Bifidobacterium longum subspecies *infantis*: champion colonizer of the infant gut

Mark A. Underwood^{1,2}, J. Bruce German^{3,5}, Carlito B. Lebrilla^{2,4} and David A. Mills^{2,3,5}

Oligosaccharides are abundant in human milk. Production of these highly diverse structures requires significant energy expenditure by the mother and yet these human milk oligosaccharides offer no direct nutritive value to her infant. A primary function of human milk oligosaccharides is to shape the infant's intestinal microbiota with life-long consequences. *Bifidobacterium longum* subspecies *infantis* (*B. infantis*) is unique among gut bacteria in its prodigious capacity to digest

and co result c of glyco in other bacterial species. *In vitro*, *B. infantis* grows better than other bacterial strains in the presence of human milk oligosaccharides, displays anti-inflammatory activity in premature intestinal cells, and decreases intestinal permeability. In premature infants, *B. infantis* strains that co-colonize with human milk

***B. infantis* reduces the risk of necrotizing enterocolitis**

B. infantis is also associated with increased vaccine responses. Probiotic organisms have historically been selected based on ease of production and stability. The advantages of *B. infantis*, selected through coevolution with human milk glycans, present an opportunity for focused manipulation of the infant intestinal microbiota.

The colonization of the fetal gut begins *in utero* with swallowing of amniotic fluid. At that point, infants begin a life-long relationship with a community of microorganisms (microbiota) and the gut microbiome) and presumably the health consequences of the phenotype of the gut microbiota occur with rupture of the fetal membranes, birth, initiation of feeding, addition of solid foods, weaning, and interventions such as antibiotics, acid-suppression, and probiotic or probiotic dietary supplements. The predominance of "bifid" microbes in the stools of healthy infants was described more than 100 y ago, prompting the

hypothesis that human milk contained "bifidogenic factors" that stimulated the growth of these bifidobacteria (1). Prebiotics are dietary supplements that promote health benefits by stimulating the growth and/or activity in the gut lumen of commensal microbes (ideally without stimulating potential pathogens); they do not contain live organisms. Probiotics are dietary supplements that do contain live organisms and are intended to promote health benefits through a variety of mechanisms, including the coevolution of human milk oligosaccharides found in bacterial subspecies, *Bifidobacterium longum* subsp. *infantis* (*B. infantis*) unique in its capacity to consume these oligosaccharides. Note that the species *B. longum* has two subspecies: *B. longum* subsp. *infantis* and *B. longum* subsp. *longum*. These subspecies will be abbreviated as *B. infantis* and *B. longum*, respectively.

Humans stand at the end of the long evolution of mammals, with differences in milk conspicuous for the volume, number of structures, and complexity of milk oligosaccharides (Figure 1) (2–4). Human milk oligosaccharides (HMOs) are the third largest solid component of human milk (after lactose and fat) even in times of famine (5), and yet these free glycans are not digestible by the infant as the human gut does not produce the glycosidases necessary to cleave the HMO linkages. The obvious evolutionary question is: What benefit is provided to the infant that justifies the metabolic expenditure of producing these complex oligosaccharides? The answer lies in the ability of select gut microbes to deconstruct and consume HMOs (6,7). Among multiple microbial species studied, only two genera, *Bifidobacterium* and *Bacteroides*, are able to comprehensively utilize HMOs as a primary food source (Table 1) (8,9). This relative resistance to microbial consumption allows the HMOs to arrive intact in the distal small bowel and the colon where the largest numbers of commensal bacteria thrive.

Propionibacteria : regulate Th17 cells

Consumption of human breast milk (HBM) attenuates the incidence of necrotizing enterocolitis (NEC), which remains a leading and intractable cause of mortality in preterm infants. Here, we report that this diminution correlates with alterations in the gut microbiota, particularly enrichment of *Propionibacterium* species. Transfaunation of microbiota from HBM-fed preterm infants or a newly identified and cultured *Propionibacterium* strain, P. UF1, to germfree mice conferred protection against pathogen infection and correlated with profound increases in intestinal Th17 cells. The induction of Th17 cells was dependent on bacterial dihydrolipoamide acetyltransferase (DlaT), a major protein expressed on the P. UF1 surface layer (S-layer). Binding of P. UF1 to its cognate receptor, SIGIRR, on dendritic cells resulted in the regulation of intestinal phagocytes. Importantly, transfer of P. UF1 profoundly mitigated induced NEC-like injury in neonatal mice. Together, these results mechanistically elucidate the protective effects of HBM and P. UF1-induced immunoregulation, which safeguard against proinflammatory diseases, including NEC.

➤ Probiotics, it's an old story

In 1536, François the 1st had been on the Throne of France for 21 years. The growing rivalry between **François the 1st** (France) and Charles V (Spain) encouraged the former to ally himself beyond the traditional chessboard with the Ottoman Sultan Suleiman the Magnificent

In 1542, **François the 1st** was subject to very severe intestinal disorders. The Turkish sovereign sends him his personal doctor. The latter brings him a yogurt made from sheep's milk. The origin of the word "yogurt" is found in the Turkish word "yogurmark", which means "to knead" or "to thicken". After a cure of several weeks, the sovereign succeeded in putting an end to the gastric problems.

➤ Probiotics, it's an old story

Product originating from the Balkans

1542, Francis I was cured of intestinal disorders thanks to a sheep's milk yogurt sent by the Ottoman Sultan: Suleiman the Magnificent

1860, discoveries by Pasteur on the role of microorganisms in lactic fermentations

1902, Metchnikoff [1845-1916] isolates the “Bulgarian” lactobacillus specific to this product and the first believes and studies the beneficial role of regular ingestion of yogurt

1930, first industrial production center D. Carasso / Danone

Since 1990, diversification: variety of fermented milks; same fermentation principle + other species added bifidobacteria, other lactobacilli (*Lactobacillus acidophilus*, *Lactobacillus casei*, etc.) “PROBIOTICS”

IBS, irritable bowel syndrome
Functional disorder
Transit disruption
Abdominal pain
Flatulence

Effect of *Lactobacillus plantarum* consumption

- ↓ severity of visceral pain
- ↓ defecation frequency
- ↓ bloating

CONCLUSIONS:

Supplementation of *L. sakei* in children with AEDS was associated with a substantial clinical improvement and a significant decrease in chemokine levels, reflecting the severity of AEDS.

Milk and dairy consumption and risk of cardiovascular diseases and all-cause mortality: dose–response meta-analysis of prospective cohort studies

Jing Guo¹ · Arne Astrup² · Julie A. Lovegrove³ · Lieke Gijsbers⁴ · David I. Givens¹ · Sabita S. Soedamah-Muthu⁴

Pas d'effet de la consommation globale de produits laitiers avec l'incidence des maladies cardiovasculaires

No associations were found for total (high-fat/low-fat) dairy, and milk with the health outcomes of mortality, CHD or CVD

En revanche, association inverse entre la consommation de produits laitiers fermentés, fromages et yaourts, et la mortalité / le risque de maladie cardiovasculaire

Inverse associations were found between total fermented dairy (included sour milk products, cheese or yogurt; per 20 g/day) with mortality (RR 0.98, 95% CI 0.97-0.99; I² = 94.4%) and CVD risk (RR 0.98, 95% CI 0.97-0.99; I² = 87.5%).

Des études épidémiologiques ont montré que la consommation d'aliments fermentés est associée avec un risque réduit de diabète de type 2, de syndrome métabolique, de maladie cardiaque, ainsi qu'avec un meilleur contrôle du poids corporel

Epidemiological studies have shown that the consumption of fermented foods is associated with reduced risks of type 2 diabetes, metabolic syndrome, and heart disease, along with improved weight management

Conclusion:

- ✓ Our food: a source of bacteria
- ✓ Potentially probiotic bacteria
- ✓ Which modulate the structure and activity of the microbiota
- ✓ With an effect on physiology and health

Fermented foods : 30% of our diet

A major source of bacteria : 10^5 to 10^9 per gram
