Abstract:	<p>Although seed represents an important means of plant pathogen dispersion, the seed-pathogen dialogue remains largely unexplored. A multi-omic approach (<i>i.e.</i> dual RNAseq, plant small RNAs and methylome) was performed at different seed developmental stages of common bean (<i>Phaseolus vulgaris</i> L.) during asymptomatic colonization by <i>Xanthomonas citri</i> pv. <i>fuscans</i> (<i>Xcf</i>). In this condition, <i>Xcf</i> did not produce disease symptoms, neither affect seed development. Although, an intense molecular dialogue, via important transcriptional changes, was observed at the early seed developmental stages with down-regulation of plant defense signal transduction, via action of plant miR, and upregulation of the bacterial Type 3 Secretion System. At later seed maturation stages, molecular dialogue between host and pathogen was reduced to few transcriptome changes, but marked by changes in DNA methylation of plant defense and germination genes, in response to <i>Xcf</i> colonization, potentially acting as defense priming to prepare the host for the post-germination battle . This distinct response of infected seeds during maturation, with a more active role at early stages refutes the widely diffused assumption considering seeds as passive carriers of microbes. Finally, our data support a novel plant-pathogen interaction model, specific to the seed tissues, which differs from others by the existence of distinct phases during seed-pathogen interaction with seeds first actively interacting with colonizing pathogens, then both belligerents switch to more passive mode at later stages. We contextualized this</p>

17 50 Introduction

18 51 Legumes provide a sustainable source of proteins for human and livestock diet,
19 52 moreover their symbiotic nitrogen fixation capacity contributes to soil preservation and reduces
20 53 the need for chemical fertilizers (Stagnari et al., 2017; Ferreira et al., 2021). An important
21 54 factor limiting legume utilization is their relatively high yield variability, greatly due to their
22 55 susceptibility to environmental factors such as biotic and abiotic stresses (Cernay et al., 2015;
23 56 Martins et al., 2020). While legumes are expected to better perform under changing climatic
24 57 conditions in relation to other crops thanks to higher biomass accumulation under increased
25 58 atmospheric CO₂ levels and higher photosynthetic efficiency under increased irradiation
26 59 levels, other traits are predicted to be negatively affected, such as seed quality and resistance
27 60 to pathogens (Myers et al., 2014).

28 61 Pathogens are responsible for 35-70% yield losses on grain legumes (Martins et al.,
29 62 2020). An important determinant of disease outbreak is pathogen dispersal through infected
30 63 seeds (Denancé and Grimault, 2022). The mode of transmission of pathogens to the seed can
31 64 be schematically summarized in three non-exclusive pathways: internal (*via* the host xylem),
32 65 floral (*via* the pistil) and external as a consequence of contact of the seed with symptomatic
33 66 fruit tissues or with threshing residues (Maude, 1996). For instance, *Xanthomonas citri* pv.
34 67 *fuscans* (*Xcf*), causal agent of common bacterial blight of bean (CBB), can use these three
35 68 pathways for its transmission to common bean seeds (Darsonval et al., 2008; Darrasse et al.,
36 69 2018). Contaminated seeds can be symptomatic or asymptomatic, and are generally
37 70 associated with high or moderate bacterial population sizes, respectively, moreover
38 71 symptomatic seeds often fail to germinate (Darrasse et al. 2018; Chen et al., 2021a) and no
39 72 viable pathogen control method to counteract bacterial seed infections exists.

Decades of research led to a comprehensive overview of the genetic (for review Dodds and Rathjen, 2010; Wirthmueller et al., 2013) and epigenetic (for review Hannan Parker et al., 2022) mechanisms involved in plant-pathogen interactions during vegetative growth. However, the molecular dialogue that takes place between seeds and pathogens was overlooked to date. On the plant side, in the event of an incompatible interaction between *Medicago truncatula* and *X. campestris* pv. *campestris* (*Xcc*), seed transcriptome exhibited an activation of defense response and a repression of seed maturation pathways (Terrasson et al., 2015). From the bacterial side, some specific genetic determinants such as the type 3 secretion system (T3SS, Darsonval et al., 2008) and adhesins (Darsonval et al., 2009) were shown to be involved in the transmission of *Xcf* to common bean seeds. Involvement of the T3SS in seed transmission was also documented for *Acidovorax citrulli* in watermelon (Dutta et al., 2014). However, a global view of bacterial transcriptomic changes occurring during seed transmission is currently missing. This lack of knowledge is partly due to the difficulties of collecting enough bacterial RNA from the seeds. Indeed seed-associated bacterial population sizes are usually very low (from 10 to 1,000 CFU per bean seed; Chesneau et al., 2022) and follow a Poisson distribution, which complicates the sampling of contaminated seeds and prevent molecular analysis of seed-pathogens interactions (Gitaitis and Walcott, 2007).

Since knowledge regarding molecular interactions occurring during bacterial seed infections is currently lacking, the objective of this work was to decipher the molecular dialogue between the common bean (*Phaseolus vulgaris* L.) seed and a seed pathogen at several stages of seed development in order to identify major molecular factors involved in seed infection establishment and pathogen transmission to the seedling. A dual RNAseq approach to identify both the host seed and the *Xcf* pathogen transcriptomes was performed at three stages of seed development during seed filling, seed maturation and seed maturity. The technical limitation of low bacterial population within seeds was successfully bypassed using bacterial transcript enrichment. This transcriptomic analysis was complemented by the analysis of small RNAs and DNA methylation changes in infected seeds to reveal the role of these mechanisms in the seed-pathogen interaction, which allowed us to propose a novel model in plant-pathogen interactions specific to seed developmental stage and explaining the efficiency of pathogen seed transmission.

Materials and Methods

Bacterial strain and inoculum preparation

The *Xcf* bacterial strain 7767R (Rif^R, Darrasse et al., 2018) was grown for 24h at 28°C in Tryptic Soy Agar at 10% (1.7 g.L⁻¹ tryptone, 0.3 g.L⁻¹ soybean peptone, 0.25 g.L⁻¹ glucose, 0.5 g.L⁻¹ NaCl, 0.5 g.L⁻¹ K₂HPO₄ and 15 g.L⁻¹ agar) supplemented with 50 mg.L⁻¹ rifamycin.

1
2
3 109 Bacterial cells were suspended in sterile distilled water, calibrated at 10^8 CFU.mL⁻¹ (OD_{600} =
4 110 0.1) and adjusted to 10^6 CFU.mL⁻¹ for spray-inoculation.

5
6 111

8 112 **Plant materials and production of contaminated seeds**

9 113 Experiments were performed with *Phaseolus vulgaris* L. cv. Flavert, a cultivar
10 114 susceptible to CBB (Darrasse et al., 2007). Seeds were sown in one liter of Tray substrate
11 115 (NF U 44–551, Klasmann- Deilmann GmbL, Rippert France). Plants were grown in a controlled
12 116 growth chamber with 16h of light at 23°C and 8h of dark at 20°C and a relative humidity (RH)
13 117 of 70%. Plants were watered twice a week during the first three weeks, then with a nutrient
14 118 solution (N/P/K=15/10/30). Plants were staked and pinched after the third leaf.

15 119 Plants were spray-inoculated at the flower bud stage (R5, Michael 1994) with either
16 120 *Xcf* bacterial suspension (10^6 CFU.mL⁻¹) or water as control. The day prior to inoculation,
17 121 temperature (day 25°C/night 23°C) and RH (95%) were increased. Inoculation was performed
18 122 using a two-step protocol. First, small green flower buds were sprayed. Three days later,
19 123 flower buds at the pollination stage were tagged. Then, a second inoculation was performed
20 124 at one day after pollination (DAP) when tagged organs turned into open flowers. Then
21 125 afterward, RH was reduced to 70% to limit pathogen symptom development and seed
22 126 abortion. Three independent replicates of five plants ($n=15$) were inoculated. Tagged pods
23 127 were harvested at 24, 35 and 42 DAP. Seeds were collected aseptically from pods to avoid
24 128 contamination by external bacterial populations (Darsonval et al., 2008).

25 129

26 130 **Monitoring of bacterial population sizes**

27 131 For each sample, *Xcf* population sizes were determined from ten individual seeds and from
28 132 five pools of three seeds. Seeds were soaked in 0.5 mL of sterile water per seed overnight at
29 133 4°C under shaking (150 rpm). Then, 50 μ L of serial dilutions were plated on 10% TSA.
30 134 Colonies were monitored five days after incubation at 28°C. The contamination rate of a
31 135 sample (p) was calculated from the analysis of N sub-samples according to the formula $p = 1 -$
32 136 $(Y/N)^{1/n}$ (Maury et al., 1985), where n is the number of seeds in each group and Y the number
33 137 of healthy groups.

34 138

35 139 **Seed physiological analyses**

36 140 Three sub-samples of ten seeds were used to determine dry weight and water content. Each
37 141 sub-sample was weighed before and after incubation (3 days) in a 96°C incubator (Memmert).

38 142

39 143 **Plant and bacterial RNA extraction and RNA sequencing**

40 144 Seed samples harvested at 24, 35 and 42 DAP were flash-frozen in liquid nitrogen.
41 145 Samples were ground in liquid nitrogen using a mechanical grinder (Retsch MM300

1
2
3 146 TissueLyser) during 1 min at 30 Hertz. Total RNAs were extracted using the NucleoSpin® RNA
4 147 Plant and Fungi Kit (Macherey-Nagel, Düren, Germany), according to the manufacturer
5 148 instructions. RNA quantity and integrity were assessed respectively using a NanoDrop
6 149 ND-1000 (NanoDrop Technologies, Wilmington, DE, USA) and a 2100 Bioanalyzer (Agilent
7 150 Technologies, Santa Clara, CA, USA). Library constructions and single-end sequencing
8 151 (SE50, 20M) were outsourced to the Beijing Genomics Institute (BGI, <https://www.bgi.com>)
9 152 using the Illumina Hiseq 2500 technology. Raw reads are available at GSE226918.
10 153

11 154 Using the same seed lots as for plant RNAs, bacterial macerates were collected after
12 155 soaking contaminated seeds (2 mL per gram of seed) overnight in KPO₄ buffer, (50 mM, pH
13 156 6.8), supplemented with 20% of blocking agent (RNAlater, ThermoFisher scientific, Carlsbad,
14 157 CA, United States). After centrifugation (15 min at 15,000 g) and removal of the supernatant,
15 158 total RNAs were extracted as previously described (Darsonval et al., 2009). Concentration
16 159 and integrity of RNAs were assessed with Qubit (Invitrogen, Carlsbad, CA, USA) and a 2100
17 160 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA), respectively. As total RNA
18 161 extracted from bacterial macerates corresponded mainly to plant transcripts (not shown), we
19 162 designed a procedure of bacterial transcript enrichment. Bacterial mRNAs were captured
20 163 using the SureSelectXT RNA Direct technology (Agilent, Santa Clara, CA, USA). A total of
21 164 54,548 probes of 120-nts length were designed based on the predicted mRNAs of *Xcf7767R*
22 165 genome sequence (GCA_900234465; Chen et al., 2018). Quality and quantity of sequencing
23 166 libraries were evaluated and quantified using Bioanalyzer and KAPA Library Quantification
24 167 assay (Roche, Basel Switzerland). Paired-end sequencing (2 × 75 bp) was performed with a
25 168 NextSeq 550 System High OutPut kit (Illumina, San Diego, CA, USA). Raw reads are available
26 169 at GSE227386.

27 170 After quality control, high-quality reads were mapped either on *Xcf7767R* transcriptome
28 171 (Briand et al., 2021) ([https://bbric-
29 172 pipelines.toulouse.inra.fr/myGenomeBrowser?browse=1&portalname=Xcf7767Rpb&owner=
30 173 armelle.darrasse@inrae.fr&key=TwzQ08DA](https://bbric-pipelines.toulouse.inra.fr/myGenomeBrowser?browse=1&portalname=Xcf7767Rpb&owner=armelle.darrasse@inrae.fr&key=TwzQ08DA)) or on *P. vulgaris* transcriptome version 2.1
31 174 (https://phytozome-next.jgi.doe.gov/info/Pvulgaris_v2_1) using quasi-mapping alignment and
32 175 quantification methods of Salmon algorithm v.1.2 (Patro et al., 2017). RNA-Seq data were
33 176 normalized as transcripts per million (TPM). Differentially expressed genes (DEGs) were
34 177 determined using DESeq2 v1.22.2 (Love et al., 2014), using an adjusted p-value <5%. *Xcf*
35 178 DEGs were analyzed between sampling dates. *P. vulgaris* DEGs were obtained by comparing
36 179 *Xcf*- versus H₂O-inoculated seeds at each developmental stage. Gene annotations were
37 180 provided with the *P. vulgaris* version 2.1 genome and Mapman functional categories v.4 were
38 181 determined using Mercator tool from the predicted protein sequences (Schwacke et al., 2019).
39 182 Bacterial Type III effectors were predicted using the automated machine-learning based web

1
2
3 183 server Effectidor (Wagner et al., 2022). Over representation analyses of MapMan or COG
4 184 terms were performed, respectively for plant and bacteria DEGs, using Clusterprofiler (Yu et
5 185 al., 2012) package in R by applying an adjusted p -value cut-off <0.05 obtained after the
6 186 Bonferroni-Hochberg procedure.

7
8
9 187 Differentially expressed genes during seed germination were identified using the data
10 188 generated by Narsai et al. (2017) available in the SRA database (accession GSE94457). Raw
11 189 reads were downloaded and mapped against the Arabidopsis transcriptome using Salmon
12 190 algorithm and DEGs during germination kinetic were determined using ImpulseDE2 algorithm
13 191 (Fischer et al., 2018) following an adjusted p -value $<1\%$.

14 192 To determine genes involved in post-germination defense, we inoculated healthy
15 193 seeds with 10^7 of *Xcf* CFU.mL⁻¹ or H₂O during 25 min followed by 3 min of vacuum infiltration
16 194 before seed drying at room temperature. Inoculated dried seeds displaying between 10^4 and
17 195 10^5 CFU.seed⁻¹ of *Xcf* were used for germination assay on Whatman paper in 16h-light growth
18 196 chamber at 25°C. *Xcf*- and H₂O-inoculated seeds were collected at 3 and 7 Days After
19 197 Imbibition (DAI) and dissected as separated cotyledons and radicles for real-time qRT-PCR
20 198 experiments. RNA were extracted at different germination timepoints and in different tissues
21 199 using the NucleoSpin® RNA Plant and Fungi Kit (Macherey-Nagel, Düren, Germany) as
22 200 described above but including a DNase treatment (Macherey-Nagel, rDNase set, Düren,
23 201 Germany). RNA were quantified using a using a NanoDrop ND-1000 (NanoDrop
24 202 Technologies, Wilmington, DE, USA) and cDNA was synthesized from 1 µg of total RNA using
25 203 the Reverse Transcription system (iScript™ cDNA synthesis kit, Bio-Rad). Quantitative Real
26 204 time PCR was performed using Sybr Green Master Mix (SYBR Green master mix, Bio-Rad)
27 205 on a CFX96 real-time detection system (Bio-Rad Laboratories). *EF1* and *UBI* genes were used
28 206 as housekeeping genes as described in Darrasse et al. (2010). Primers used for Real-time
29 207 PCR are listed in Supplementary Table S4.

30 208

31 209 **small RNA extraction and analysis (sRNA-seq)**

32 210 Using the same frozen powders obtained from *Xcf*- and H₂O-inoculated seeds from 24
33 211 DAP and 42 DAP, we extracted small RNA using the NucleoSpin® miRNA Kit
34 212 (Macherey-Nagel, Düren, Germany), according to the manufacturer's instructions. Small RNA
35 213 enrichment was validated using Bioanalyzer small RNA analysis. Small RNAs were
36 214 sequenced using DNBseq sequencing technology (SE50 40M, BGI) and Unique Sequence
37 215 identifiers (UMI) to correctly quantify unique reads. Reads of 20 to 24 nucleotides were
38 216 extracted and mapped on the reference mature miRNA database available in miRBase version
39 217 22 (Kozomara et al., 2019) using bowtie (Langmead et al., 2009) and quantified using
40 218 SAMtools (Li et al., 2009). Differentially expressed small RNA between *Xcf*-inoculated versus

219 **Plant DNA extraction and Bisulfite sequencing experiments (BS-seq)**

20 230 From the same frozen seed powders used for RNA extractions, we performed DNA
21 231 extraction, on the three biological replicates of *Xcf*- and H₂O-inoculated seeds at 42 DAP,
22 232 using the NucleoSpin® DNA Food Kit (Macherey-Nagel, Düren, Germany), according to the
23 233 manufacturer's instructions. DNA samples were sent to the BGI Genomics (Hong Kong) for
24 234 bisulfite treatment using a ZYMO EZ DNA Methylation-Gold kit, library construction and
25 235 paired-end sequencing using BGISEQ-500 sequencing technology (PE100 45M). FastQC
26 236 was used to check sequencing quality and clean reads were mapped to the *P. vulgaris*
27 237 genome version 2.1 using Bismark software (Krueger and Andrews, 2011). After mapping,
28 238 deduplication of sequences and quantification of cytosine methylation were performed using
29 239 Bismark_deduplicate and Bismark_methylation_extractor. Each context of methylation was
30 240 considered independently: CG, CHG, or CHH and corresponding bigwig files were generated
31 241 using bismark_to_bigwig python script and displayed in the dedicated Jbrowse:
32 242 https://iris.angers.inrae.fr/pvulgaris_v2. Putative differentially methylated regions (DMRs)
33 243 were identified in each independent methylation context using DMRCaller algorithm available
34 244 in R (Catoni et al., 2018). Raw reads are publicly available at
35 245 <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE226919>.

3 254 described in Darsonval et al. (2008), we used 10^6 CFU.mL⁻¹ for *Xcf* spray-inoculation at
4 255 flowering time to allow seed bacterial transmission without apparition of symptoms during seed
5 256 development. Otherwise, higher concentration could generate symptomatic seed bacterial
6 257 transmission leading to defect in germination of infected seeds. Following this mild treatment,
7 258 about 80% of seeds were contaminated with *Xcf* with an average population size of 10^5 CFU.g⁻¹
8 259 of seeds at 24 DAP (Fig. 1C). Over the course of seed development, the frequency of
9 260 detection of *Xcf* decreased from 80% to 50%. This was accompanied by a significant decrease
10 261 in *Xcf* population size from 35 to 42 DAP, down to an average of 10^3 CFU.g⁻¹ of seeds at
11 262 maturity (Fig. 1C).

18 263 **Changes in the *Xcf* bacterial transcriptome during seed development**

21 264 To explore the genetic determinants involved in *Xcf* seed transmission, dual (host and
22 265 pathogen) transcriptome sequencing was performed at 24, 35 and 42 DAP. An essential step
23 266 to obtain sufficient bacterial transcript data was to enrich RNA-Seq libraries for *Xcf* transcripts
24 267 using 54,656 capture-probes. Among a total of 27.7 to 61.3 M sequenced reads that were
25 268 obtained for each sample, 4.7 to 55.1 M mapped on the predicted transcriptome of *Xcf* strain
26 269 7767R (Supplementary Table S1). A total of 4,372 mRNA were detected in at least one sample
27 270 (count ≥ 10), which corresponded to >96% of the 4,537 predicted mRNA, thus validating our
28 271 *Xcf* transcriptome enrichment strategy. Extensive changes in *Xcf* transcriptome were
29 272 observed between seed filling (24 DAP) and the two other seed maturation stages (35 and 42
30 273 DAP). Indeed, 865 and 1,674 DEGs were detected between 24 and 35 DAP and 24 and 42
31 274 DAP, respectively, (Fig. 2A). On the other hand, only 17 DEGs were detected between 35 and
32 275 42 DAP, indicating that transcriptomic levels stabilized between seed maturation and maturity
33 276 stages. In line with this result, over-representation analyses of COG terms associated to
34 277 bacterial DEGs were performed and revealed that intracellular trafficking and secretion terms
35 278 were enriched at 24 DAP and post-translational modification at 35 and 42 DAP (Fig. 2B). The
36 279 other enriched categories were translation and repair, both enriched at 42 DAP,
37 280 and extracellular structure and cell motility, both enriched at 24 DAP (Fig. 2B).

38 281 A focus on the COG related to secretion processes revealed that all T3SS encoding
39 282 genes and several *xps* genes involved in the T2SS were up-regulated at the seed filling stage,
40 283 but not later during seed maturation (Supplementary Table S1). This was consistent with the
41 284 observed up-regulation of the master regulator *hrpG* that is known to control many genes
42 285 involved in the interaction with the host plant (Teper et al., 2021) such as the T3SS
43 286 transcriptional activator *hrpX* and cognate effectors (T3Es) but also the *xps* genes involved in
44 287 the secretion of cell wall degrading enzymes (Szczyzny et al., 2010). In line with this result,
45 288 26/40 (65%) of T3E-encoding genes and several genes encoding pectin lyase (1), pectate

60

1
2
3 289 lyases (2), glycoside hydrolases (34) and proteases (40) were only up-regulated at early stage
4 290 (Supplementary Table S1). As demonstrated in Darsonval et al. (2008), T3SS encoding
5 291 genes, including hrpG and hrpX are essential genes for efficient bacterial seed transmission.
6
7 292 Together, these results suggested that bacteria were actively interacting with the host plant
8
9 293 only at early seed maturation stages, but not later.

294 ***Transcriptomic analysis of bean seeds in response to pathogen colonization***

295 Changes in *P. vulgaris* transcriptome were assessed using the same seed lots as for
296 the *Xcf* transcriptome analyses described above. All results from this RNA-Seq analysis are
297 displayed in the dedicated Jbrowse (https://iris.angers.inrae.fr/pvulgaris_v2) and in
298 Supplementary Table S1. Similar to what was observed in *Xcf* transcriptome changes, RNA-
299 Seq analysis revealed that the plant response to the bacteria was higher at early than later
300 stages of seed maturation, with 1,826 DEGs at 24 DAP, 1,351 at 35 DAP and only 105 at 42
301 DAP (Fig. 2C). Only 137 DEGs (7.5% of 24 DAP DEGs) were shared between 24 and 35 DAP,
302 indicating that the plant's response was different between these stages, ending up with almost
303 no response in mature seeds. Only one DEG, encoding a CHAPERONE PROTEIN DNAJ-
304 LIKE PROTEIN, was found to be in common between all the three stages
305 (*Phvul.001G262000*) and could reflect a cellular stress in seeds inoculated with *Xcf*. This low
306 overlap in DEGs across different seed developmental stages was also reflected at the level of
307 functional category enrichments, which were different between 24, 35 and 42 DAP (Fig. 2D).
308 The 24 DAP timepoint displayed the most complex response, with six up-regulated and nine
309 down-regulated Mapman functional categories detected through functional enrichment
310 analysis of DEGs. Some categories had well characterized roles in the plant-microbe
311 molecular dialogue, such as Leucine Rich Repeat protein kinases (LRRs), which were up-
312 regulated in *Xcf*-inoculated seeds (*i.e.* up-regulation of 15 annotated LRR related proteins),
313 whereas the Mitogen-Activated Protein Kinases (MAPKs) and transcription factors (TF) of the
314 bZIP, TIFY and AP2/ERF classes were down-regulated. At 24 DAP, in parallel to the down-
315 regulation of MAPKs known to be involved in defense signal transduction such as MAPKKK3,
316 MAPK3 or MAPK4, we also identified down-regulation of defense related genes such as two
317 encoding thaumatin pathogenesis-related (PR) proteins, five JAZ and one JAR genes involved
318 in the jasmonic acid pathway, but also *PAD4*, a central regulator of the salicylic acid pathway
319 (Supplementary Table S1). At 35 DAP, functional ontology enrichment detected four up-
320 regulated categories related to peptidase/protease activities and transfer of carbon skeletons.
321 At 42 DAP, only two up-regulated categories (chromatin regulation and calcium-permeable
322 channel) were detected.

323 ***Small RNAs associated with Xcf seed colonization***

1
2
3 324 To further characterize the molecular dialogue between the colonized seeds and *Xcf*
4 and the changes in plant transcript expression we focused our analysis on small RNA changes
5 325 between colonized and healthy seeds at two contrasted stages, at 24 DAP to decipher if
6 326 transcriptome changes due to plant response to pathogen could be mediated by small RNAs
7 and at 42 DAP to reveal if specific small RNA could be stored at seed maturity to mediate
8 327 defense response at post-germinative stage. Following sequencing and mapping against the
9 328 mature miRNA database (miRBase release 22), we observed a total of 255 and 112 mature
10 329 miRNAs differentially expressed ($p < 0.05$) between *Xcf*-colonized and healthy seeds at 24 and
11 330 42 DAP, respectively. At 24 DAP, mature miRNA up-regulated in *Xcf*-colonized seeds
12 331 belonged to six miRNA families (miR162, miR172, miR396, miR482, miR6478 and miR8175),
13 332 while four miRNA families showed down-regulation (let7, miR21, miR2111 and miR482)
14 333 (Supplementary Table S2, Table 1). Similarly, at 42 DAP, we observed up-regulation of only
15 334 one miRNA family (miR31) and down-regulation of two miRNA families (miR164 and miR451)
16 335 (Supplementary Table S2, table 1). These data further confirmed that the molecular dialogue
17 336 was more intense at early stages compared to later stages. Moreover, several miRNA families
18 337 differentially regulated in *Xcf*-inoculated seeds were known to be involved in plant defense
19 338 response such as miR482 (Shivaprasad et al., 2012), miR396 (Soto-Suárez et al., 2017) and
20 339 miR172 (Holt et al., 2015). Known and unknown identified small RNAs were mapped to the
21 340 genome using ShortStack version 4 and are available in the dedicated *P. vulgaris* Jbrowse
22 341 (https://iris.angers.inrae.fr/pvulgaris_v2).
23 342
24 343

25 344 To reveal the potential response mediated by these miRNAs, we identified putative
26 345 transcript targets using (i) psRNATarget predictive tool (Dai et al. 2018) combined with (ii) our
27 346 generated transcriptomic data at these two stages (Supplementary Table S2). To clarify, a
28 347 transcript was considered as putative miRNA target if (i) its expectation (E) score from
29 348 PsRNATarget was below 5 and if (ii) its expression was down-regulated when miRNA was up-
30 349 regulated or inversely. Following these criteria, we identified between one to 11 putative
31 350 miRNA target transcripts depending on miRNA families (Table 1). Among miRNAs up-
32 351 regulated at 24 DAP in *Xcf*-inoculated, there were target transcripts related to defense such
33 352 as miR8175 that could down-regulate key defense genes such as *PAD4-LIKE* involved in the
34 353 defense pathway mediated by salicylic acid or more generic ones potentially involved in
35 354 defense signaling such as a calcium-dependent-lipid-binding domain gene (CalB) or
36 355 phospholipase A1 (Table 1). At the opposite, in the *Xcf*-inoculated seeds, we observed down-
37 356 regulation of miRNA families such as let7, miR21, miR2111 and miR482 that potentially
38 357 enhanced expression of developmental/growth genes such as TOR-LIKE, MED15, MED13,
39 358 NOC1/SWA2. At 42 DAP, only three miR families, miR31, miR451 and miR164, showed
40 359 significant expression changes between *Xcf*-infected and healthy seeds. An unique putative

transcript target was identified associated with miR451, which encodes a UBP26-LIKE protein potentially involved in the heterochromatin silencing at the end of the seed maturation (Luo et al., 2008). In conclusion, these results suggested that miRNA did mediate seed growth by silencing defense response at 24 DAP during early seed development. On the other hand at maturity, even if miR164 up-regulation was already shown to be involved in plant defense against fungi in cotton (*Gossypium hirsutum*) and *Populus tomentosa* (Hu et al., 2020; Chen et al., 2021b), in our susceptible host this miR was down-regulated at 42 DAP, which did not support the hypothesis that specific miRNA were accumulated in *Xcf*-inoculated seeds to prepare plant defense during germination. Interestingly, at 24 and 42 DAP, we observed that plant miRNA could support seed defense silencing probably due to the bacteria infection arsenal such as its T3Es activated early during seed development.

Seed methylome dynamics associated with *Xanthomonas* seed colonization

To better understand the plant defense response and the impact of the bacterial colonization during seed development, we analyzed the changes in the seed methylomes of healthy and *Xcf*-colonized bean seeds at seed maturity (42 DAP). Indeed, DNA methylation was already described as a relevant mechanism in defense priming and plant immunity (for review see Deleris et al., 2016; Espinas et al., 2016). By focusing on the mature stage, we intended to capture the cumulative impact on DNA methylation of the bacterial colonization throughout seed development. The comparison of *Xcf*-colonized versus healthy seeds samples revealed 954 Differentially Methylated Regions (DMRs), of which 61.95% were hypomethylated (loss of methylation due to bacterial colonization) and 38.05% hypermethylated (gain of methylation due to bacterial colonization) (Supplementary Table S3). Not surprisingly, DMRs were predominantly localized on sequences containing transposable elements or repeats (74.1% of total DMRs), while 7.9% and 4.5% were located within gene and promoter sequences, respectively (Fig. 3A). Regarding the methylation context, we mainly observed DMRs in the CHH (*i.e.* 481 DMRs) and CHG (*i.e.* 394 DMRs) contexts, while only 79 were related to the CG context. The complete list of the differentially methylated genes can be found in Supplementary Table S3 and in the dedicated Jbrowse (https://iris.angers.inrae.fr/pvulgaris_v2).

We identified a total of 102 DMRs located within either coding ($n=66$) or promoter regions ($n=36$) of annotated genes, affecting 99 unique genes. Among coding sequences, 33 genes resulted in hypomethylation and 33 hypermethylation, while among promoter regions 27 genes were hypomethylated and 9 hypermethylated (Fig. 3B). To understand the role of genes differentially methylated in promoter and coding sequences at seed maturity, we compared with their changes in expression and did not observe any overlap with the DEGs

1
2
3 395 between *Xcf*-colonized and non-colonized mature seeds, suggesting that differentially
4 396 methylated regions did not regulate gene expression during seed development. To understand
5 397 the potential role of these DMRs in the host-pathogen interaction, we looked at genes involved
6 398 both in the germination and defense processes. First, from the dataset generated from Narsai
7 399 et al. (2017) during ten early stages of *A. thaliana* seed germination, we identified 21,015
8 400 genes showing a differential expression (adjusted *p*value <1% using ImpulseDE2) during
9 401 germination process, therefore potentially involved in germination. By mapping *P. vulgaris*
10 402 transcripts on Arabidopsis transcripts, we identified potential homologous transcripts in these
11 403 two species and revealed a statistically significant enrichment (Fig. 3B, Fisher's Exact test *p*-
12 404 value < 2.2e-16) of *P. vulgaris* genes displaying DMRs following pathogen colonization with
13 405 those differentially expressed during germination. Indeed, out of the 90 homologous genes
14 406 identified in *A. thaliana* and displaying DMR, 78 were genes differentially expressed during
15 407 germination (Fig. 3C). Second, by analyzing the list of 99 unique genes displaying changes in
16 408 methylation levels following bacterial colonization, we compiled a list of genes with putative
17 409 roles in defense. We identified 17 genes, 10 hypomethylated and 7 hypermethylated following
18 410 bacterial infection (Table 2). As example, we observed five LRR-related protein kinases, two
19 411 PR proteins, and some genes identified as involved in immune response such as *PUB13-*
20 412 *LIKE*, *CES11-LIKE* or *WRKY72* (complete list in Supplementary Table S3). As it is known that
21 413 changes in the methylation state of transposable regions can also spread to adjacent regions
22 414 and regulate nearby gene expression (Ahmed et al., 2011), we extended our search to coding
23 415 sequences that are 5kb nearby DMRs located in transposable regions. This analysis detected
24 416 additional 280 genes potentially associated with DMRs located in transposable regions (61.4%
25 417 with hypomethylated regions and 38.6% with hypermethylated regions). Among these genes,
26 418 we observed a subgroup coding for disease resistance proteins, with 5 additional putative TIR-
27 419 NB-LRR proteins (*Phvul.004G105600*, *Phvul.004G100300*, *Phvul.010G026400*,
28 420 *Phvul.010G027900*, *Phvul.010G028000*), 3 putative NB-ARC proteins (*Phvul.002G130300*,
29 421 *Phvul.002G130400*, *Phvul.004G076100*) and 4 putative LRR kinases (*Phvul.008G164500*,
30 422 *Phvul.008G164600*, *Phvul.005G162100*, *Phvul.005G162000*) (Table 2, Supplementary Table
31 423 S3 and in the dedicated Jbrowse). In total, we listed 17 DMRs nearby genes associated with
32 424 defense processes (Table 2). A comparison between these two lists revealed that 5 genes
33 425 encoding three *LRR related proteins* (*Phvul.008G164600*, *Phvul.005G162000* and
34 426 *Phvul.005G163000*), one *TIR NBS LRR protein* (*Phvul.010G026400*) and *WRKY72 TF*
35 427 (*Phvul.003G068700*), displayed DMRs both within their gene sequences and in transposable
36 428 elements located in proximal genomic regions. To define if these DMRs present in defense
37 429 genes could be associated to a mechanism of defense priming induced by the presence of
38 430 the pathogen during seed development, we selected the most differentially methylated, the
39 431 *WRKY72* gene, and validated its implication in *Xcf* response during germination. By qRT-PCR,

1
2
3 432 we analyzed the expression profile of *WRKY72* during germination in healthy seeds that
4 433 germinated in presence of water versus *Xcf*. We clearly observed an over-expression of
5 434 *WRKY72* at 7 days after imbibition in radicle of germinated seeds in presence of *Xcf*, showing
6 435 the role of this gene in the defense response to *Xcf* infection during germination (Fig. 3D).

7
8
9
10 436 Together, these results suggested that DMRs due to the presence of *Xcf* were mainly
11 437 located in genes that could serve during the germination process and/or to the plant immune
12 438 response to *Xcf*. In other word, pathogen-specific DNA methylations occurring during seed
13 439 development could serve as defense priming to regulate gene expressions during the
14 440 germination process, including a resumption of the molecular dialogue with the pathogen.

15
16
17
18
19 441

20 442 Discussion

21
22
23 443 Seeds are essential components of plants fitness and represent an important means
24 444 of pathogen dispersion. To date, seed-pathogen interactions have been understudied at the
25 445 molecular level, with, to our knowledge, only one plant-orientated study describing the
26 446 transcriptomic response of *Medicago truncatula* seeds to bacterial pathogens of the
27 447 Xanthomonadaceae family (Terrasson et al., 2015). We thus attempted to mitigate this
28 448 knowledge gap by describing the molecular dialogue between common bean seeds and *Xcf*
29 449 in conditions that seed bacterial transmission was asymptomatic. A first central result
30 450 regarding this interaction is that *Xcf* was able to colonize seeds without major impact on seed
31 451 physiology parameters, which was reflected by similar dry weights and water contents in
32 452 healthy- and infected-seeds (Fig. 1). Consequently, we could not observe any obvious
33 453 morphological changes in *Xcf*-colonized seeds compared to mock treated samples. Such
34 454 findings indicate that asymptomatic *Xcf* colonization does not impact seed development or
35 455 alter seed growth. This is consistent with previous report in *M. truncatula* during compatible
36 456 interaction with *X. euvesicatoria* pv. *alfalfae*, while incompatible interaction with *X. campestris*
37 457 pv. *campestris* resulted in developmental defects alongside a strong activation of defense
38 458 pathways (Terrasson et al., 2015).

39
40
41
42
43 459 To look into molecular dialogue, transcriptomic changes were assessed using dual
44 460 RNAseq, which implies that we profiled both bacterial and plant transcripts during seed
45 461 development generating the first dual transcriptomic analysis of a seed-pathogen interaction
46 462 ever made. Profiling of bacterial transcripts represented the main challenge we faced due to
47 463 the low concentration of bacterial cells within seeds. In this study, we successfully achieved
48 464 this technological breakthrough by an enrichment step of bacterial transcripts using an RNA
49 465 capture technology provided by Agilent. Our study revealed that *Xcf* and common bean seeds
50
51
52

55
56
57
58
59
60

1
2
3 466 establish an intense molecular dialogue at the early stages of seed development that appears
4
5 467 to become less intense as seed maturity approaches (Fig. 2).

6 468 On the pathogen side, the up-regulation of the T3SS genes and cognate effectors
7
8 469 observed in the early stages in comparison with 42 DAP suggests they could play a role in the
9
10 470 host defense silencing during the early step of seed colonization (Buttner, 2016). Indeed,
11 471 **Xanthomonads** T3SS and T3Es are known to play two crucial roles in allowing efficient
12
13 472 bacterial seed transmission (Darsonval et al., 2008) and in suppressing plant innate immunity
14
15 473 and modulate plant pathways for the benefits of the bacteria (Büttner, 2016). Interestingly,
16 474 down-regulated categories at early stages include basic biological processes such as
17
18 475 translation, protein turnover and DNA replication. This might suggest that *Xcf* multiplication is
19 476 hampered, consistently with the observation that number of *Xcf* cells in seeds does not
20
21 477 increase significantly throughout seed developmental stages (Fig. 1C). Fewer functional
22 478 categories were enriched at 35 DAP (Fig. 2D). The up-regulated ones (4 out of 5) included
23
24 479 peptidases, glycosylases and methyl transferases. Such functions can be associated with both
25 480 suppression of defense (peptidases, Figaj et al., 2019) and cell wall remodeling, which could
26
27 481 help bacterial colonization of seed tissues, with no detectable impact on the seed physiology
28
29 482 and morphology, although more subtle microscopical effects cannot be excluded (Fig. 1).

30 483 On the host side, we also observed intense gene expression changes at early seed
31
32 484 developmental stage (24 DAP) in comparison to later ones, concomitantly with the intense
33
34 485 bacterial secretion activity. We observed an enrichment of up-regulated Leucine Rich Repeat
35 486 (LRR) protein kinases (2 categories out of 6, LRR class VIII and class Xb), which are known
36 487 to have prominent roles in microbe perception and defense activation **in non-seed tissues**
37
38 488 (Chakraborty et al., 2019), suggesting that the host may be able to recognize the pathogen.
39
40 489 On the other hand, RNA-Seq data highlighted a down-regulation of gene categories with well
41 490 characterized roles in the transduction of defense signaling pathways, including Mitogen-
42
43 491 Activated Protein Kinases (MAPKs such as MAPKKK3, MAPK3 or MAPK4) and transcription
44 492 factors of the bZIP (basic leucine ZIPper), TIFY, and AP2/ERF (APETALA 2/ Ethylene
45
46 493 Responsive Factor) families (Bethke et al., 2009; Bai et al., 2011; Tintor et al., 2013; Noman
47
48 494 et al., 2017). In line with this, we observed down-regulation of transcription factor families
49 495 known to have wider functions in plant stress signaling, such as the TUB or TLP (TUBBY-Like
50
51 496 Proteins) and the HSF (Heat Shock Transcription factor), as well as genes encoding PR
52 497 proteins, including *JAZ* and *JAR* genes involved in the jasmonic acid pathway, and *PAD4*
53 498 involved in the salicylic acid pathway. Such data suggest that even the transduction
54
55 499 components of the defense pathway are inhibited, potentially due to the bacterial T3E,
56
57 500 ultimately avoiding a defense response.

58 501 Similar to transcriptomic data, changes in expression of small RNA at 24 DAP and 42
59
60 502 DAP were consistent with silencing of downstream defense gene response. Indeed, analysis

1
2
3 503 of the differentially expressed miRNA at 24 DAP and their putative target genes suggest a
4 504 growth/defense trade-off mechanism in favor of growth in *Xcf*-inoculated seeds, with down-
5 505 regulation of defense-associated transcripts (e.g. putative ortholog of PAD4
6 506 (*Phvul002G274500*, Phyto Alexin Deficient 4, involved in salicylic acid signaling in *A. thaliana*
7 507 (Pruitt et al., 2021)), a pepsin-type protease (*Phvul001G229200*) and up-regulation of
8 508 development-associated transcripts (e.g. TOR-LIKE (*Phvul011G050300*) and
9 509 MED15 (*Phvul010G157900*, MEDIATOR 15, required for correct embryogenesis in *A. thaliana*
10 510 (Kim et al., 2016)). Interestingly, a heat shock protein (HSP70, *Phvul003G154800*) was
11 511 detected as down-regulated genes at 24 DAP in *Xcf*-inoculated seeds and potential target of
12 512 miR396, which complete the observed downregulation of HSF and smallHSP from our infected
13 513 host transcriptome data (Fig. 2D). Recently it was showed that heat shock proteins are the
14 514 most represented family among the down-regulated DEGs in leaf in a resistant common bean
15 515 genotype towards common bacterial blight (caused by *Xcf* and *Xanthomonas phaseoli* pv.
16 516 *phaseoli*) in comparison to a susceptible one (Foucher et al., 2020). On the other hand, data
17 517 obtained at 42 DAP revealed only down-regulation of one miRNA family miR451, potentially
18 518 regulating the up-regulation of its predicted target gene (*Phvul009G100000*) (Table 1). Its *A.*
19 519 *thaliana* homolog (AT3G49600.1) deubiquitinates the histone H2B and is required for
20 520 heterochromatin silencing during seed development (Luo et al., 2008). It is worth noting that
21 521 chromatin reorganization processes due to histone modifications are among the categories
22 522 enriched at 42 DAP (Fig. 2D), therefore suggesting that epigenetic regulation is a relevant
23 523 component of the seed-pathogen molecular dialogue at this stage, potentially acting as
24 524 priming for post-germination phase. Globally, the transcriptomic response of the susceptible
25 525 host plant suggests that developing seeds are able to perceive the pathogen, and that defense
26 526 responses might be largely inhibited by the bacterial T3SS arsenal. Consistent with
27 527 suppression of the plant defense, up-regulation of photosynthesis and down-regulation of cell
28 528 wall organization enzymes (Fig.2D) were also previously observed in leaves of susceptible
29 529 common bean plants upon infection (Foucher et al., 2020). On the other hand, down-regulation
30 530 of HSP and HSF, and AP2/ERF transcription factors (Fig.2D) were the hallmark of resistant
31 531 plants. This suggests that a balance between susceptibility and resistance exist in *Xcf*-infected
32 532 seeds, which could explain why, despite active bacterial colonization, the seeds were
33 533 asymptomatic and presented no obvious physiological impact.

534

535 In this study, we also revealed that DNA methylation changes in *Xcf*-inoculated seed
536 536 may also act as defense priming for post-germination phase. Indeed, the seed host methylome
537 537 analysis at 42 DAP revealed significant changes in methylation status in 826 different genomic
538 538 regions, affecting a total of 99 different genes, which did not display any change in gene
539 539 expression during seed maturation. Of these, 17 can be associated to defense processes in

1
2
3 540 a relatively straightforward manner (Table 2). As hypomethylation of defense genes has been
4 541 widely associated with increased resistance to biotic stress (Downen et al., 2012; Annacondia
5 542 et al., 2021), the hypomethylated genes of this list (10 out of 17) can be considered as
6 543 candidates for epigenetic-dependent defense priming. The concept of defense priming
7 544 postulates that plants conserve the memory of previous encounters with pathogens by
8 545 preparing their defense networks to respond more rapidly and strongly to a future aggression
9 546 (Martinez-Medina et al., 2016). Enhanced chromatin access to defense genes through
10 547 hypomethylation is one of the best characterized mechanisms in this sense (Hannan Parker
11 548 et al., 2022). Furthermore, epigenetic defense priming can be transmitted to the next
12 549 generations (Slaughter et al., 2012). This would be consistent with a scenario where *Xcf*
13 550 colonization does not directly induce defense gene activation in common bean seeds, but
14 551 rather triggers a primed state that prepare defense networks for the moment when the
15 552 pathogen will again become virulent (after germination). Hypomethylation of transposable
16 553 elements is another well-characterized mechanism of epigenetic regulation of plant defenses,
17 554 as it can lead to the euchromatisation of wide genomic regions, both proximal and distal (López
18 555 Sánchez et al., 2016; Halter et al., 2021). The five defense genes present in Table 2 are thus
19 556 likely to be good candidates for relevant roles in bean resistance against *Xcf*. They include
20 557 three genes affected by hypomethylation (*Phvul.008G164600*, *Phvul.005G163000*,
21 558 *Phvul.010G026400*), namely two putative LRR kinase receptors and one effector receptor, all
22 559 uncharacterized. The other two genes affected by hypermethylation are another
23 560 uncharacterized LRR kinase receptor (*Phvul.005G162000*) and the putative bean homolog of
24 561 WRKY72 (*Phvul.003G068700*). This transcription factor has the highest methylation gain
25 562 among all the genes detected (fold change of +4,3), suggesting that its methylation status
26 563 might be important in response to *Xcf* infection. Indeed, the role of WRKY72 orthologs is
27 564 contradictory in different species. A positive role on defense responses was showed in *A.*
28 565 *thaliana* and tomato (*Solanum lycopersicum*) against oomycetes and bacteria, respectively
29 566 (Bhattarai et al., 2010), but regarding the interaction between rice (*Oryza sativa*) and
30 567 *Xanthomonas oryzae* pv. *Oryzae*, it was showed to negatively regulate rice defense responses
31 568 by repressing jasmonate biosynthetic genes (Hou et al., 2019). In our study, we validated its
32 569 role as *Xcf*-response genes during germination by highlighting its over-expression at 7 DAI in
33 570 radicles of germinated seeds in presence of *Xcf*. Another consideration regarding our
34 571 methylome data is the high overlap between DMRs-containing genes and germination-DEGs
35 572 (Fig. 3B). This suggests that the DMR-containing genes following bacterial infection detected
36 573 in this study may serve during the germination process through a defense priming mechanism.
37 574 More investigation will be required to define if these methylation changes will have positive or
38 575 negative impacts on defense- and/or germination-related gene expressions and will require
39 576 extensive transcriptomic analyses.

1
2
3 577

4 578 All together, these results indicate that the molecular mechanisms involved in the
5 579 pathogen-seed dialogue change radically across the developmental stages for both the host
6 580 and the pathogen side, potentially suggesting the existence of distinct phases in the
7 581 considered seed-pathogen interaction. It would be interesting to explore whether such **pattern**
8 582 takes place in other seed-pathogen interactions. By summing our physiological and molecular
9 583 observations, with the previous findings of Terrasson et al. (2015), we can propose a model
10 584 where the recognition of a host-specific pathogen at the early stages of seed development
11 585 fails to trigger seed defense activation, as if the presence of the pathogen was “accepted” by
12 586 the host. Even if we cannot define whether this suppression is caused by the pathogen or by
13 587 the host, two *Xanthomonas* studies would support the role of bacterial T3SS in host defense
14 588 silencing. Darsonval et al. (2008) showed the essential role of T3E for an efficient seed
15 589 colonization in the *X. citri* pv. *fuscans*-bean seed interaction and Terrasson et al. (2015)
16 590 showed that *X. euvesicatoria* pv. *Alfalfae* was able to silence some defense genes in a
17 591 compatible interaction, but not in an incompatible one. In any case, the result is a situation
18 592 where the seed develops normally without any obvious fitness costs associated to an eventual
19 593 defense activation, while the host-specific pathogen displays a non-aggressive behavior
20 594 throughout all the seed development and limits its proliferation (Fig. 4). Such “ceasefire”
21 595 scenario might be advantageous for both parts: the seed is able to reach maturity, which would
22 596 potentially be beneficial for the pathogen as well by allowing it to infect the future germinated
23 597 seedling, therefore giving it access to nourishment and facilitating its dispersal. On the other
24 598 hand, data at 42 DAP suggest a relevant role for epigenetic modifications in the host. It is
25 599 tempting to speculate that such modifications contribute to prepare the host to face a novel
30 600 pathogen assault after germination (Fig. 4). Detailed analysis of the transcriptome and
31 601 epigenome of the bean-*Xcf* interaction during the germination process would be a promising
32 602 future research direction in this sense. Recent data from the compatible interaction *Alternaria*
33 603 *brassicicola*-*A. thaliana*, used as seed transmission model, showed that host defense
34 604 pathways are subjected to drastic changes during the germination process (Ortega-Cuadros
35 605 et al., 2022). It would be interesting to explore whether such rearrangements take place in
36 606 other compatible interactions such as *Xcf*-bean and if a link with epigenetic modifications
37 607 exists.

51 607
52 608
53 609

54 609 To summarize, the present study adds novel elements to the current knowledge gap
55 610 of seed-pathogen interactions. The dual transcriptomic analysis allowed for the first time to
56 611 describe the molecular dialogue from both host and pathogen sides, while methylome and
57 612 sRNAs profiling added further indications on the potential regulatory mechanisms and the
58 613 genes involved. A dedicated Jbrowse containing all these generated data will serve as

1
2
3 614 baseline tool for the scientific communities and will be enriched by future related studies. An
4 615 important general conclusion that we can draw is that seeds have primarily an active role in
5 616 this interaction at early seed maturation stage, contrary to the widely diffused assumption
6 617 considering seeds as passive carriers of microbes (Dutta et al., 2014). As the role of
7 618 seedborne pathogens in causing yield losses receives relatively little attention, we hope that
8 619 the present study can stimulate novel research efforts in this sense to shed light on the many
9 620 obscure points still shrouding seed-pathogen interactions.

1
2
3 869 **Figure 4. Schematic model of the *Xcf*-bean seed dialogue.** Left panel: at early seed
4 870 development stages (24 DAP), *Xcf* is recognized by the host. Despite the bacterial recognition,
5 871 defense transduction pathways based on MAP kinases cascades (MAPKs) and transcription
6 872 factors (TFs) activation are suppressed in seeds, thus failing to induce a defense reaction.
7
8 873 Red dotted lines with flat end indicate hypothetical inhibition. Middle Panel: at 35 DAP, both
9 874 the bacterial pathogen and the host plant are still transcriptionally active. Bacterial populations
10 875 continue to grow, but the T3SS is no longer active, suggesting that the bacteria lowered its
11 876 weapons, keeping the seed alive and healthy. Right panel: at seed maturation (42 DAP), the
12 877 dialogue between *Xcf* and seed is much less detectable in comparison to earlier stages but
13 878 epigenetic mechanisms such as DNA methylation could be active, which was observed at
14 879 seed maturity by the changes in the methylation status of genes identified as involved in both
15 880 defense and germination processes. This change in DNA methylation could prime genes
16 881 involved in defense/germination, ultimately preparing the host for the post-germination battle
17 882 with the virulent *Xcf* (see text for more details).

Table 2. List of differentially methylated regions located in defense-associated genes in of *P. vulgaris* seeds following *Xcf* colonization at 42 DAP. DMRs were located in promoter or gene sequences, but also in transposable elements located within 5kb of genic regions. The *P. vulgaris* annotation column was filled according to the *P. vulgaris* genome (v2.1). The location indicates whether the region is localized in a coding region (gene) or in the promoter (1kbprom) or in TE within 5kb of genic regions (within 5kb). The putative ortholog was assigned as best hit based on sequence similarity in the *A. thaliana* genome (v.11). The “gain or loss” column shows whether the differentially methylated region associated with the corresponding *P. vulgaris* gene is hypo- (loss) or hypermethylated (gain) in response to *Xcf* colonization at 42 DAP. FC, fold change of methylation between *Xcf*- versus H₂O-treated seeds. FC ratios are not indicated for DMRs within 5kb of genic regions because they correspond to multiple DMRs.

<i>P. vulgaris</i> locus ID	Location	<i>P. vulgaris</i> annotation	<i>A. thaliana</i> putative ortholog	<i>A. thaliana</i> symbol	<i>A. thaliana</i> annotation	Methylation FC (Xcf vs H ₂ O)	Gain or loss of methylation in <i>Xcf</i> -treated seeds

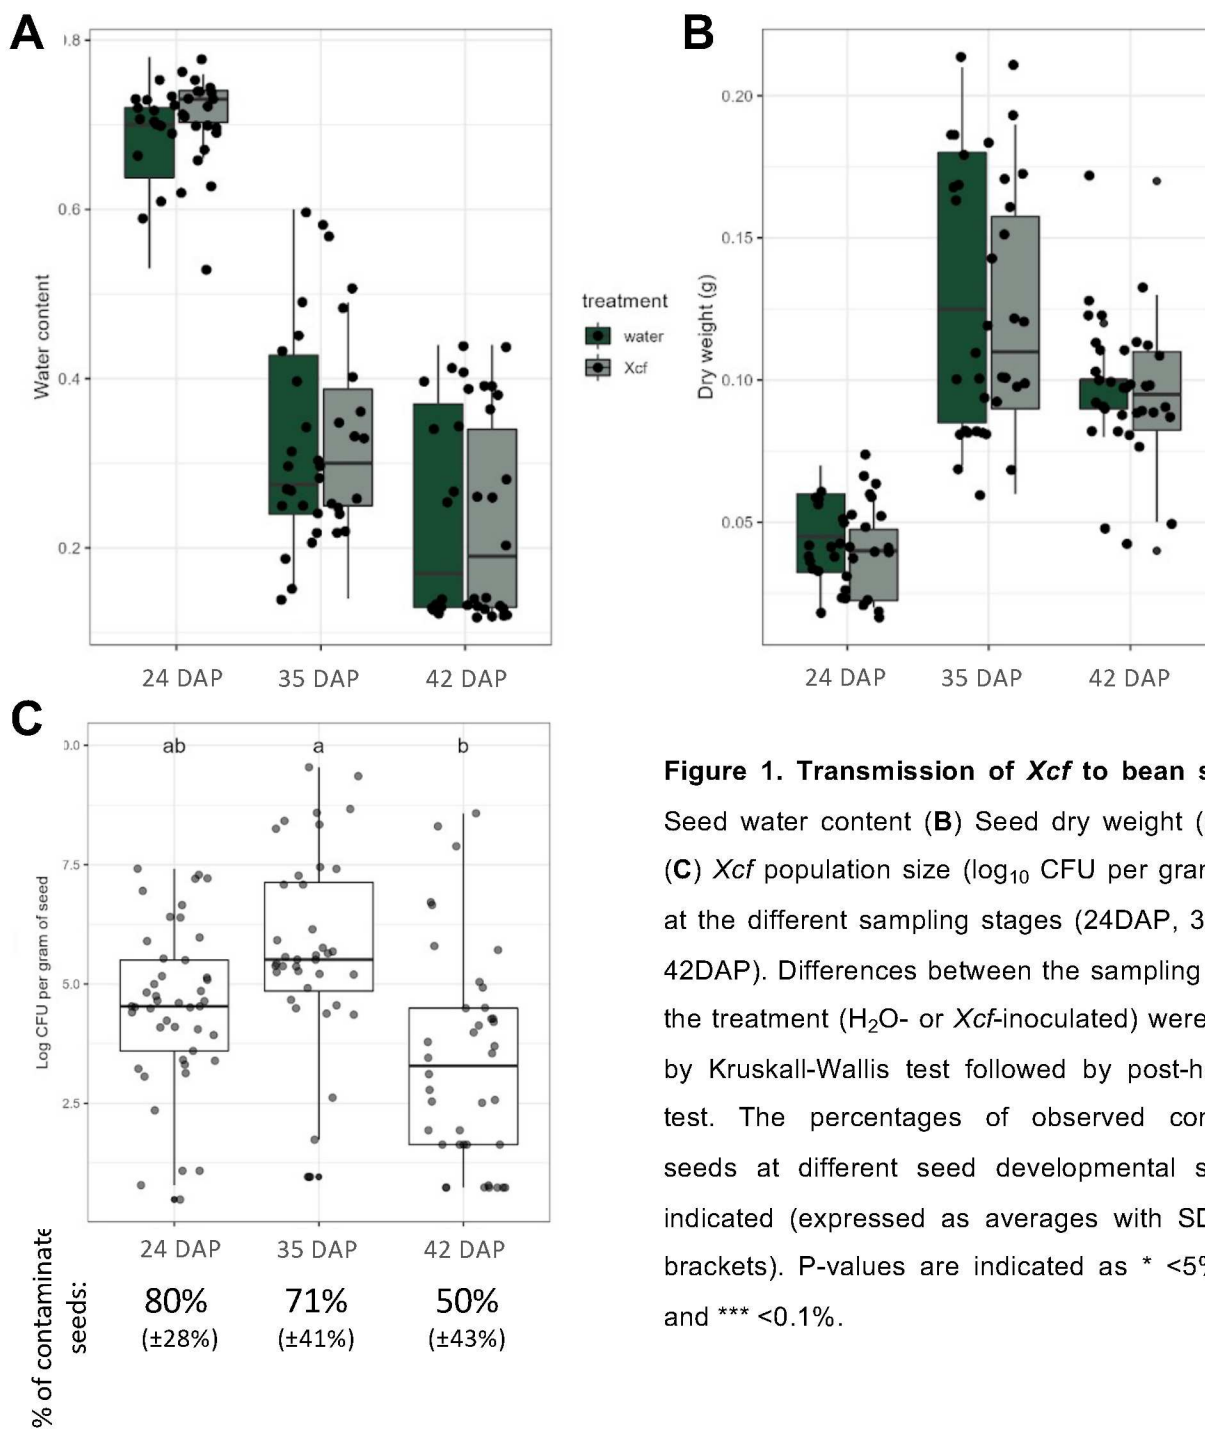

Figure 1. Transmission of *Xcf* to bean seeds. (A) Seed water content (B) Seed dry weight (gram) and (C) *Xcf* population size (\log_{10} CFU per gram of seed) at the different sampling stages (24DAP, 35DAP and 42DAP). Differences between the sampling stage and the treatment (H_2O - or *Xcf*-inoculated) were assessed by Kruskal-Wallis test followed by post-hoc Dunn's test. The percentages of observed contaminated seeds at different seed developmental stages are indicated (expressed as averages with SD between brackets). P-values are indicated as * <5%, ** <1% and *** <0.1%.

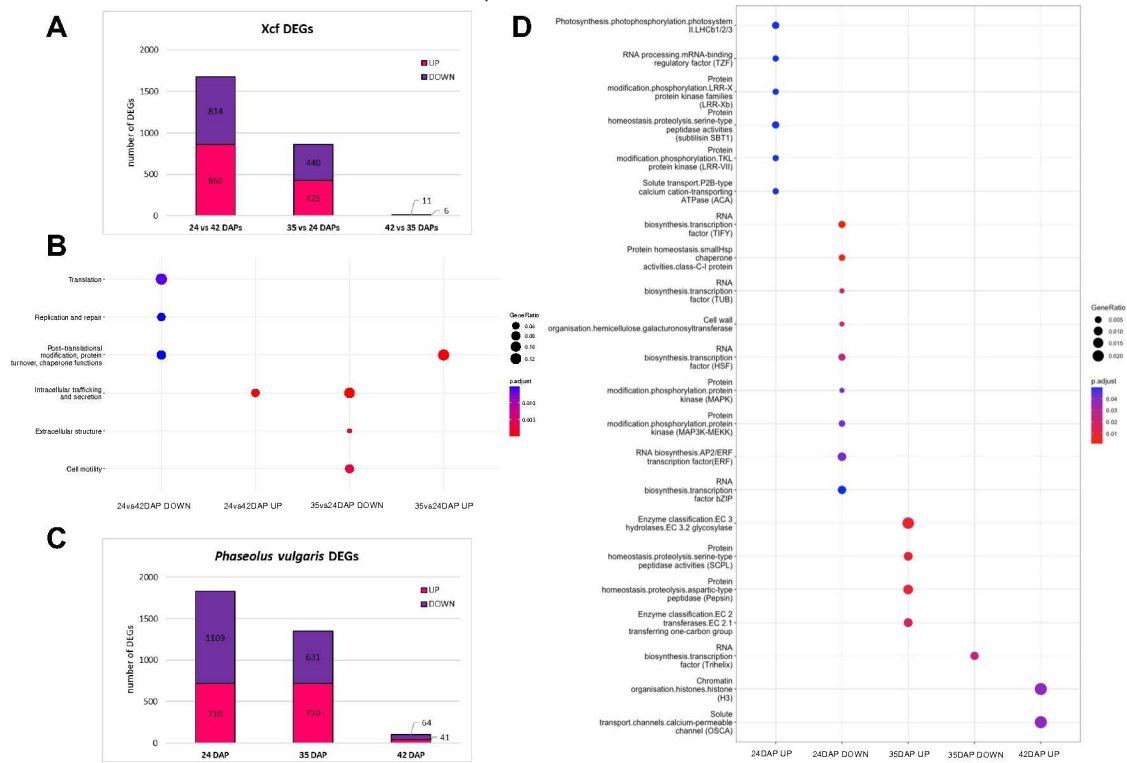

Figure 2. Dual transcriptomic analysis of the *Xcf-P. vulgaris* seed interaction.

(A)(C) Histograms summarizing the number of differentially expressed genes (DEGs) detected comparing datasets from different seed development stages from *Xcf* samples (A) and DEGs from different development stages from *P. vulgaris* samples (C). The number of DEGs is indicated on the bars. (B) (D) Dot plots showing category enrichment results obtained through gene ontology analysis of DEGs from *Xcf* (B) and *P. vulgaris* (D). Gene ontology analysis was performed with the ClusterProfiler package for R.

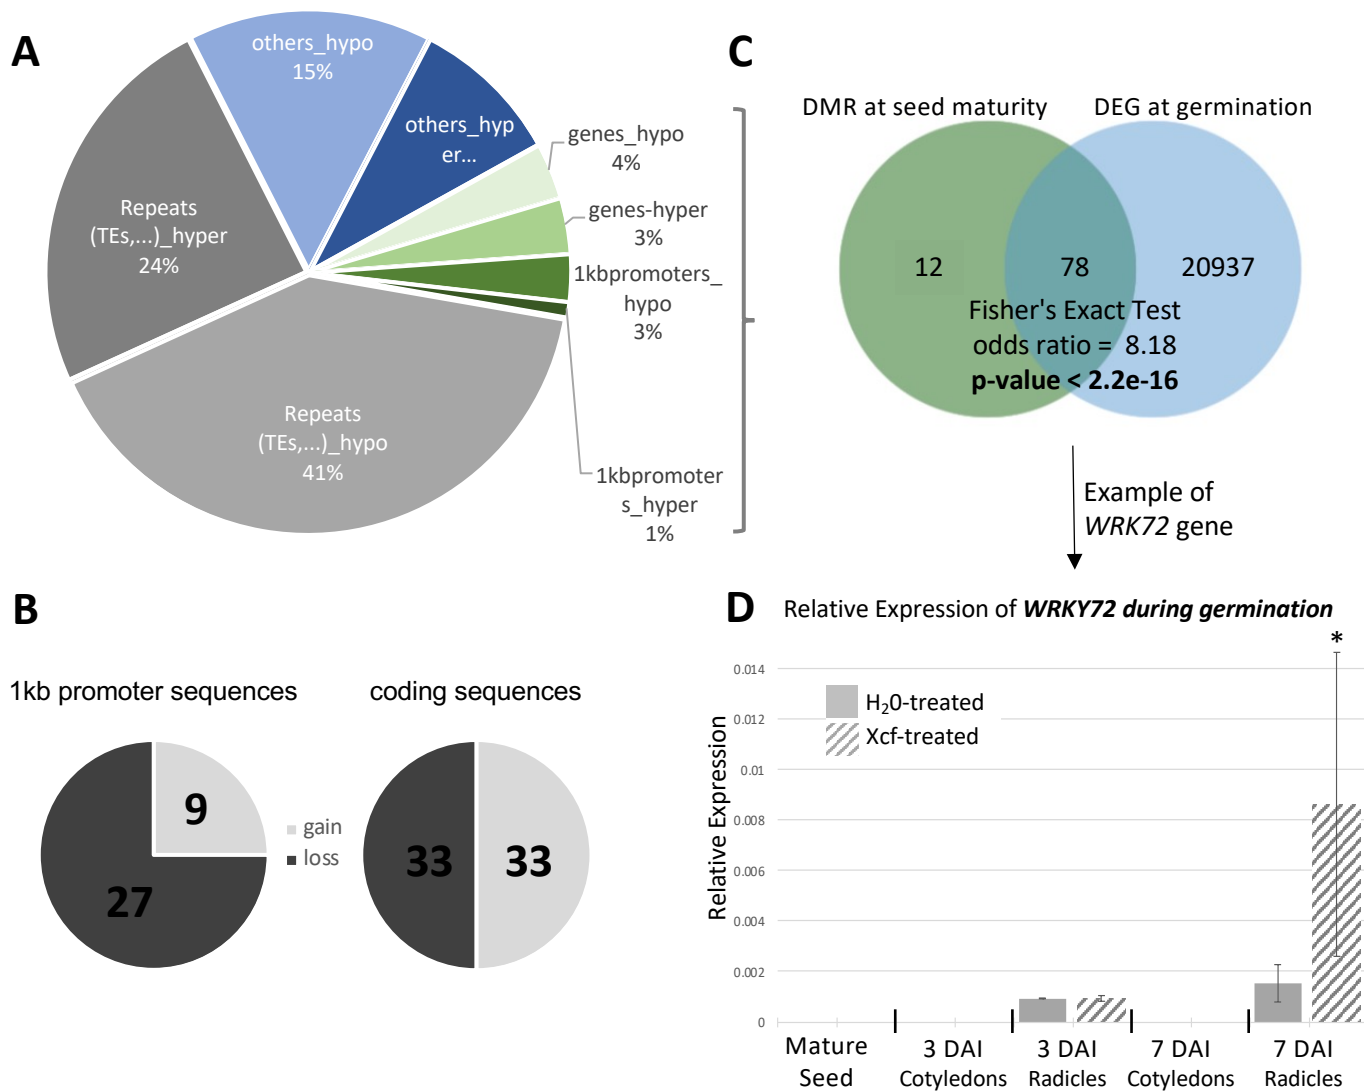

Figure 3. Summary of methylome analysis data generated by comparing *Xcf*-colonized and uncolonized seeds at 42 DAP. (A) Pie chart illustrating the repartition of differentially methylated regions (DMRs) following *Xcf* colonization on *P. vulgaris* genome at 42 DAP. (B) Pie charts illustrating the number of hypo-(loss) and hyper-(gain) methylated DMRs located in annotated genes (1kb promoter or coding sequences). (C) Venn diagram illustrating the overlap between gene sequences containing DMRs at 42 DAP and differentially expressed genes (DEGs) during germination (see details in text). (D) Relative expression of *WRKY72* during germination (at 3 and 7 Days after imbibition, DAI) in H₂O- and *Xcf*-treated seeds.

Figure 4. Schematic model of the *Xcf*-bean seed dialogue. Left panel: at early seed development stages (24 DAP), *Xcf* is recognized by the host. Despite the bacterial recognition, defense transduction pathways based on MAP kinases cascades (MAPKs) and transcription factors (TFs) activation are suppressed in seeds, thus failing to induce a defense reaction. Red dotted lines with flat end indicate hypothetical inhibition. Middle Panel: at 35 DAP, both the bacterial pathogen and the host plant are still transcriptionally active. Bacterial populations continue to grow, but the T3SS is no longer active, suggesting that the bacteria lowered its weapons, keeping the seed alive and healthy. Right panel: at seed maturation (42 DAP), the dialogue between *Xcf* and seed is much less detectable in comparison to earlier stages but epigenetic mechanisms such as DNA methylation could be active, which was observed at seed maturity by the changes in the methylation status of genes identified as involved in both defense and germination processes. This change in DNA methylation could prime genes involved in defense/germination, ultimately preparing the host for the post-germination battle with the virulent *Xcf* (see text for more details).

Table 2. List of differentially methylated regions located in defense-associated genes in of *P. vulg*

<i>P. vulgaris</i> locus ID	Location	<i>P. vulgaris</i> annotation
Phvul.001G233000	gene	protein kinase (SD-1)
Phvul.002G125500	within 5kb	not annotated
Phvul.002G130300	within 5kb	not annotated
Phvul.002G130400	within 5kb	not annotated
Phvul.003G021700	1kbProm	transferase transferring phosphorus-containing group
Phvul.003G040300	1kbProm	6-deoxocastasterone 6-oxidase
Phvul.003G056900	within 5kb	systemic acquired resistance (SAR) regulator protein (SNI1)
Phvul.003G068700	gene	transcription factor (WRKY)
Phvul.003G068700	within 5kb	transcription factor (WRKY)
Phvul.003G175700	gene	DRB4-DRB7.1 regulator complex.component DRB7
Phvul.004G076100	within 5kb	not annotated
Phvul.004G105600	within 5kb	not annotated
Phvul.005G162000	1kbProm	transferase transferring phosphorus-containing group
Phvul.005G162000	within 5kb	transferase transferring phosphorus-containing group
Phvul.005G162100	within 5kb	transferase transferring phosphorus-containing group
Phvul.005G163000	gene	transferase transferring phosphorus-containing group
Phvul.005G163000	within 5kb	transferase transferring phosphorus-containing group
Phvul.006G006800	gene	TKL protein kinase superfamily.protein kinase (DUF26)
Phvul.006G033200	gene	not annotated
Phvul.007G187700	1kbProm	not annotated
Phvul.007G241200	gene	transcription factor (MYB-related)
Phvul.007G241200	within 5kb	transcription factor (MYB-related)
Phvul.007G241300	within 5kb	Ser/Thr protein kinase
Phvul.008G164500	within 5kb	transferase transferring phosphorus-containing group
Phvul.008G164600	gene	not annotated
Phvul.008G164600	within 5kb	not annotated
Phvul.008G228714	gene	S8-class protease (subtilisin) families.protease (SBT4)
Phvul.008G229400	gene	S8-class protease (subtilisin) families.protease (SBT4)
Phvul.010G026400	1kbProm	effector receptor (NLR)
Phvul.010G026400	within 5kb	effector receptor (NLR)
Phvul.010G027900	within 5kb	effector receptor (NLR)
Phvul.010G028000	within 5kb	effector receptor (NLR)
Phvul.010G062500	within 5kb	WRKY33-dependent plant immunity transcription factor
Phvul.011G064700	gene	U-Box E3 ligase activities.E3 ubiquitin ligase (PUB)
Phvul.011G108300	gene	transferase transferring phosphorus-containing group
Phvul.011G176100	gene	transferase transferring one-carbon group

3aris seeds following Xcf colonization at 42 DAP. DMRs were located in promoter or gene sequences:

<i>A. thaliana</i> putative ortholog	<i>A. thaliana</i> symbol	<i>A. thaliana</i> annotation
AT3G16030	CES101	lectin protein kinase family protein
AT5G08315		Defensin-like (DEFL) family protein
AT3G14470		NB-ARC domain-containing disease resistance protein
AT3G14470		NB-ARC domain-containing disease resistance protein
AT1G70740		Protein kinase superfamily protein
AT3G30180	BR6OX2	brassinosteroid-6-oxidase 2
AT4G18470	SNI1	negative regulator of systemic acquired resistance (SNI1)
AT5G15130	WRKY72	WRKY DNA-binding protein 72
AT5G15130	WRKY72	WRKY DNA-binding protein 72
AT5G20320	DCL4	dicer-like 4
AT3G14470		NB-ARC domain-containing disease resistance protein
AT2G34930		disease resistance family protein / LRR family protein
AT4G29990		Leucine-rich repeat transmembrane protein kinase protein
AT4G29990		Leucine-rich repeat transmembrane protein kinase protein
AT1G51800		Leucine-rich repeat protein kinase family protein
AT4G29990		Leucine-rich repeat transmembrane protein kinase protein
AT4G29990		Leucine-rich repeat transmembrane protein kinase protein
AT4G05200	CRK25	cysteine-rich RLK (RECEPTOR-like protein kinase) 25
AT5G38280	PR5K	PR5-like receptor kinase
AT3G04720	PR4	pathogenesis-related 4
AT5G47390		myb-like transcription factor family protein
AT5G47390		myb-like transcription factor family protein
AT1G50240	FU	Protein kinase family protein with ARM repeat domain
AT3G21340		Leucine-rich repeat protein kinase family protein
AT1G05700		Leucine-rich repeat transmembrane protein kinase protein
AT1G05700		Leucine-rich repeat transmembrane protein kinase protein
AT3G46850		Subtilase family protein
AT5G59100		Subtilisin-like serine endopeptidase family protein
AT5G36930		Disease resistance protein (TIR-NBS-LRR class) family
AT5G36930		Disease resistance protein (TIR-NBS-LRR class) family
AT5G36930		Disease resistance protein (TIR-NBS-LRR class) family
AT5G36930		Disease resistance protein (TIR-NBS-LRR class) family
AT2G38470	WRKY33	WRKY DNA-binding protein 33
AT3G46510	PUB13	plant U-box 13
AT1G29730		Leucine-rich repeat transmembrane protein kinase
AT3G11480	BSMT1	S-adenosyl-L-methionine-dependent methyltransferases family protein

s, but also in transposable elements located within 5kb of genic regions. The *P. vulgaris* annotation column
