## ➤ Context

- Drive toward a greener European agriculture with reduced inputs as part of [The European Green Deal](#)
- **Resurgence of the threat** posed by wireworms and increase in crop damage (e.g. maize, potatoes, vegetables)
- Mandatory<sup>1</sup> application of the principles of IPM  
→ **risk assessment** can promote IPM strategies [Furlan et al., 2017]<sup>2</sup> in view to reduce the dependence to and use of chemical pesticides

Poggi et al., 2021. Agriculture, 11 (5), 436

Assessing the risk associated with wireworm infestation and the potential damage to crops can benefit from statistical and mathematical modelling

<sup>1</sup> UE Directive 128/2009/EC

<sup>2</sup> Furlan et al., 2017. Crop Protection 97, 52-59

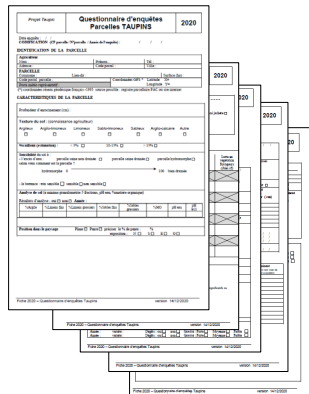

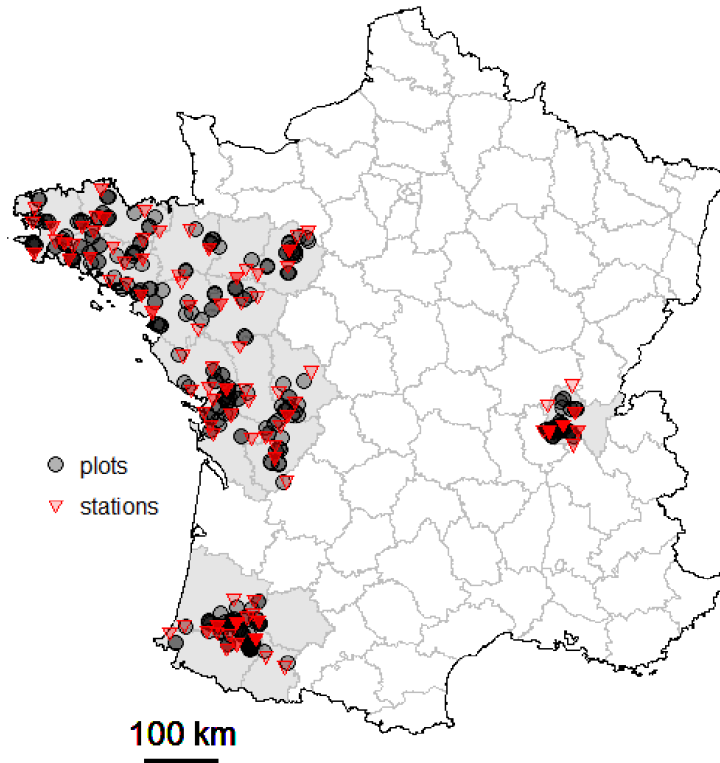

## Relative influence of climate and agroenvironmental factors on wireworm damage risk in maize crops

Sylvain Poggi<sup>1</sup> · Ronan Le Cointe<sup>1</sup> · Jean-Baptiste Riou<sup>1,2</sup> · Philippe Larroude<sup>2</sup> · Jean-Baptiste Thibord<sup>2</sup> · Manuel Plantegenest<sup>1,3</sup>

**336** survey data  
(2012-2014)

**ARVALIS**  
Institut du végétal

### 37 explanatory variables (X)

Presence of wireworms and identity of predominant species

Weather conditions

Soil characteristics

Agricultural practices

Field history

Local landscape features

### Response variable (y)

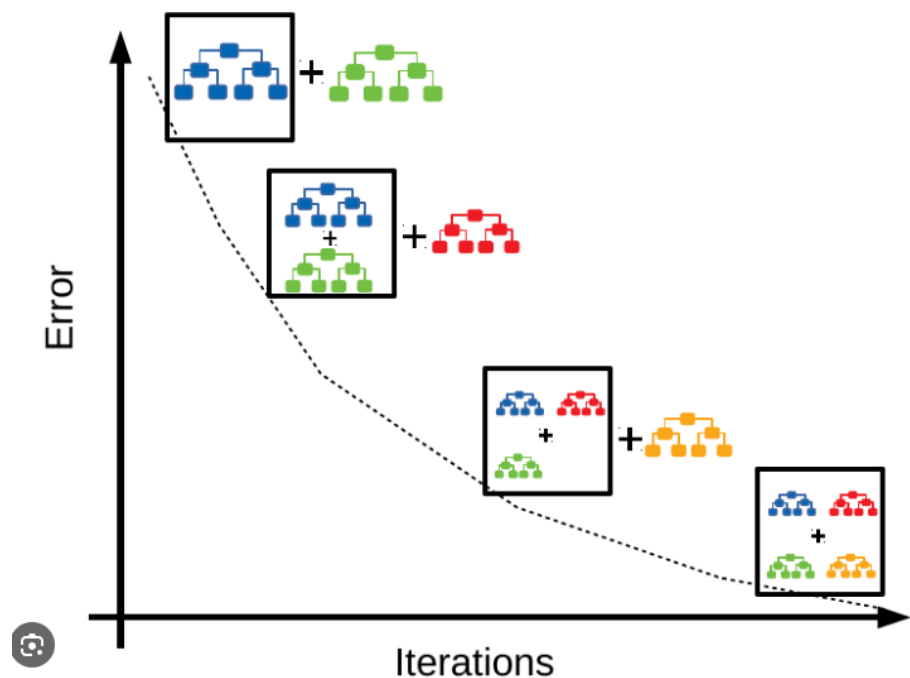

Rate of damaged plants along 3 transects (3\*10 metres) randomly chosen

DATA

MODEL

RISK  
FACTORS

CLASSIFIER  
& DSS

$$y = f(X, \varepsilon)$$

- $y \in [0,1]$  : rate of damaged plants
- $X \in \mathbb{R}^n$  : covariates
- $\varepsilon$  : some kind of error
- $f : \mathbb{R}^n \rightarrow [0,1]$  : some kind of function

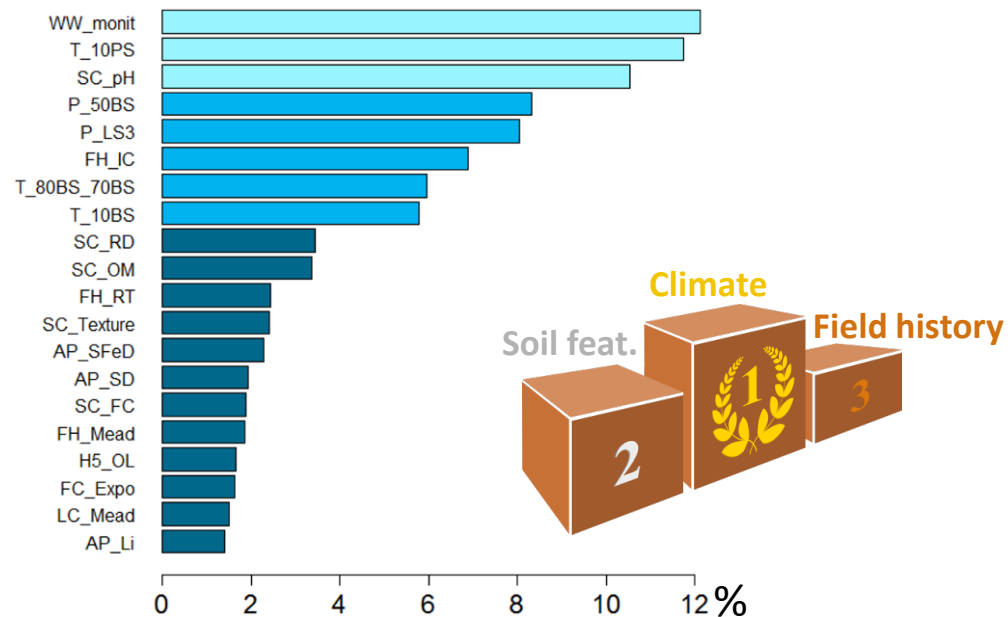

### Boosted Regression Trees (*machine learning*)

Stochastic, nonlinear regression model inheriting the strengths of regression trees and boosting

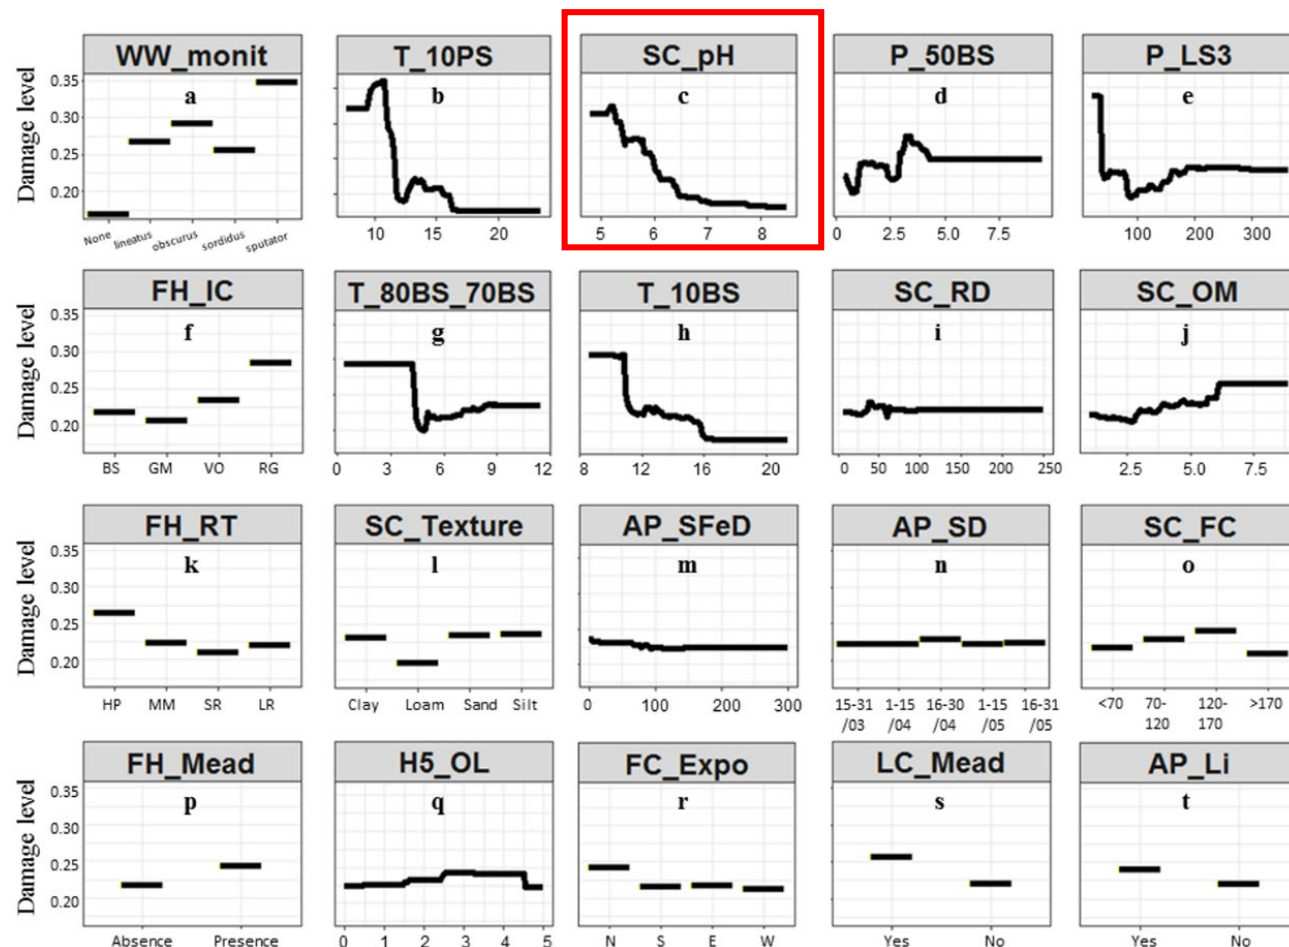

# ➤ Data-based regression models

## Relative influence of variables

## Marginal effects of the main influential variables

## ➤ Data-based regression models

Given the **economic threshold** 15%<sup>3</sup>, observed field status is

167	169	(336)
<i>undamaged</i> ("negative")	<i>damaged</i> ("positive")	

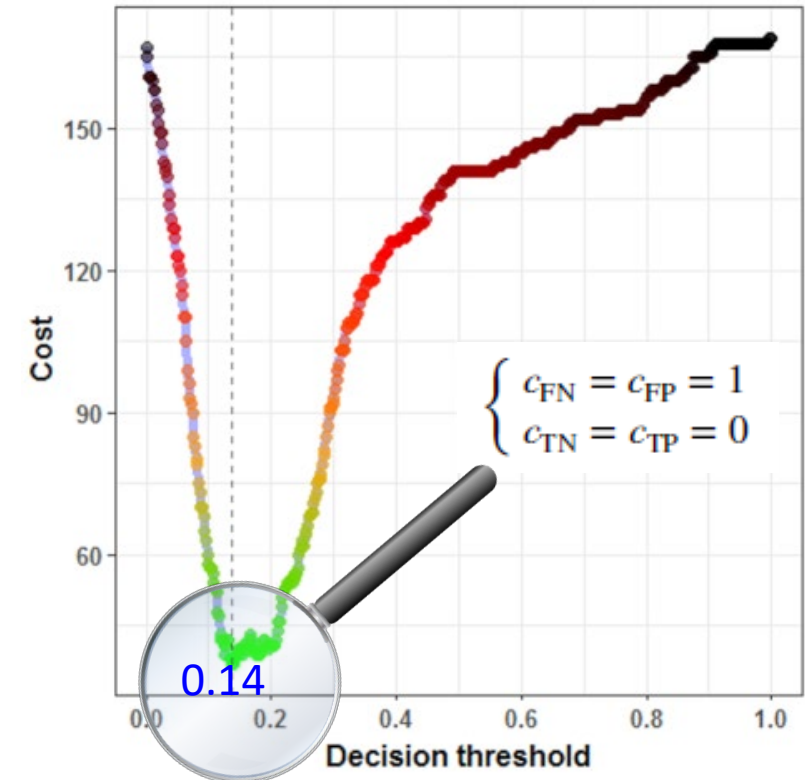

Downgrade BRT model in a **binary classifier** with 4 possible outcomes: **TN, TP, FN, FP**

- Define an "expected cost" function:

$$C(D_{dec}) = c_{FN} \times P(FN) + c_{FP} \times P(FP) + c_{TN} \times P(TN) + c_{TP} \times P(TP)$$

- Infer the **decision threshold**  $D_{dec}$  that minimizes the expected cost

<sup>3</sup>Furlan et al., 2017. Environ Sci Pollut Res 24, 236-251

### Performance of the binary classifier

<b>Classification error:</b>	<b>11%</b>	
<b>Sensitivity</b>	93%	Probability of (risk) detection
<b>Specificity</b>	85%	Probability of false alarm 15%
<b>False Negative (FN)</b>	~4%	
<b>False Positive (FP)</b>	~7%	

## CONCLUSION PART ONE

---

- Identification and ranking of the main risk factors for wireworm damage
- Proof of concept of a DSS for risk management
- Further requirements:
  - inform the binary classifier with real economic costs (incl. treatment, yield loss)
  - compare forecast with a set of test data

## LIMITATIONS

---

- Approach dependent on data quality: how informative? How representative? Etc.
- “Black-box model”, i.e. no consideration of mechanisms at stake

## PERSPECTIVE

---

- Apply this methodology to the wireworm/potato system (project TAUPIC, coord. inov3PT)

## ➤ Latent variable models

A decision support system based on Bayesian modelling for pest management: Application to wireworm risk assessment in maize fields

Julien Roche<sup>a</sup>, Manuel Plantegenest<sup>a,b</sup>, Philippe Larroude<sup>c</sup>, Jean-Baptiste Thibord<sup>c</sup>, Le Cointe Ronan<sup>a</sup>, Sylvain Poggi<sup>a,\*</sup>

**419** maize fields with different levels of infestation

**15** explanatory variables ( $X$ )

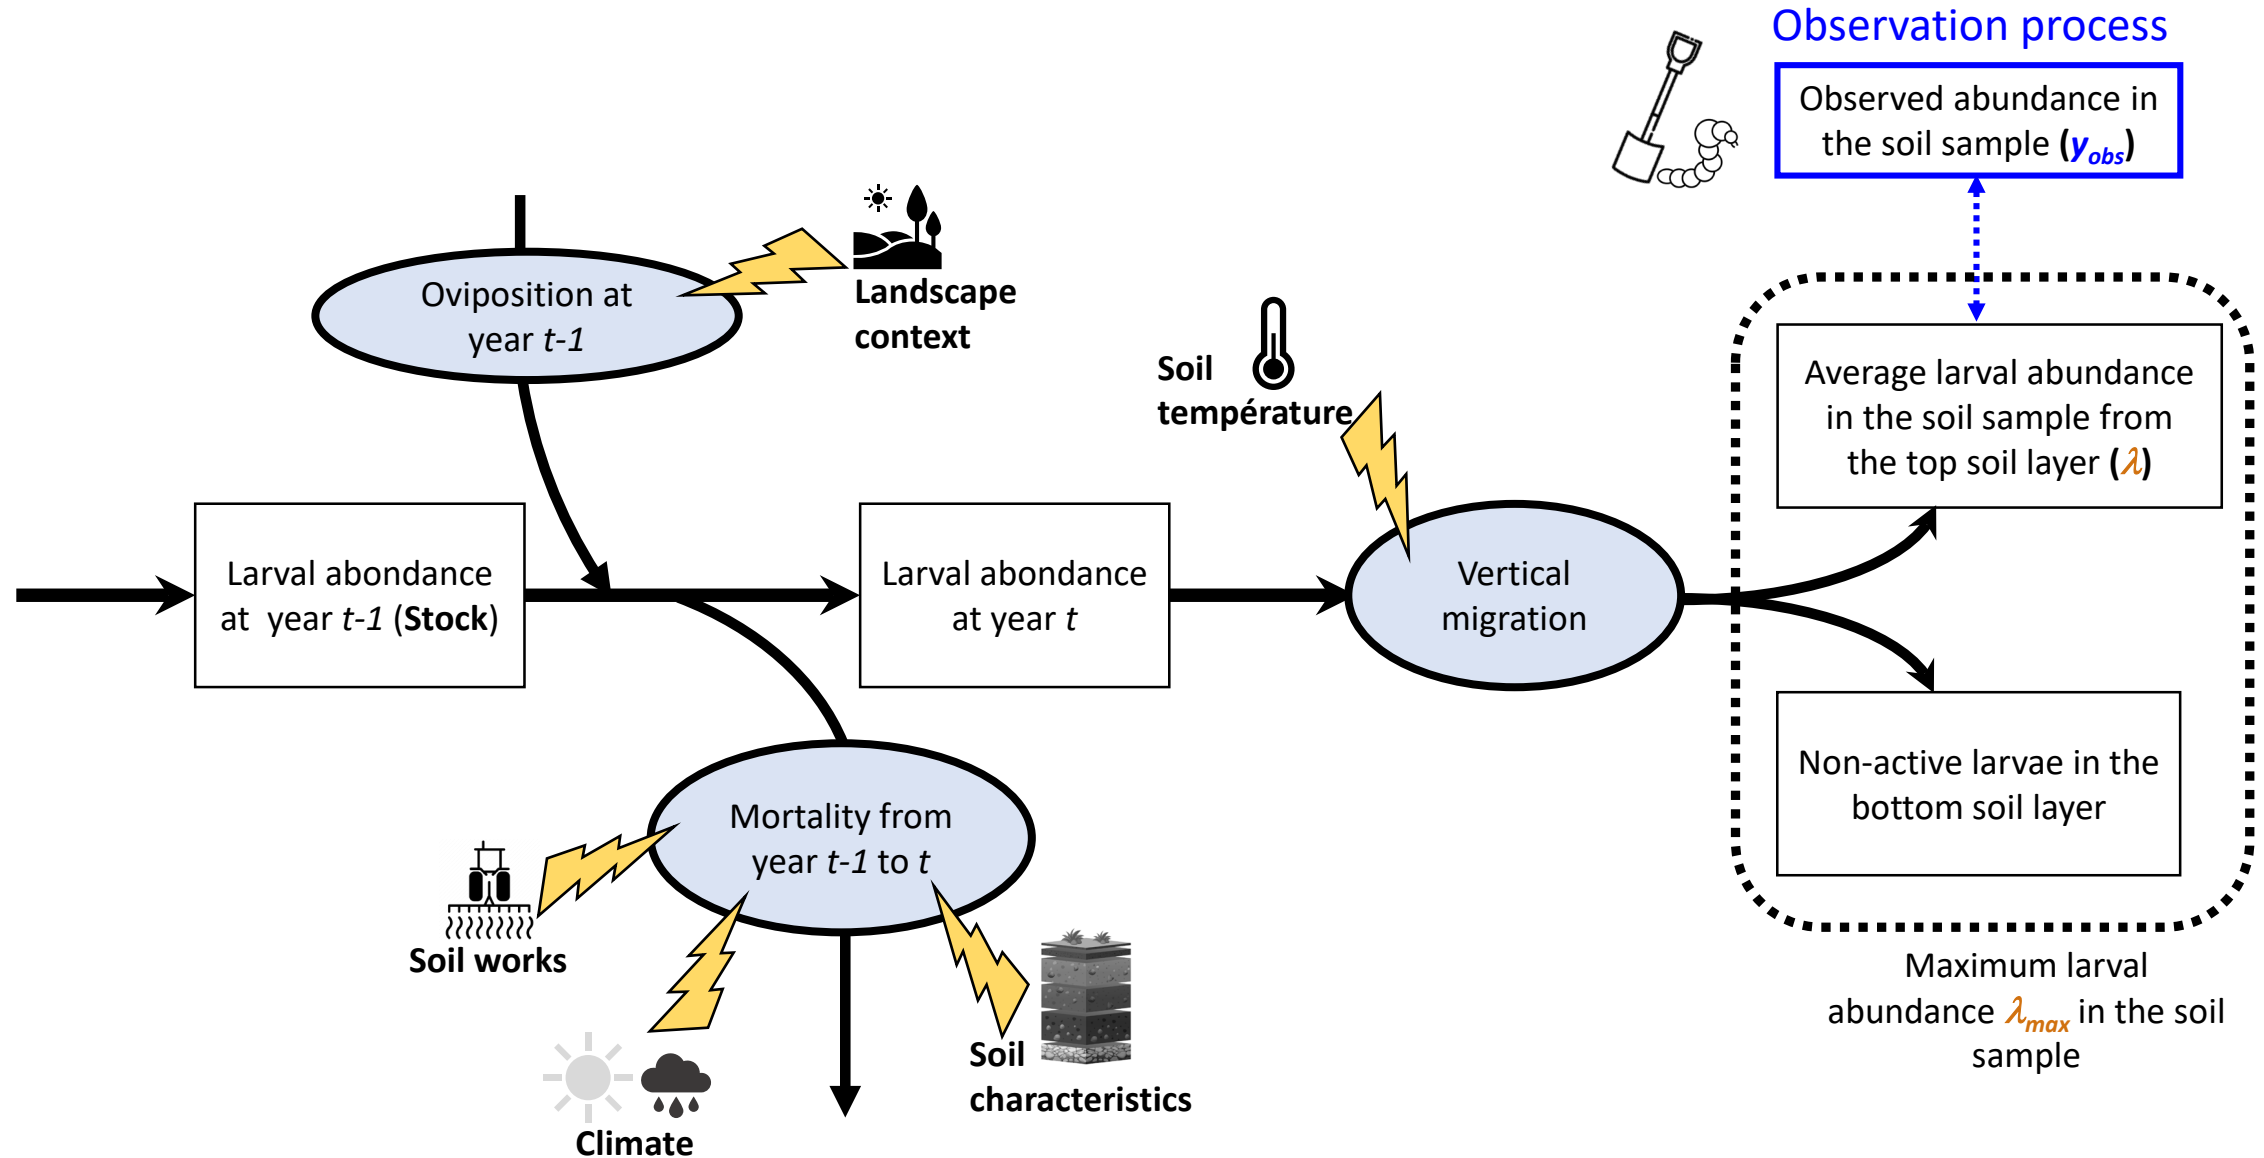

Response variable  $y_{obs}$ : wireworm abundance

→ *Pooled soil samples obtained from 3 randomized spade holes (20x20x20 cm<sup>3</sup>) in each field*

# MOTIVATION FOR HIERARCHICAL BAYESIAN MODELLING

- Appropriate framework for risk assessment: random variable with credible intervals
- Incorporate biological/ecological expertise
- Address the uncertainty associated with field sampling: observations (pest abundance in soil samples) are described as realisations of a stochastic process

## ➤ Latent variable models

## ➤ Latent variable models

$$Y_{obs_i} \sim P(\lambda_i) \quad \begin{array}{c} i: \text{field id} \\ \vdots \end{array} \quad \log(\lambda_i) = VM(T_i) * \left( \sum_k \alpha_k * X_{quanti(i,k)} + \sum_l \beta_l X_{quali(i,l)} + C \right)$$

## ➤ Latent variable models

$$Y_{obs_i} \sim P(\lambda_i)$$

$i$ : field id

⋮

$$\log(\lambda_i) = \text{VM}(T_i) * \left( \sum_k \alpha_k * X_{quanti}(i,k) + \sum_l \beta_l * X_{quali}(i,l) + C \right)$$

Jung et al., 2014. J Appl Entomol 138, 183-194

# ➤ Latent variable models

$$Y_{obs_i} \sim P(\lambda_i)$$

Larval counting process

Poisson distribution with parameter  $\lambda$

$i$ : field id

$$\log(\lambda_i) = VM(T_i) * \left( \sum_k \alpha_k * X_{quanti}(i,k) + \sum_l \beta_l * X_{quali}(i,l) + C \right)$$

Jung et al., 2014. J Appl Entomol 138, 183-194

# ➤ Latent variable models

$$Y_{obs_i} \sim P(\lambda_i)$$

Larval counting process

Poisson distribution with parameter  $\lambda$

$i$ : field id

$$\log(\lambda_i) = VM(T_i) * \left( \sum_k \alpha_k * X_{quanti}(i,k) + \sum_l \beta_l * X_{quali}(i,l) + C \right)$$

Jung et al., 2014. J Appl Entomol 138, 183-194

Parameter inference using a MCMC algorithm → posterior distributions  
 $\alpha_k, \beta_l$  : standardized coefficients

## CONCLUSION PART TWO

---

- Model outcomes show good agreement with current knowledge from literature and field expertise in terms of the effects of variables on wireworm abundance
- Fairly good predictive capacity (cf. publication)
- Ongoing test step before encapsulating as a DSS for the implementation of IPM strategies

## PERSPECTIVES

---

- Incremental improvement with better biological and ecological knowledge (processes at stake)
- Conceptual framework that can be adapted to a wide range of similar situations involving other crops and pests

Dynamic role of grasslands as sources of soil-dwelling insect pests: New insights from *in silico* experiments for pest management strategies

Sylvain Poggi<sup>a,\*</sup>, Mike Sergent<sup>a</sup>, Youcef Mammeri<sup>b</sup>, Manuel Plantegenest<sup>a</sup>, Ronan Le Cointe<sup>a</sup>, Yoann Bourhis<sup>c</sup>

## MOTIVATIONS

---

- Explicitly describe the main processes at stake → e.g. can inform model with pest life traits (incl. dispersal)
- Derive a framework for combining (i) a spatially explicit and mechanistic model describing the pest population dynamics in both aerial and soil compartments involved along its life cycle, and (ii) spatiotemporal representations of various landscape contexts → *in silico* experiments
- Focus: examine the role of grassland arrangements in field colonisation and implications for pest management

### Biological and ecological hypotheses

Larvae only move vertically ('in z')

Adults are mobile in the agricultural landscape ('in x and y')

Adults lay eggs, disperse in space and then die

Larvae develop and emerge at maturity

Larval mortality depends on their density and the quality of the habitat in which they are found

Etc.

### Mathematical formalism (choice of the modelling approach)

#### **Mechanistic approach:**

Explicit consideration of biological and ecological processes

Modelling the pest population dynamics

Spatially explicit

Understanding the processes governing population dynamics (at  $\neq$  stages)

Discrimination between local and non-local processes (reproduction vs. immigration, mortality vs. emigration)

Sensitivity of responses to different processes

### Software development

#### **Model parameterisation**

#### ***In silico* experiments**

**Reaction-diffusion-advection model**

$$\begin{cases}
 \partial_t A(x, t) & = \tau B(x, t, m_c) + D\Delta A(x, t) - \vec{u}(x, t) \cdot \nabla_x A(x, t) - \mu_A A(x, t) \\
 \partial_t B(x, t, m) & = -\tau B(x, t, m_c) + \pi A(x, t) - c \partial_m B(x, t, m) - \mu_B \left( B(x, t, m) / K(x, t) \right)^\beta B(x, t, m)
 \end{cases}$$

Aboveground population  
Belowground population

Key processes

- Emergence
- Diffusion
- Advection
- Mortality
- Oviposition
- Maturation

x: location in 2D space  
 t: time dimension  
 m: maturity dimension  
 $m_c$ : critical maturity for emergence  
 K: carrying capacity  
 $K_M=120 \text{ ind/m}^2$   
 $K_G=2000 \text{ ind/m}^2$

# ➤ Mechanistic models

Simplistic dynamic landscapes

Time Landscape	$t < 0$	$t = [0, 2[$	$t = [2, 4[$	$t \geq 4$

 Temporary grassland  
 Plot A = plot of interest

# ➤ Mechanistic models

Simplistic dynamic landscapes

Model outcomes

Confirmation of expected population dynamics

Life cycle duration (c<sup>-1</sup>)

- 2 years
- 4 years

Effect of long vs. short life cycle

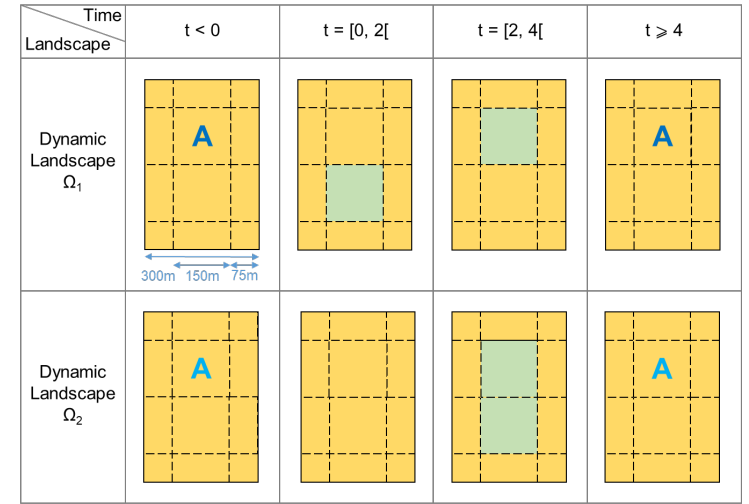

Time Landscape	$t < 0$	$t = [0, 2[$	$t = [2, 4[$	$t \geq 4$
Dynamic Landscape $\Omega_1$				
Dynamic Landscape $\Omega_2$				

**Legend** ■ Cultivated crop ■ Temporary grassland  
Plot A = plot of interest

# ➤ Mechanistic models

Simplistic dynamic landscapes

Model outcomes

Confirmation of expected population dynamics

Life cycle duration ( $c^{-1}$ )

- 2 years
- 4 years

Effect of long vs. short life cycle

Same composition over the period under study but contrasted spatial configurations  $\Rightarrow$  significant effect on wireworm infestation

## CONCLUSION PART THREE

---

- Explicit consideration of processes at stake
- *In silico* exploration of landscape manipulation (effect of land-use legacy, neighbourhood, or their interaction)

Also:

- understanding dispersal mechanisms may help design effective pest management strategies
- Example of a case study: the role of grassland on pest populations (pseudo-sink vs. source)

## LIMITATION

---

- Parameterisation step based on published literature, sometimes rudimentary or dated

## PERSPECTIVE

---

- Explore suppressive patterns in simplified but realistic agricultural landscapes, generated under agronomic constraints at the farm or landscape scales

# GENERAL CONCLUSION

---

MODELLING CAN PROVIDE TOOLS FOR THE IDENTIFICATION AND RANKING OF MAIN RISK FACTORS ALSO FOR THE DESIGN OF DECISION SUPPORT SYSTEMS

Enrich datasets ; Share standardized protocols for data collection at long-term and larger spatial scale

IMPROVING KNOWLEDGE ON THE BIOLOGY AND ECOLOGY OF WIREWORMS/CLICK BEETLES WILL BENEFIT TO MODELS (AND VICE VERSA)

Click beetle dispersal ; Species-specific life traits ; Relationship between wireworm infestation and crop damage (species-crop economic threshold, etc.)

MECHANISTIC MODELS DESERVE GREATER ATTENTION SINCE THEY ARE USEFUL SIMULATION TOOLS

Knowledge-hungry models that must be informed by some critical pest traits, land-use characteristics and their interaction

Explore scenarios of land-use manipulation to design potential suppressive landscape contexts ; Study the relative contribution of local vs. landscape factors to wireworm colonisation
