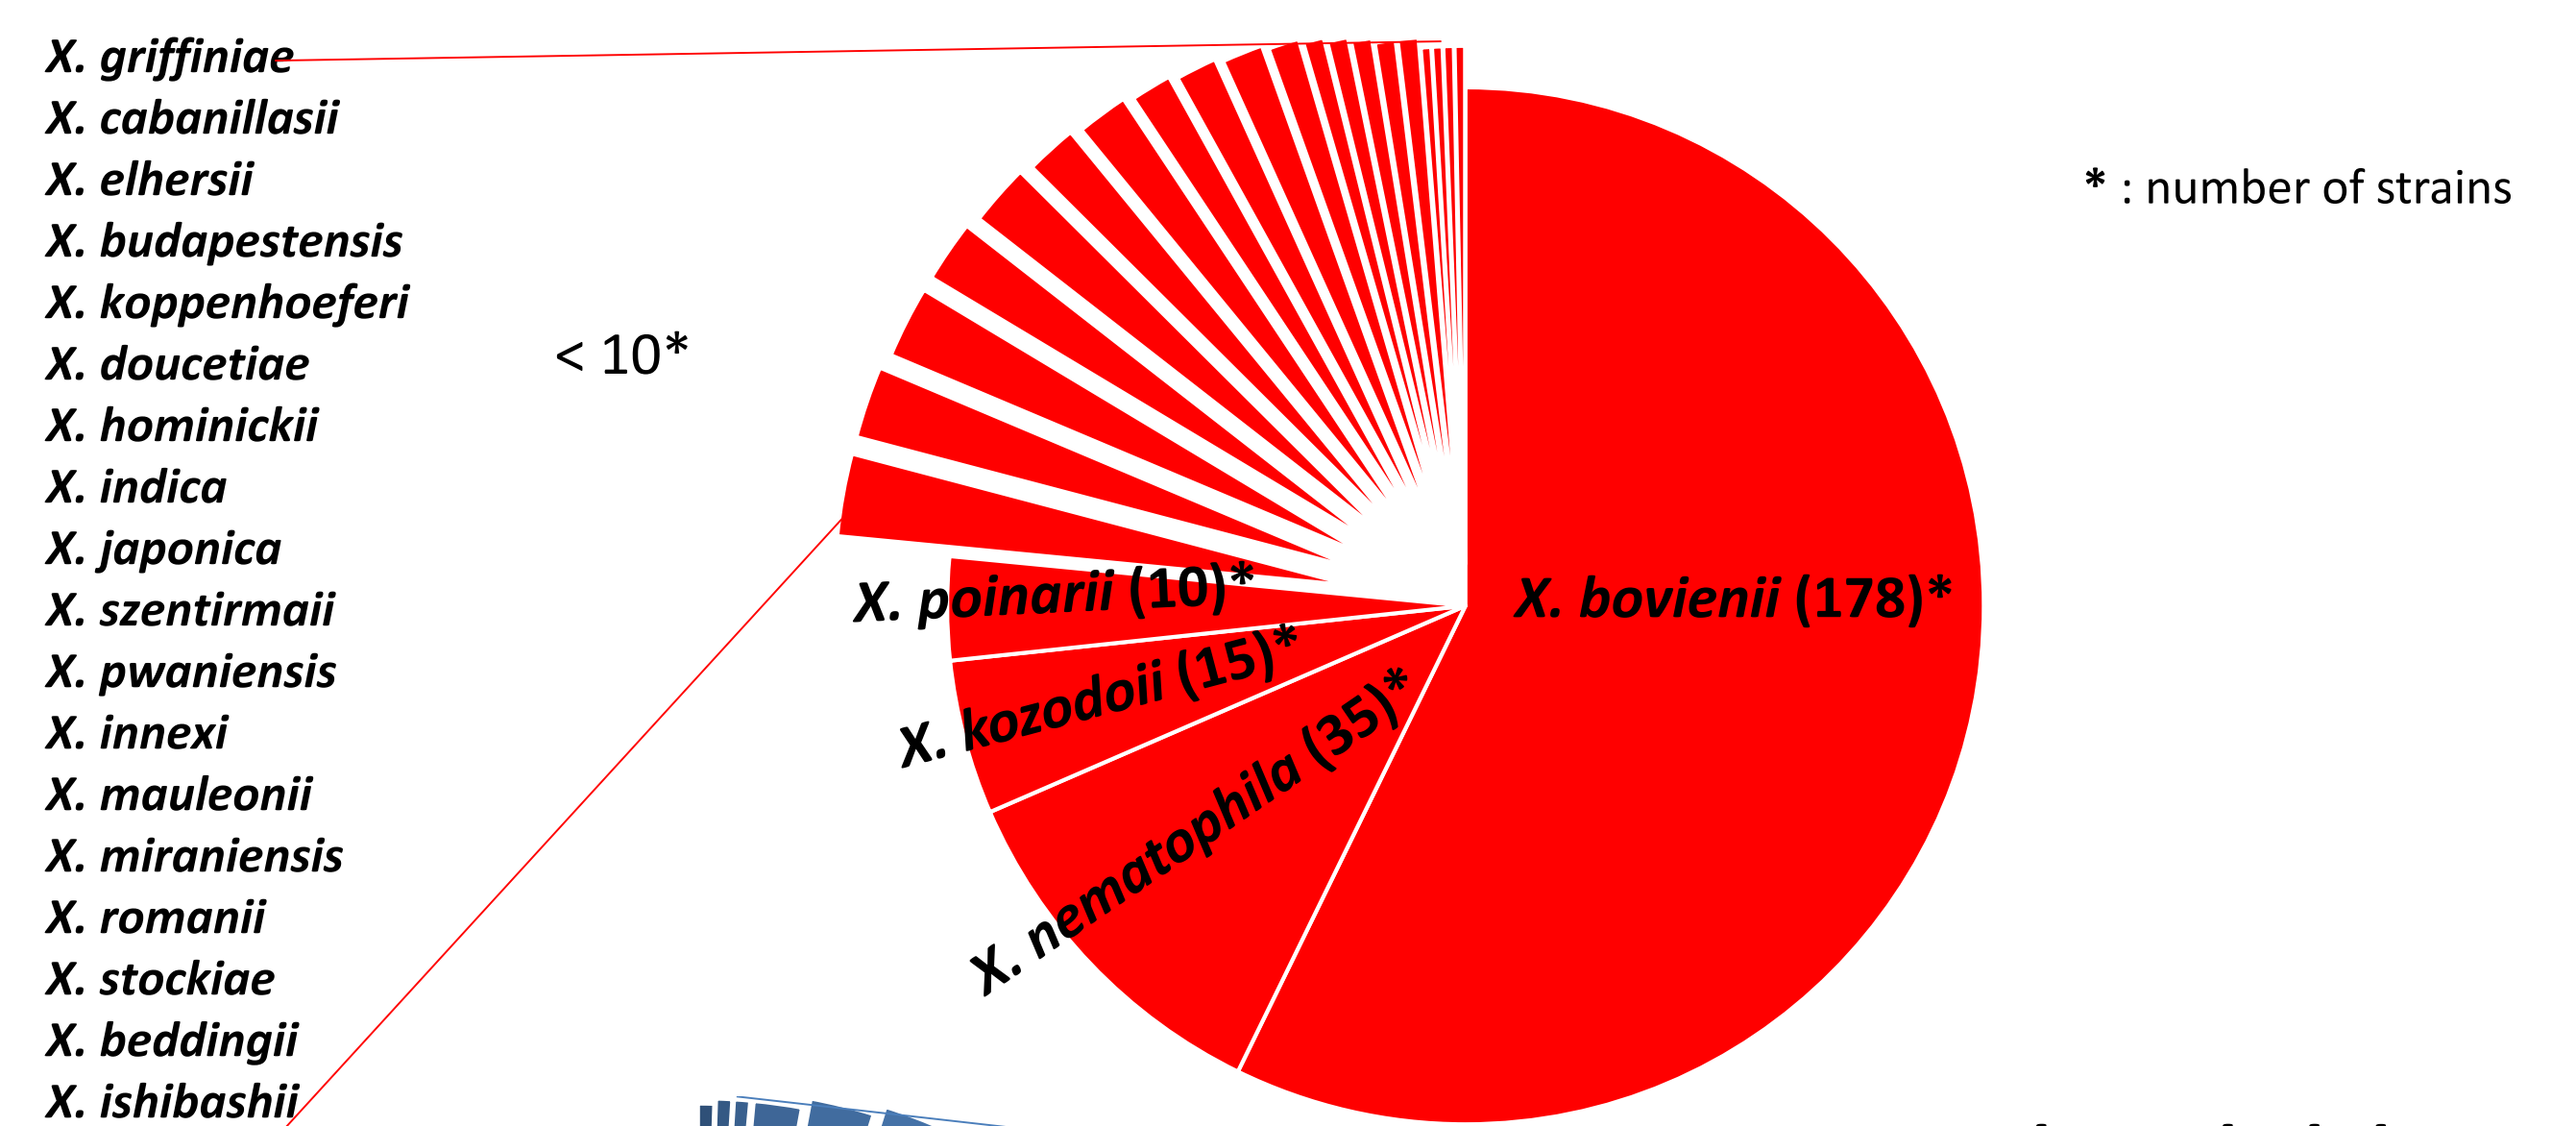

Bacterial species in collection: Historically, the lab has been a reference in the field of taxonomy and phylogeny of *Xenorhabdus* and *Photorhabdus*, bacteria associated with EPNs. Today, more than 1200 strains are stored in the collection. It also includes strains of the frequently associated microbiota (FAM) of EPNs (Ogier, Pagès et al; Microbiome, 2020). Since 2016, the collection has been affiliated with the environmental pillar of the Agronomic Resource Center for Research <https://www.brc4env.fr/BRCs-and-collections/Invertebrates/Nematodes/Entomopathogenic-nematodes>

Photorhabdus species

Database EPNs and Bacteria: By implementing a PostgreSQL database with phpPgAdmin in 2021, we have improved our organization's ability to effectively manage and analyze strain-related data. By using a centralized database, we can store all strain data in one place, it easy to manage and access. Finally, a structured database is crucial for maintaining traceability and ensuring data integrity.
